ELSEVIER

Table of Contents

[Cover image](#)

[Title page](#)

[Copyright](#)

[Dedication](#)

[Contributors](#)

[Foreword](#)

[Preface](#)

[Acknowledgments](#)

[Using the Evidence-Versus-Harm Grading Icons](#)

[Part I. Integrative Medicine](#)

[Chapter 1. Philosophy of Integrative Medicine](#)

[A Brief History of Integrative Medicine](#)

[Integrative Medicine](#)

[Reducing Suffering](#)

[The Future](#)

[Conclusion](#)

[Chapter 2. Creating Optimal Healing Environments](#)

[The Optimal Healing Environment](#)

[Spiritual Connection](#)

[Creating an Optimal Healing Environment in the Clinical Setting](#)

[Foundations of a Healing Encounter](#)

[The Value of Creating Optimal Healing Environments](#)

[Chapter 3. The Healing Encounter](#)

[Practitioner Versus Pill](#)

[Mindfulness in Your Practice](#)

[The 3 Ps: Pause, Presence, and Proceed](#)

[Five Questions to Consider Before Prescribing a Therapy](#)

[Steps to Enhance the Healing Encounter](#)

[Conclusion](#)

[Chapter 4. The Whole Health Process](#)

[Value Over Volume](#)

[Patient-Defined Goals](#)

[Innovative Health Systems](#)

[The Circle of Health](#)

[Three Questions](#)

[Developing the Personal Health Plan](#)

[Four-Step Process for Health Planning](#)

[The Value of the Whole Health Process](#)

Part II. Integrative Approach To Disease

Section I. Affective Disorders

Chapter 5. Depression

Pathophysiology

Integrative Therapy

Nutrition

Dietary Supplements

Botanicals

Mind–Body Therapy

Other Traditional Healing Techniques

Acupuncture

Phototherapy

Pharmaceuticals

Electroconvulsive Therapy

Therapies to Consider for Depression

Novel Treatments Having Preliminary Studies

Chapter 6. Anxiety

Definition and Diagnostic Criteria

Comorbid Conditions

Pathophysiology

Integrative Therapy

Chapter 7. Attention Deficit Disorder

Definitions, Epidemiology, and Pathophysiology

[Integrative Therapy](#)

[Lifestyle](#)

[Biochemical Therapies](#)

[Chapter 8. Autism Spectrum Disorder](#)

[Prevalence, Characteristics, and Guidelines for Complementary and Alternative Medicine Therapies in Autism](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Pharmaceuticals](#)

[Supplements](#)

[Botanicals and Herbal](#)

[Mind-Body Medicine](#)

[Chapter 9. Insomnia](#)

[Definitions](#)

[Etiology](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Mind-Body Therapy](#)

[Chapter 10. Posttraumatic Stress Disorder \(PTSD\)](#)

[Definition and Diagnostic Criteria](#)

[Integrative Therapy](#)

[Mind-Body](#)

[Acupuncture](#)

[Repetitive Transcranial Magnetic Stimulation](#)

[Pharmacotherapies](#)

Section II. Neurology

Chapter 11. Alzheimer Disease

Pathophysiology

Integrative Therapy

Chapter 12. Headache

Migraine Pathophysiology

Integrative Therapy

Tension-Type Headache

Integrative Therapy

Chapter 13. Peripheral Neuropathy

Pathophysiology

Integrative Therapy

Chapter 14. Multiple Sclerosis

Pathophysiology

Etiology

Diagnosis

Integrative Therapy

Chapter 15. Parkinson's Disease

Clinical Signs and Symptoms of Parkinson's Disease

Pathophysiology

Integrative Therapy

Acupuncture

Pharmaceuticals

[Surgery](#)

[Mind-Body Connection](#)

[Section III. Infectious Disease](#)

[Chapter 16. Otitis Media](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 17. Chronic Sinusitis](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Integrative Therapy: Treating and Preventing Sinus Infections and Colds](#)

[Chapter 18. Viral Upper Respiratory Infection](#)

[Integrative Therapies](#)

[Chapter 19. HIV Disease and AIDS](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 20. Herpes Simplex Virus](#)

[Epidemiology](#)

[Clinical Manifestation](#)

[Integrative Therapy](#)

[Chapter 21. Chronic Hepatitis](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Nutrition](#)

[Chapter 22. Urinary Tract Infection \(UTI\)](#)

[Integrative Therapies](#)

[Chapter 23. Lyme Disease](#)

[Epidemiology](#)

[Integrative Therapy](#)

[Acute Infection](#)

[Chronic Persistent Symptoms](#)

[Section IV. Cardiovascular Disease](#)

[Chapter 24. Hypertension](#)

[Integrative Therapy](#)

[Therapies to Consider](#)

[Chapter 25. Heart Failure](#)

[Integrative Therapy](#)

[Chapter 26. Coronary Artery Disease](#)

[Integrative Approaches to Cardiovascular Disease](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Supplements](#)

[Other Therapies](#)

Chapter 27. Dyslipidemia

Introduction

Pathophysiology

Testing

Integrative Therapy

Chapter 28. Arrhythmias

Pathophysiology

Integrative Therapy

Conclusion

Section V. Allergy/ Intolerance

Chapter 29. Asthma

Pathophysiology

Integrative Therapy

Chapter 30. The Allergic Patient

Pathophysiology

Integrative Therapy

Chapter 31. Food Allergy and Intolerance

Nomenclature

Pathophysiology

Research Validation

Diagnosis

Integrative Therapy

Section VI. Metabolic/Endocrine Disorders

Chapter 32. Insulin Resistance and the Metabolic Syndrome

Defining Metabolic Syndrome

Prevalence

Pathophysiology

Diagnosis

Integrative Therapy

Chapter 33. Diabetes Mellitus

Pathophysiology

Integrative Therapy

Chapter 34. Hypothyroidism

Pathophysiology

Integrative Therapy

Chapter 35. Polycystic Ovarian Syndrome

Pathophysiology

Integrative Therapy

Chapter 36. Osteoporosis

Epidemiology and Pathophysiology

Integrative Therapy

Chapter 37. An Integrative Approach to Obesity

Introduction

Pathophysiology

[Integrative Therapy](#)

[Chapter 38. MTHFR, Homocysteine and Nutrient Needs](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 39. Adrenal Fatigue](#)

[The Natural Stress Response](#)

[Diagnosing Adrenal Fatigue](#)

[Integrative Therapy](#)

[Section VII. Nephrology](#)

[Chapter 40. Chronic Kidney Disease](#)

[Introduction](#)

[Integrative Therapy](#)

[Section VIII. Gastrointestinal Disorders](#)

[Chapter 41. Irritable Bowel Syndrome](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 42. Gastroesophageal Reflux Disease](#)

[Pathophysiology](#)

[Integrative Therapy](#)

Chapter 43. Peptic Ulcer Disease

Pathophysiology

Integrative Therapy

Chapter 44. Cholelithiasis

Pathophysiology

Integrative Therapy

Chapter 45. Recurring Abdominal Pain in Pediatrics

Pathophysiology

Integrative Therapy

Chapter 46. Constipation

Pathophysiology

Integrative Therapy

Section IX. Autoimmune Disorders

Chapter 47. Fibromyalgia

Pathophysiology

Integrative Therapy

Chapter 48. Chronic Fatigue Syndrome

Pathophysiology

Integrative Therapy

Chapter 49. Rheumatoid Arthritis

Pathophysiology

[Integrative Therapy](#)

[Chapter 50. Inflammatory Bowel Disease](#)

[Introduction and Pathophysiology](#)

[Integrative Therapies for Inflammatory Bowel Disease](#)

[Section X. Obstetrics/Gynecology](#)

[Chapter 51. Preconception Counseling and Fertility](#)

[Overview](#)

[Introduction](#)

[Integrative Therapy](#)

[Chapter 52. Labor Pain Management](#)

[Physiology](#)

[Integrative Therapy](#)

[Chapter 53. Postdates Pregnancy](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 54. Nausea and Vomiting in Pregnancy](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 55. Managing Menopausal Symptoms](#)

[Introduction](#)

[Physiology of the Female Reproductive Life Cycle](#)

[Integrative Therapy](#)

[Chapter 56. Premenstrual Syndrome](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 57. Dysmenorrhea](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 58. Uterine Fibroids \(Leiomyomata\)](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 59. Vaginal Dryness](#)

[Description and Prevalence](#)

[Physiology of Vaginal Lubrication](#)

[Pathophysiology of Vaginal Epithelium](#)

[Integrative Therapy](#)

[Section XI. Urology](#)

[Chapter 60. Benign Prostatic Hyperplasia](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 61. Urolithiasis \(Kidney and Bladder Stones\)](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 62. Chronic Prostatitis/Chronic Pelvic Pain Syndrome](#)

[Pathophysiology](#)

[Diagnosis](#)

[Integrative Therapy](#)

[Chapter 63. Erectile Dysfunction](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 64. Testosterone Deficiency](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Section XII. Musculoskeletal](#)

[Chapter 65. Osteoarthritis](#)

[Pathophysiology](#)

[Integrative Approaches](#)

[Chapter 66. Myofascial Pain Syndrome](#)

[Epidemiology](#)

[Diagnosis](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 67. Chronic Low Back Pain](#)

[Introduction](#)

[Pathophysiology](#)

[Evaluation](#)

[History](#)

[Physical Examination](#)

[Red Flags](#)

[Yellow Flags](#)

[Subgrouping](#)

[Imaging](#)

[Integrative Therapy](#)

[Chapter 68. Neck Pain](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 69. Gout](#)

[Pathogenesis and History](#)

[Integrative Therapy](#)

[Chapter 70. Carpal Tunnel Syndrome](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 71. Epicondylitis](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Section XIII. Dermatology](#)

Chapter 72. Atopic Dermatitis

Pathophysiology and Diagnosis

Integrative Therapy

Lifestyle and Supportive Care

Nutrition

Chapter 73. Psoriasis

Pathophysiology and Clinical Background

Integrative Therapy

Chapter 74. Urticaria

Pathophysiology

Integrative Therapy

Chapter 75. Aphthous Stomatitis

Pathophysiology

Integrative Therapy

Chapter 76. Seborrheic Dermatitis

Pathophysiology

Integrative Therapy

Chapter 77. Acne Vulgaris and Acne Rosacea

Acne Vulgaris

Integrative Therapy

Rosacea

Pathophysiology of Rosacea

[Integrative Therapy](#)

[Section XIV. Cancer](#)

[Chapter 78. Breast Cancer](#)

[Pathophysiology](#)

[Risk Factors](#)

[Screening](#)

[Integrative Therapies](#)

[Integrative Management of Side Effects From Breast Cancer Treatment](#)

[Chapter 79. Lung Cancer](#)

[Introduction](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Chapter 80. Prostate Cancer](#)

[Background](#)

[Prostate Cancer Screening](#)

[Prostate Cancer Diagnosis and Staging](#)

[Integrative Therapy](#)

[Chapter 81. Colorectal Cancer](#)

[Natural History](#)

[Incidence and Prevalence](#)

[Screening](#)

[Risk Factors](#)

[Primary and Secondary Prevention](#)

[Medications](#)

[Treatment](#)

[Survivorship and Tertiary Prevention](#)

[Chapter 82. Palliative and End-of-Life Care](#)

[Pathophysiology](#)

[Common Issues in Palliative Care](#)

[Pain Management](#)

[Nausea, Vomiting, and Constipation](#)

[Dyspnea](#)

[Anxiety and Depression](#)

[Anxiety and Depression](#)

[Delirium](#)

[Spiritual Care](#)

[Bereavement](#)

[Integrative Therapies](#)

[Section XV. Substance Abuse](#)

[Chapter 83. Alcoholism and Substance Abuse](#)

[Pathophysiology](#)

[Integrative Therapy](#)

[Section XVI. Ophthalmology](#)

[Chapter 84. Cataracts](#)

[Pathophysiology](#)

[Screening](#)

[Epidemiology](#)

[Risk Factors](#)

[Integrative Therapy](#)

[Nutrition](#)

[Supplements](#)

[Botanicals](#)

[Surgery](#)

[Chapter 85. Age-Related Macular Degeneration](#)

[Pathophysiology](#)

[Screening](#)

[Risk Factors](#)

[Integrative Therapy](#)

[Part III. Tools For Your Practice](#)

[Section IA. Lifestyle: Nutrition](#)

[Chapter 86. The Elimination Diet](#)

[Pathophysiology of Nonallergic Food Intolerances](#)

[Pathophysiology of Leaky Gut Syndrome: Gut-Immune Barrier](#)

[Summary of a Pragmatic Approach for Recommending an Elimination Diet](#)

[Chapter 87. Glycemic Index and Glycemic Load](#)

[Glycemic Index](#)

[Glycemic Load](#)

[Disease Prevention and Management](#)

[Conclusion](#)

[Chapter 88. Antiinflammatory Diet](#)

[Introduction](#)

[Conclusion](#)

[Chapter 89. The DASH Diet](#)

[What is the DASH Diet?](#)

[How Much Can I Expect My Blood Pressure to Come Down?](#)

[Besides Lowering Sodium, by What Other Means Might the DASH Diet Benefit Health?](#)

[Besides Lowering Blood Pressure, How Else Does this Diet Affect Cardiovascular Health?](#)

[Does this Diet Reduce the Risk for Cancer?](#)

[How does this Diet Affect Bone Health?](#)

[Can the DASH Diet Slow Cognitive Decline?](#)

[What Foods are Emphasized in this Diet, and How Do they Influence One's Health?](#)

[Chapter 90. The FODMaP Diet](#)

[What Does FODMaP Stand For?](#)

[What is the Mechanism of Action?](#)

[What Type of Condition is FODMaP Best Used For?](#)

[Which IBS Symptoms are Reduced the Most?](#)

[Is it the Elimination of Sugar or Food Proteins that Results in the Greatest Benefit?](#)

[What to Tell Your Patients When Placing them on the FODMaP Diet](#)

[What are the Limitations of the FODMaP Diet?](#)

[Section IB. Lifestyle: Exercise](#)

[Chapter 91. Writing an Exercise Prescription](#)

[Basic Principles](#)

[The Five Components of Fitness](#)

[The FITT Principle for Exercise Programming](#)

[Cardiorespiratory Training](#)

[Resistance Training](#)

[Levels of Exercise Prescription](#)

[The Key Three Strength Program](#)

[Flexibility Versus Stability](#)

[Balance and Agility](#)

[Chapter 92. Therapeutic Breathing](#)

[What is Therapeutic Breathing?](#)

[The Mechanism of Breathing](#)

[Paced and Patterned Breathing](#)

[Muscle/Body Emphasis in Breath Work](#)

[Airway Resistance in Breath Work](#)

[Resources for Practicing Therapeutic Breathing](#)

[Chapter 93. Low Back Pain Exercises](#)

[Breathing and Relaxation Training](#)

[Flexibility Training](#)

[Strength Training](#)

[Coordination Training](#)

[Section II. Mind-Body](#)

[Chapter 94. Relaxation Techniques](#)

[Introduction](#)

[Chapter 95. Self-Hypnosis Techniques](#)

[The Six Main Steps](#)

[Homework for the Patient](#)

[What to Look for in a Consultant](#)

[Chapter 96. Enhancing Heart Rate Variability](#)

[Background](#)

[Polyvagal Theory](#)

[Physiology and Measurement of Heart Rate Variability](#)

[Heart Rate Variability and Health](#)

[The Basics Matter](#)

[Making Recommendations to the Patient](#)

[Steps to Enhance Heart Rate Variability](#)

[A Simple Beginning](#)

[Chapter 97. Guided Imagery and Interactive Guided Imagery](#)

[What is Guided Imagery?](#)

[Applications in Medicine](#)

[How does Imagery Work?](#)

[Commonly Used Treatment Techniques](#)

[How to Get Started with Guided Imagery](#)

[The Structure of a Typical Interactive Guided Imagery Session](#)

[Precautions and Contraindications](#)

[Resources](#)

[Chapter 98. Journaling for Health](#)

[Pathophysiology of Disclosure](#)

[Journaling After a Stressful Event](#)

[Key Areas of Research](#)

[Writing Characteristics Associated with Health](#)

[Precautions](#)

[Relationship-Centered Care](#)

[Chapter 99. Forgiveness](#)

[The Health Effects of Forgiveness](#)

[The Nature of Forgiveness](#)

[Guidelines for Helping People to Forgive](#)

[Conclusion](#)

[Chapter 100. Recommending Meditation](#)

[What is Meditation?](#)

[Why Meditate?](#)

[Review of Meditation Research](#)

[Mindfulness in Medical Practice](#)

[Types of Meditation](#)

[Movement as Meditation](#)

[Chapter 101. Motivational Interviewing](#)

[Three Helping Styles](#)

[Foundation or Spirit of Motivational Interviewing](#)

[What Difference May it Make if a Motivational Interviewing Approach is Used?](#)

[Helping Clients Find and Use Their Motivation](#)

[Helping the Client Access His or Her Motivation for Change](#)

[Enhancing Your Motivational Interviewing Skills](#)

[Chapter 102. Emotional Awareness for Pain](#)

[Introduction](#)

[Their Pain is Real](#)

[The Psychology of Pain](#)

[Diagnosis of Psychophysiologic Disorders](#)

[Treatment Approach](#)

[Conclusion](#)

[Chapter 103. Energy Psychology](#)

[Case Study 1: Fear of a Flu Shot](#)

[Case Study 2: Bloating, Weight Gain, and Anxiety](#)

[What is Energy Psychology?](#)

[What is the Evidence for Energy Psychology?](#)

[How Does Energy Psychology Work?](#)

[How Do I Get Started?](#)

[How Do I Get Trained?](#)

[Importance of Personal Practice and Development](#)

[Energy Psychology as a First-Line Treatment](#)

[Section III. Biochemical](#)

[Chapter 104. Prescribing Botanicals](#)

[Overview](#)

[Who Uses Herbs?](#)

[What Else are they Taking?](#)

[Talking About Herbs with Patients](#)

[Efficacy](#)

[Safety Considerations](#)

[Choosing a Brand or Product: a Question of Quality](#)

[Dosing](#)

[Conclusion](#)

[Chapter 105. Prescribing Probiotics](#)

[Why Probiotics?](#)

[How the Human Microbiota is Established and Altered](#)

[What are Probiotics, Prebiotics, and Synbiotics?](#)

[How Do Probiotics Work? Potential Mechanisms](#)

[What are the Clinical Indications for Prebiotics and Probiotics?](#)

[Prescribing Probiotics: Which Ones, What Dose, and How Should They be Taken?](#)

[Do Natural Food Sources Provide Probiotics?](#)

[How Safe are Probiotics?](#)

[Conclusion](#)

[Chapter 106. Detoxification](#)

[What is Detoxification and Why Do it?](#)

[Testing for Toxins](#)

[Chelation Therapy](#)

[Sauna Therapy](#)

[Exercise](#)

[Nutrition](#)

[Manual Therapies](#)

[Chapter 107. Chelation Therapy](#)

[Introduction](#)

[History of Chelation Uses](#)

[The Trial to Assess Chelation Therapy](#)

[Clinical Use of Chelation Therapy](#)

[Treatment of Heavy Metal Intoxication](#)

[Pharmacological Approaches](#)

[Natural Products](#)

[Summary](#)

[Chapter 108. Integrative Strategies for Planetary Health](#)

[A Systems Approach](#)

[The Precautionary Principle](#)

[Pressing Ecological Problems in Today's World: Three Examples](#)

[Personal and Planetary Health in Everyday Life](#)

[Conclusion](#)

[Section IV. Biomechanical](#)

[Chapter 109. Strain/Counterstrain](#)

[History and Theory of Counterstrain Therapy](#)

[Practical Applications of Counterstrain Therapy](#)

[Examples of the Technique](#)

[Benefits](#)

[Limitations](#)

[Chapter 110. Acupuncture for Headache](#)

[Overview](#)

[Mechanism of Action](#)

[Safety of Acupuncture](#)

[Training in Acupuncture](#)

[Techniques](#)

[Evidence for Acupuncture in Headache](#)

[Selecting Acupuncture and Acupressure Points](#)

[During an Acupuncture Treatment](#)

[Posttreatment Home Program](#)

[What to Look for in an Acupuncturist](#)

[Conclusion](#)

[Chapter 111. Acupuncture for Nausea and Vomiting](#)

[Overview](#)

[Postoperative Nausea and Vomiting](#)

[Chemotherapy-Induced Nausea and Vomiting](#)

[Pregnancy-Related Nausea and Vomiting](#)

[Motion Sickness](#)

[Acupuncture Points for Nausea and Vomiting](#)

[During an Acupuncture Treatment](#)

[Posttreatment Home Program](#)

[What to Look for in an Acupuncturist](#)

[Conclusion](#)

[Chapter 112. Prolotherapy for Chronic Musculoskeletal Pain](#)

[Introduction and History](#)

[What Is Prolotherapy?](#)

[Basic Science](#)

[Clinical Research](#)

[Contraindications](#)

[Common Side Effects](#)

[Adverse Events](#)

[Practical Considerations](#)

[A Case Example: Lateral Epicondylitis](#)

[Insurance Coverage](#)

[Chapter 113. Nasal Irrigation for Upper Respiratory Conditions](#)

[The Science](#)

[Technique Variations](#)

[Irrigant Variations](#)

[Pediatric Use](#)

[Recommended Dose for Treatment and Prevention](#)

[Safety](#)

[Practical Use of Sni](#)

[Section V. Bioenergetics](#)

[Chapter 114. Integrating Spiritual Assessment and Care](#)

[The Five Clinical Goals of Spiritual Assessment and Care](#)

[Chapter 115. Therapeutic Homeopathy](#)

[Why homeopathy?](#)

[What is Homeopathy?](#)

[How are Homeopathic Remedies Prepared?](#)

[How do Homeopathic Remedies Work?](#)

[How are Homeopathic Medicines Prescribed?](#)

[For which Conditions can Homeopathic Treatments be Used?](#)

[Conclusion](#)

[Chapter 116. Biofield Therapies](#)

[Defining Energy Medicine](#)

[Energy Medicine Research](#)

[Guidelines for Making an Energy Medicine Referral](#)

[Incorporating Energy Medicine Approaches Into One's Own Practice](#)

Section VI. Other

Chapter 117. Creating a Greener Clinic: The Impact of Global Warming on Health

[A Primer on Life Cycle Assessment](#)

[Conclusion](#)

Chapter 118. Integrative Medicine for the Underserved

[Introduction](#)

[Health Inequities](#)

[Social Determinants of Health \(SDH\)](#)

[Why Integrative Care is Especially Valuable with the Underserved](#)

[Facilitating Behavioral Change](#)

[Provider Characteristics for Healing the Underserved](#)

[Affordable Approaches and Sustainable Programs](#)

[Examples of Affordable Services by Intervention Type](#)

[Characteristics of Successful Integrative Programs for the Underserved](#)

[An Example of a Sustainable Alternative Medicine Hospital Practice](#)

[Example of Group Visit at a Federally Qualified Community Health Center](#)

[Achieving Buy-In from Administration](#)

[Outside the Exam Room: Activism](#)

[Index](#)

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in

research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

† Deceased

Foreword

After the publication of the first edition of *Integrative Medicine* in 2003, this text, now in its fourth edition, has become the go-to textbook for clinicians wanting evidence-informed guidance to make the best integrative therapeutic choices.

In medical education it is important that our tools adapt to the changing needs of clinicians in their chosen environments. *Integrative Medicine* does just that.

More than 140 integrative medicine experts have contributed 118 chapters to this volume. As the focus of our national medical system shifts from volume to value, we need reliable information on value-based care. Integrative medicine uses evidence within the context of an individual's life to select the best methods of treatment to achieve a healthy outcome. In general, it prefers safer, less invasive, less costly therapies over more aggressive ones, as dictated by the circumstances of illness.

As with previous editions, the text is divided into three parts. The first presents the philosophy and foundational principles of integrative medicine. The second focuses on integrative approaches to specific conditions, and the third covers "tools for your practice," with practical advice on how to best select and implement specific treatments and interventions.

Each chapter in the second part of the book has a *Therapeutic Review* summary that weighs the evidence for benefit versus the evidence for harm. Each method is rated with a visual icon to give you a time-efficient way to assess it. Each chapter also includes highlighted clinical pearls that the author feels are most important, as well as a *Prevention Prescription* of recommendations based on the best research to prevent a condition from occurring or reoccurring.

Fifteen new chapters have been added to the updated 103 chapters from the third edition. The growth of the field of integrative medicine

has allowed for the recruitment of many new gifted authors (35%) who have given their time to keep the information fresh and useful to busy clinicians.

Some of these new chapters include guidance on posttraumatic stress disorder, adrenal fatigue, MTHFR mutation, food allergy and intolerance, the FODMaPs diet, chelation therapy, integrative medicine for the underserved, and the whole-health process of care.

As we work together to create a true health care system, Rakel's *Integrative Medicine* uses the best available data to empower us to be of service to others in achieving healthy outcomes. I highly recommend it.

Andrew Weil, MD, Director, Arizona Center for Integrative Medicine, Clinical Professor of Medicine, Professor of Public Health, University of Arizona, Tucson, Arizona

July, 2016

Preface

As the field of integrative medicine continues its health mission, the larger medical culture of which it is a part is adopting and implementing its therapeutic strategies. Reducing cost and improving quality with better outcomes can be achieved with an integrative approach where professionals combine their expertise in service of facilitating health within the complexity of people's lives. This text is a tool to guide this important process.

The fourth edition includes expertise from 148 authors, 35% of whom are new. They have contributed to 118 chapters, including 15 new chapters on hot topics such as posttraumatic stress disorder, adrenal fatigue, the FODMaPs diet, integrative medicine for the underserved, chelation therapy, and MTHFR mutation, to name a few.

New to this edition is the inclusion of three to four multiple choice questions that follow each chapter on [ExpertConsult.com](https://www.expertconsult.com). These were included to prepare the reader for taking and passing the board exam in integrative medicine. The answer includes a short explanation that provides insight and further education on clinical topics.

As with previous editions, the text is divided into three parts. Part 1, Integrative Medicine, is an overview of the field and the foundations from which it is delivered. Part 2, Integrative Approach to Disease, is the core of the text and discusses integrative approaches to treating disorders that range from insomnia to diabetes to the most common types of cancer. Part 3, Tools for Your Practice, includes practical, how-to information on the most clinically useful integrative therapeutic interventions.

We strive to make extracting the information you need as efficient as possible. Each disease-focused chapter concludes with a Therapeutic Review that summarizes an integrative approach. After each recommendation, there is an evidence versus harm icon that provides the busy clinician a quick assessment of the balance of the level of evidence

for benefit with the level of potential harm. Each chapter also has a Prevention Prescription that lists those interventions that have been found to be most useful in preventing the specific disease and its recurrence. Clinical pearls are highlighted in note boxes throughout the text.

The science and research of our work is often linear. We have a cause, a result, and a treatment. But how we apply it is circular. It intertwines within the context of someone's life, artfully prescribed based on insight gained from listening to someone's story. I hope the information within these pages empowers you to use the best science to serve your patients. We likely will never master this craft, but we can strive together to improve our understanding how to reproduce health, healing, and resiliency within circular and dynamic ecosystems. Thank you for engaging in this important work.

David Rakel, MD

Acknowledgments

It has taken the expertise of a talented group of professionals to complete this fourth edition. I am very grateful to Joan Ryan for her persistence in managing the content and gracefully supporting the authors in completing the many manuscripts. Kate Mannix took it from there to produce and edit the final drafts and Sarah Barth and Kate Dimock oversaw the big picture towards completion. This Elsevier team has been a joy to work with and their investment has supported a high quality text that has been checked and double-checked for accuracy.

As I transition from the University of Wisconsin in Madison to The University of New Mexico in Albuquerque, I would also like to acknowledge the students, residents, faculty, and staff to whom this book is dedicated. I am also grateful to my long-time colleague Adam Rindfleisch for his support over the years and for continuing to lead the Integrative Medicine program at the University of Wisconsin. I am grateful to my practice partners, Greta Kuphal, Michael Weber, and Samantha Sharp, for their back up when other, nonclinical tasks required attention, and to Bruce Barrett for his friendship, education, and research collaboration. I'm also grateful to Char Luchterhand, Mike Johnson, Jackie Kuta-Bangsberg, and Katharine Bonus for their support for our UW Integrative Medicine program over the years.

I have also been honored to be part of a national educational initiative with the Pacific Institute of Research and Evaluation (PIRE) and the Office of Patient Centered Care and Cultural Transformation within the Veteran's Health Administration. I am grateful to have been able to learn from a variety of gifted and passionate people to work towards a more personalized, proactive, and patient-driven VA health system. I am grateful to Tracy Gaudet, David Rychener, Bernie Murphy, Kathy Atwood, Russ Greenfield, Marite Hagman, David Kiefer, Kelly Peyton-Howard, Janet Vertrees, and Christine Milovani. Their work is, in part, summarized in [Chapter 4](#), The Whole Health Process.

I would not have the energy to do this work if it were not for those that give me energy: my wife, Denise, and three children, Justin, Sarah (and our future son-in-law Adam), and Lucas.

As always, I am grateful to the 148 authors that contributed their time and expertise to help us all do our job a little better.

Using the Evidence-Versus-Harm Grading Icons

In the busy practice of medicine, being able to access information quickly and efficiently is important for obtaining the highest quality data in the shortest period of time in the effort to enhance care.

The Strength of Recommendation Taxonomy (SORT)¹ rating for evidence has been an excellent step in this direction. The A, B, and C ratings give us a quick and simple way to judge the quality of evidence for a particular intervention. There are limitations to making decisions based only on the evidence of benefit. One limitation is the absence of the potential harm of the evidence. Even if the evidence may be grade A, the potential harm of that intervention may negate its effect.

An example is the Randomized Aldactone Evaluation Study (RALES) published in the *New England Journal of Medicine* in 1999.² This study showed that spironolactone significantly improved outcomes in patients with severe heart failure. A follow-up article published in the same journal in 2004³ showed that after the publication of this study, the number of prescriptions written for spironolactone significantly increased in Ontario, Canada, from 34 per 1000 patients in 1994 to 149 per 1000 patients in 2001. Thus the Canadian physicians were practicing evidence-based medicine, and their prescribing habits resonated with this. The follow-up study also noted that despite this evidence-based practice, there was a significant increase in the number of hospital admission and in the death rate related to hyperkalemia when spironolactone and ACE inhibitors were used together. In fact, when the investigators took into account the number of deaths related to hyperkalemia, there was no decrease in the number of admissions or the death rate for congestive heart failure patients after the publication of RALES. The initial benefit of improving outcomes in congestive heart failure with spironolactone seen in the original study was not evident in the application of the evidence in the clinical setting. The potential harm

of the evidence was not taken into account, and this drug may have caused more harm than good.

Adding a rating for potential harm will enhance the rating of the evidence for the clinician but is by no means a final guiding rule. Decision making goes beyond the evidence and the harm and is grounded in the much broader insights obtained through relationship-centered care. It is only a tool that we hope will make the clinician’s life a little easier in recommending specific therapeutic interventions.

Grading the Evidence

The authors of this text used the SORT criteria for grading the evidence for the therapies that are recommended in the Therapeutic Review sections of the chapters. A simplified summary follows:

Grade A	Based on consistent, good-quality, patient-oriented evidence (e.g., systematic review or meta-analysis showing benefit, Cochrane Review with clear recommendation, high-quality patient-oriented randomized controlled trial). Example: Acupuncture for nausea and vomiting.
Grade B	Based on inconsistent or limited-quality patient-oriented evidence. Example: Ginger for osteoarthritis.
Grade C	Based on consensus, usual practice, opinion, disease-oriented evidence (e.g., study showing a reduction in blood sugar but no studies in humans to show a benefit to those with diabetes).

Grading the Potential Harm

Unlike grading for evidence, there is no unified, acceptable grading system for harm. In grading the three levels of harm, we used the following grading scale:

Grade 3 (most harm)	This therapy has the potential to result in death or permanent disability. Example: Major surgery under general anesthesia or carcinogenic effects of the botanical <i>Aristolochia</i> (birthwort).
Grade 2 (moderate harm)	This therapy has the potential to cause reversible side effects or interact in a negative way with other therapies. Example: Pharmaceutical or neutraceutical side effects.
Grade 1 (least harm)	This therapy poses little, if any, risk of harm. Examples: Eating more vegetables, increasing exercise, elimination diets, encouraging social connection.

The resulting icons incorporate a weighing of the evidence versus the potential harm. If the evidence is strong (A) with the least potential harm (1), the arrow will point up. If the evidence is weak (C) with the most potential harm (3), the arrow will point down.

Examples:

Clinical Recommendation

- Exercise for diabetes management (A,1)

- Hypnosis for irritable bowel syndrome (B,1)

- Zinc supplementation for infectious diarrhea (B,2)

Evidence

B

2

Harm

- Astragalus root for infectious hepatitis (C,2)

Evidence

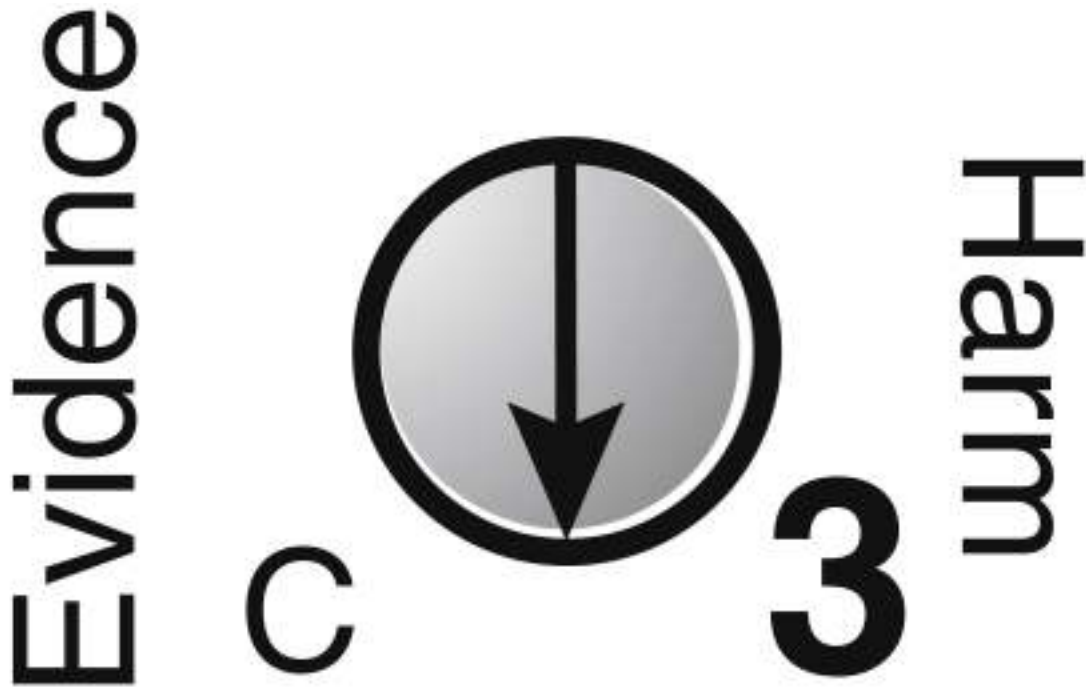

C

2

Harm

- *Aristolochia* (birthwort) to support immunity (C,3)

Rating Options	Arrow Icon	Arrow Icon
(A,1)	↑	
(A,2) (B,1)	↗	
(A,3) (B,2) (C,1)	→	
(B,3) (C,2)	↘	
(C,3)	↓	

Strengths of Evidence-Versus-Harm Grading

- Gives quick access to the balance of available evidence and potential harm for a given therapy.
- Works best for therapeutic interventions for chronic disease compared with acute or emergency treatments.
- Gives more credibility to therapies that have little potential harm. For example, we know that encouraging social support, reducing stress, and enhancing spiritual connection are beneficial for quality of life and

health, but the evidence may not be strong. The potential harm will always be low, giving the benefit a more positive outlook.

- Helps us honor our primary goal, which is to “first, do no harm.” This rating scale allows us to include this important fact in medical decision making. This is very important, seeing that adverse drug reactions from medical therapy have been found to be the sixth leading cause of hospital deaths in the United States.⁴

Limitations of Evidence-Versus-Harm Grading

- Is used only for those therapies proved to have a positive benefit. There may be good evidence showing that a therapy does not work. If this was the case, the therapy was not included in the Therapeutic Review.
- Does not reward the potentially life-saving interventions that are risky and have little available evidence showing benefit. For example, there has not been a meta-analysis showing that emergency repair of a dissecting aortic aneurysm has therapeutic benefit. The potential harm of this therapy is high (Grade 3). On the evidence-versus-harm scale, this therapy would have an arrow pointing toward the negative side, but without the therapy the patient would likely die.
- Those therapies that have the most potential for economic gain often have the most evidence. For example, there are more resources to do high-quality research for a potentially profitable pharmaceutical that can be patented than for a whole food or plant that cannot. Therapies such as pharmaceuticals will have a higher quality of evidence in general when compared with botanicals, mind-body therapy, and spiritual connection.
- This rating scale can be reductionistic. It is much easier to complete high-quality research based on our scientific model on a physical process, drug, or supplement. It is harder to show an enhanced quality of life or a reduction in suffering from reducing social isolation, for example.

Summary

This model includes potential harm along with the strength of the evidence. The arrows will give a quick reference for potential benefit

when the evidence and harm are weighted against each other. For example, strong (heavy) evidence with little (light) potential harm will result in an arrow pointing up. This will be most helpful for recommendations for chronic disease. Unlike acute life-threatening conditions that often need more aggressive intervention with higher potential risk, chronic disease is often managed using lifestyle choices that will be supported by this model.

CHAPTER 1

Philosophy of Integrative Medicine

David Rakel, MD, and Andrew Weil, MD

A Brief History of Integrative Medicine

When religion was strong and medicine weak, men mistook magic for medicine;

Now, when science is strong and religion weak, men mistake medicine for magic.

Thomas Szasz, The Second Sin

The philosophy of integrative medicine is not new. It has been talked about for ages across many disciplines. It has simply been overlooked as the pendulum of accepted medical care swings from one extreme to the other. We are currently experiencing the beginning of a shift toward recognizing the benefits of combining the external, physical, and technological successes of curing with the internal, nonphysical exploration of healing.

Long before magnetic resonance imaging and computed tomographic scanners existed, Aristotle (384–322 BC) was simply able to experience, observe, and reflect on the human condition. He was one of the first holistic physicians who believed that every person was a combination of both physical and spiritual properties with no separation between mind and body. It was not until the 1600s that a spiritual mathematician became worried that prevailing scientific materialistic thought would reduce the conscious mind to something that could be manipulated and controlled. René Descartes (1596–1650), respecting the great unknown, did his best to separate the mind from the body to protect the spirit from science. He believed that the mind and spirit should be the focus of the

church thus leaving science to dissect the physical body. This philosophy led to the “Cartesian split” of mind–body duality.

Shortly afterward, John Locke (1632–1704) and David Hume (1711–1776) influenced the reductionist movement that shaped our science and medical system. The idea was that if we could reduce the natural phenomena to greater simplicity, we could understand the larger whole. So, to learn about a clock, all we need to do is study its parts. Reductionism facilitated great discoveries that helped humans gain control over their environment. Despite this progress, clinicians had few tools to treat disease effectively. In the early 20th century, applied science started to transform medicine through the development of medical technologies. In 1910, the Flexner report¹ was written, and it had a significant impact on the development of allopathic academic institutions. They came to emphasize the triad that prevails today: research, education, and clinical practice. Reductionism and the scientific method produced the knowledge that encouraged the growth of these institutions.

The scientific model led to greater understanding of the pathophysiological basis of disease and the development of tools to help combat its influence. Subspecialization of medical care facilitated the application of the new information. We now have practitioners who focus on the pieces and a society that appreciates their abilities to fix problems. Unfortunately, this approach does not work well for chronic disease that involves more than just a single organ. In fact, all body organs are interconnected, so simply repairing a part without addressing the underlying causes provides only temporary relief and a false sense of security. This, in part, resulted in a very expensive health care system in America with poor health outcomes.²

More Technology, Less Communication

The tremendous success of medical science in the 20th century was not without cost. Total health care expenditures reached \$2.9 trillion in 2013, an amount that was 17.4% of the gross domestic product (GDP), and translated to \$9255 per U.S. resident. The health care market grows when more attention is focused on single diseases that can be treated with drugs or procedures. In 10 years (2003–2013), drug spending in the United States rose 66.4% from \$180 billion to \$271 billion.³ Financial rewards increase when we have more subtypes of disease to which treatments can be matched. The system encourages patients to believe

that tools are the answer to their physical woes and discourages them from paying attention to the interplay of the mind, community, and spirit. Technology is the golden calf in this scenario. We have become dependent on it, and overuse has widened the barrier of communication between the patient and provider. The old tools of the trade—rapport, gestalt, intuition, and laying on of hands—were used less and less as powerful drugs and high-tech interventions became available.

To help curtail costs, managed care and capitation were born. These new models reduced excessive costs and further eroded the patient-provider relationship by placing increased time demands on physicians that did not involve patient care. Physician and patient unrest followed. Physicians are unhappy, in part, because of the loss of autonomy in practicing medicine. Patients are unhappy, in part, because they believe they are not receiving the attention they need. Most upset are patients with chronic medical conditions whose diseases do not respond well to the treatments of specialized medicine. This comes at a time when the incidence of chronic and degenerative diseases is at an all-time high. Diseases such as heart disease, diabetes, irritable bowel syndrome, chronic fatigue, and chronic pain syndromes are quite common. They require evaluation and treatment of much more than any one organ. The public has started to realize the limitations of Western medicine and wants more attention paid to health and healing of the whole person, especially when someone has no “part” to be fixed.

Public Interest Influences Change

The deterioration of the patient-provider relationship, the overuse of technology, and the inability of the medical system to treat chronic disease adequately has contributed to rising interest in complementary and alternative medicine (CAM). The public has sent this message with their feet and their pocketbooks. In fact, more visits were made to CAM providers in the early 1990s than to all primary care medical physicians, and patients paid for these visits out of pocket, with an estimated expenditure of \$13 billion.⁴ This trend continued throughout the 1990s; 42% of the public used alternative therapies, and expenditures increased to \$27 billion from 1990 to 1997.⁵ Patients are also demanding less aggressive forms of therapy, and they are especially leery of the toxicity of pharmaceutical drugs. Adverse drug reactions had become the sixth leading cause of death in hospitalized patients,⁶ and in 1994, botanicals were the largest growth area in retail pharmacy.⁷ Research shows that

people find complementary approaches to be more aligned with “their own values, beliefs, and philosophical orientations toward health and life.”⁸ The public, before the medical establishment, realized that health and healing involved more than pills and surgery. Less invasive, more traditional treatments such as nutrition, botanicals, manipulation, meditation, massage, and others that were neglected during the explosion of medical science and technology are now being rediscovered with great enthusiasm ([Fig. 1.1](#)).

Medicine Gets the Message

The popularity of CAM therapies created a need for research in these areas. In 1993, an Office of Alternative Medicine was started within the National Institutes of Health (NIH). The initial budget was \$2 million, a fraction of the \$80 billion budget of the NIH. The office was later upgraded to the National Center for Complementary and Alternative Medicine (NCCAM), and in 2014, the name was changed to the National Center for Complementary and Integrative Health (NCCIH). The amount of money available for scholarly research kept pace with this growth. By 2010, the NCCAM budget grew to \$127 million.⁹ Unfortunately, with a shrinking NIH budget, the NCCIH budget dropped in 2013 to \$120.6 million and rose only to \$124.5 million in 2015, still lower than in the previous decade.¹⁰ Despite the challenges in research funding, there was still the opportunity to explore ways in which these areas of medicine could enhance health care delivery. At first, researchers tried to use traditional methods to learn about CAM therapies. These methods were sufficient for studying some areas such as botanicals. The limitations of the reductionist model became apparent, however, when it was applied to more dynamic systems of healing such as homeopathy, traditional Chinese medicine, and energy medicine. New methods were required to understand the multiple influences involved. Outcome studies with attention to quality of life were initiated. Research grants in “frontier medicine” were created to help learn about fields such as energy medicine, homeopathy, magnet therapy, and therapeutic prayer. Interest grew in learning how to combine the successes of the scientific model with the potential of CAM to improve the delivery of health care.

INTEGRATIVE MEDICINE

FIG. 1.1 Integrative medicine pie chart.

Academic Centers Respond

In 1997, one of the authors of this chapter, Andrew Weil, started the first fellowship program in integrative medicine at the University of Arizona. This 2-year clinical and research fellowship was created to train physicians in the science of health and healing and to teach more about therapies that were not part of Western medical practice. Since then,

other fellowship programs have been created, as well as projects to incorporate integrative medicine into 4-year family medicine and pediatric residency training models. NIH-sponsored R25 grants have been awarded to medical schools across the country to bring these concepts into medical school curriculums. The Academic Consortium for Integrative Health and Medicine (ACIHM) now comprises more than 62 medical schools (40%) across the United States and Canada, and it brings academic leaders together to transform health care through rigorous scientific studies, new models of clinical care, and innovative educational programs that integrate biomedicine, the complexity of humans, the intrinsic nature of healing, and the rich diversity of therapeutic systems.¹¹

Integrative medicine reaffirms the importance of the relationship between the practitioner and patient, focuses on the whole person, is informed by evidence, and makes use of all appropriate therapeutic and lifestyle approaches, health care professionals, and disciplines to achieve optimal health and healing.

Complementary and Alternative Medicine Use Grows in the United States

Because of the popularity of CAM in the United States, the Institute of Medicine (IOM) published the results of a review of CAM in 2004 to create a better understanding of how it can best be translated into conventional medical practice. The IOM recommended that health profession schools incorporate sufficient information about CAM into the standard curriculum to enable licensed professionals to advise their patients competently about CAM.¹²

Data collected from the National Health Interview Survey in 2002 by the Centers for Disease Control and Prevention's National Center for Health Statistics showed that 62% of U.S. adults used CAM within 12 months of being interviewed. When prayer was excluded as a CAM therapy, the percentage dropped to 36%.¹³ This survey was repeated in 2007, during which the use of CAM rose slightly from 36% to 38.3%. The 2007 survey included children, in whom it showed 11.8% use of CAM therapy, most commonly for back/neck pain (6.7%) and colds (6.6%) (Fig. 1.2). The 10 most commonly used CAM therapies can be reviewed in Fig. 1.3. The use of natural products was the most common at 17.7%.

Pain conditions were the most common reason for CAM therapy in adults, and low back pain accounted for the highest percentage of CAM use at 17.1% ([Fig. 1.4](#)).¹⁴ A review also showed an increase in the use of CAM in those who did not have access to conventional medical care, thus showing the importance of CAM as an option for the uninsured.¹⁵ These data suggest that people value other ways of treating illness and that they want to be empowered to be active participants in their care. They also feel that CAM offers them more opportunity to tell their story and explore a more holistic view of their problem.¹⁶

CAM USE BY U.S. ADULTS AND CHILDREN

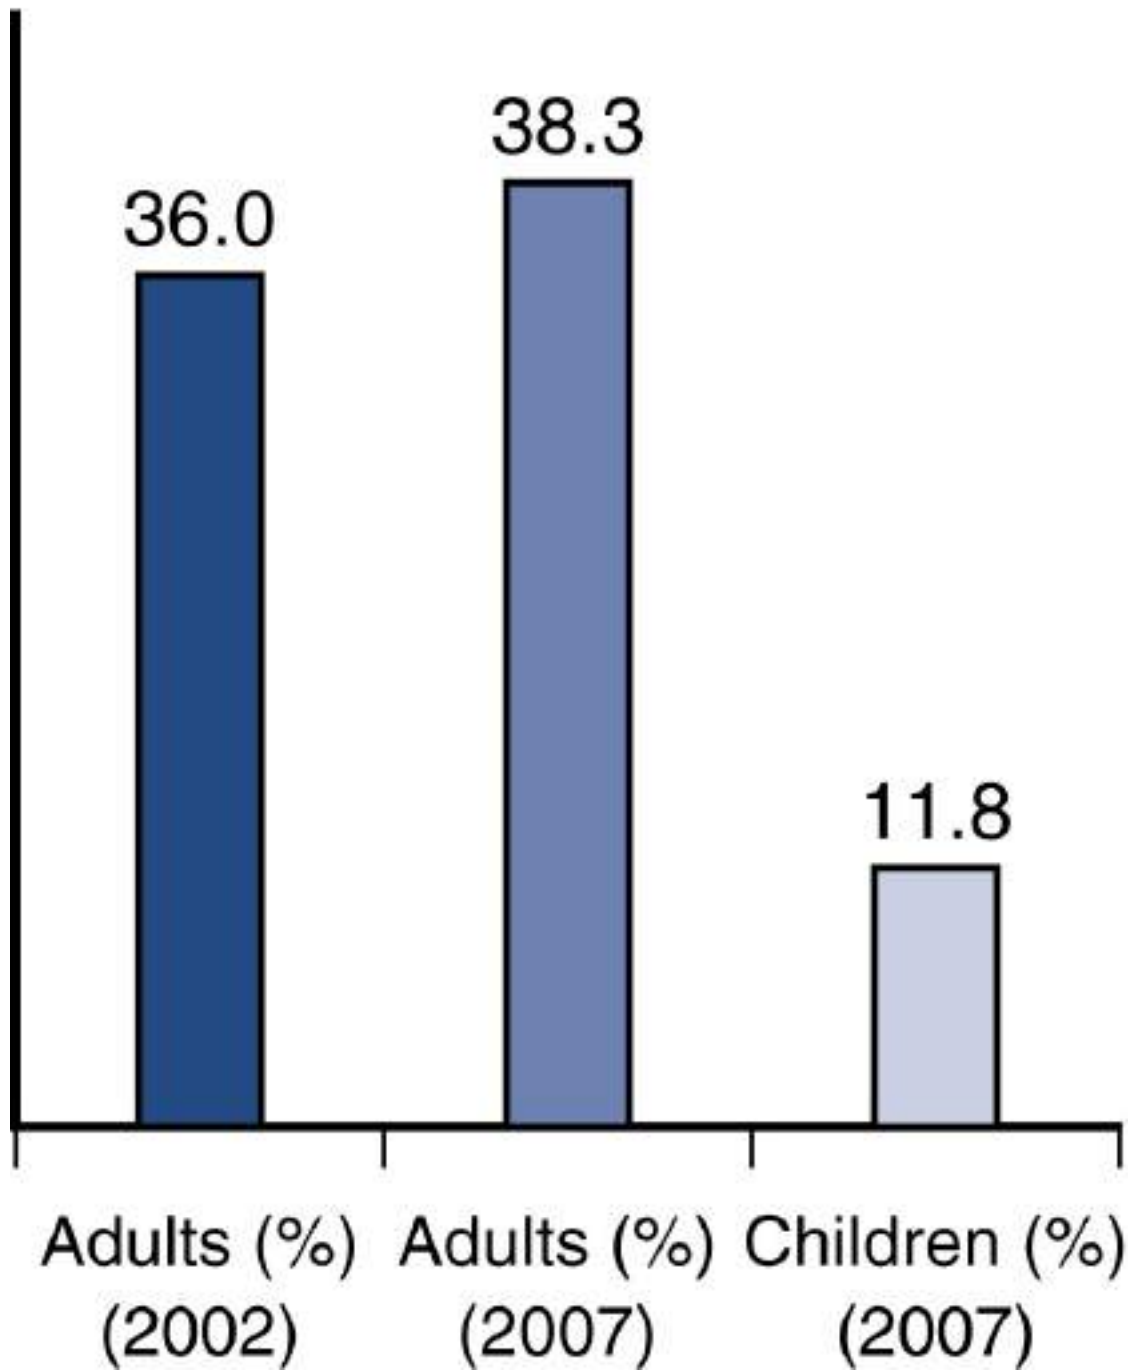

FIG. 1.2 Adults and children who have used complementary and alternative

medicine (CAM): United States, 2007. (From Barnes PM, Blook B, Nahin R. *Complementary and alternative medicine use among adults and children: United States, 2007*. National Health Statistics Report No. 12. Hyattsville, MD: National Center for Health Statistics; 2008.)

Avoiding Complementary and Alternative Medicine Labels

With the growth of good scientific research regarding many CAM therapies, we are realizing that the labels once used to classify these therapies are no longer needed ([Fig. 1.5](#)). The use of the terms *complementary* and *alternative* serve only to detract from a therapy by making it sound second class. Therapies that are often labeled under the heading of CAM include nutrition and spirituality. Many would argue that a lack of attention to these important influences on health has resulted in epidemics of obesity, diabetes, and substance abuse. Stress, which many CAM-labeled mind–body therapies address, was found to be the second leading risk factor for heart disease after smoking in one of the largest studies ever completed across multiple cultures.¹⁷ CAM therapies are hardly of lesser significance than conventional therapies.

Labeling therapies as CAM also avoids the deeper issues that need to be addressed in health care delivery and promotes further fragmentation of care. Simply adding CAM therapies without changing our health care model is like increasing the number of specialists with no primary care infrastructure, an approach that increases cost and reduces the quality of care.¹⁸ Having multiple providers treating the patient in many different ways prevents what is needed most in the restructuring of health delivery: a medical home that is founded in relationship-centered care.

The term *integrative medicine* stressed on the importance of using evidence to understand how best to integrate CAM therapies into our health care model and allowed us to better understand how they can be used to facilitate health and healing. This evolving understanding helped influence positive change in our health care system.

Signs of this evolution away from CAM are the name changes of many of the educational and research organizations supporting its mission. A general theme is a transition from integrative medicine to integrative health that supports the importance of the process of achieving health outcomes ([Table 1.1](#)).

Changing the Medical Culture

In 2001, the IOM published a report on the overall state of U.S. health care. The IOM concluded that the U.S. health care system was so flawed it could not be fixed and an overhaul was required.¹⁹ In 2006, a report from the American College of Physicians (ACP) stated that “Primary care, the backbone of the nation’s health care system, is at grave risk of collapse due to a dysfunctional financing and delivery system. Immediate and comprehensive reforms are required to replace systems that undermine and undervalue the relationship between patients and their personal physician.”²⁰

This crisis has led to proposals for a restructuring of health care that resonate with the philosophy of integrative medicine. The family medicine community has joined the IOM and the ACP in creating their own proposal for a new model of care that promotes a relationship-centered medical home for the establishment of excellence in health creation in the outpatient setting. Principles of the medical home include the following²¹:

1. Access to care based on an ongoing relationship with a personal primary care clinician who is able to provide first contact and continuous and comprehensive care
2. Care provided by a physician-led team of professionals within the practice who collectively take responsibility for the ongoing needs of patients

10 MOST COMMON CAM THERAPIES AMONG ADULTS—2007

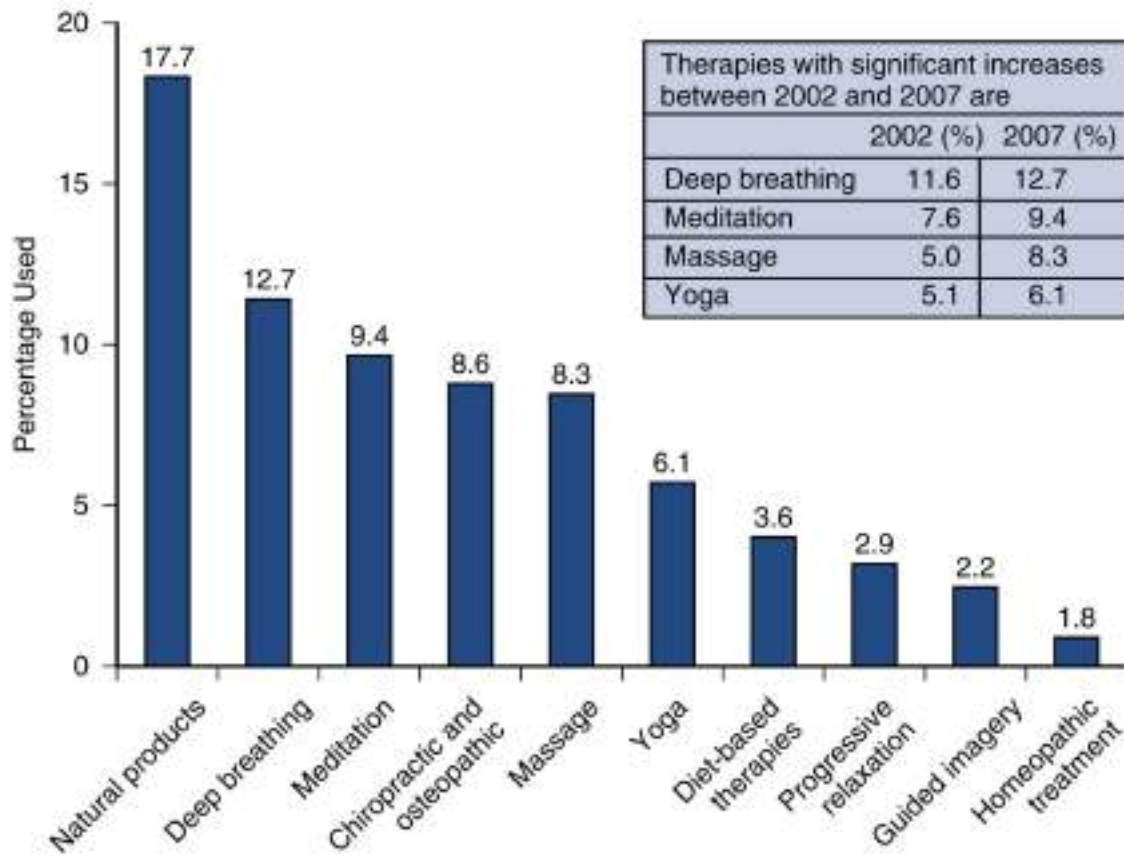

FIG. 1.3 The 10 most commonly used complementary and alternative medicine (CAM) therapies among adults and a list of the most significant increases in therapies from 2002–2007. (From Barnes PM, Blook B, Nahin R.

Complementary and alternative medicine use among adults and children: United States, 2007.

National Health Statistics Report No. 12. Hyattsville, MD: National Center for Health Statistics; 2008.)

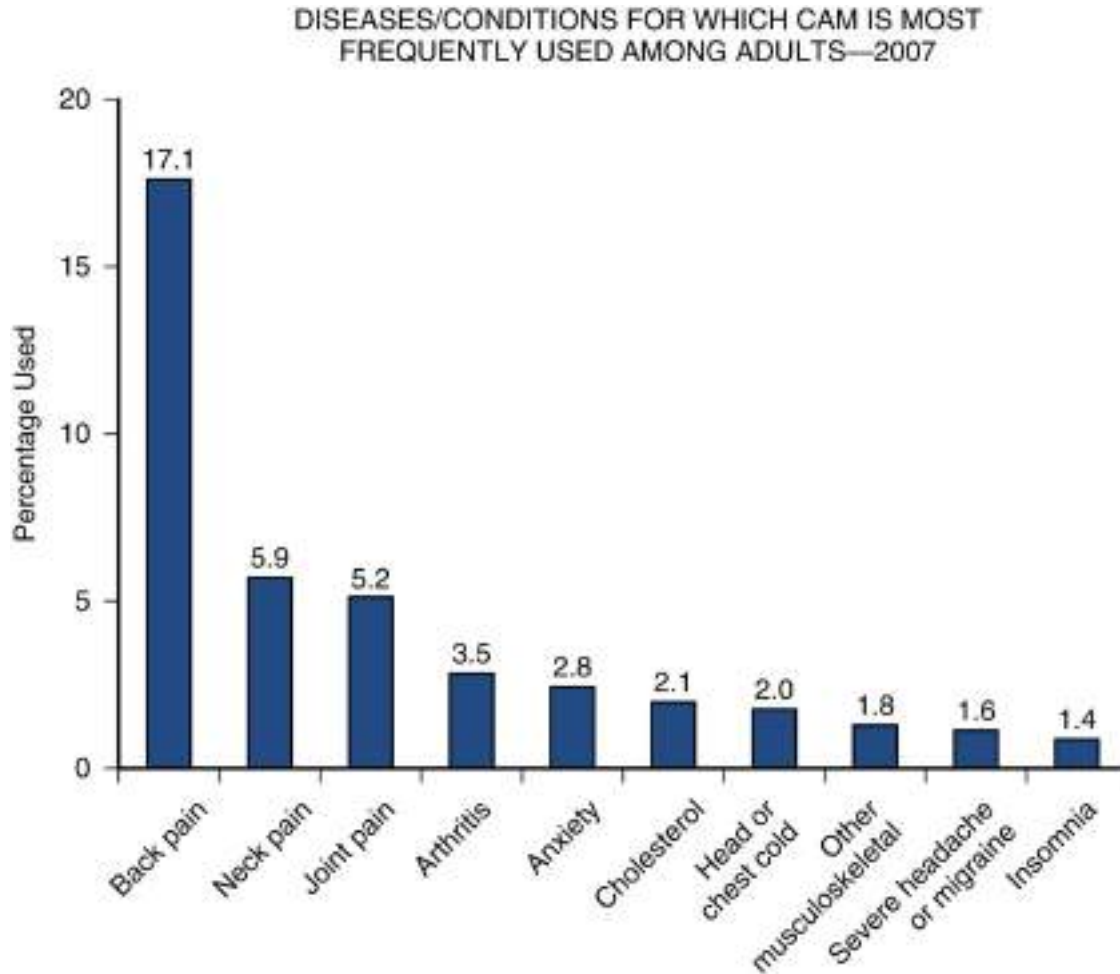

FIG. 1.4 Diseases and conditions for which complementary and alternative medicine (CAM) is most frequently used in adults. (From Barnes PM, Blook B, Nahin R. *Complementary and alternative medicine use among adults and children: United States, 2007*. National Health Statistics Report No. 12. Hyattsville, MD: National Center for Health Statistics; 2008.)

3. Care based on a whole-person orientation in which the practice team takes responsibility for either providing care that encompasses all patient needs or arranging for the care to be done by other qualified professionals
4. Care coordinated or integrated across all elements of the complex health care system and the patient's community
5. Care facilitated by the use of office practice systems such as registries, information technology, health information exchange, and other systems to ensure that patients receive the indicated care when and where they need and want it in a culturally and linguistically appropriate manner

6. A reimbursement structure that supports and encourages this model of care

A similar set of goals was stated by the IOM in their proposal for a new health system for the twenty-first century ([Table 1.2](#)).

In 2009, the Bravewell Collaborative sponsored a summit on Integrative Medicine and the Health of the Public at the IOM in Washington, D.C. The goal of this conference was to share the science in the field and the potential for ways in which it can improve the health care of the nation. It succeeded in opening up dialogue among clinicians, administrators, and politicians to bring awareness of how the field could bring balance to a health care system that is weighted heavily toward disease management. A report of the meeting is available online.²²

The field of integrative medicine was created not to fragment the medical culture further by devising another silo of care but to encourage the incorporation of health and healing into the larger medical model. The culture of health care delivery is changing to adopt this philosophy, and the integration of nontraditional healing modalities will make this goal more successful.

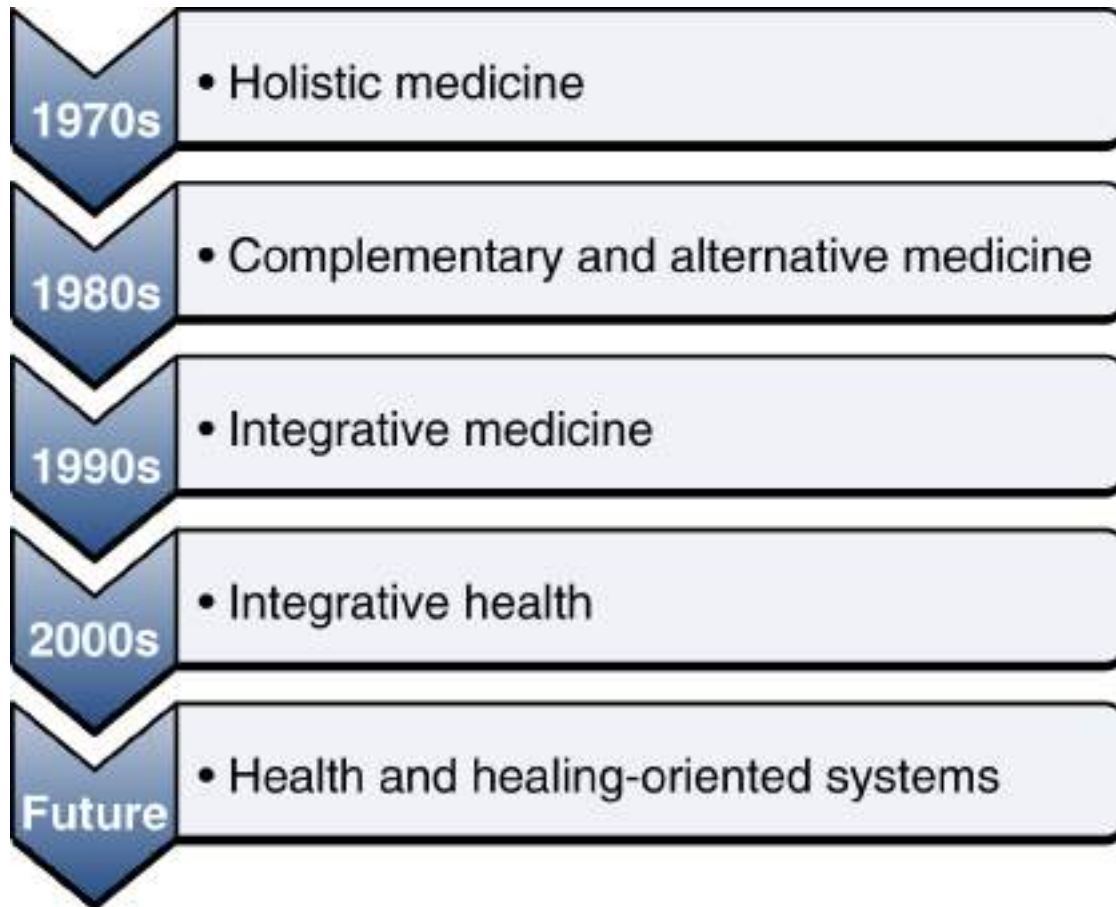

FIG. 1.5 Evolution of titles in the field.

It is important to see the benefits and limitations of our current allopathic system and realize that science alone will not meet all the complex needs of our patients.²³

The Creation of Board Certification In Integrative Medicine

Creating a board certification process for physicians in integrative medicine was not without controversy. There were competing incentives. The underlying philosophy of integrative medicine was not to create a new field, potentially fragmenting care further, but to enhance the process of the medical delivery model. With the growth of interest in integrative medicine, acknowledgment of competency in the field was

required, particularly with training programs arising that were not adequate in time and scope.

Another challenge for the field was the importance of the creation of interdisciplinary teams that required collaboration across professions to improve health outcomes. This could not be accomplished through one profession alone. Board certification only recognized the training of physicians and not the whole health team. Despite these challenges, it was decided that a board certification process was needed to recognize the time and commitment invested in learning a body of knowledge for physicians that supported competence in the field.

In 2013, The American Board of Integrative Medicine (ABIOM) was formed through the American Board of Physician Specialties (ABPS). The first diplomats were awarded board certification in 2014. Although grandfathering was allowed initially, fellowship training in integrative medicine will be required after 2016 to sit for the board exam. The requirements for fellowship training programs to meet eligibility are currently being defined and will be available through the ABPS website²⁴ (see [Key Web Resources](#)).

Integrative Medicine

Integrative medicine is healing-oriented and emphasizes the centrality of the physician-patient relationship. It focuses on the least invasive, least toxic, and least costly methods to help facilitate health by integrating both allopathic and complementary therapies. These therapies are recommended based on an understanding of the physical, emotional, psychological, and spiritual aspects of the individual ([Table 1.3](#)).

TABLE 1.1

Name Changes of Integrative Medicine Organizations as Examples of a Shift in Intention From the Tools of Integrative Medicine to the Process of Integrative Health

Old Name	New Name
National Center for Complementary and Alternative Medicine (NCCAM)	National Center for Complementary and Integrative Health (NCCIH)
The Consortium of Academic Health Centers for Integrative Medicine (CAHCIM)	Academic Consortium for Integrative Medicine and Health (ACIMH)
The American Board of Integrative and Holistic Medicine (ABIHM)	Academy of Integrative Health and Medicine (AIHM)

TABLE 1.2**Simple Rules for the Twenty-First Century Health Care System**

Old Rule	New Rule
Care is based primarily on visits.	Care is based on continuous healing relationships.
Professional autonomy drives variability.	Care is customized according to the patient's needs and values.
Professionals control care.	The patient is the source of control.
Information is a record.	Knowledge is shared, and information flows freely.
Decision making is based on training and experience.	Decision making is evidence based.
"Do no harm" is an individual responsibility.	Safety is a system priority.
Secrecy is necessary.	Transparency is necessary.
The system reacts to needs.	Needs are anticipated.
Cost reduction is sought.	Waste is continuously decreased.
Preference is given to professional roles rather than the system.	Cooperation among clinicians is a priority.

From Institute of Medicine, Committee on Quality of Health Care in America. *Crossing the quality chasm: a new health system for the 21st century*. Washington, D.C.: National Academy Press; 2001.

TABLE 1.3**Defining Integrative Medicine**

- Emphasizes relationship-centered care
- Integrates conventional and complementary methods for treatment and prevention
- Involves removing barriers that may activate the body's innate healing response
- Uses natural, less invasive interventions before costly, invasive ones when possible
- Engages mind, body, spirit, and community to facilitate healing
- Maintains that healing is always possible, even when curing is not

The goal of integrative medicine is to facilitate health within complex systems, from the individual to the communities and environment in

which all things live.

Health and Healing-Oriented Medicine

“Health” comes from the Old English word *Hal*, which means wholeness, soundness, or spiritual wellness. Health is defined by the World Health Organization (WHO) as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.”²⁵ Cure, on the other hand, refers to doing something (e.g., giving drugs or performing surgery) that alleviates a troublesome condition or disease. Healing does not equal curing. We can cure a condition such as hypertension with a pharmaceutical product without healing the patient. Healing would facilitate changes that reduce stress, improve diet, promote exercise, and increase the person’s sense of community. In doing this, we help improve the balance of health of the body that may result in the ability to discontinue a pharmaceutical agent and thereby reduce the need for the cure.

An example of this can be seen in [Fig. 1.6](#). Here we have two trees, A and B. Tree A is obviously in a better state of health than tree B. This is likely because of its ability to be in balance with its environment. If a branch breaks on tree A, we can feel comfortable that if we mend the branch, it will likely heal well, or even heal itself. If a branch breaks on tree B and we mend it, the branch is not going to heal because the tree is not in a state of health. The point here is that our focus in medicine has been on fixing the branch while neglecting the health of the tree. If we give more attention to helping tree B find health either by removing barriers that are blocking its own ability to heal or by improving areas of deficiency, the branch will heal itself—we will not need to spend as much time and money fixing the parts.

Integrative medicine is about changing the focus in medicine to one of health and healing rather than disease. This involves understanding the influences of the mind, spirit, and community, as well as the body. It entails developing insight into the patient’s culture, beliefs, and lifestyle that will help the clinician understand how best to trigger the necessary changes in behavior that will result in improved health and thus bring more value to health care delivery.

Cure and fix when able, but if we ignore healing, the cure will likely not last or will give way to another disease that may not have a cure.

Increasing Value Through Integrative Medicine

You get what you pay for. In the past, the economics of health care delivery rewarded treating disease. When this is what is rewarded, health systems need more disease to sustain themselves financially. Here lie the crossroads. If we are to truly shift health care delivery to health, we have to start financially rewarding health outcomes.

FIG. 1.6 Healthy (A) and sickly (B) trees. It is important to see the benefits and limitations of our current allopathic system and to realize that science alone will not meet all the complex needs of our patients.²³

If the United States spent as much of their GDP as the second most expensive country after the United States, there would be an extra trillion dollars available for the United States to support health outcomes. The state with the lowest health care costs (Colorado) still outspends all of the Organisation for Economic Co-operation and Development (OECD) countries, most of which offer universal health care coverage. Those states with the lowest incomes have similar spending with worse than average life expectancy ([Fig. 1.7](#)).²⁶

Achieving high value for patients and incentivizing practitioners to foster health will become the overarching goal of health reimbursement in the future. In fact, Sylvia Burwell, the U.S. Secretary of Health and Human Services, has stated that *“Our goal is to have 85% of all Medicare fee-for-service payments tied to quality or value by 2016 and 90% by 2018.”*²⁷ Value is defined by the health outcomes achieved per dollar spent. It depends on results, not just inputs, and should be measured by the ways we can improve the quality of patients’ lives, not by the number of patients seen in a day. This will require a reimbursement model that rewards team-based care that transcends the one-on-one office visit and allows multiple avenues for patient communication and education among an interdisciplinary team of professionals. This is more complicated than attaching a payment to a procedure or diagnostic code. To understand how to promote health, the interprofessional team must address all aspects of what it means to be human, both physical and nonphysical.

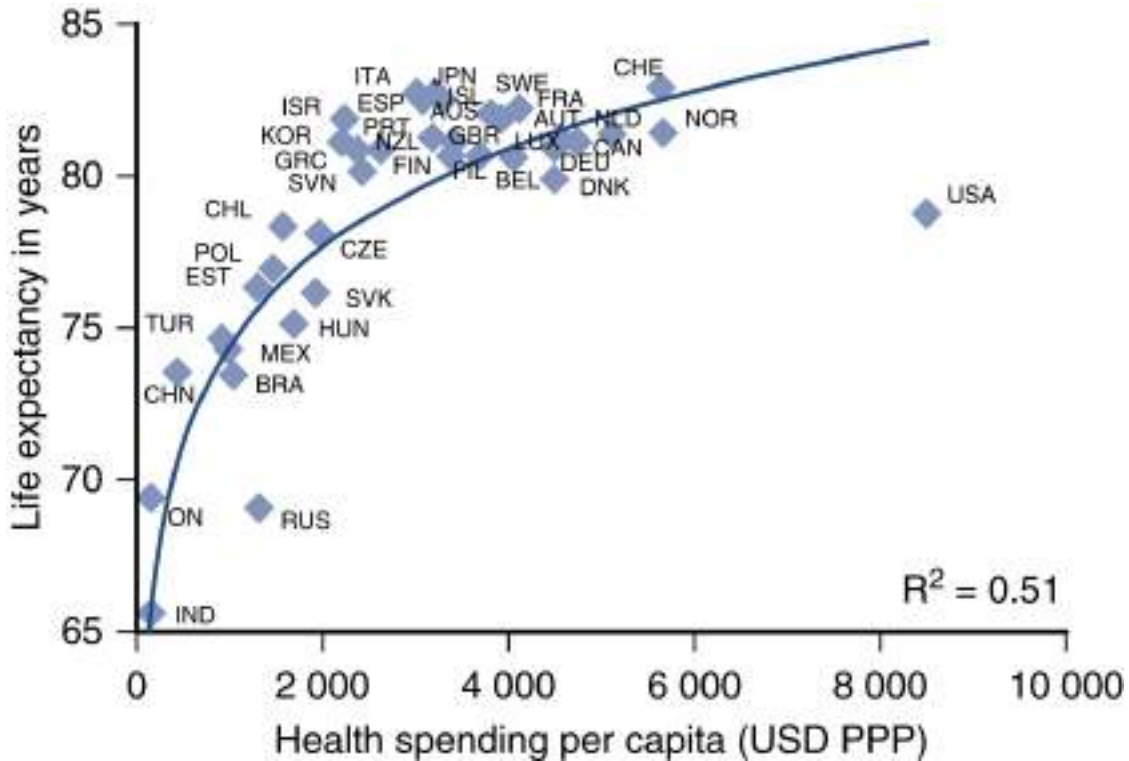

FIG. 1.7 Data points comparing Organizations for Economic Co-operation and Development (OECD) countries with high- and low-income U.S. states in relation to average life expectancy in years and health care expenditures by percentage of the gross domestic product (GDP). (From Fuchs VR. Critiquing US health care. *JAMA* . 2014;312:2095–2096.)

Integrative medicine can increase value and lower costs through two of its foundational values: (1) by shifting the emphasis of health care to health promotion, disease prevention, and enhanced resiliency through attention to lifestyle behaviors; and (2) by bringing low-tech, less expensive interventions into the mainstream that preserve or improve health outcomes. This approach requires that these professionals have time to recognize the complexity of someone’s life, and it cannot be done without a sound commitment to the practitioner-patient relationship.

Relationship-Centered Care

It is much more important to know what sort of patient has a disease than what sort of disease a patient has.

Sir William Osler

Observing practitioners of various trades, such as biomedicine, manual medicine, Chinese medicine, and herbal medicine, helps us realize that some practitioners have better results with their chosen trade. Those with more success are able to develop a rapport, understanding, and empathy that help them facilitate healing with their therapy. The relationship fosters healing not only by allowing the practitioner to gain insight into the patient's situation but also by building the patient's trust and confidence in the provider. This trust acts as a tool to activate the patient's natural healing response and supports whatever technique the provider uses, whether it is acupuncture, botanicals, pharmaceuticals, or surgery.

The evidence behind the benefits of relationship-centered care is solid, particularly with regard to reducing health care costs. This approach to care has been found to reduce expenditures on diagnostic tests,²⁸ reduce hospital admissions,²⁹ and lower total health care costs.^{30,31}

Developing a holistic understanding and relationship with patients allows the practitioner to guide them toward health more efficiently. The integrative clinician can point the way toward health while realizing that the patient will have to do the work to get there. This attitude does a great deal to remove pressure and guilt from providers who have been trained to think of themselves as failures when they cannot fix problems. In fact, relationship-centered care is a necessity when dealing with the many chronic conditions that do not have simple cures. Success is now defined as helping the patient find an inner peace that results in a better quality of life, whether the problem can be fixed or not (see [Chapter 3](#)).

Prevention

Integrative medicine encourages more time and effort on disease prevention instead of waiting to treat disease once it manifests. Chronic disease now accounts for much of our health care costs and also causes significant morbidity and mortality. The incidences of heart disease, diabetes, and cancer could be significantly reduced through better lifestyle choices. Instead, these diseases are occurring in epidemic proportions. The system needs a reallocation of resources. Unfortunately, this is a large ship to turn. In the meantime, integrative practitioners can use their broad understanding of the patient to make recommendations that will lead to disease prevention and slow or reverse disease progression.

Integration

Integrative medicine involves using the best possible treatments from both CAM and allopathic medicine based on the patient's individual needs and condition. This selection should be based on good science and neither rejects conventional medicine nor uncritically accepts alternative practices. It integrates successes from both worlds and is tailored to the patient's needs using the safest, least invasive, most cost-effective approach while incorporating a holistic understanding of the individual.

CAM is not synonymous with integrative medicine. CAM is a collection of therapies, many of which have a similar holistic philosophy. Unfortunately, the Western system views these therapies as tools that are simply added on to the current model, one that attempts to understand healing by studying tools in the toolbox. David Reilly said it well in an editorial in *Clinical Evidence*: "We are the artists hoping to emulate Michelangelo's David only by studying the chisels that made it. Meantime, our statue is alive and struggling to get out of the stone."³²

Integration involves a larger mission that calls for a restoration of the focus on health and healing based on the provider-patient relationship.

Reducing Suffering

The secret of the care of the patient is in caring for the patient.

Francis Peabody, MD

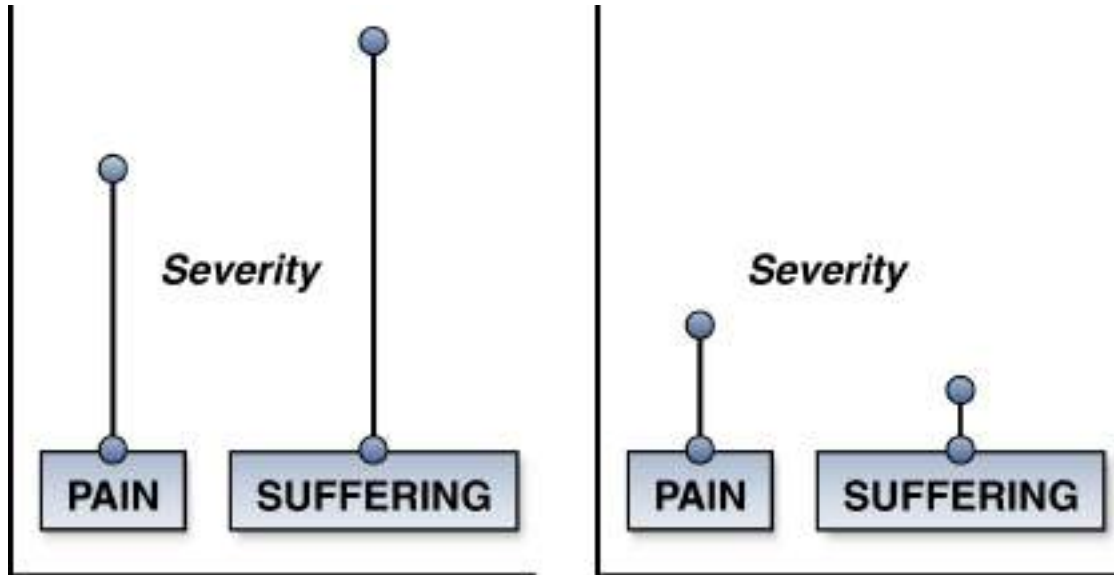

FIG. 1.8 Suffering's effect on the same source of pain. Treating suffering will help reduce the severity of pain and improve the quality of life and should be at the core of our work in integrative medicine.

Good caring and a weak medicine can give a better outcome than poor caring and a strong medicine.

Unknown

At the core of the delivery of health and healing is our ability to relieve suffering. This is not something that we learn in a book, but it requires that we explore our own suffering before we can understand how to help others with theirs. We are our own first patient, and part of our continuing education requires a recurring exploration of our inner self, so we can understand what it means to be truly present without judgment.

The integrative medicine practitioner is not afraid to turn toward suffering in the care of another. As each addresses what is real, the authenticity of the truth draws both toward healing.

In learning this, it is helpful to understand how suffering influences the severity of pain and our quality of life. Pain and suffering are intricately connected but are not the same. Pain is a normal bodily reaction; suffering is not. Pain helps protect us from further harm;

suffering is an opportunity to learn. Suffering influences how our body perceives pain—“the more I suffer, the more pain I experience” ([Fig. 1.8](#)). Our job is to reduce suffering so we can distil the pain to the most physiological reason for its presence. In treating someone’s suffering, we can often make pain more tolerable. In recognizing the severity of suffering, we can often avoid long-term medications that are used to suppress the symptom. It is often through our listening and our presence that we are best able to treat suffering. When no “right” answer or “drug cure” exists, it is our human compassion, connection, and unconditional positive regard that always works, even when our tools do not. This is the most important part of our work and is the reason that we heal in the process of helping others do the same.

The Future

Although the information age will continue to increase the amount of data on the variety of therapies available, it will only complicate how we apply them. Informed patients will be looking for competent providers who can help them navigate the myriad therapeutic options, particularly for those conditions for which conventional approaches are not effective. These patients will demand scientifically trained providers who are knowledgeable about the body’s innate healing mechanisms and who understand the role of lifestyle factors in creating health, including nutrition and the appropriate use of supplements, herbs, and other forms of treatment from osteopathic manipulation to Chinese and Ayurvedic practices. They will be seeking providers who can understand their unique interplay of mind, body, and spirit to help them better understand what is needed to create their own balance of health. This will require a restructuring of medical training that will involve more research and education on how the body heals and how the process can be facilitated.

Health-focused teams will be created within delivery models that assess the health needs of the population being served. Based on this need, the optimal team of professionals will be recruited to work together to improve health outcomes. This requires a common vision in which everyone works together toward each community’s unique health needs.

Conclusion

The philosophy of health based on a balance of mind, body, and spirit is not new or unique to integrative medicine. This understanding has been around since the time of Aristotle. What we call it is not important, but the underlying concepts are. It is time that the pendulum swings back to the middle, where technology is used in the context of healing and physicians acknowledge the complexity of the mind and body as a whole. Integrative medicine can provide the balance needed to create the best possible medicine for both the physician and patient. We will know that we are near this balance when we can drop the term integrative. The integrative medicine of today will then simply be the good medicine of the future.

Therapeutic Review

Integrative Medicine

- Emphasizes relationship-centered care
- Develops an understanding of the patient's culture and beliefs to help facilitate the healing response
- Focuses on the unique characteristics of the individual person based on the interaction of the mind, body, spirit, and community
- Regards the patient as an active partner who takes personal responsibility for health
- Focuses on prevention and maintenance of health with attention to lifestyle choices, including nutrition, exercise, stress management, and emotional well-being
- Encourages providers to explore their own balance of health that will allow them better to facilitate this change in their patients
- Requires providers to act as educators, role models, and mentors to their patients
- Uses natural, less invasive interventions before costly, invasive ones when possible
- Recognizes that we are part of a larger ecosystem that requires our efforts in sustaining its health so we can continue to be a part of it
- Uses an evidence-based approach from multiple sources of information to integrate the best therapy for the patient, be it

conventional or complementary

- Searches for and removes barriers that may be blocking the body's innate healing response
- Sees compassion as always helpful, even when other therapies are not
- Focuses on the research and understanding of the process of health and healing (salutogenesis) and how to reproduce it
- Accepts that health and healing are unique to the individual and may differ for two people with the same disease
- Works collaboratively with the patient and a team of interdisciplinary providers to improve the delivery of care
- Maintains that healing is always possible, even when curing is not
- Agrees that the job of the physician is to cure sometimes, heal often, support always—*Hippocrates*

CHAPTER 2

Creating Optimal Healing Environments

David Rakel, MD, Bonnie R. Sakallaris, PhD, RN, and Wayne Jonas, MD

Many health practitioners who go into primary care want to both treat and heal, to care for the whole person, to be patient advocates, to apply the best science, and to serve the suffering. In short, we seek to be healers.

However, we often find in medical school and in our practice that the skills needed to be healers and the environment needed to execute those skills are not taught, available, or funded. We know, for example, the factors that increase the risk of disease, but we wait until illness arrives. We understand that relationships, a positive attitude, and behavioral skills form the foundation for compliance and self-care, prevention, and well-being, but we find ourselves without the time to develop them. We see the search for meaning in patients' eyes when they suffer from a serious illness, and yet our science cannot help them find the coherence they seek. For optimal healing to take place, we need to be proactive in creating an environment where these things can happen—to give patients realistic hope.

Every medical recommendation is done in a dynamic environment of care delivery. This environment consists of both physical and nonphysical elements. It often includes a synergy among factors that can either promote or hinder the healing process. Our goal in this chapter is to describe the foundational characteristics of an optimal healing environment (OHE) so that any therapy that is prescribed within this space (shown as a container in [Fig. 2.1](#)) will be more successful.

The Optimal Healing Environment

We define an OHE as an environment in which the social, psychological, spiritual, physical, and behavioral components of health care are oriented toward support and stimulation of innate healing capacities and the achievement of wholeness. This definition is an expansion of Engel's biopsychosocial model, which created a foundation for understanding the dynamic influences of health.¹ An OHE consists of people in relationships, their health-creating behaviors, and the surrounding physical environment.² The Samueli Institute has been a leader in researching and implementing a framework to optimize the potential for healing.^{2,3} To enhance clinical delivery, this framework is organized into four environments as shown in [Fig. 2.2](#): internal, interpersonal, behavioral, and external. Each of these environments has two essential constructs that work synergistically to support and stimulate health as shown in [Table 2.1](#).

Internal

- Healing intention
- Personal wholeness

The internal environment recognizes that each person has a unique interaction of mind, body, and spirit that can be directed and supported towards healing. The internal environment is vital to healing because our thoughts, emotions, and spirit have a direct effect on our bodies, our choices, and our relationships. This process is fostered by inner beliefs and expectations that healing and wellness can and will occur.³ Such belief requires self-reflection, in which each individual becomes aware of his or her own internal wholeness, trusting its healing potential.

It is difficult to connect truly with intention until we have explored our own inner nature.

Patient care starts with us and our preparation to be healers through practices that foster cohesion of body, mind, and spirit. As this connection grows, our ability to sit fully with another suffering human will be enhanced, and appreciation in our work will grow. This growth brings forward foundations in healing that include personal wholeness, positive expectation, hope, faith, and compassion.⁴

Interpersonal

- Healing relationships
- Healing organizations

The interpersonal environment stresses the importance of personal, family, professional, and organizational therapeutic relationships that support and encourage healing. Healing relationships are the connections between persons who hold an intention for healing to occur. The attribute that distinguishes a healing relationship from other positive relationships is the intentional and covenantal nature of the connection, which involves positive emotional engagement with mutual benefit.³ This relationship includes the art of the clinician, who intentionally learns about the patient in the context of life to recruit the innate ability present in each person for healing^{5,6} (see [Chapter 3](#), The Healing Encounter). Healing organizations are as important, as they provide the structures, processes, and resources to stimulate and support healing through intention, relationships, person-centered strategic planning, and shared decision-making.

Through the intent of healing relationship, unhealthy emotions are released and optimism and positive expectations are born. This can be the fulcrum that shifts behavior.

Optimal Healing Environments

FIG. 2.1 Schematic showing that the therapy we prescribe comes from within a container of influences that can enhance its effectiveness.

Behavioral

- Healthy lifestyles
- Integrative care

Healthy lifestyles and behaviors involve actions that promote health, prevent or even treat disease, and enhance self-healing mechanisms.^{7,8} These actions should be directed by the patient but supported by the most appropriate professional in an integrative care team to help the individual succeed in achieving their health goals (see [Chapter 4](#), The Whole Health Process). These behaviors, when motivated by personal meaning, are the main drivers of health outcomes.⁹⁻¹³ Empowering the individual to best care for himself or herself so both the provider and the patient are active participants in the healing process is a key factor. Some would say that all healing is self-healing, and we, as integrative medicine practitioners, are at our best when we are able to facilitate individuals to care for themselves most successfully. The integrative care team should have this principle as their collective goal. These behaviors can have epigenetic influences on the expression of a healthy phenotype.^{14,15}

TABLE 2.1

Optimal Healing Environments

Inner Environment to the Outer Environment						
Healing intention	Personal wholeness	Healing relationships	Healing organization	Healthy lifestyles	Integrative collaborative medicine	Healing spaces
Empowerment	Mind	Compassion	Leadership	Diet	Person-oriented	Nature
Hope	Body	Empathy	Mission	Movement	Conventional	Light
Understanding	Spirit	Social support	Culture	Relaxation	Complementary	Color
Belief	Family Continuity	Communication	Teamwork	Addictions	Culturally appropriate	Architecture
Enhanced awareness expectancy	Dihaical personal integration	Enhanced caring communication	Enhanced delivery process	Enhanced healthy habits	Enhanced medical care	Enhanced healing structure

Modified from Jones WB, Chez RA: Toward optimal healing environments in health care, *J Altern Complement Med.* 10(suppl 1):51-56, 2004.

External

- Healing spaces
- Ecological resilience

The external environment consists of using and sustaining a physical place that supports the health of living beings and the global environment in which all things live. Nature, color, light, fresh air, music, fine arts, and architecture should be used to create influences that support the health and well-being of those who enter the space. This healing space is not only aesthetically pleasing but supports the engagement of its occupants to explore the internal, interpersonal, and behavioral process described above. The importance of ecological resilience is vital, as our health is impeded if we are not able to live within a healthy ecosystem (see [Chapter 108](#), Reducing Toxic Exposure; [Chapter 117](#), Creating a Green Clinic).

Healing can be defined as the dynamic process of recovery, repair, reintegration, and renewal that increases resilience, coherence, and wholeness. Healing is an emergent, transformative process of the whole person—physical, mental, social, spiritual, and environmental.

Healing is a unique personal and communal process and experience that may or may not involve curing.¹⁶

Spiritual Connection

Spirituality is a journey toward, or experience of, a connection that gives life meaning. This journey is unique to each individual and often drives action. Motivation for changing behaviors often comes from an

individual's connection to meaning. As Viktor Frankl writes, *"Those who have a 'why' to live, can bear with almost any 'how'."* It is unfortunate that the importance of this connection rarely enters consciousness until it is threatened by a heart attack or the diagnosis of cancer. Creating awareness between the chasm of our behaviors and what gives life meaning is the key ingredient in the success of motivational interviewing (see [Chapter 101](#), Motivational Interviewing Techniques). The spiritual process of connecting to meaning and purpose empowers the OHE to be effective and sustainable.

Creating an Optimal Healing Environment in the Clinical Setting

How can we bring the components of an OHE into a busy practice? Although transforming a practice into a healing environment may seem like a daunting task, or one with little practical value, experience and evidence indicate that attention to simple and inexpensive details often gradually moves the focus of care from cure alone to one filled with healing activity.¹⁷

The practitioner can develop healing-oriented sessions within the clinical space without having to go through major renovations. The primary care practitioner already has the foundational relationship-centered tools needed to create an OHE. The nonphysical intention is much more important than the physical space. Healing can occur anywhere, whether it is in an \$8 million healing center or in an underfunded inner city clinic for the homeless ([Table 2.2](#)).

Foundations of a Healing Encounter

To understand the intrinsic value of a therapeutic modality, the scientific model requires that we isolate it from the environment in which it is prescribed. The investigation is also blinded so that the belief systems of the patient and the prescriber do not influence the results. This model is important for research but unrealistic when we look at the more complicated environment in which health care is delivered. In fact, the environment in which the prescribed therapy is given may be more effective than the therapy itself.¹⁸

In the early 1990s, Frank and Frank¹⁹ described four ingredients that

are present in a healing encounter:

1. An emotionally charged relationship with a helping person
2. A healing setting (an expected place to go for healing)
3. An explanation for the symptoms that resulted in a sense of control and understanding
4. A ritual, procedure, or plan that involves active participation of both parties that each believes will restore the person to a state of health (a mutual belief followed by an action to overcome the problem)

When one of the chapter authors, David Rakel, was in practice in rural Idaho, he believed that a selective serotonin reuptake inhibitor was the most successful drug he prescribed. In retrospect, however, the fulfillment of these four criteria may have played a major role in patient improvement. If we look at an example of what happens before we prescribe medication to someone who is depressed, we can better understand this concept.

A depressed gentleman whose life is in chaos comes to see you, his physician, with whom he has a relationship based on trust and a holistic understanding of who he is. The patient has come to a healing setting (medical clinic), where he has the expectation that he will receive help. You give him a logical explanation for his symptoms (“a reduction in the level of serotonin”) that offers a sense of control and understanding. Both you and the patient agree on a prescribed therapy that you believe will restore health. You then write down the “answer” on a prescription pad and hand it to him, which then completes the healing ceremony.

When this ritual was performed in a study of St. John’s wort, sertraline (Zoloft), and placebo for major depression, it was not the plant or the pill that had the greatest effect, but the ritual (placebo) 8 weeks after initiating therapy.²⁰ A meta-analysis and review of data submitted to the U.S. Food and Drug Administration for drug treatment of depression also found little difference between the medication and the placebo for mild to moderate depression; both had beneficial effects^{21,22} (see [Chapter 3, The Healing Encounter](#)).

TABLE 2.2

Optimal Healing Environment

Description of Sample Case Study		
OHE	OHE Present	OHE Absent
General case description	Mike is a 42-year-old man with low back pain for 8 weeks. He has no history of acute injury, no radicular symptoms, and no improvement despite chiropractic manipulation and over-the-counter NSAIDs.	Mike is a 42-year-old man with low back pain for 8 weeks. He has no history of acute injury, no radicular symptoms, and no improvement despite chiropractic manipulation and over-the-counter NSAIDs.
Relationship-centered care	Mike goes to see Dr. Smith because he knows and trusts her. She helped him through his divorce several years ago.	Mike has no primary care provider. He goes to a local health care clinic close to his home, and sees whichever physician is available at the time he visits.
Healing space	Mike likes Dr. Smith's office. It is warm and welcoming, and makes him feel at ease, safe, and comfortable.	The clinic is cold and uninviting. You can hear the voices from the busy street as you hear the paging system overhead telling the physician that the patient is ready in Exam 2.
Self-care	Dr. Smith seems to "walk the talk." Mike sees her jogging around town at lunch, and she never seems stressed out like so many other physicians.	Dr. Jones seems rushed and stressed by the demands of all the patients backed up in the waiting room. She appears to be overweight, pale, and fatigued.
Attention and attention	What Mike likes best about his physician is that she seems totally present when she sees him. He feels like he is the most important thing on her mind during his visits.	Mike finds sorry for the overworked physician and wants to give her information in an efficient manner so that she can do her job quickly. She maintains eye contact, often little eye contact, and seems distracted by the many demands on her time. Mike feels disconnected.
History	Dr. Smith does a full physical examination that shows muscle spasm in the right quadratus lumborum muscle group but no other concerning signs. Mike feels comfortable telling Dr. Smith about the loss of his job a few months back. She educates him about how the body can compensate and experience symptoms when the mind is under stress.	Dr. Jones focuses on Mike's back pain and asks directed questions related to his discomfort. There does not appear for questions beyond Mike's physical symptoms. The examination shows muscle spasm in the right quadratus lumborum muscle group, but no other concerning signs are noted.
Collaborative care	Dr. Smith refers Mike for counseling to develop further insight into how his life situation can influence his health. He will also see an acupuncturist to help reduce the severity of his pain.	Dr. Jones is concerned about the length of Mike's symptoms without resolution. She orders an MRI scan and refers Mike to an orthopedic surgeon for further evaluation. She educates Mike about the potential benefits of an epidural block.
Lifestyle	Dr. Smith sees that Mike has gained 15 lb in the last year and discusses the need for him to start a gradual exercise program and work on getting back to his ideal body weight. She also recommends a book that discusses the relationship between back pain and stress.	Mike is given a prescription for hydrocodone and a patient education handout on low back pain exercises. He is told that if walking helps, he may be a candidate for long-term opioid pain management.
Spiritual connection	Dr. Smith knows that Mike has a love of photography and the outdoors. Many of his photographs can be found around town in local shops. She encourages Mike to take this opportunity to direct his career to fulfill those things that he loves to do.	Mike leaves hopeful that the medications will reduce his pain and discomfort.

Compare and Contrast	OHE Present	OHE Absent
Outcome	Dr. Smith encourages the development of personal insight into how Mike's life situation is influencing his health. She understands what Mike can do to help this situation resolve.	Dr. Jones focuses on symptom resolution.
Goal	The initial goal is symptom resolution.	The initial goal is symptom suppression.
Symptom management	Dr. Smith recruits internal resources to facilitate health and healing.	With Dr. Jones' approach, the lack of a holistic view and of relationship-centered care results in a focus on the physical symptom without encouraging the patient's insight.
Use of resources	The use of resources is reduced.	The use of resources increases.
Cost	The long-term cost is low.	The long-term cost is high.
Side effects	Most side effects are potentially positive (e.g., joy in a new hobby, insight into behavior, increased well-being, and reduced risk factors).	Most side effects are potentially negative (e.g., nausea from hydrocodone, potential drug addiction, and possible surgery).

MRI, magnetic resonance imaging; NSAIDs, nonsteroidal antiinflammatory drugs; OHE, optimal healing environment.

During the early development of family medicine, this process was known as the “art of medicine” and was held to be an important feature of the specialty. With the rise and dominance of pharmaceuticals and evidence-based medicine, it became known as the placebo effect and was not supported in medical care. Subsequently, accumulating evidence on the importance of the healing context and encounter resulted in a re-interpretation of this effect as the creation of an OHE.⁵ It is important to be aware of these key healing elements so they can be systematically brought into clinical practice.

A Case of Low Back Pain

The case of Mike, a 42-year-old man with low back pain discussed in [Table 2.2](#), illustrates how treatment may progress in the presence or absence of an OHE. This case touches on the complexity of applying the best evidence within the context of each human being's unique life, culture, and belief system. Actively recruiting the ingredients of an OHE can dramatically influence the outcomes achieved with the therapy prescribed.

Acupuncture Versus Epidural Steroids

Acupuncture and epidural steroids have been studied for the treatment of low back pain. Both involve sticking an object through the skin and both include a therapeutic ritual between clinician and patient. As with all therapies, each may be perceived differently by the patient based on their culture and belief system. If we look at the evidence regarding acupuncture, it appears to work better than no treatment but not significantly better than sham acupuncture for low back pain.²³ If we look at the evidence for epidural steroids, they work better than no treatment, but adding a steroid does not seem to result in better outcomes compared to injecting xylocaine alone.²⁴ Acupuncture's effect may last longer, up to 2 years,²⁵ whereas epidural steroids have only short-term benefits.²⁶ Acupuncture is less expensive and less invasive than epidural steroids and likely explains why acupuncture but not epidural steroids was approved by the United Kingdom's National Institute for Health and Care Excellence (NICE) guidelines for treating low back pain.²⁷

Specific and Nonspecific Variables

Evidence suggests that the specific effect of acupuncture may be slightly better than the specific effects of epidural steroids, with lower cost and less potential for harm. The OHE is used to enhance the effect size of a therapy through nonspecific variables that include meaning and context (MAC). Examples of the importance of meaning and context include the choice of words used by a clinician while administering a therapy and the matching of a therapy to the culture that has influenced the patients' beliefs. Both of these actions can enhance the OHE by creating positive expectations.

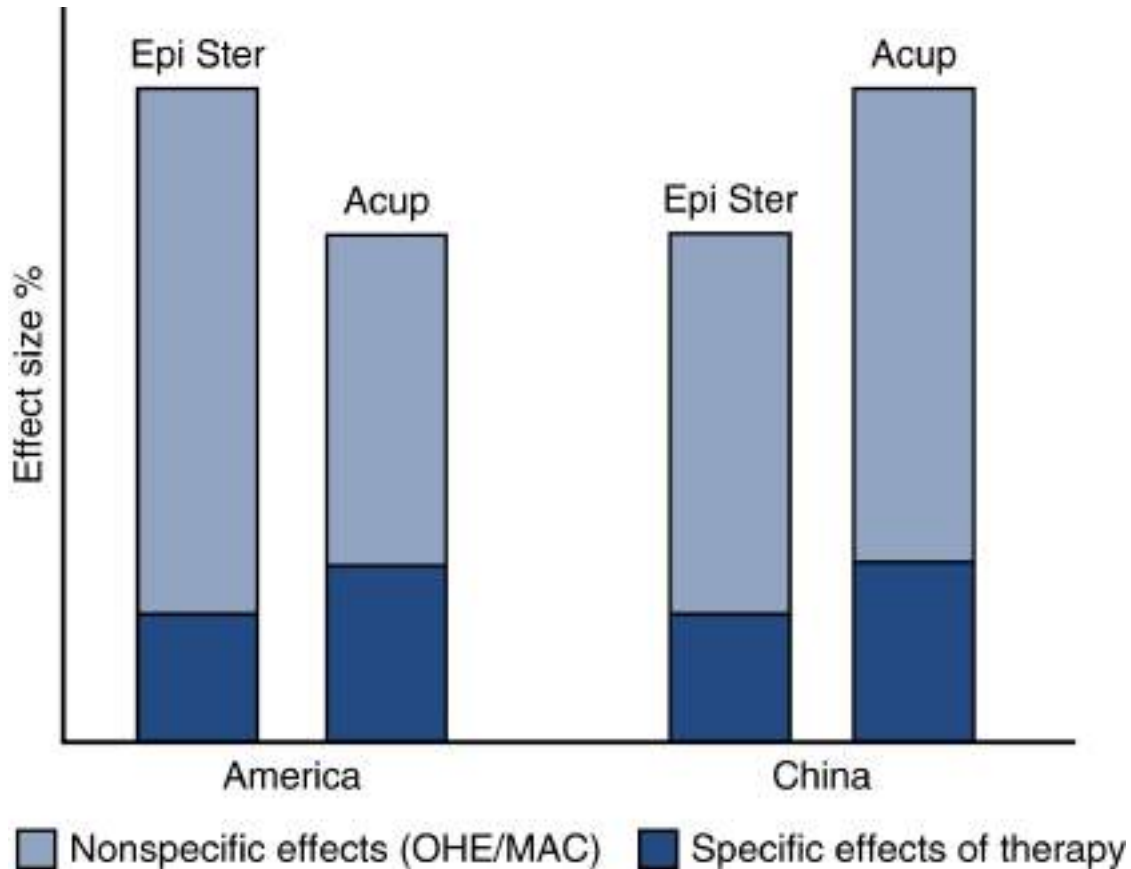

FIG. 2.3 Acupuncture vs epidural steroids. Epi Ster, epidural steroids; MAC, meaning and context; OHE, optimal healing environment.

In a study evaluating areas of the brain affected by the administration of acupuncture needles, there was a significant difference if the needles were simply placed without words compared to being placed by a therapist who created positive therapeutic expectations. The former action merely activated the sensory cortical areas of the brain, while the latter stimulated both the sensory and the limbic centers.²⁸ Using encouraging words (“This acupuncture meridian will help calm your pain”) to create positive expectations can have dramatic effects on the therapeutic outcome, adding to the specific effects.²⁹ An OHE stacks the deck towards a more robust healing response.

Moerman looked at the healing of ulcers in dozens of placebo-controlled studies from multiple countries. The healing effects of the therapeutic ritual (placebo group) ranged from 0% to 100%, with wide variation from country to country. Patients in Germany experienced large effects, while those in the Netherlands experienced small effects.³⁰ What was effective in one country was not effective in another. This

“country of origin” effect shows that the outcomes are affected in part by the context of the patient and the culture they grew up in. These are just a few of many examples of the power that the OHE can add to the specific effects of any therapy. [Fig. 2.3](#) shows the hypothetical power of these multiple effects, which honors the power of meaning and context supported by the OHE. Even though the evidence indicates that acupuncture is more effective than epidural regarding specific effects, the context and culture in which the treatment is given can determine how well it works. The reason the data in [Fig. 2.3](#) is so variable is that there are many important nonspecific effects that can influence outcomes. These factors are summarized in [Table 2.3](#).

TABLE 2.3**Techniques to Maximize Healing Through an OHE**

Have a skilled clinician in communication create positive expectation towards healing. [34,35](#)

Listen and provide empathy and understanding. [34,51](#)

Match the therapy to the patient’s culture and belief system. [30,52](#)

Provide an explanation for a problem that increases the sense of control and understanding. [53](#)

Create positive expectations of the therapy being prescribed. [54](#)

Deliver the therapy with confidence from a credible source. [55](#)

Provide therapy in a therapeutic setting that includes elements of nature. [56](#)

Research the treatment so the prescriber has belief in the therapy being recommended. [57](#)

Touch the patient. [58,59](#)

Use the newest therapy. [60,61](#)

Use a name brand well-known by the culture with more information on the label. [62](#)

Charge a higher price but not too high. [62,63](#)

Cut or stick the skin when it is believed to be important. [60](#)

Create a therapeutic ritual using a tool such as a knife, pin, pill, laser, or light. [62,64](#)

Write down a plan that both the clinician and patient agree

will facilitate health (therapeutic contract).¹⁹

From Jonas WB: Reframing placebo in research and practice, *Philosophical Transactions of the Royal Society of London. Series B, Biological Sciences* 366(1572):1896-1904, 2011.

The Practitioner's Influence on Healing

Psychotherapy is a good area to explore the ways in which therapeutic interaction influences healing because it employs few external physical tools such as drugs and surgery. When researchers looked at factors that influence positive health change in psychotherapy, the factor within the therapist's control that influenced healing the most (30%) was the establishment of a therapeutic relationship in which the patient felt a sense of trust and rapport.³¹ A study on the "most effective" psychotherapists found that those patients receiving counseling from therapists most talented in developing trusting relationships were much more likely to respond positively to medications than were those patients seeing less effective therapists.³² In fact, when psychiatrists who were rated "high" in relationship and rapport treated depressed patients using a placebo, they had better outcomes than did psychiatrists who were rated lower and who used active drugs.³³ Thus, the practitioner, rather than the pill, had the largest impact on the outcome.

The quality of the clinician-patient interaction influences outcomes. Studies of practitioners' effects on the severity and duration of the common cold and irritable bowel syndrome showed significant enhancement of the therapeutic effect when the treatment was given through an "enhanced" or "augmented" clinical visit in which the clinician took time to create a connection that was perceived as empathetic.^{34,35}

Contributions to the Healing Process

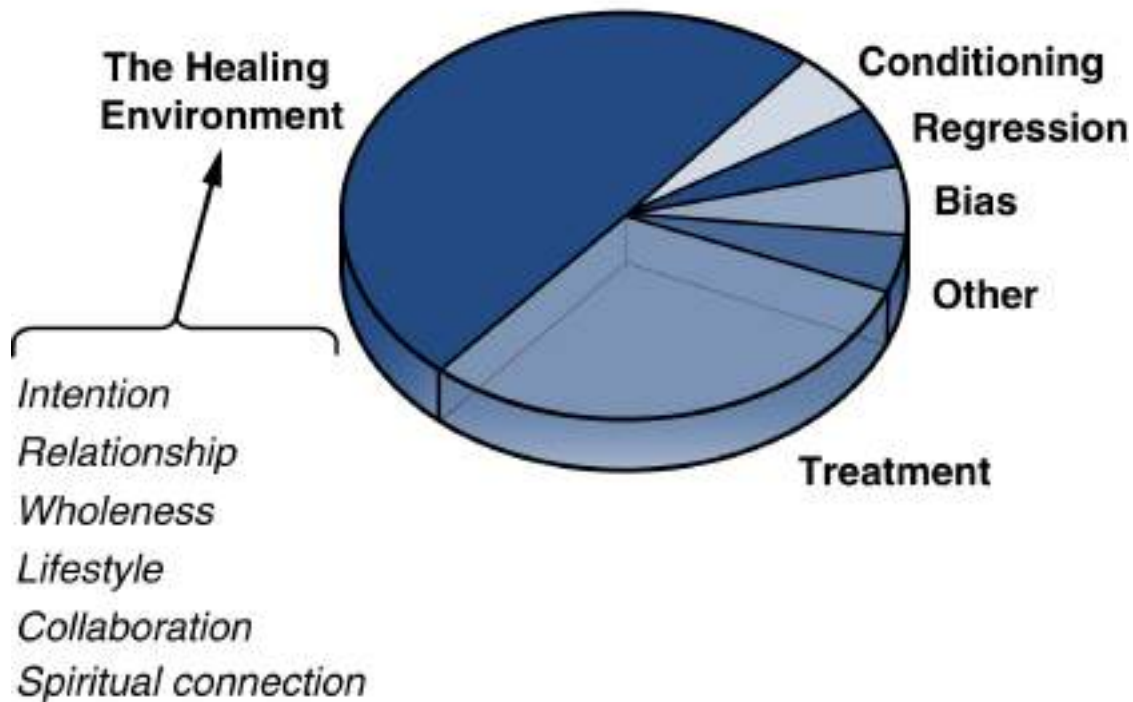

FIG. 2.4 Influences on the healing process.

In treating one of the most common conditions encountered in primary care—diabetes—high ratings of physician empathy by diabetic patients correlated with better outcomes in diabetes management.³⁶ Nonspecific healing influences found within the clinical encounter should be the foundational intent of interdisciplinary teams focusing on health outcomes of populations (Fig. 2.4).³⁷

Creating an OHE will bring more joy to your work. It will allow you to connect with those key elements that attracted you to health care, and in doing so, you will find more meaning and purpose.

Health Teams

New models of care are being designed to improve value and access and reduce cost in the United States. The practitioners of integrative medicine will be leaders in this movement because its philosophy places health creation as its highest priority. Both integrative and conventional medicine will require the assembly of teams of professionals based on the health needs of the community they serve. However, these teams are not

simply a potpourri of professionals working independently in proximity. For example, if 30% of a community suffers from obesity, metabolic syndrome, and diabetes, the strategic medical home base will recruit professionals best suited to address this need. This team may include nutritionists, exercise physiologists, spiritual guides, psychologists, health coaches, and physicians. These team members need adequate communication so that the services of each are used to maximize the benefit to the patient. When professionals from varied disciplines come together, shared knowledge allows for insight from different perspectives that can stimulate an “ah ha!” moment in which new ideas allow them to transcend old models of care. When this happens, an interdisciplinary team becomes a transdisciplinary team, and new models of delivery are defined.³⁸ Multifaceted team-based interventions in primary care are more effective in influencing positive lifestyle behaviors than is isolated specialty care ([Table 2.4](#)).³⁹⁻⁴¹

TABLE 2.4
Defining Disciplinary Teams

Multidisciplinary team	Additive. “Comprising more than two professionals from different health care disciplines who work with the same patient, set of patients, or clinical condition, but provide care independently of each other” (interdisciplinary team building). For example, a patient may have visits with both a primary care practitioner (PCP) and a physical therapist (PT). Although the PCP may view clinical notes or a report from the PT, the two disciplines usually do not interact.
Interdisciplinary team	Interactive. “Dedicated to the ongoing and integrated care of one patient, set of patients, or clinical condition” (interdisciplinary team building). Team members develop collegial relationships with shared goals and joint decision making. They interact, support, as well as question each other’s opinions and negotiate to develop health strategies based on the needs of the individual.
Transdisciplinary team	Holistic. Professionals learn from each other and in the process transcend traditional disciplinary boundaries that may result in the emergence of new knowledge. Often, the greater the difference between professions (epistemologic distance; e.g., engineering and humanities), the more likely insight will develop toward the creation of a new way to solve a problem.

From Raket DP, Jonas W: The patient-centered medical home. In Raket R, Raket D, editors: *Textbook of Family Medicine*. 8th ed, Philadelphia, 2011, Saunders; data from Choi BC, Pak AW: Multidisciplinarity, interdisciplinarity, and transdisciplinarity in health research, services, education and policy: 3. Discipline, inter-discipline distance, and selection of discipline, *Clin Invest Med* 31:E41-E48, 2008.

Environment’s Influence on Genetic Expression

The goal of an integrative medicine health-oriented team is to work together to create OHEs. Environments can have an influence on the genome of the organisms that live within them. The scientific evidence for this epigenetic influence is exploding and gives power and hope to

the individual to make positive lifestyle choices by attending to and changing their environment (Fig. 2.5).

Animal studies showed that genetically identical agouti mice that were bred to develop obesity and diabetes could have this expression suppressed when the mothers were fed methyl-donating foods (genistein) before they gave birth.⁴² An Amish community was assessed to see whether carriers of the *FTO* obesity gene would become overweight, and it was found that carriers who averaged 18,000 steps in 1 day remained at a normal weight. Their lifestyle habits trumped their genetic risk.¹⁵

Telomeres are the protective DNA-protein complexes at the end of the chromosomes that promote stability. Loss in their length has been associated with increased risk of disease and premature mortality. Telomere shortening is counteracted by the enzyme telomerase, and more of this enzyme is beneficial. Ornish et al.^{14,43,44} investigated telomerase levels in 30 men with prostate cancer. After 3 months of healthy lifestyle changes including moderate exercise, a low-fat, plant-based diet, and social support, the telomerase levels rose⁴³ and oncogene expression was inhibited.⁴⁴ Exercise alone can increase telomerase activity⁴⁵ and brain volume.⁴⁶ Stress can decrease telomerase levels,⁴⁷ whereas practicing the relaxation response can have a positive influence on genetic expression⁴⁸ and reduce the expression of genes that promote inflammation.⁴⁹ Although these behaviors are powerful, they are not the sole dictator of outcomes. The body–mind is complex and mysterious. The clinician should be careful not to instill guilt regarding lifestyle habits when cancer or heart disease is diagnosed. Instead, the clinician should reassure the patient that, even when disease progresses, improved well being and function are more likely if he or she continues or adopts healthy behaviors while incorporating interventions that will have the most benefit.

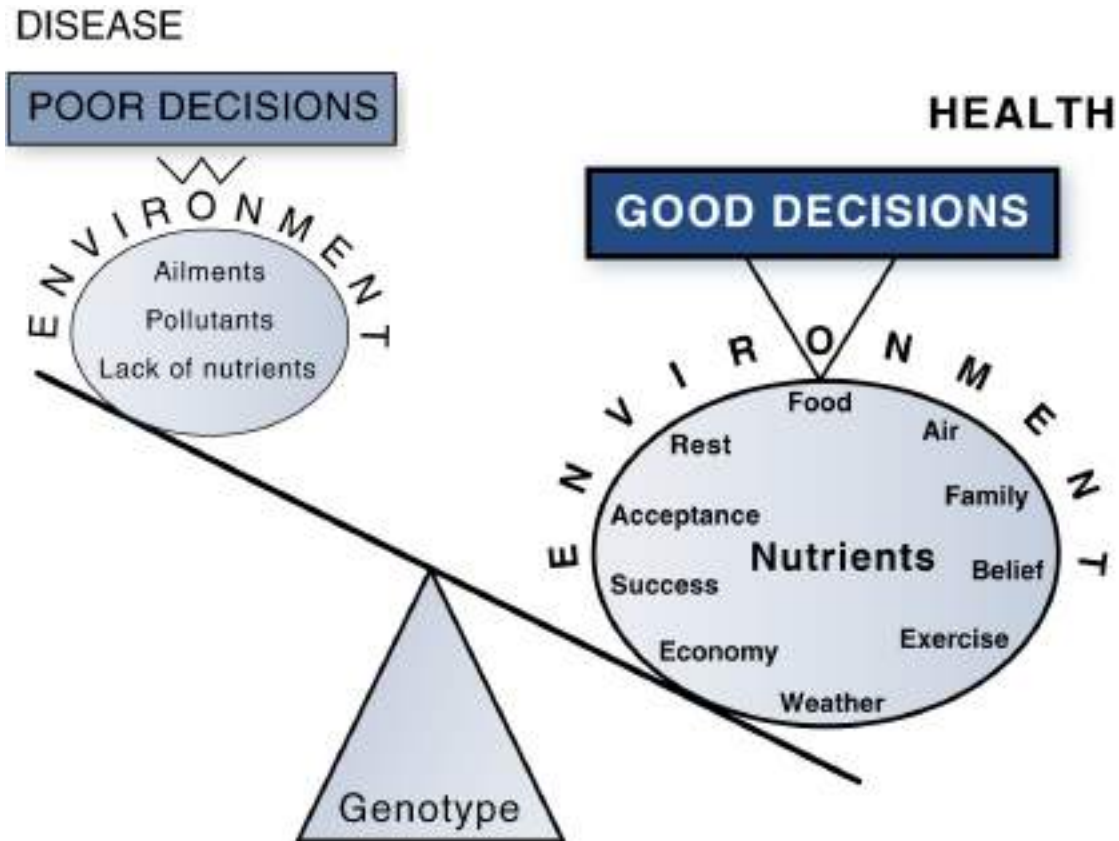

FIG. 2.5 Depicted is a balance representing the person's unique genetic constitution and the direction into which his or her decisions will poise the organism's well-being, determined by the presence of nutrients, ailments, or pollutants. A nutrient can be understood as any element that nourishes the body and mind.

The Value of Creating Optimal Healing Environments

Business Case for Optimal Healing Environments

Most health care leaders agree that healing is at the core of their mission. The reality of current incentives and cost-containment initiatives has caused many practices to set aside healing practices in favor of direct revenue-producing activities. The Samueli Institute studied three financially-thriving organizations who committed additional time and resources to create an OHE. Each of the organizations reported a cost per

patient day or encounter that is higher than the average. However, the costs are minimal when compared to overall budgets. They found that creating an OHE provided market differentiation, improved community engagement, and promoted positive staff and physician engagement and positive patient experience scores.⁵⁰ In addition, the organizations studied realized efficiencies related to the emphasis on person-centered and team-based care. When patients are involved in decisions and in the plan of care, wait times and frustration points are minimized. Integrating multiple disciplines into care provides checks and balances and communication patterns that reduce errors.

Health as a Continuum

The continuum of health starts with ourselves, is supported by others, is influenced by lifestyle choices, and is shaped by our inner and outer environments. This continuum recognizes the importance of the interconnectedness of all things. Health is not found in isolated parts but throughout the whole. Being an integrative medicine practitioner means recognizing the dynamic and complex ecosystem in which we live and working to support its health. In doing so, we occasionally pause to witness the mystery of how nature continuously strives for balance despite the odds we have created against it.

I would rather live in a world where my life is surrounded by mystery than live in a world so small that my mind could comprehend it.

Harry Emerson Fosdick

Several years ago, a primary care clinic in England introduced a spiritual healer into its practice. This was done quietly, without advertisement. Patients who had refractory, chronic illnesses, were high-frequency health care users, and were taking multiple drugs were offered 12 sessions with the healer. Health care use costs, symptoms, and well-being were measured before and after the study period. Almost all patients got better: health care visits decreased; patients improved in their energy and well-being; and although the diseases were not actually cured, suffering was relieved.

Costs were reduced by \$2000 per patient per year. Most interesting, however, was the change this approach had on the physicians in the practice. When the investigators examined what the healer did during sessions, the procedures were simple. The healer spent a long time

listening intently to the patients and hearing what their concerns were about the illness, linking it up with family events, and challenging patients to perceive their connectivity beyond themselves, to imagine a future that was better and improved. The healer then spent time doing some bioenergy work, holding her hands over the patient in the traditional laying-on-of-hands manner. The physicians in the clinic soon realized that many of these same behaviors were similar to things they had been taught to value in medical school but had not often been able to incorporate into their own practice. These physicians then found themselves spending a few more moments with patients and asking them about social and family issues that earlier they would have glossed over or ignored. They provided and received feedback about the meaning of a person’s illness and listened and responded in a warmer fashion.

In other words, the physicians realized that they, too, could become healers in the classic sense of the term.⁶¹

CHAPTER 3

The Healing Encounter

David Rakel, MD, and Luke Fortney, MD, FAAFP

To find health should be the object of the doctor. Anyone can find disease.

T. Still, MD

To write prescriptions is easy, but to come to an understanding of people is hard.

Franz Kafka

What kind of doctor do I need to be for this patient today?

Michael Balint

Medical encounters in the recent past have been dominated by the 15-minute “problem-focused” office visit that only addresses symptoms and disease. While this *pathogenesis*-focused encounter addresses the creation of disease, the healing encounter has a different goal of *salutogenesis*, which focuses on health and prevention.¹ Here the clinician’s intent is to develop an understanding of what the person needs to self-heal and be well. This chapter focuses on how the clinician can most efficiently *allow* this process to unfold. At its deepest level, this healing process is not one-sided, but allows both the patient and the clinician to be transformed by the process together. The result can be the most rewarding aspect of the medical profession.

Salutogenesis means “the creation of health,” which is the opposite of *pathogenesis* (the creation of suffering and disease). The goal of the healing encounter is to facilitate health and well-being that transcends

the physical alone and results in less suffering, greater understanding, and improved quality of life.

Practitioner Versus Pill

The mind often attributes healing to external influences outside of ourselves, such as from drugs, herbs, an acupuncture needle, etc. These specific variables are often the most thoroughly studied and are thought to contribute the most benefit, partly because they are physical treatments that can be easily quantified. The gold standard in medical research, the double-blind placebo-controlled trial, focuses on removing nonspecific variables that can often be more powerful than the pill or procedure being studied. These nonspecific variables include aspects of care that are difficult to quantify and include trust, empathy, a sense of control, and compassion, which are key ingredients of the healing encounter. These nonspecific variables are important to healing. For example, they have been found to enhance the effects of acupuncture for irritable bowel syndrome,² shorten the duration of the common cold,³ trump antidepressants for mild to moderate depression,⁴⁻⁶ and improve clinical outcomes in patients with diabetes,⁷ among others. The nonspecific effects that have been most thoroughly studied in influencing healing in the clinical encounter can be summarized through the *PEECE mnemonic*: P, positive prognosis; E, empathy; E, empowerment; C, connection; and E, education.⁸ Many of these healing influences can be cultivated through the practice of mindful awareness.

Mindfulness in Your Practice

Mindfulness is a way of being in the present moment, on purpose, non-judgmentally.

Jon Kabat-Zinn⁹

When we sit with a patient, the mind will naturally wander and be distracted. Without intentional redirection of the attention back to the patient, however, we may lose the opportunity to understand the person sitting across from us. When we are not present and anchored in the moment, we can slip into seeing patients not as who they truly are but as

we prematurely judge them to be. Medical training conditions us to label patients with disease. As we become more adept at recognizing the disease states within people, however, our perception of each other can shift and only recognize the label rather than the individual.

The previous edition of the International Classification of Disease code book (ICD-9) had approximately 13,000 diagnostic codes. The 10th edition (ICD-10) has more than 68,000.

In an observational study from 1973, eight *sane* people presented to eight different psychiatric hospitals in California with the complaint of, “*I am hearing thuds.*” After being admitted, these people behaved in a normal and healthy way. The researchers wanted to see what diagnoses they would be given and how long they would remain in the hospital. All eight were given the diagnosis of schizophrenia in remission, and the average length of stay was 19 days. One of the eight participants was in the hospital for 52 days.¹⁰ The doctors and nurses were not able to see the *sane* patients for who they really were because of their disease-focused conditioned thinking. Recognizing disease patterns is an important part of a clinician’s everyday work. If we are not aware and do not recognize the habitual nature of these snap judgments, however, we risk being stuck in these conditioned perspectives and may not recognize arising moments and situations when it is appropriate to step out of these perspectives. The people who questioned the appropriateness of the eight *sane* patients’ admissions to the psychiatric hospital were not the doctors or nurses but their fellow inpatients—those with whom the sane people developed relationships through meals, group therapy, and daily activities. Through close relationships, the other inpatients were able to see the individuals as they truly were.

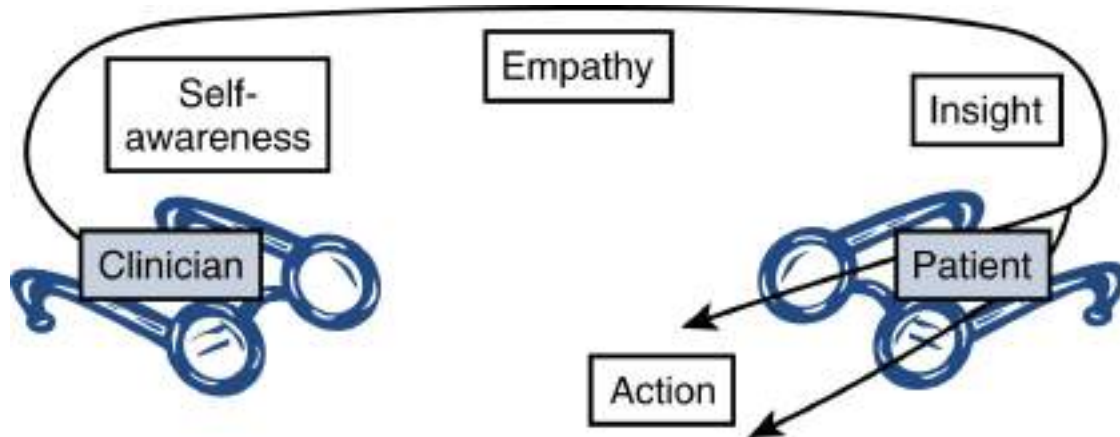

FIG. 3.1 Seeing From the Patient's Perspective.

Self-Reflection

The healing encounter requires that the practitioner be aware of and recognize his/her own mind states, which may or may not be helpful in any given moment. Noticing personal bias can help minimize unconscious snap-judgments and projections. The mindful clinician will be better equipped to meet patients where they are by recognizing their true needs. In being aware and present in the moment, we can be more successful in helping others if we are able to recognize our own beliefs and then do our best to also see the world through the lens of our patient from his/her life perspective (Fig. 3.1). For example, primary care clinicians trained in mindfulness report improved mood and sense of personal well-being, which, in turn, can have a positive impact on patient care.^{11,12} A study of psychotherapists in training found that the patients under the care of those therapists who practiced mindfulness had better outcomes and greater symptom reduction than the patients of therapists who did not practice mindfulness. This study indicates that the personal practice of clinicians may influence the outcomes of patients in their care.¹²

To be of service to a person in need is difficult if the clinician is suffering more than the patient. As the saying goes, "you can't give what you don't have."

There is nothing like a difficult patient to show us ourselves.

William Carlos Williams

Most people do not listen with the intent to understand; they listen with the intent to reply. They're either speaking or preparing to speak. They're filtering everything through their own paradigms, reading their autobiography into other people's lives.

Stephen Covey

Empathy

Empathy is defined as a cognitive attribute that involves an understanding of experiences, concerns, and perspectives of another person, combined with the capacity to communicate this understanding.¹³ Empathy is a foundational ingredient of the healing encounter. It asks that we initially set aside what we know, feel what patients are communicating, and then communicate this back to them so they know they were heard. Patients often do not remember what you tell them, but they remember how you made them feel. We perceive first through empathy, and *then* we proceed in taking action based on the information obtained through mindful listening combined with medical knowledge and training. Unfortunately, it is not surprising that empathy declines significantly through medical school and residency as learners focus solely on increasing their technical-medical knowledge at the expense of emotional health and personal awareness.¹⁴ The combination of empathetic insight with knowledge best serves the authentic needs of the patient to experience healing—both are important and necessary.

Compassion Training

The challenge with empathy is that when you feel someone's suffering day in and day out, it can lead to negative feelings, withdrawal, nonsocial behavior, and even burnout. This process is known as *empathic distress*.^{1,15} A helpful remedy for this is compassion training. In a study where groups were shown videos of human suffering, one group was first given empathy training and then compassion training. The other group was taught a memory exercise at both time points. The researchers evaluated positive and negative effects after each training program. The memory group had a gradual decline in positive effect. The group taught empathy had more negative emotions; however, negative effect went down and positive effect went up after being taught compassion. Functional MRI analysis showed that the compassion training activated

the same areas of the brain that are associated with reward, affiliation, and love.¹⁶

Why is compassion training a remedy for empathic distress? Compassion comes from “compati” (to feel pity), “com” (come together), and “pati” (to suffer). In short, it means that when one person suffers, we all suffer together. This social integration activates areas of the brain (ventromedial prefrontal cortex and ventral striatum) that are associated with enhanced well-being and love, even when experiencing suffering in another. Compassion training encourages us to love one another as part of an interconnected whole, and this gives us resiliency to be with one another during difficult times (see [Table 3.1](#), which summarizes a type of compassion training used in this study).

Insight and Intuition

Insight requires empathy and is the process by which information is gained that allows clinicians to understand how best to serve the health needs of the patient. Intuition is a unique human ability that is both subtle and complex. It is a process of perception, of incorporating a variety of different unrelated bits of information (both conscious and unconscious), and arriving at a logical conclusion. The more information we have to work with, the more accurate the intuition. If a patient is seen only as a disease or a dysfunctional organ system, the clinician will often start with what he or she already knows from medical training, and the additional information obtained through listening and feeling will not be incorporated into the patient’s care. This is why ongoing face-to-face, relationship-centered care is so important: it can enhance the accuracy of our intuition and insight. A clinician who has an established therapeutic relationship with a patient is more likely to have accurate insight and intuition based on the many bits of information (analytical and emotional) assimilated over time. This ongoing therapeutic relationship is why a strong primary care infrastructure results in a 15-fold return on investment in medical spending.¹⁷ Insight obtained in this way results in action that guides the patient most efficiently to health ([Fig. 3.2](#)).

TABLE 3.1
Compassion Training

Start with yourself	May I be filled with loving kindness May I be well
---------------------	---

	May I be peaceful and at ease May I be happy
Then to your loved ones	May you be filled with loving kindness May you be well May you be peaceful and at ease May you be happy
Then to a neutral person you do not know	May you be...
Then to someone who is challenging or difficult for you	May you be...
Then to all living beings	May all beings be filled with loving kindness May all be well May all be peaceful and at ease May all be happy

Start by taking a few calming breaths and then focus your attention to each of the five groups in the order shown. This short practice, if done regularly, can have neuroplastic effects that build therapeutic resiliency, which can protect against burnout.

(This practice is adapted from the book *Loving-Kindness* by Sharon Salzberg. Boston. Shambhala Publishing; 2002).

Functional magnetic resonance imaging research has shown a strong coupling between speakers' and listeners' brains that vanishes when communication is poor. With good communication, the listener can anticipate what is going to be communicated before speech is produced, thus leading to greater understanding of the information conveyed.¹⁸

Action

The Buddhist tradition has a saying, "action without wisdom is dangerous, and wisdom without action is useless." The healing encounter requires a collaborative action that both the clinician and patient believe will bring health. If we do not bring a mindful approach to listening *before* moving into action, we may not serve the true needs of the patient and may even cause harm. When we recommend a therapy that the patient does not follow through with, the clinician may blame the patient for being noncompliant. In actuality, the clinician should assume partial responsibility for not making the effort to fully understand the patient's concerns and make recommendations that would better match the patient's needs. Nonadherence is really a situation where two people are miscommunicating and working toward different goals. The healing encounter involves a process that must unfold before action can be of service and the patient's goals can be met. To simplify, we summarize this process into the three Ps of a healing

encounter: *Pause, Presence, and Proceed.*

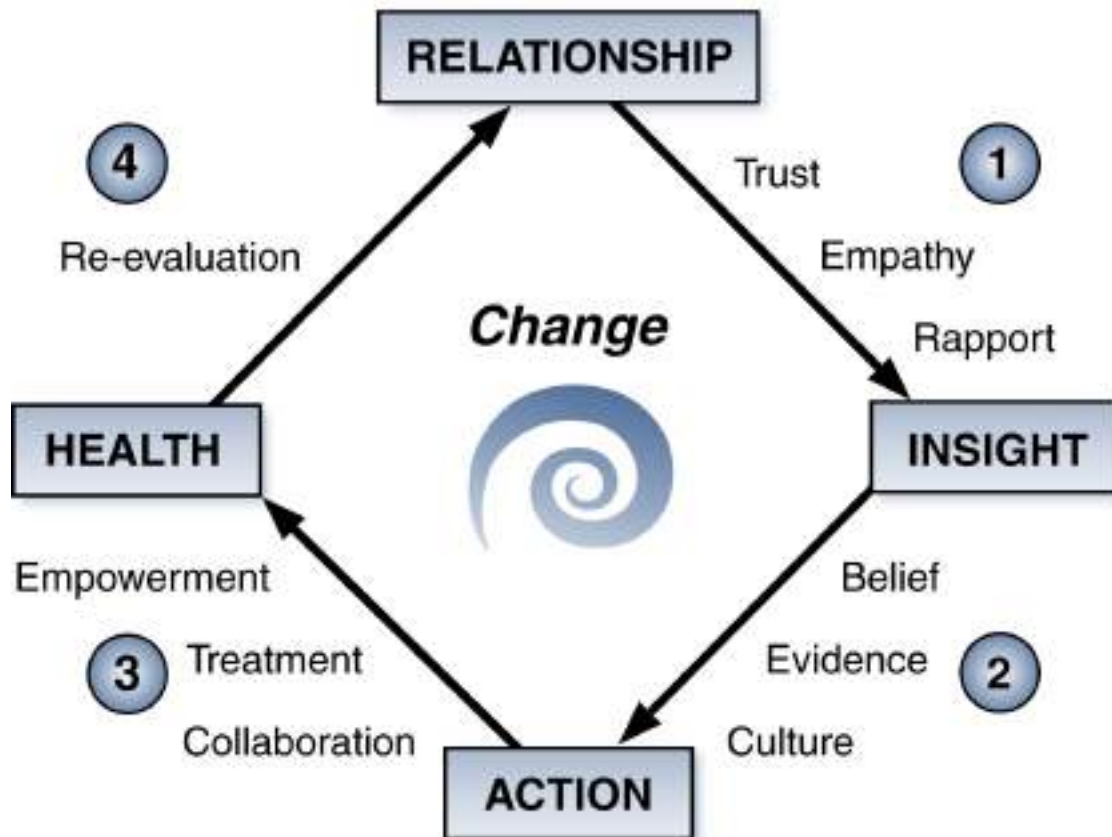

FIG. 3.2 The Dynamic Process of Facilitating Health and Healing.
(From Raket DP. The healing power of relationship-centered care. In: Raket DP, Faass N, eds.
Complementary medicine in clinical practice. Boston: Jones & Bartlett; 2006).

The 3 Ps: Pause, Presence, and Proceed

Pause

Before entering the clinical examination room, take a moment to pause, take a deep breath, and allow yourself to direct your full attention to the patient in the room. Use the threshold of the exam room doorway to remind you to drop into the sensations of your own breathing so that you may be more present with the patient. A threshold is a metaphor for a transition to a new understanding or awareness that the clinician and

patient find together. Taking advantage of the opportunity to pause, drop in, and be present can help us center and be more attentive to the patient.*

FIG. 3.3 The Four As of the Healing Encounter.

Presence

Intentionally directing the attention to the physical sensations of breathing or feeling the feet making contact with the floor helps ground and center the mind. Taking two to three deep breaths into the lower abdomen just beneath the umbilicus is a good start (see [Chapter 92](#)). In martial arts, this area is called the *hara*, and bringing awareness to this area of the body allows the settled mind to respond more appropriately to the changing needs of each moment. According to some Eastern practices, life energy flows from the *hara* (see [Chapter 116](#)). A suggestion to “practice in your practice” involves using your computer log-in as an opportunity to drop in and check in with your own body as you prepare to work with a patient. When the mind and body show up in the same place at the same time, the clinician is better equipped to engage with the patient. The computerized or paper chart need not be a barrier between

patient and provider.

Being present and alert moment by moment can awaken us to mystery and awe in an authentic way (Fig. 3.3). When we pause and become present with what is really happening, we are more likely to recognize what is beautiful in each moment, such as in seeing a flower or a living cell. The same is true with suffering; even though suffering is associated with pain and discomfort, the more we explore and lean into it, the more we come to understand and learn from it. The mindful encounter brings two people together in the fullness of life including suffering, joy, peace, unrest, creativity, and frustration. The mindful clinician is able to remain present with a wide range of emotions and experiences without being overwhelmed by or overidentifying with suffering.

Patients are able to feel whether you are truly present and listening. If they sense that you are compassionate and attentive, they will feel more comfortable and will often share important information and amazing stories. Creating this space results in more meaningful conversation that engenders understanding. In telling their stories, patients are able to reflect on the cause of their symptoms. This insight can be empowering and help motivate the patient to make changes. The clinician's empathy can provide comfort and reduce the feeling of isolation that patients with chronic illness often have. Ultimately, mindful listening may be our most effective therapeutic tool.¹⁹ As the saying goes, "you were given two ears and one mouth to be used in that proportion."

BOX 3.1 Helpful Questions to Consider Asking in the Healing Encounter

- If those tears could speak, what would they be saying?
- I noticed that your eyes welled up when you talked about your daughter. Why was that?
- What do you feel may be at the root of this illness?
- In a time of need, to whom do you turn for support?
- What gives your life a sense of meaning and purpose?
- In a perfect world, what would your life look like?
- What are you most proud of?
- What words would help me to know what you are feeling?

Modified from Maizes V, Koffler K, Fleishman S. The integrative assessment. In: Rakel DP, ed. *Integrative Medicine*. 2nd ed. Philadelphia: Saunders; 2007:36.

Proceed

In pausing, being present, and listening to the patient, insight arises. This insight allows a plan to be created that both the clinician and patient believe will be of benefit. The plan should increase the sense of control that patients feel in taking action that helps them move from disease to wellness. The health plan should recognize both physical and nonphysical factors that the patient can use to manage symptoms and prevent illness in the future. Helpful questions that can bring an understanding to this process are reviewed in [Box 3.1](#).

The health plan may have one recommendation or several, based on the needs of the patient. For example, if a patient has had recurring headaches and diarrhea ever since his or her divorce, the health plan may only involve one recommendation, such as working toward self-care and forgiveness (see [Chapter 99](#)). If another patient wants to prevent a recurrence of breast cancer, however, the health plan may include recommendations on stress reduction, nutrition, spiritual connection, improving sleep, and the use of medications and supplements.

Before computerized medical records, the “answer” to the patient’s problem was often conveyed as a quick fix on the prescription pad. The practice of integrative medicine recognizes that health be defined by much more than a medication. Instead, the power of the ritual process around the actual prescription should be cultivated. This ritual transfers knowledge and a sense of control that gives confidence that something may help the patient transcend suffering. The clinician’s recommendations, based on the insight that arises from the healing encounter, should be summarized in writing and given to the patient at the conclusion of the visit.

Healing is not something easily reproduced or taught. Often, the best we can do is create an environment where it can unfold, grow, and teach us.

Five Questions to Consider Before Prescribing a Therapy

The integrative medicine practitioner uses relationship-centered care to develop insight into the most effective therapy for the patient’s needs.

Before prescribing a specific therapy, the practitioner should consider the following five questions:

1. Does the therapy result in symptom resolution or symptom suppression? Our initial goal should always be the resolution of the symptom to enable us to use fewer external influences to maintain health. This often requires that we explore the mind and spiritual aspects of a symptom. A physical symptom can also be seen as our body asking for some type of change. If we simply suppress the symptom without understanding what it may need to go away, it will likely recur or arise in another part of the body. A good example of this is the use of proton pump inhibitors (omeprazole [Prilosec], lansoprazole [Prevacid], and rabeprazole [Aciphex]) for epigastric pain. These are excellent medications to help suppress symptoms or heal ulcers. If we over-rely on this pharmacotherapy, however, it may prevent us from exploring the symptom further. It may also keep us from listening to the patient's story, in which the use of metaphor may give us further insight into the mind-body influences on health. For example, a person with epigastric pain may say that his or her job is "eating me up inside." If we do not deal with this stress, the body will not truly heal even though the symptom may be suppressed through use of a medication. Ultimately, this can lead to long-term use of a medication that may result in a change of the natural environment of the body. Long-term acid suppression is now known to be associated with increased risk of pneumonia²⁰; malabsorption of B vitamins, calcium, magnesium, and iron²¹; a higher prevalence of *Clostridium difficile* colitis²²; and increased risk of myocardial infarction²³ and fractures of the hip^{24,25} and spine.²⁶

To foster symptom resolution, we need to explore both the external and internal reasons for its expression (Fig. 3.4). An external therapy (medications, acupuncture, surgery, or manual therapies) will not have lasting benefit unless it is coupled with an internal exploration and understanding of why the symptom is there in the first place (e.g., emotions, stress, meaning, and purpose). The physical and nonphysical are inseparable, and if we do not address both, it will be difficult for the symptom to fully resolve. However, when a condition has been fully evaluated and we have explored all aspects of it but find no resolution, it is appropriate to consider suppression of the symptom with medication and procedures to reduce suffering and improve quality of life.

2. What is the evidence? The scientific model allows us to understand which therapies have the most intrinsic value. Once we have reviewed the evidence, we can combine it with the "art of medicine" to stack the

deck further in favor of a positive response. Unfortunately, the amount of evidence we have to rely on is limited. Out of 2404 treatments reviewed in medical care, 15% were found to be beneficial and 47% to have not been adequately tested.²⁷

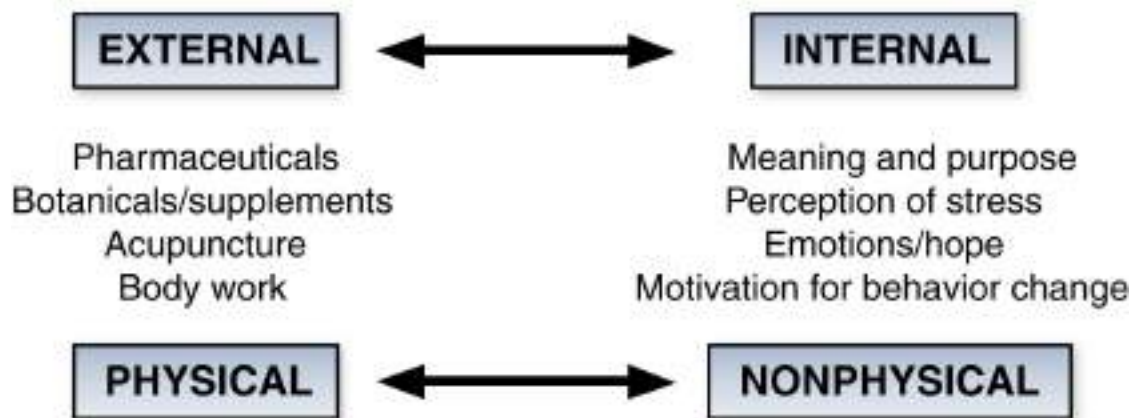

FIG. 3.4 Dynamic Interplay Between the Physical and Nonphysical Influences on Health and Disease.

It is expensive and time and labor intensive to conduct meaningful research, and the therapies that have the best quality of evidence are often those therapies that have the greatest potential for economic gain. Unfortunately, little economic incentive exists to promote therapies that result in healing in our current health care model. You will not see representatives from the wood and paper industry promoting the use of pencils and paper to support the health benefits of journaling on asthma and rheumatoid arthritis despite the evidence showing benefit.²⁸ The responsibility falls to the academic institutions and the government to provide funding to research all potential therapies despite their lack of economic rewards.

3. What is the potential harm? It can be dangerous if we look only at the evidence for the benefits of any given therapy without also considering the evidence for potential harm. For example, in the 1950s, evidence showed that diethylstilbestrol prevented miscarriages; however, the potential harm to the unborn fetus was not taken into consideration until after many lives were affected. In addition, evidence initially indicated that flecainide improved arrhythmias observed on electrocardiography in cases of supraventricular tachycardia; however, subsequent research demonstrated that flecainide can also increase mortality.²⁹ The integrative

medicine practitioner first considers the least harmful, least invasive therapies before moving on to more invasive therapies. As a result, it is imperative that we continue to research not only the potential benefits but also the potential harms of the therapies we prescribe. Because of the potential risks associated with many extrinsic medical therapies (e.g., medications and surgeries), we should first encourage healthy lifestyle changes with the least risk (e.g., nutrition, stress-reduction, exercise, spiritual connection, etc.). This can lead to fewer high-risk interventions, thereby resulting in overall harm reduction. For this reason, this text includes an icon that weighs the evidence of benefit against the evidence of harm to help guide the clinician.

4. What is the cost?

One of the first duties of the physician is to educate the masses not to take medicine.

Sir William Osler

Complementary therapies are generally low tech and low cost and reduce the need for more expensive interventions. Users of CAM report that their use of prescription drugs and conventional therapies decreases.³³ When CAM was combined with biomedicine, one study showed a reduction of pharmaceutical use by 51.8%, a decrease in outpatient surgeries and procedures use by 43.2%, and a reduction of hospital admissions by 43%.³⁴

Incorporating mind-body stress reduction techniques into the treatment of 4452 subjects enrolled in the Relaxation Response Resiliency Program compared to a cohort of controls that did not receive this training showed that the program participants had a 43% reduction in billable medical encounters, reducing costs by \$2360 per patient per year.³⁵

Another study randomized participants to three groups: a wait list control, an 8-week exercise program, or an 8-week mindfulness program to see if this training would reduce the incidence and cost of upper respiratory illness. The cost of care related to upper respiratory illness per group member was \$214 for the wait list control, \$136 for the exercise program, and \$65 for the mindfulness meditation program.³⁶ In addition, as far back as the 1980s, Dean Ornish et al.³⁷ showed how coronary heart disease can be reversed by incorporating lifestyle changes, including nutrition, exercise, stress management, group psychosocial support, and smoking cessation.

Much of the economic incentive for physicians in the United States is fixated on acute care management and driven by relative unit value (RVU), with little incentive for lifestyle education and prevention that would reduce the need for expensive medications and procedures. These studies are examples of how an integrative approach can result not only in self-healing but also in economic savings in morbidity, mortality, and the money needed to treat them. The implementation of lifestyle modification and prevention medicine has the potential for tremendous cost savings and improved quality of care.

5. Does the therapy match the patient's culture and belief system? In our conventional medical system, we have traditionally pulled patients into our paradigm of thought and have told them what they need. This method is often necessary for acute illness; however, we will be more effective if we offer treatment plans that better match patients' belief systems for chronic conditions that have no "easy" answer (see [Chapter 4](#)). In this way, we can activate the internal healing response, a process that we know as the placebo effect. Instead of brushing this off as a nuisance, the talented clinician will use it to enhance healing. Being able to integrate various methods of healing from different cultures can enable the clinician to better match the therapy to the individual. The art of medicine may lie in the clinician's ability to activate this response without deception. We should give patients what they need before we give them what we know.

Steps to Enhance the Healing Encounter

Creating Salutogenesis-Oriented Sessions

A healing encounter can be created in a brief 5-minute interaction or during an hour-long discussion. To serve the complexity of health and healing most effectively, however, practitioners need to protect time in their schedules to create the space for a healing ritual (i.e., the salutogenesis-oriented session, SOS).³⁸ Any health care clinic can create an SOS that stacks the deck in favor of the healing encounter. The following subsections describe key ingredients that will help create a healing environment for this approach to unfold and be sustainable.

Protect Time in Your Schedule

Reserve time in your weekly work schedule for SOS appointments. Some

practitioners may schedule these as they would a yearly physical; others may protect a half-day a week focused only on these sessions. Many integrative medicine consultative clinics work in this way. Each session should be scheduled for at least 40 minutes, and patients should be encouraged to arrive 15 minutes before their appointments to allow as much face-to-face time as possible with the clinician.

Create Space

Consider redecorating an existing examination room to give the feeling that you are in a special and comforting place. Incorporate soft colors and fabric, and limit sterile and cold medical equipment when possible. If you are unable to do this, simply introduce an element of nature, such as a flower, plant, or water fountain.

Create Patient Expectations

Let the patient know that these sessions are intended to allow time for exploring deeper issues that may help facilitate salutogenesis. A typical scenario for creating expectation may be something like the following:

“We have ruled out a physical cause for your headaches, and no evidence indicates a tumor. We do not have time scheduled today, but I would like you to come back on a Wednesday morning when I have set aside time for a session that will allow us more time to explore other aspects of life that can have a significant impact on your physical health and symptoms. I want to understand more clearly what may be going on in your life that may be influencing the amount of pain, fatigue, and sleep problems you have been experiencing. Often, in these sessions, we find common underlying causes that may help us get at the root of many of your symptoms.”

Offer Support

Relationship-centered care is based on trust and support. An SOS can result in the emergence of past traumas or events that must be supported and processed further. Often, we may need to collaborate with a psychologist to help understand how we can help patients heal from these events. We should not create an environment in which this information comes out and then not offer support and guidance on how to process it. This represents abandonment and can turn an SOS into a

pathogenesis-oriented session. Interprofessional collaborative care allows healing to occur within a team that can support it.

Code Appropriately

We need to make sure that our time is appropriately coded so these sessions can be incorporated into clinical care as an important factor. The hope is that the medical system will eventually recognize the cost-saving potential of an SOS. As we explore the root of how the body self-heals, we may need fewer costly interventions. As the cost of disease-focused care escalates, this approach will gain more acceptance.

You need 45 minutes of face-to-face time to bill a “99204” (new patient) or 40 minutes for a “99215” (established patient). Be sure to document the amount of time spent and include that “greater than 50% of time was spent counseling and/or coordinating care.” This needs to be included if you are billing based on time spent with the patient. If you document only total time and not the percentage of time spent counseling and coordinating care, then you must document the required components of the history, examination, and medical decision making per usual.

For integrative medicine consultations, the code is “99244” for a 60-minute and “99245” for an 80-minute consult appointment. Be sure to document the practitioner who referred the patient for consultation.

Conclusion

Pausing to be present before proceeding with an action plan for health is a simple task that, if practiced, can help two people efficiently find a healing path within a dynamic and complex setting. Ideally, the visit itself is therapeutic, even before something is prescribed. Communication between clinician and patient gives the patient perspective and support that encourages both parties to pause, learn from symptoms, and proceed toward a better place together.

The meeting of two personalities is like the contact of two chemical substances; if there is any reaction, both are transformed.

Carl Jung

Therapeutic Review

- Self-reflect to learn of your own implicit biases so these unconscious beliefs become conscious and do not interfere with your goal of facilitating health in another.
- Pause before crossing the threshold of the clinic room to clear your own clutter so the clinical stool becomes your meditation cushion where you focus on one thing well, the person in front of you.
- Practice compassion, realizing that in serving others you serve yourself.
- Be fully present and mindfully aware, creating insight into the individual's authentic needs.
- Proceed towards action that you both agree will bring focus to a healing path.

CHAPTER 4

The Whole Health Process

David Rakel, MD, J. Adam Rindfleisch, MPhil, MD, and Tracy Gaudet, MD

We can't solve problems by using the same kind of thinking we used when we created them.

Albert Einstein

Value Over Volume

As health care spending in the US surpasses three trillion dollars a year, there is a push to shift the focus of health care delivery away from volume and toward increased value by improving quality at less cost. This “Value over Volume” approach is quickly changing reimbursement models and encouraging health care systems to create new models of care.¹

This evolution honors the advances achieved using the biomedical model while at the same time enhancing it with a much needed transition away from a reactive, disease-centric approach toward one that prioritizes improving health outcomes. New approaches place greater importance on patient engagement, highlight health promotion, and place care within the context of each individual.

One of the most important ways to enhance value is to strategically tailor health care resources according to the context of each person's life. Ongoing, relationship-centered care allows the clinician to understand what sort of person has a disease (to paraphrase Osler) instead of simply focusing on what disease the person has. This context helps explain why there is a predicted 15-fold return on investment when health systems have a strong primary care foundation.²

Patient-Defined Goals

To improve health outcomes, goals that drive clinical care must arise from the individual or community that is served. This structure requires that we work beyond the traditional biomedical model that has been directed by physician-dominated dialogue.

Research on contextual errors has shown that even when clinicians are told by a patient that “I can’t afford my asthma medication,” 50% of physicians will prescribe it anyway.^{3,4} Often the clinician will “do the right thing” according to the evidence protocol for a condition that is concrete instead of working the evidence into the context of someone’s real life, which is more complex than general guidelines can accommodate ([Table 4.1](#)).

A better balance is needed to combine the scientific, biomedical model by artfully adapting it to be as relevant and useful as possible to the person being treated.⁵ Doing so will ensure patient adherence to a plan of care that emphasizes what is needed most to change behavior over time. Ideally, this approach recruits the self-healing mechanisms possessed by all living beings. When the self-healing potential is tapped, there will be less need for costly and potentially harmful interventions, be they pharmaceuticals, surgery, or acupuncture needles. How is this value most efficiently obtained? We start by asking each patient to explore what matters to them most and then to define his or her own health goals.

Organizing resources around patients’ self-defined health goals is the most efficient way to motivate sustainable behavior change. These goals are those most relevant within the context of people’s lives, so they are much more likely to foster patient engagement and adherence to the plan of care. This approach shifts our focus from asking, “what’s the matter with you” to “what matters to you.”

Innovative Health Systems

After more than 50 years of treatment by the Indian Health Services, more than 60,000 Alaska Native and American Indians living in Southcentral Alaska became the owners of their own health care system, the Southcentral Alaska Foundation. Known as the Nuka System of Care,⁶ the system focuses on establishing long-term, trusting, accountable relationships built upon a shared-decision model where the patient’s

health goals are primary.^{7,8} After implementation in 1999, urgent care and emergency department use decreased by 40%, specialist use decreased by 50%, and hospitalization days decreased by 30%.⁹ Blood sugar and blood pressure control improved,¹⁰ and customer satisfaction data showed that 91% of customer-owners rated their care as “favorable.”⁷ In this model, patients and their families are the principal drivers of health, which has reduced dependence on the health system (Fig. 4.1).

The Nuka strategy resulted in significant improvements in the health of a population that was at high risk for disease. A similar high-risk population is American Veterans. A conventional biomedical model that places the patient in a passive role as they receive treatments for symptoms and disease states does not serve Veterans (or other Americans) well. Such a model risks the potential harm of polypharmacy while not recruiting the person’s active participation in their health.¹¹ In 2012, The Office of Patient-Centered Care and Cultural Transformation (OPCCCT) was created to bring needed change to the largest health care system in the US, The Veterans Health Administration (VHA). Directed by one of the coauthors, Tracy Gaudet, the OPCCCT is leading the charge towards a shift in health care delivery. The VHA has declared that its primary strategic priority is “to provide personalized, proactive, patient-driven health care to Veterans, and engages and inspires Veterans to their highest possible level of health and well-being.”¹² This model moves beyond the traditional health assessment, as is highlighted in Table 4.2.

TABLE 4.1
Patient-Defined Goals

Volume (Biomedical Model)	Value (Health Outcomes Model)
Concrete	Context
Reductionistic	Holistic
Data and science	Poetry and the arts
More things	Less things
Projection of science’s “truth”	Internal motivation for change
Requires compliance	Self-sustaining

FIG. 4.1 The Alaska Native Health Care model moved the column to the left, reducing dependence on high-cost medical interventions by increasing the control of the patient, their family, and community. This change resulted in better health and fewer acute health care needs. (From Rakel DP, Jonas WB:

The patient-centered medical home. In Rakel RE, Rakel DP, editors: *Textbook of family*

medicine, ed 9, Philadelphia, 2016, Elsevier, pp 17-24.) ²⁴

The Circle of Health

The diagram “Components of Proactive Health and Well-Being,” known more informally as the “Circle of Health,” is featured in [Fig. 4.2](#). This elegant framework focuses attention on “Me,” the individual, who is placed at the center. Moving outward from the center, “mindful awareness”—paying attention to one’s thoughts and patterns—is the next circle. Next is the light blue circle, which encompasses eight smaller circles, the “Circles of Proactive Self-Care.” Here, after we see that the central focus is on the individual and on what a person can do for self-care, does the diagram then draw in the navy blue “Professional Care” circle, which incorporates prevention, conventional therapy, and complementary approaches—all the aspects of care that involve other people besides oneself. The outermost circle, “Community,” encompasses the entire circle, emphasizing that while self-care is fundamental, no one has to seek health alone. The person at the center of

the circle is the captain of a team of people who all value that person's well-being at many different levels.

TABLE 4.2
Models of Care

Traditional Medical Assessment	Whole Health Process
Chief complaint	Engage patient's meaning
History of present illness	Personalized health assessment
Family and social history	Patient-defined goals
Physical exam	Professional expertise and alignment
Diagnostic tests and imaging	Interdisciplinary team support
Assessment with appropriate coding	Personalized health plan
Therapeutic plan	Tracking outcomes and goal achievement

Both these models are valuable, but the Whole Health Process will add more value.

Personalized, Proactive, Patient-Driven Care

A personalized process recognizes that every human being has a unique story that puts any therapy into the context of their lives. For example, 20 people with hypertension may have 20 different therapeutic plans to lower blood pressure. One person may need to change diet, while another may need to address stress. A personalized health plan is more likely to promote long-term health, as each individual's main health needs are explored.

A proactive approach encourages recognition of health risks and seeks to proactively minimize them. It supports each human being's powerful, innate self-healing process, attempting to mobilize it rather than just suppress symptoms.

Patient-driven care requires that the locus of control be given to each individual. Clinicians assist patients with recruiting the most appropriate professionals needed for their individual success. All healing is self-healing, and the Whole Health process empowers people to find their particular paths to self healing. They are placed in charge of their own health destiny.

Three Questions

The Whole Health process can be challenging to incorporate, as it

suggests a shift in focus that is unfamiliar to both clinicians and patients. Several key questions can be asked to initiate the Whole Health encounter, but the first question below is perhaps the most important and the most challenging. If framed correctly, it can connect people to their personal meaning, getting to the heart of a personalized, proactive, and patient-driven approach. The first question is at the center of the [Fig. 4.2](#), the mindful awareness of ME.

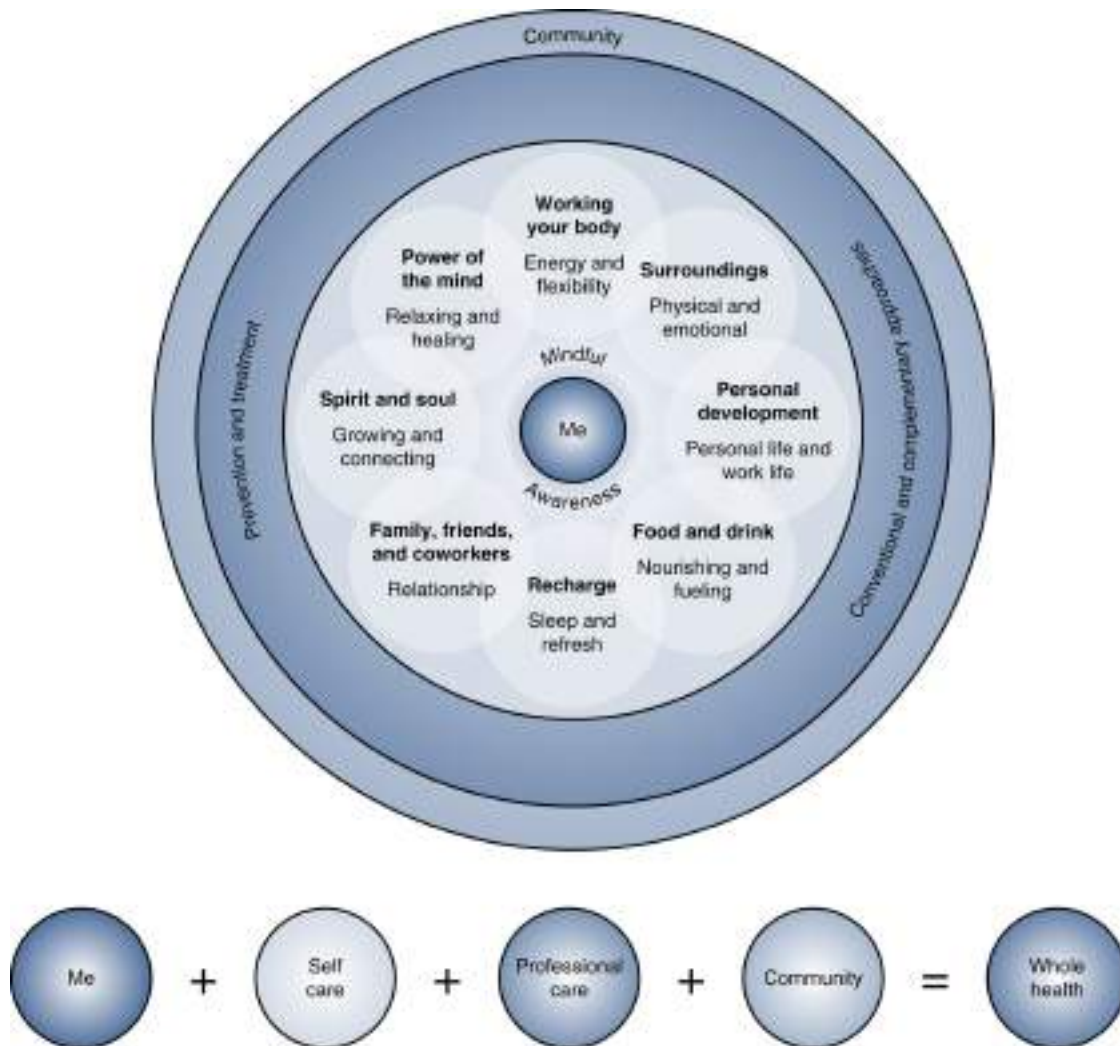

FIG. 4.2 Circle of Health.

Question #1, What?

What Gives Your Life Meaning?

This question can be asked in a number of different ways, but the goal of the question is to connect the individual to what is most important. Without this connection, even a health goal that is defined by the individual will most likely be unsustainable. This deeper exploration helps to discover the underlying motivational driver that can allow for sustainable healthy behaviors.^{13,14} For example, a smoker whose clinician informs them of the evidence linking smoking to increased risk of cancer, heart disease, and death is much less likely to change their behavior than the person who wants to stop smoking because the daughter they love recently developed asthma. The hemoglobin (Hgb) A1c test may just be an abstract idea, while the fear of losing one's eyesight or requiring dialysis may be much more real. Eliciting emotional reasons for change is much more effective than recruiting cognitive reasoning.

Experience in asking this question has provided valuable lessons. Many people initially may not understand the question or may say, "I don't know, you're the doctor, you tell me." Providing context before asking the question can help with comprehension. Consider the following script:

In our clinic we are shifting focus from what is wrong with you to a process that helps us understand what you want your health for. This way we can use the resources of the health system to help you live your fullest life. Achieving health is much more about what you do than what you take. I want to know what matters most to you, because this will help us both know where to invest our time and energy to help you get where you want to go.

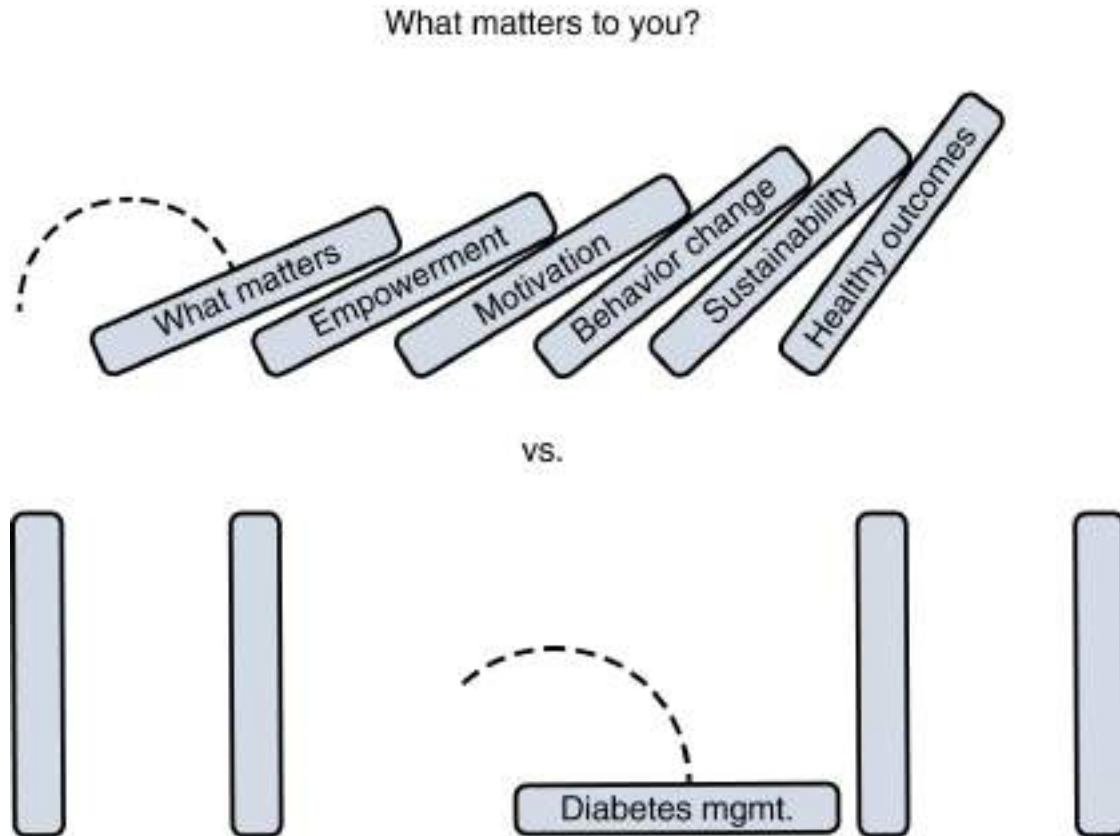

FIG. 4.3 Aligning our work with what matters to the individual empowers them to be a proactive participant in care. Such patient involvement is the most important factor in sustaining healthy outcomes. Treating one disease at a time (e.g., diabetes management) is disconnected from the larger whole. T.S. Eliot describes the bottom graphic well in his introduction to *Dante's Inferno*: "The definition of hell is a place where nothing connects with nothing."

If the response is, *"I want to be healthy,"* explore further, as in the following sample dialog:

"If you were healthy, what would your life look like?"

"I would be able to travel and spend time with my wife and kids."

"What will you need to be able to travel and connect to your wife and kids?"

"I need to get this arthritis pain under better control."

"That's a great health goal! I am going to put down in your chart that your

health goal is that you want to travel and spend time with your wife and kids.”

The process of asking this question is as important as the answer. The focus of the office visit changes from a superficial conversation to a place of deeper meaning that is rewarding and energizing for both the clinician and the patient. Such interaction enhances the therapeutic relationship while directing care towards value because the action that follows the question will have significant downstream health effects. This first question invites the patient to begin exploring what is most meaningful to them and is a powerful first domino that drives positive health outcomes ([Fig. 4.3](#)). Surprisingly, the data show that such interaction does not require more time and, more importantly, changes the type of conversation we are having with our patients.⁴ It is important to recognize that this question is deep, and to truly explore it will take time and iterations. Typically, people begin to reflect on such matters when they are in health crisis, facing cancer or recovering from a heart attack. To explore this issue before such an event is a great opportunity but also a significant shift. This exploration can be further supported by self-reflection tools or group approaches outside of the clinical encounter.

Other Versions of Question 1 Include

What really matters to you?

For what do you want your health?

Why do you want to be healthy or improve your health?

What is a health goal that will help you connect to what is most meaningful in your life?

Question #2, Where?

Where Do You Need to Start to Achieve Your Health Goal?

This question allows the patient to self-reflect and to prioritize which area of self-care depicted by the light blue circles in [Fig. 4.2](#) are of highest priority. Each of the eight circles incorporate the foundational ingredients that facilitate the proactive, self-healing mechanisms within each individual.

A script that one may use to ask question #2 could go something like this:

These eight circles include key ingredients that are important in the health of any human being. What they all have in common is that they are linked to self-care. That is, they are things that you can work on yourself, though we will be sure to talk about who can support you with them along the way. Point to one or two areas that you feel you need to work on most to achieve your health goal.

Ideally, the savvy information technology (IT) team of the health system would populate each of the circles with available community resources relevant to the patient's health goal. For example, the "Food and Drink" circle would include resources on how to access a nutrition consultant, healthy cooking classes, or mindful eating classes.

To continue the previous scenario:

The patient whose health goal is to travel and spend time with his wife and kids points to "Working Your Body" and "Personal Development" as the two areas that he feels need the most attention. He wants to move his body more since he feels his arthritis is leading to a sedentary lifestyle. He also wants to make sure he can afford the travel that he is looking forward to with his loved ones, so he wants to add money to his retirement plan at work. For that reason, he wants to get a promotion.

Question #3, Who?

Who Do You Need to Support You in Achieving Your Health Goal?

This question recruits the most appropriate professionals, family members, friends, or community resources needed to support achievement of the health goal. The Whole Health process identifies the interdisciplinary team that will offer support and guidance with the next steps of the process. This team is linked to the outer two rings in the Circle of Health (see [Fig. 4.2](#)). The Whole Health approach stresses the importance of creating a team that will help the individual succeed in achieving his or her goals.

A script for question #3 could go something like this:

Now we need to recruit services or individuals to help you achieve your

health goal. Who do you feel will be most important in helping you be successful?

To use the military metaphor, we ask the Veteran **what** is their mission for health, **where** do they need the most support, and **who** do we need to recruit to ensure a successful outcome?

In the case of the man whose health goal is to travel and spend time with his wife and kids, we recruit an acupuncturist to help improve the pain and function of his knees. We refer him to physical therapy to increase his strength and improve his mobility. Finally, we recommend that he connect to human resources at work to improve his chances of getting a better-paying job that was posted recently. This Whole Health process is directed and organized by his primary health care team in the patient-centered medical home, but he, the patient, has been consistently directing the process.

Case Scenario: Mt. Kilimanjaro

A 48-year-old female veteran named Betty visited her physician every 3 to 4 months to monitor her type II diabetes. She would often feel frustrated because she never felt good enough. She would hear that she needed to lose more weight and improve her nutrition to get her Hgb A1C and low-density lipoprotein (LDL) cholesterol under better control. She soon became frustrated with how many medicines she was asked to take.

After a period of self-reflection, she realized that she wanted the resources of the VA medical system to help her achieve what she wanted to work towards. She had a personal goal of climbing to the top of Mt. Kilimanjaro by her 50th birthday. So the next time she visited her doctor, she told him of this goal. He was resistant initially, but was eventually swayed to refocus attention not just on her Hgb A1C levels but towards helping her achieve her health goal, that which connected her to meaning.

Betty's health care team now consisted of the professionals she needed to help her achieve her goal, including a nutritionist, physical

therapist, and a health psychologist; her primary care physician organized her care. In her 50th year, she made it to the top of Mt. Kilimanjaro. Betty was happy to have reached her health goal, and Betty's team shared in the joy of her success. Everyone was energized, as the focus of work was on connecting to meaning, not only for the patient but for that of the whole medical team. Not surprisingly, Betty's Hgb A1C and LDL cholesterol improved as a side effect.

Developing the Personal Health Plan

Whole Health has been introduced to dozens of VA facilities since 2013. Different facilities have experimented with innovative approaches to making care more personalized, proactive, and patient driven. One of the questions that frequently comes up is, "But how do I apply this model to the real world of practice? I have time constraints, I have to be sure I always ask about things like tobacco use and safety at home. How can I possibly fit more in?" Many clinicians find it helpful to keep a few key pointers in mind as they begin to do Personal Health Planning under the Whole Health model.

No clinician writes the health plan alone. We have been indoctrinated with the idea that care happens in a one-to-one interaction, with the clinician—often a physician—taking responsibility for the plan. This approach can be effective on its own but is enhanced by a team approach. There are clinics in which the entire team collaborates on health planning, from the receptionist who provides the intake forms (the VA has created a "Personal Health Inventory," see the following [Key Web Resources](#)) to the nurse who reviews the inventory with them and the psychologist and social workers who are integrated into the team to help with various aspects of follow up and support. Health coaches can also be invaluable to the process.

Much of the foundation for the personalized health plan can be done outside of the clinic, allowing more time and support to reflect on one's life. The VA has created a 9-week Whole Health program in which facilitators are trained to lead the group and guide Veterans through the Circle of Health. Through this process, the Veteran creates the foundation of their overarching personal health plan, and interactions with their providers in the clinical setting can be much more streamlined.

Health plans take many forms. A health plan may be as simple as a one-item recommendation. "Bob, it sounds like you are up for switching

over to sparkling water between now and our next visit, what do you think?" If this is all Bob is up for, it is best not to hit him with more than he can handle. Another person may be just the opposite. Some people love to have multiple items on a to-do-list to follow. Remember, though, that they should be coauthors of that list!

Health plans are built on continuity and follow up. No one expects you to cover every issue during a single visit. Everyone who interacts with the person can help with the plan, tweaking it as appropriate. Focusing on question one helps to clear the clutter of the crowded problem list, allowing the team to focus on what matters most. A useful question may be, *if we focused on one thing that would help all your other problems get better as a side effect, what would that one thing be?*

Believe it or not, this approach saves time. People who adopt it find that not only does their work feel much more gratifying, but they are also more efficient. Time and energy are saved by asking someone what they think is going to help them the most. The question "What are you willing to do today to make your health better?" can write the health plan itself.

You, as the clinician, also have a place at the center. One of the most powerful ways to understand this process is to apply it to your own life. Clinician self-care matters. You may find that you learn a great deal by applying this entire process to your own individualized care needs. For what do *you* want your health? And you might just find that this process gives you a kick-start that reconnects you to meaning in your work.

Four-Step Process for Health Planning

Largely due to the efforts of the VA facilities in the Boston area, a pragmatic process for health planning has been developed.¹⁵ This process involves four steps, which may not all happen at once:

1. Assessment. Gathering information—and doing it in a different way—is critical. Yes, if the patient is being seen for a specific concern, you should have that in mind. Rarely, someone will not want you to use this approach; fair enough—respecting their choice is a way to personalize care. However, if they are willing, asking the three questions listed above can be an excellent way of doing an assessment.

2. Shared goal setting. In health professions training, we learn about how to interview people. One of the issues that arises during such training is agenda setting. Remember, *you do not give up your own priorities for the visit*. Rather, you weave them into the overall process. For our example patient previously, the clinician may have the goal of bringing down the

patient's heart disease risk. The items noted in the health plan, such as a potential reduction in financial stress by attaining a better-paying job, are useful for this process.

3. Health planning. Health planning is the step in which the clinician and patient work together to talk about what they will do. Patients often have great ideas already—just ask. Clinicians should bring up their own ideas as well. Remember, for a plan to be successful, you have to have their buy-in. Now is the time for you to decide whether you do have their buy-in and how to increase it.

4. Skill-building and support. Health planning does not end when the patient leaves the room. It is incumbent upon the health care team to provide guidance to the person seeking care. What skills do they need to have? Does someone teach them a mind-body approach? Do they need help signing up to do volunteer work? Is there a meditation practice you would like them to try? Providing the information and connections they need is important. As is the case with any clinical visit, you also need be very clear in stating what steps will follow. When will they see you again? When will they follow up with other members of the team? The quest for health is lifelong, and you can show them possible routes that they can follow along the way.

The Value of the Whole Health Process

The Whole Health process incorporates key ingredients that promote sustainable health outcomes, as shown in Figs. 4.2 and 4.3. Patients sit in the driver's seat and clarify, with support, which areas are most important to them. This process is not only empowering but also activates their innate capacity to heal, tapping into the wisdom within each of us.

The value of this approach has become increasingly clear through recent research. For example, many people choose “Power of the Mind” as an area of focus on the Circle of Health because of the high levels of perceived stress in their lives. Self-care in this area can result in significant cost savings. In a 2015 study, 4452 subjects were taught mind-body skills to reduce stress and build resiliency. After following this cohort for 4.2 years, those who completed the training had a 43% overall reduction in the use of health-related care than did the 13,149 controls. Clinical encounters decreased by 41.9%, lab encounters dropped by 43.5%, and procedures were decreased by 21.4%.¹⁶ In another study investigating the incidence and cost of treatment for upper respiratory

illness, those who were taught mindfulness had a 70% lower cost (\$65 per meditator vs \$214 per control) than did untreated controls.¹⁷

The Diabetes Prevention Trial confirmed the value of healthy lifestyle choices, noting they were not only more effective clinically in reducing the incidence of progression to diabetes when compared to metformin¹⁸ but were also more cost effective.¹⁹ Avoiding smoking, moving the body, improving nutrition, maintaining a healthy body weight, and limiting excessive alcohol use dramatically improved the cost effectiveness. Practicing these lifestyle behaviors was shown to decrease the incidence of coronary events by 83% in 84,129 women followed in the Nurse's Health Study^{20,21} and by 79% in 20,721 Swedish men followed for 11 years.²² These key determinants of health were also associated with living 14 years longer in 20,244 people followed in the EPIC–Norfolk Study.²³ The Whole Health approach allows us to link meaning to action so that those we serve are more likely to incorporate these powerful behaviors into their own lives.

What one does is much more effective than what one takes. Value is added when we are able to encourage and support personalized, proactive, patient-driven care. The Whole Health approach is a powerful and innovative way to achieve value by valuing what matters to the people who seek our care.

Key Web Resources

The Veterans Administration Office of Patient-Centered Care and Cultural Transformation http://www.va.gov/PATIENTCENTEREDCARE/about.asp	Provides information on incorporating this Whole Health Concept within the VA Medical System. Includes resources and strategies on a personalized, proactive, patient-centered approach.
The Veterans Administration www.va.gov/patientcenteredcare/research-and-resources.asp	Videos from the VA's patient-centered care that explore the Whole Health process.
Whole Health Video http://bcove.us/7e4Huv	A VA-sponsored video that conveys the vision of the Whole Health Process of Care.
Personal Health Planning Video http://bcove.us/35HfwoJ	A VA-sponsored video that summarizes the process of Personal Health Planning.

CHAPTER 5

Depression

Craig Schneider, MD, and Theodore Wissink, MD

Centers for Disease Control and Prevention surveys indicate that nearly 1 in 10 residents of the United States who is 18 years old or older has a depressive disorder.¹ Annual prevalence rates in patients with chronic disease are about 25%.² In fact, depression is one of the chronic conditions for which alternative therapies are most frequently used.³ This statistic is not surprising considering that pharmaceutical antidepressant medications are not as effective as once believed for many patients with less severe forms of depression.⁴ Many people seen in primary care settings fall under the DSM-5 category “persistent depressive disorder.” The Patient Health Questionnaire-2 (PHQ-2) can be used for screening,⁵ and the longer Patient Health Questionnaire (PHQ-9) (see [Key Web Resources](#), later) can be used both for diagnosis and tracking of depression treatment outcomes in the primary care setting.⁶ Clinicians should discuss the spectrum of treatment options including antidepressant medications and/or psychotherapy and integrative medicine treatments.⁷

Pathophysiology

The pathophysiology of depression is not fully understood. The stress–diathesis model of illness emphasizes that significant emotional, social, and environmental antecedents such as the loss of a family member or a romantic or professional disappointment, as well as genetic and acquired vulnerabilities, are clearly involved. Significant stressors appear to be more frequently involved with initial episodes. In recurrent depression, vulnerability appears to increase as episodes become less and less related to stress and more autonomous in a process known as kindling.^{8,9} With repeated episodes of illness (kindling), central nervous system

dysfunction increases, as manifested by hypercortisolemia, decreased slow-wave (restful) sleep, and increased rapid eye movement (arousing) sleep and disruption of neuroplasticity.¹⁰ Inflammation is now considered another important mediator. High levels of inflammatory biomarkers are found in depressed patients and improve as symptoms resolve.¹¹ The biochemical impact of depression may be stored in neurons through changes in the activity of gene transcription factors and neuronal growth factors.¹² A common final pathway is the biochemical imbalance of biogenic amines or neurotransmitters (e.g., serotonin, norepinephrine, gamma-aminobutyric acid [GABA], and dopamine) and their relationships with their respective receptors in the brain. Potential effects on neurotransmitters include impaired synthesis, increased breakdown, and increased pump uptake, with consequent alterations in neurotransmitter levels. This increasingly sophisticated understanding of the underpinnings of depression may one day lead to improved treatment, but for now pharmaceutical approaches to treating depression involve correction of altered neurotransmitter levels and of neurotransmitter receptor interactions.

Integrative Therapy

Exercise as Medicine

More than 1000 trials have examined the relationship between exercise and depression, and most have demonstrated an inverse relationship between them.^{13,14} Physical activity may also prevent the initial onset of depression.^{15,16}

Regularly performed exercise is as effective an antidepressant as psychotherapy or pharmaceutical approaches.^{13,17-21} Well-designed studies also support that exercise combined with pharmacologic treatment is superior to either alone, but exercise appears to be superior in maintaining therapeutic benefit and preventing recurrence of depression.²²⁻²⁶ Evidence provides some support for the use of exercise. A recent Cochrane review (updated from 2009) included 32 studies (n=1858) involving exercise for the treatment of researcher-defined depression. From these studies, 28 randomized controlled trials (RCTs) (n=1101) were included in a meta-analysis revealing a moderate to large effect in favor of exercise over standard treatment or control. However, only four trials (n=326) with adequate allocation concealment, blinding, and ITT analysis were found, resulting in a more modest effect size in

favor of exercise. Pooled data from seven trials (n=373) with long-term follow-up data also found a small clinical effect in favor of exercise.²⁸ The additional benefits that may be attained by patients who exercise, including increased self-esteem, increased level of fitness, and reduced risk of relapse, make exercise an ideal intervention for patients suffering from depression.

Both aerobic and anaerobic activities are effective.^{19,23,33,34} Regardless of the type of exercise, the total energy expenditure appears more important than the number of times a week a person exercises, and high-energy exercises are superior to low-energy exercises.

Exercise to Prevent Pregnancy-Related Depression

According to recommendations from both the American College of Obstetricians and Gynecologists and the Royal College of Obstetricians and Gynaecologists, pregnant women without medical contraindications should engage in regular aerobic and strength-conditioning exercise during the perinatal period.²⁹ A study of prenatal aerobic exercise in women without depression has shown that exercise or physical activity was associated with fewer depressive symptoms in pregnancy.³⁰ Few controlled studies have evaluated the effectiveness of exercise as a treatment for postpartum depression. Two RCTs comparing a 12-week intervention of exercise to a control situation in postnatal depression symptoms demonstrated a significantly greater reduction in these symptoms with exercise as compared to controls.^{31,32} Based on this small number of studies, we recommend the following for the general health of perinatal patients: 30 minutes of exercise per day, most days of the week, in the absence of either medical or obstetric complications and after consultation with a physician.

Exactly why exercise relieves or prevents depression is not understood. Although exercise may increase levels of serotonin, norepinephrine, and endorphins, its benefits have been reported even when naloxone is administered to block endorphins. Exercise may also increase nerve cell growth in the area of brain that modulates mood, similar to pharmaceuticals.^{35,36}

Exercise is inexpensive, has proven benefits beyond the treatment of depression, has a low occurrence of side effects, and is available to everyone. The appropriate exercise prescription depends on the specific patient's health, motivation, level of fitness, and interests (see [Chapter 91](#),

[Writing an Exercise Prescription](#)). For more seriously depressed patients and those with significant psychomotor retardation, the exercise regimen should be started as adjunct therapy.

Write an exercise prescription for all patients; tailor the type of exercise to something the patient enjoys, whether aerobic or anaerobic.

Nutrition

Caffeine and Simple Sugars

Cross-national epidemiologic studies suggest a correlation between sugar intake and rates of major depressive disorders.³⁷ Examination of the diets of people suffering from depression reveals increased consumption of sucrose compared with the general population.³⁸ A small cohort trial found that eliminating refined sucrose and caffeine from the diets of people experiencing unexplained depression resulted in improvements by 1 week, and symptoms worsened when patients were challenged with these substances but not with placebo.³⁹ However, protective effects in women of drinking 2 to 5 cups of coffee daily have been demonstrated,⁴⁰ and an inverse relationship appears to exist between daily tea drinking and depression.⁴¹ At this point, no clear cause and effect has been demonstrated.

Dietary Patterns

Prospective data suggest a protective effect of a whole foods traditional diet (vegetables, fruit, beef, lamb, fish, and whole grains) or Mediterranean-style diet (omega-3 fatty acids [from fish], monounsaturated fatty acids [from olive oil], and natural folate and other B vitamins [from legumes, fruit and nuts, and vegetables]) versus a Western-style diet (high levels of energy, saturated fats, and refined sugar, as well as fried and highly processed foods)⁴² across a number of populations (British, Australian, Spanish, Korean) after adjusting for potential confounders.⁴³⁻⁴⁶ At this point, no large, high-quality clinical trials have been published supporting the use of diet for treating depression (although one is underway),⁴⁷ but the evolving understanding of the underpinnings of depression, including inflammation, suggest a

rationale for dietary manipulation in treatment.

Alcohol

A systematic review confirmed that alcohol-related problems are more common in depressed individuals than in the general population and are associated with worse outcomes.⁴⁸ Although consumption of alcohol transiently increases the turnover of serotonin, the long-term result is diminished levels of serotonin and catecholamines.⁴⁹ Elimination of alcohol intake appeared to reduce depressive symptoms in a number of studies.⁴² Because of the safety, potential health benefits in other areas, and low cost of this intervention, limiting alcohol consumption is warranted.

Recommend that patients adhere to a traditional or Mediterranean dietary pattern and limit sugar and alcohol consumption.

Omega-3 Fatty Acids

Epidemiologic data suggest that a deficiency of omega-3 fatty acids or an imbalance in the ratio of omega-6 and omega-3 fatty acids correlates positively with increased rates of depression.⁵⁰ Because dietary polyunsaturated fatty acids and cholesterol are the major determinants of membrane fluidity in synaptic membranes involved in the synthesis, binding, and uptake of neurotransmitters, it is hypothesized that alterations may lead to abnormalities contributing to increased rates of depression.⁵¹ Although the current evidence does not support using omega-3 fatty acids as monotherapy to treat depression,⁵² small, well-designed studies support the use of omega-3 fatty acids as adjuncts to conventional antidepressant therapy.^{53,54} Preliminary evidence also suggests that children with depression and women with depression during pregnancy may benefit from supplementation with omega-3 fatty acids.^{55,56}

A recent meta-analysis suggests omega-3 supplements containing 60% or more eicosapentaenoic acid (EPA), with a ceiling of 2000 mg of EPA in excess of docosahexaenoic acid (DHA), appears to be most effective.⁵⁷ Consumption of two or three servings each week of smaller cold-water fish (herring, mackerel, wild salmon, sardine) may be comparable. One

caveat to consider is the issue of heavy metal and pesticide contamination of available seafood and supplemental fatty acids. Larger fish and some farmed fish may bioconcentrate toxins, including mercury and polychlorinated biphenyls. Vegetarian alternatives to consider include flaxseed oil or ground flaxseed meal (2 tablespoons daily) and a small handful of walnuts each day, but these substances have not been studied with respect to depression (see [Chapter 88, The Antiinflammatory Diet](#)).

The role of docosahexaenoic acid is generally more structural (important for brain and retina development), while that of eicosapentaenoic acid is generally more functional (improves communication across cell membranes).

Dietary Supplements

Vitamin D

Epidemiological evidence shows that Vitamin D deficiency is associated with an 8% to 14% increase in depression.⁵⁸⁻⁶⁰ However, causality and efficacy of supplementation remain controversial awaiting confirmation by systematic review and meta-analysis. These reviews have produced conflicting results but include studies with many different designs and flaws (e.g., ineffective interventions that failed to increase or actually decreased 25OHD [25-hydroxy vitamin D] levels or failed to measure a baseline 25OHD level). A recent meta-analysis that included only studies without such flaws found a statically significant effect of vitamin D supplementation on depression scores, comparable to the magnitude of the effect of typical antidepressant medications.⁶¹ These results are promising, but clearly, more studies are needed to make a more definitive statement on the effectiveness of Vitamin D supplementation on depression.

B Vitamins

Folic acid and vitamin B₁₂ are intimately linked with the synthesis of S-adenosylmethionine (SAMe), and each functions as a methyl donor, carrying and donating methyl groups to a variety of brain chemicals,

including neurotransmitters. Although large-scale clinical studies are lacking, a trial of a B-complex vitamin is advisable, particularly for older patients, in whom B₁₂ deficiency is common, and for persons with suboptimal diets. Vitamin B₆ is essential in the manufacture of serotonin, and vitamin B₆ levels have been found to be low in many depressed patients, particularly in premenopausal women taking oral contraceptive pills or replacement estrogen.^{25,50,62}

Dosage

One B-complex vitamin daily. A B-50 has approximately 50 mcg or mg of most of the B vitamins, and a B-100 has about 100 mcg or mg. Both are safe. The one B-vitamin that can be neurotoxic at doses > 200 mg daily is B₆ (pyridoxine).

Folic Acid

Up to one-third of depressed adults have borderline or low folate levels. A subgroup of depressed patients with folate deficiency and impaired methylation and monoamine neurotransmitter metabolism has been identified.⁶³ In fact, depression is the most common symptom of folate deficiency.⁶⁴ Patients with low levels of folate also appear to respond more poorly to therapy with selective serotonin reuptake inhibitors (SSRIs).⁶⁷ Limited evidence from a Cochrane Review suggests that the addition of folate to conventional antidepressant therapy is beneficial.⁶⁵ More recent trials have used L-methylfolate, the active and more bioavailable form of folic acid.⁶⁶

Folate may also have other health benefits (e.g., prevention of neural tube defects and reduction of elevated homocysteine). Supplementation with vitamin B₁₂ concomitantly makes sense to avoid masking a deficiency (see [Chapter 38, MTHFR Mutation](#)).

Dosage

400 mcg to 1 mg daily (although doses of 5 to 20 mg daily have been used in studies). Consider L-methylfolate 7.5 to 15 mg, which may be better tolerated.

Precautions

High doses of folic acid have been reported to cause altered sleep patterns, vivid dreaming, irritability, exacerbation of seizure frequency, gastrointestinal disturbances, and a bitter taste in the mouth, and concerns have emerged about possible increased risk of some cancers.

S-Adenosylmethionine

SAMe ([Fig. 5.1](#)) is the major methyl donor in the body and is involved in the metabolism of norepinephrine, dopamine, and serotonin. Its synthesis is impaired in depression, and supplementation results in increased brain monoamine levels, enhanced binding of neurotransmitters to receptors, and increased brain cell-membrane fluidity. Although larger trials are warranted, multiple open and RCTs suggest that SAMe is an effective natural antidepressant. An RCT comparing SAMe (1600 mg orally, daily) with imipramine (150 mg orally, daily) over 6 weeks demonstrated equivalent efficacy and superior tolerability of SAMe.⁶⁷ Another small, double-blind, placebo-controlled trial of SSRI nonresponders with major depression compared adjunctive SAMe (800 mg orally, twice daily) with placebo and found SAMe significantly more likely to lead to remission.⁶⁸ A more recent RCT from 2014 compared SAMe, escitalopram, and placebo and showed similar significant improvement in depression for all three treatments after 12 weeks.⁶⁹ An agency for Healthcare Research and Quality evidence report and technology assessment in 2002 found SAMe to be superior to placebo and comparable to conventional antidepressants, based on available evidence. SAMe is generally well-tolerated and has a more rapid onset of action than that of standard pharmaceutical antidepressants.⁷⁰ Because of this characteristic, some clinicians start SAMe concurrently with another dietary supplement or pharmaceutical approach to therapy of depression that has been more thoroughly studied and then taper the dose of SAMe to zero as the other antidepressant begins to take effect. The most stable and bioavailable oral form appears to be 1,4-butane-disulfonate (Actimet), which is stable for up to 2 years at room temperature. SAMe does not have known cardiac, anticholinergic, or orthostatic effects. Larger clinical trials comparing SAMe with placebo and standard of care will help elucidate its role in treating depression.

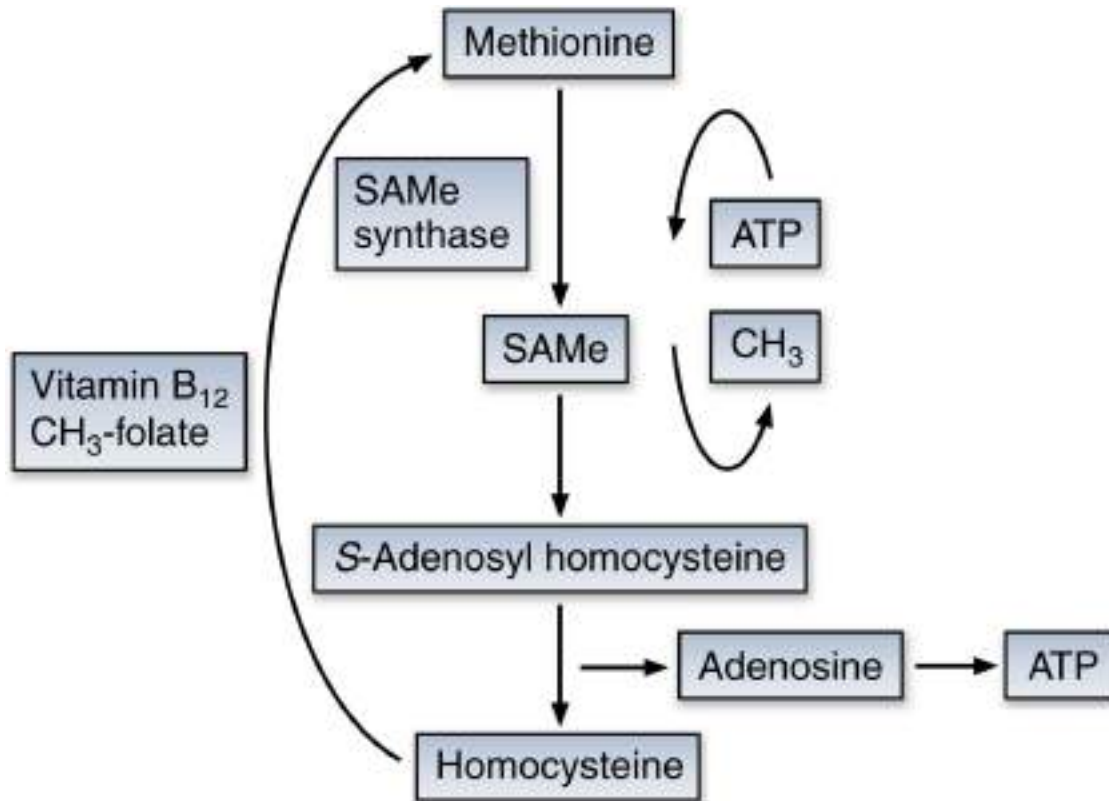

FIG. 5.1 S-Adenosylmethionine (SAMe) metabolism.

SAMe may cause hypomania or mania in patients with bipolar disease and should be avoided in this population. *ATP*, adenosine triphosphate; *CH₃*, methyl group.

Dosage

Initial treatment of depression may require 1600 mg daily given in two equal doses. We recommend starting with 200 mg once or twice daily followed by slow titration up over 2 weeks to minimize gastrointestinal side effects.

Precautions

High dosages can cause nausea, vomiting, flatulence, and diarrhea. Avoid giving the second dose close to bedtime because it can cause insomnia.

Hydroxytryptophan

Hydroxytryptophan (5-HTP) is the intermediate in the metabolism of tryptophan to serotonin. Open trials and RCTs have suggested that 5-HTP is as effective as standard antidepressants.^{71,72} A Cochrane Review found only 2 of 108 trials of sufficient quality for inclusion, but in these trials, 5-HTP was superior to placebo.⁷³ Tryptophan itself appeared promising as a treatment for insomnia and depression but was removed from the market (although it is available again) when a contaminated batch was linked to an outbreak of eosinophilia myalgia syndrome in people with abnormal activation of the kynurenin pathway. Although 5-HTP is not metabolized along this pathway, case reports link 5-HTP to an illness resembling eosinophilia myalgia syndrome. The suspected culprit is a family of contaminants known as peak X that is commonly found in commercially available 5-HTP.⁷⁴ Because uncertainty surrounding 5-HTP remains, it seems advisable to avoid recommending its use pending further information. Case reports of seizures in Down syndrome and dermatomyositis in conjunction with the use of carbidopa have appeared in the literature. Use with other serotonin agonists is not recommended, to avoid serotonin syndrome.

Dosage

5-HTP 50-200 mg three times daily. We recommend starting with 50 mg and titrating up over a few weeks if needed.

Botanicals

St. John's Wort (*Hypericum perforatum*)

The exact mechanism of action of St. John's wort (SJW) remains unknown, but this botanical affects serotonin, dopamine, norepinephrine, and GABA reuptake inhibition and also in vitro monoamine oxidase inhibition and L-glutamate.⁶⁷ SJW also appears to inhibit interleukin-6 and increase cortisol production, which may result in an additional indirect antidepressant effect.⁷⁵ Clinical effects are probably the result of a combined contribution of multiple mechanisms, each individually too weak to account for the action.⁷⁶ SJW has been a

licensed prescription medication in Germany since 1984, and nearly twice the number of prescriptions are written for it as for all other antidepressants in that country. Two large US trials found that SJW was not effective for treating severe major depression.⁷⁷ The most recent Cochrane Reviews examined the findings of 29 trials (nearly 5500 patients) comparing SJW with placebo or standard antidepressants and concluded that available evidence suggests that SJW is superior to placebo and is as effective as conventional antidepressants and better tolerated.⁷⁸ Large-scale postmarketing surveillance studies of SJW extracts (14,245 patients) recorded rates of adverse effects 10-fold lower than for conventional antidepressants.⁷⁹

Indication

SJW is indicated for mild to moderate depression.

Dosage

300 mg three times daily has been used most frequently in clinical trials. 450 mg twice daily has also been used. Choose a product standardized to a minimum of 2% to 5% hyperforin or 0.3% hypericin such as those used in clinical trials. Examples include Lichtwer LI 160 found in Kira and WS5572, containing a minimum level of 3% hyperforin found in Perika (Schwabe, Nature's Way).

Once clinical improvement has been obtained, consider twice-daily dosing. Up to 2 months may be required before full effects are noted.

Precautions

Although side effects are fewer than with current pharmacologic antidepressants, they can include gastrointestinal upset, allergic reaction, fatigue, dry mouth, restlessness, constipation, sexual side effects, and possibly increased risk of cataracts.

St. John's wort can activate the cytochrome P-450 3A4 detoxification system in the liver, as well as p-glycoprotein, and thereby reduce the serum levels of drugs metabolized by this pathway. Caution should be used in patients receiving antiretroviral, warfarin, cyclosporine, and

oral contraceptive therapy.

Saffron

In addition to its well-known culinary uses, saffron has long been used in traditional Persian medicine to treat mood disorders.

Small, controlled trials now suggest that a specific saffron extract can improve symptoms of depression as effectively as imipramine (100 mg daily) and fluoxetine (20 mg daily) in patients with mild to moderate depression after 6 weeks of treatment and is well-tolerated.^{80,81}

Dosage

30 mg daily (Novin Zaferan Co., Iran)

Safety

Saffron has “Generally Recognized as Safe (GRAS)” status in the US

Mind–Body Therapy

Antidepressants and psychotherapy are first-line treatments for depression according to the American Psychiatric Association (APA); even so, only 60% of those treated will have a clinically significant response, and many others may have residual symptoms.⁸² Many psychotherapies can be considered mind–body approaches. One-fourth of patients with depression have tried some type of mind–body therapy,^{83,84} and two-thirds of those found it beneficial.⁸⁴

Depression-specific psychotherapies are designed to provide acute, time-limited interventions. They are present-oriented and pragmatic, focusing on depression and issues considered relevant to both its onset and its perpetuation.⁸⁵ Primary care physicians can provide limited, supportive psychotherapy at frequent visits necessary to monitor the effectiveness of medications.⁸⁶ In fact, generic counseling appears to be preferred by patients over antidepressant drugs and is as effective, although slower in onset, for treating mild to moderate depressive illness.⁸⁷ Cognitive therapy in which the physician or therapist assists the patient in replacing negative patterns of thinking with a more positive

and realistic approach is the most-studied psychotherapeutic approach to major depression. Multiple studies have demonstrated the equivalency of this modality to rigorous antidepressant medication regimens.⁸⁵

Mind–body therapies encourage an active process through which the patient learns from their symptoms versus taking a medication or supplement during which the individual is a passive recipient.

There is an ever-growing diversity of psychotherapeutic approaches including “third wave cognitive behavioral therapies” (e.g., mindfulness-based cognitive therapy, compassionate mind training, acceptance and commitment therapy) and psychodynamic therapies, as well as integrative approaches that combine aspects of various models. However, evidence is lacking as to which psychotherapeutic approach is most effective.^{87A}

Mindfulness-Based Cognitive Therapy

Based upon the work of Jon Kabat Zinn’s “Mindfulness Based Stress Reduction,” MBCT focuses on allowing distressing emotions, thoughts, and sensations to come and go, without grasping onto the need to suppress, fight, or escape them.⁸⁸ This specific method has been successful for treating depression in a variety of patient populations.⁸⁹ Several initial studies also demonstrate that MBCT can decrease the recurrence of depression.^{90–92} MBCT appears to be particularly effective in patients who have had three or more relapses and may be equal to medication in preventing relapse in this difficult-to-treat population.

Other Mind–Body Therapies

Yoga

Yoga is rooted in Indian philosophy and has become a popular route in Western culture towards improving physical and mental well-being. Yoga is most often associated with physical postures, breath control, and meditation. Different yoga schools have emerged that put varying degrees of focus on the physical and meditation practices. A recent systematic review located 12 RCTs (pooled n=619) studying the effect of yoga on the severity of depression. Moderate evidence indicated a

beneficial short-term effect of yoga compared to usual care, and limited evidence indicated such a benefit compared to relaxation and aerobic exercise.⁹³ Aside from the physiological benefits of yoga, the mindfulness component may also provide a form of focus that may quell rumination (which is common in depression).

At this point, distinguishing between the different types of yoga is not possible, although initial studies using Hatha and Vinyasa yoga both appeared promising.^{94,95}

Tai Chi

Tai chi combines martial arts and meditative movements that promote balance and healing of the mind and body. Tai chi involves a series of slowly performed, dance-like postures that flow into one another. As it comprises concentration, balance, muscle relaxation, and relaxed breathing, tai chi shows potential for becoming widely integrated into the prevention and rehabilitation of a number of medical and psychological conditions. One recent meta-analysis was performed on three RCTs that used depression as an outcome measure and demonstrated that tai chi interventions have beneficial effects for various populations on a range of psychological well-being measures including depression, anxiety, general stress management, and exercise self-efficacy.⁹⁶ The authors concluded that despite these positive outcomes, the studies had significant methodological limitations, and more RCTs with rigorous research design are needed to establish the efficacy of tai chi in improving psychological well-being and its potential to be used in interventions for populations with various clinical conditions.

Other Traditional Healing Techniques

Although well-designed clinical studies investigating the role of hypnosis and imagery in the treatment of depression are limited, centuries of experience in traditional healing systems (e.g., Ayurvedic, Tibetan) support this kind of therapeutic approach. In our experience, these mind–body techniques are often extremely useful therapeutic adjuncts that appear to enhance the efficacy of other treatments.

Emerging data suggest that relaxation therapy appears promising.⁹⁷ Some evidence has also shown the effectiveness and durability of prayer as an adjunct to other therapy for depression.^{98,99} We recommend that interested patients explore one of these approaches (see [Chapter 94](#),

[Relaxation Techniques](#)).

Acupuncture

Acupuncture has been used for centuries in Asia for the treatment of virtually all known disease states. The exact mechanism of action is unknown, but human and animal studies have demonstrated that the stimulation of certain acupuncture points can alter neurotransmitter levels.¹⁰⁰ The United Nations World Health Organization recognized acupuncture as effective in treating mild to moderate depression. Published data suggest that acupuncture, including manual-, electrical-, and laser-based modalities, is a generally beneficial, well-tolerated, and safe monotherapy for depression. However, acupuncture augmentation in antidepressant partial responders and nonresponders is not as well studied as monotherapy.¹⁰¹ A recent review of the current literature (January 2000 through April 2013) for acupuncture in cancer-related psychological symptoms showed positive results for acupuncture for the treatment of depression, anxiety, sleep disturbance, and for improving quality of life, with most results showing statistical significance. However, only a handful of acupuncture studies were specifically designed to evaluate depression, sleep disturbance, and quality of life as primary outcomes. Published studies in cancer patients and survivors show that acupuncture treatment is not only safe but also more acceptable, with fewer side effects than standard of care pharmacological treatments like antidepressants.¹⁰² However, there are several limitations of these studies (small sample sizes, imprecise enrollment criteria, problems with randomization and blinding, brief duration of study, and lack of follow-up); thus evidence supporting acupuncture for depression remains inconclusive pending further study. The Cochrane Reviews investigators concluded that evidence was insufficient to recommend acupuncture for depression.^{103,104}

Phototherapy

Phototherapy is commonly used for patients with seasonal affective disorder and appears to be useful as an adjunctive modality with pharmacotherapy in both unipolar and bipolar depression.¹⁰⁵ The effect of phototherapy is thought to involve manipulation of the sleep-wake cycle and biological rhythms. Two meta-analyses supported at least

modest benefit of bright light phototherapy when compared with placebo for nonseasonal depression.^{106,107} In small studies, it appears to be an effective adjunct for adolescents, adults, and the elderly.¹⁰⁸⁻¹¹⁰ The APA guidelines for the treatment of major depressive disorder consider bright light therapy a low-risk and low-cost option.¹¹¹ Consider recommending 30 to 60 minutes of bright, white light (full-spectrum, 10,000 Lux) daily from special bulbs, lamps, or light boxes.

Pharmaceuticals

Antidepressants are believed to work by inhibiting the degradation and reuptake of neurotransmitters important in regulating psychological and neurovegetative function (serotonin, norepinephrine, dopamine), thus increasing neurotransmitter availability at the synaptic level. Newer theories suggest that pharmaceuticals may also mediate intracellular signaling systems that affect neurotrophic factors vital to the functioning of neuronal systems involved in mood regulation. Attempts to determine the most cost-effective approach to treating depression are limited by the quality of these evaluations, but SSRIs and newer antidepressants such as venlafaxine, mirtazapine, and nefazodone consistently are superior to tricyclic antidepressants (TCAs).¹¹² Systematic reviews suggest that escitalopram and sertraline may offer the best combination of efficacy and tolerability.^{113,114} Studies of antidepressant medications increasingly are questioned because of the potential bias owing to unblinding, given that side effects of the drugs (as opposed to inert placebos) may reveal the identity of the true medication to participants or investigators. Trials using an “active” placebo that mimics some of the side effects of antidepressants to counteract this potential bias suggest that differences between antidepressants and active placebos are small.¹¹⁵

Selective Serotonin Reuptake Inhibitors and Mixed Reuptake Blockers

The APA continues to recommend the use of an SSRI as first-line treatment for all levels of depression: mild, moderate, and severe.¹¹⁶ Recommendations for secondary steps include switching or augmenting current therapy (pharmacotherapy or psychotherapy) and depend on the initial treatment choice. *Maintenance therapy* is defined as continuation of the initial treatment to prevent recurrence of depression. For acute

treatment of major depressive disorder (MDD), approximately 60% of patients respond to second-generation antidepressants¹¹⁷ with a 40% relapse rate after 1 year.¹¹⁸ A relatively recent meta-analysis of second-generation antidepressants summarized 4 comparative trials and 23 placebo-controlled trials and found that second-generation antidepressants were generally comparable to each other.¹¹⁹ Safety in overdose and side effect profiles for SSRIs and mixed reuptake blockers are greatly improved over those of cyclic antidepressants and monoamine oxidase inhibitors. Even so, one-half of all patients discontinue their medication in the first 4 months after treatment initiation, and two-thirds of these patients report a side effect as the reason for stopping treatment.¹²⁰ In addition, meta-analyses of antidepressant medications have reported only modest benefits over placebo treatments.¹²¹

Be aware that concern is emerging over the long-term effects of SSRIs, including uncommon but serious neurologic sequelae of seizures and extrapyramidal symptoms,¹²² as well as worsening of long-term outcomes despite effective short-term control.¹²³ The Food and Drug Administration (FDA) has mandated a black box warning on SSRIs regarding the risk of increasing suicidality in children and adolescents. This risk appears to occur within the first 2 weeks of initiating therapy, and whether this risk exists for adults is unclear.¹²⁰ Some work suggests that adults treated with antidepressant drugs, including SSRIs, are no more likely to attempt or complete suicide than those not treated with an antidepressant.¹²⁴

Dosage

See [Table 5.1](#).

Precautions

Nausea, cramping, agitation, insomnia, headache, decreased libido, delayed ejaculation, erectile dysfunction, and anorgasmia have been reported in patients taking SSRIs.¹²⁰ Gastrointestinal side effects are more pronounced with sertraline but may be minimized by taking the drug with food and water. Fluoxetine is generally the most activating. Paroxetine has mild anticholinergic properties, including nausea and possibly weight gain. Venlafaxine has side effects similar to those of the

other SSRIs but may cause serious hypertension over time. Although venlafaxine and paroxetine may have an increased risk of nausea, this can be reduced by using the extended-release forms.¹²⁰ Citalopram and escitalopram have the fewest side effects and the least impact on the cytochrome P-450 enzyme system. Duloxetine appears to play a role in mediating chronic pain and appears effective in older patients.¹²⁵ Rare side effects of SSRIs may include increased risk of gastrointestinal bleeding when these drugs are used with nonsteroidal antiinflammatory drugs, but more research is needed.¹²⁰ Other rare side effects include cardiac conduction abnormalities with venlafaxine and liver enzyme abnormalities with duloxetine.¹²⁰

TABLE 5.1
Drug and Supplement Dosages Used in Depression Treatment

Drug/supplement	Initial dose (mg/day [†])	Range (mg/day [†])	Frequency
Vitamin B complex 100	1 tablet	—	Daily
Folic acid or L-methylfolate	400 mcg	400–800 mcg	Daily
Fish oil	1000	1000–6000	Daily
SAMe (1,4-butane-disulfonate)	200	200–800	bid
Hydroxytryptophan (enteric coated)	100	100–200	tid
St. John's wort (standardized to 5% hyperforin) *	300	900–1200	tid
Saffron	30 mg		bid

Selective Serotonin Reuptake Inhibitors and Mixed Reuptake Blockers			
Fluoxetine	20	20–60	Daily (AM) [‡]
Sertraline	50	50–200	Daily
Paroxetine	20	20–60	Daily (AM)
Paroxetine, extended release	12.5	25–75	Daily
Citalopram	20	20–60	Daily
Escitalopram	10	10–20	Daily

Serotonin Norepinephrine Reuptake Inhibitors			
Venlafaxine, immediate release	37.5	75–375	bid
Venlafaxine, extended release	37.5	75–375	Daily (at bedtime)
Desvenlafaxine	50	50	
Duloxetine	60	60–120	Divided daily–bid

Dopamine Norepinephrine Reuptake Inhibitor			
Bupropion, immediate release	150	300–450	tid
Bupropion, sustained release	150	300–400	bid
Bupropion, extended release	150	300–450	Daily
Serotonin Modulators			
Nefazodone	50	200–300	bid
Trazodone	150	150–400	bid–tid

Norepinephrine Serotonin Modulator, Alpha 2 Antagonist			
Mirtazapine	15	15–45	Daily (at bedtime)

bid, twice daily; SAME, S-adenosylmethionine; tid, three times daily.

[§]Doses greater than 100 mg should be divided dose, with the greater dose given at bedtime.

[‡] Cytochrome P-450 3A4 and drug pump P-glycoprotein induction by St. John's wort requires that care be taken when prescribing this botanical in the setting of other drugs metabolized along these pathways. Perhaps the most clinically relevant interactions occur with cyclosporine (lowering serum cyclosporine concentration) and with other antidepressants, particularly the selective serotonin reuptake inhibitors (SSRIs; serotonin syndrome), antiretroviral therapy (reducing the concentration of protease inhibitors in patients infected with human immunodeficiency virus), and warfarin-type anticoagulants (increasing anticoagulation). Concern exists that St. John's wort may interfere with the efficacy of oral contraceptives. Avoid the use of St. John's wort concurrently with SSRIs; also avoid its use in pregnancy and lactation. High doses may predispose patients to photodermatitis.

[†] Unless otherwise indicated.

‡ Maximum range, 20 to 80 mg.

‡ Initial dose: 100 mg bid for 3 days; then 100 mg tid.

Tricyclic Antidepressants

TCAs have significant side effects (anticholinergic effects, weight gain, and cardiac dysrhythmias) and can be lethal in overdoses as small as an average 10-day supply.

Heterocyclic Serotonin Modulator and Dopamine Norepinephrine Reuptake Inhibitor Antidepressants

Heterocyclic antidepressants are much safer than TCAs in overdose, and they have side effect profiles that make them useful in specific clinical circumstances. Several studies have demonstrated that heterocyclic antidepressants are equally effective as SSRIs.¹²⁶ Amoxapine is useful in treating psychotic depression. Trazodone is highly sedating and is useful in low doses (25 to 50 mg nightly) when taken in combination with SSRIs to induce sleep. Bupropion is highly stimulating and may be a good option for patients wishing to discontinue smoking tobacco; it also has decreased fatigue and somnolence, but it is associated with seizures in underweight people. Nefazodone has anxiolytic properties and may be useful in patients who develop anxiety and insomnia while taking SSRIs. Nefazodone and bupropion also tend to have fewer sexual side effects compared with the SSRIs and serotonin norepinephrine reuptake inhibitors. Nefazodone and bupropion have the least likelihood of causing weight gain compared with SSRIs, whereas mirtazapine increases appetite and tends to cause weight gain. Mirtazapine also increases fatigue and somnolence, which may be desirable in some cases.¹²⁰

Rare side effects that need further investigation in heterocyclic antidepressants include the following: seizures and atopic reactions with bupropion; thrombocytopenia, neutropenia, and bone marrow suppression with mirtazapine; and hepatotoxicity, cardiac conduction problems, and priapism with trazodone.

Electroconvulsive Therapy

Electroconvulsive therapy (ECT) reportedly is effective in achieving remission in 70% to 90% of patients with depression within 7 to 14 days in clinical trials (although it is less effective in community settings).¹²⁷ Generally, ECT is reserved for suicidal, psychotic, or catatonic patients; it is also helpful in patients refractory to other treatment modalities. ECT should be used with caution in patients with recent myocardial infarction, cardiac arrhythmia, or intracranial space-occupying lesions. Transient postictal confusion and anterograde and retrograde memory impairment are expected.¹¹¹

Dosage

ECT, which requires referral to an experienced treatment center, generally involves sessions three times a week for up to 4 weeks, until symptoms abate.

Therapies to Consider for Depression

Estrogen Replacement Therapy

No abnormality of ovarian hormones has been identified that distinguishes women with depression from those without depression during the menopause transition.¹²⁸ However, estrogen replacement was demonstrated to reduce symptoms in perimenopausal and postmenopausal women with depression in some small studies, and discontinuation of hormone replacement therapy (HRT) appears to be associated with the rapid recurrence of depression in some women with a history of depression.¹²⁹ An RCT comparing HRT (estradiol valerate 2 mg, dienogest 2 mg) with placebo suggests that in women with mild to moderate depression in the setting of postmenopausal syndrome, HRT clearly and clinically relevantly reduced symptom severity by the Hamilton Rating Scale for Depression (HAM-D) at 24 weeks.¹³⁰ Studies assessing the relationship between hormone status and depression are inconsistent, and this topic remains an active area of research. Practitioners should consider recommending HRT after weighing the risks and benefits.

Transcranial Magnetic Stimulation

Transcranial magnetic stimulation uses a magnetic coil close to the scalp to generate rapidly alternating magnetic fields to produce electrical stimulation of superficial cortical neurons. It requires no general anesthesia and has minimal side effects. This technique was cleared by the FDA in 2008 for use in patients with major depressive disorder who have not responded adequately to at least one antidepressant trial. Meta-analysis suggests that TMS may be as effective as electrical convulsive therapy (ECT) for nonpsychotic depression.¹³¹

Aromatherapy

Aromatherapy, which is the use of essential oils most often topically combined with MT or as inhaled vapors, has roots in ancient healing traditions. Several small studies demonstrate the impact of aroma on mood. One small open pilot trial found that adjunctive aromatherapy allowed for reductions in the dose of antidepressants compared with usual therapy. This nonrandomized trial included patients using various types and doses of antidepressants.¹³² Short-term but not persistent benefits were found for aromatherapy MT with citrus oil in patients with cancer who were dealing with depression.¹³³ Aromatherapy may be promising as a gentle adjunctive therapy, but larger, well-designed trials are necessary before conclusions can be drawn.

Music Therapy

In music therapy, patients actively perform or listen to music to promote health and healing. Numerous trials of music therapy, largely in an older population, suggest potential antidepressant benefits when this modality is added to usual care, and a dose effect exists with increased response as treatment continues.¹³⁴⁻¹³⁶ Most trials are small and lack blinding to intervention and appropriate control for attention of professionals. In addition, concurrent interventions that are not music specific (e.g., guided imagery and relaxation) make conclusions difficult to draw. A Cochrane Review identified only five trials meeting inclusion criteria and concluded that although music therapy is well tolerated by people with depression and appears to be associated with improvements in mood, the small number and low quality of studies preclude clear determination of effectiveness until better studies are conducted.¹³⁷

Although proof of benefits will require more thorough study, music therapy may be a useful intervention, especially for the elderly, in whom avoiding polypharmacy is of great importance.

Sleep Deprivation Therapy

Sleep deprivation therapy (SDT) is defined as maintaining wakefulness in patients all or part of the night. Multiple studies have suggested a rapid antidepressant effect of sleep deprivation therapy, but unfortunately, the effect tends to be limited, often followed by full or partial relapse after recovery sleep or even small naps. Some trials have suggested a more durable effect may be achieved through the addition of phototherapy or sleep-phase advancement.¹³⁸ One limitation of these studies is the inability for blinding, but chronobiology remains an active area of depression research.

Novel Treatments Having Preliminary Studies

Psilocybin

A small pilot study investigated the effect of psilocybin on 12 patients with advanced-stage cancer and a diagnosis of adjustment disorder with anxiety and generalized anxiety disorder. Using a crossover design, the patients were treated with psilocybin and niacin placebo (to cause flushing) several weeks apart. Psilocybin did not cause any clinically significant adverse effects. It caused a significant decrease in anxiety, as assessed by the State-Trait Anxiety Inventory at 1 and 3 months after treatment, and improved mood, as measured by the Beck Depression Inventory after 6 months.¹³⁹

Botox

The theory that treatment of frown lines with botulinum toxin might improve the mood of depressed patients might seem farfetched. Wollmer and colleagues¹⁴⁰ studied the effect of injecting botulinum toxin into 3 sites in the glabella region of 15 depressed patients who were stable on up to 2 antidepressant treatments. The treatment was the same as that used in the cosmetic treatment of frown lines, and 15 participants

received a placebo of saline injections at the same sites. There was a significant decrease in depression scores from 2 weeks to the end of the trial at 4 months for the active treatment relative to placebo. Similar results were seen on the Beck Depression Inventory and the Clinical Global Impressions Scale.¹⁴⁰

CHAPTER 6

Anxiety

Roberta Lee, MD, CaC

Anxiety disorders are some of the most commonly encountered medical conditions in primary care. According to the National Institute of Mental Health, the 1-year prevalence rate of anxiety disorders is 18.1% of the US population, a total of 40 million individuals. Underdiagnosis is common, with the average patient with an anxiety disorder consulting 10 health care professionals before receiving a definitive diagnosis.^{1,2} Furthermore, patients with a diagnosis of anxiety use primary care services at significantly higher rates than other patients.³ In the past, underdiagnosis was more common with patients receiving elaborate medical workups despite a definitive diagnosis remaining elusive in many cases. These patients became categorized as the “worried well.” Nevertheless, because anxiety can be masked in numerous psychosomatic ways, practitioners must maintain a high index of suspicion for this disorder.

Anxiety disorders encompass a wide variety of subtypes, the most common being generalized anxiety disorder (GAD), obsessive-compulsive disorder (OCD), panic disorder, phobias, and posttraumatic stress disorder (PTSD). All are marked by irrational, involuntary thoughts. One of the most defining diagnostic elements of anxiety disorders is the disruption of daily life by overt distress. Frequently, patients have a significant reduction in the ability to carry out routine tasks, whether social, personal, or professional, with the prevalence of GAD as high as 8% to 10% in primary care practice.⁴ This chapter provides an integrative approach to the management of GAD, as defined in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5).⁴

Definition and Diagnostic Criteria

GAD involves unremitting, excessive worry involving a variety of issues. These concerns may be related to family, health, money, or work. Once the initial concern subsides, another quickly takes its place. The practitioner observes the development of pervasive and repetitive concerns over time. Additionally, the distress seems out of proportion to actual life circumstances.

To meet the DSM-5 criteria for GAD, intense worrying must occur on majority of days during a period of at least 6 continuous months.⁴ In addition, three of the following signs and symptoms must be present: easy fatigability, difficulty concentrating, irritability, muscle tension, restlessness, and sleep disturbance. Patients usually present with physical complaints and fail to recognize stress as the causative factor. The most frequent signs and symptoms are diaphoresis, headache, and trembling.⁵ GAD is also associated with psychological manifestations. Patients often report impaired memory or a diminished ability to concentrate or take directions and frequently make statements such as “I can’t seem to stop thinking of...”

Comorbid Conditions

Approximately 40% of individuals with GAD have no comorbid conditions, but many develop other disorders as time evolves.⁵ In fact, concurrent or coexistent organic or psychiatric disease is the rule rather than the exception in patients with GAD.⁶ For example, panic disorder is common among persons who have irritable bowel syndrome, with a shared brain-gut mechanism incorporating a link with serotonin hypothesized.⁷ Psychiatric overlap is common. Anxiety disorders and depression frequently coincide and either may trigger the other. In cases of coexisting depression, particularly of significant severity, the treatment of depression is the primary objective. Subsequent visits may reveal whether the anxiety is relieved simply by addressing underlying depression. Many individuals coping with anxiety use alcohol or drugs to mask their distress, with approximately 30% of individuals with panic disorder reported to abuse alcohol, and use of drugs occurs in 17%.¹

Pathophysiology

The pathophysiology of GAD is multifactorial and remains incompletely understood. Studies in animals and humans have attempted to identify

body structures and systems involved in the pathogenesis of anxiety. One such structure is thought to be the amygdala, a small structure deep inside the brain that communicates with the autonomic nervous system to relay perceived danger to other centers of the brain which, in turn, readies the body to respond to perceived danger. Furthermore, the memory of these dangers stored in the amygdala appears to be indelible, thus creating a pathophysiologic phenomenon that may contribute to the pathogenesis of GAD.

Although the pathophysiology of generalized anxiety disorder is multifactorial, the amygdala in the brain appears to be a focus for stressful memories that stimulate the autonomic nervous system when the body and mind perceive danger.

Other contributing factors may lie in the realm of cognitive phenomena. Current research is evaluating the association between exposure to stress early in life and subsequent development of GAD.⁷

In PTSD, a subtype of anxiety, studies have identified low cortisol levels (and high levels of corticotropin-releasing factor) and an overabundance of norepinephrine and epinephrine as contributing factors.⁸

Finally, genetic factors are also thought to contribute to GAD, with previous studies reporting genetic concordance with certain genetic loci that produce functional serotonin polymorphisms.⁹

Ruling out Organic Disease

The symptoms of anxiety disorders can resemble those of a variety of medical conditions, and a full medical workup is required for accurate diagnosis ([Table 6.1](#)).

Integrative Therapy

Exercise

Numerous studies have assessed the effects of both short-term and long-term exercise on anxiety. The bulk of these studies have measured the effects of exercise according to the presence of signs and symptoms of

elevated anxiety rather than by using a diagnostic system such as the DSM.¹⁰ Nonetheless, the results of the majority of studies have generally indicated a reduction in symptoms with increased physical activity.

TABLE 6.1

Medical Conditions Often Associated With Symptoms of Anxiety

System	Specific Disorder
Cardiovascular	Acute myocardial infarction Angina pectoris Arrhythmias Congestive heart failure Hypertension Ischemic heart disease Mitral valve prolapse
Endocrine	Carcinoid syndrome Cushing's disease Hyperthyroidism Hypothyroidism Hypoglycemia Parathyroid disease Pheochromocytoma Porphyria Electrolyte imbalance
Gastrointestinal	Irritable bowel syndrome
Gynecologic	Menopause Premenstrual syndrome
Hematologic	Anemia Chronic immune diseases
Neurologic	Brain tumor Delirium Encephalopathy Epilepsy Parkinson disease Seizure disorder Vertigo Transient ischemic attack
Respiratory	Asthma Chronic obstructive pulmonary disease Pulmonary embolism Dyspnea Pulmonary edema

Aerobic exercise programs appear to produce a larger effect than obtained with weight training and flexibility regimens, although all forms of exercise appear to be effective in improving mood.^{10,11} The length of physical activity also appears to be important. In one study, programs exceeding 12 minutes for a minimum of 10 weeks were required to achieve significant anxiety reduction,¹² with the beneficial effect of exercise reportedly maximal at 40 minutes per session.¹⁰ Furthermore, the benefits appear to be long-lasting. In one study assessing the long-term effects of aerobic exercise, initially recorded psychological benefits were maintained in participants evaluated at 1-year follow-up. Participants reported their exercise routines were either the same as those in the original study design or less intensive at 12-month follow-up.¹³

The exact mechanisms underlying the improvement of mood with exercise are not completely understood. However, increased physical activity has been correlated with changes in brain levels of monoamines, namely norepinephrine, dopamine, and serotonin, which may account for improved mood.¹⁴ The endorphin hypothesis is another explanation for the beneficial effects of exercise on mood. Many studies have demonstrated significant endorphin secretion with increased exercise, with beneficial effects on state of mind. However, blockade of endorphin elevation with antagonists, such as naloxone, during exercise has not been shown to decrease mental health benefits.¹⁴ A number of investigators have argued that the latter findings are explained by flaws in methodologic design.

Both length of exercise session and physical activity program duration appears to be important in maximizing the beneficial effect of exercise on anxiety reduction.

Regardless of the underlying mechanisms, the involvement of individual patients in active recovery may confer a sense of independence leading to increased self-confidence. In turn, patient ability to cope with challenging life events is increased. This process is consistent with the integrative philosophy of healing. Furthermore, the paucity of side effects, low cost, and general availability of exercise make it a crucial component of integrative management.

The level of exertion and specific exercise prescription should be

determined according to patient level of fitness, interest in specific physical activities, and health concerns (see [Chapter 91](#)).

Nutrition

Caffeine

On average, U.S. residents consume 1 or 2 cups of coffee per day, which represents approximately 150 to 300 mg of caffeine. Although the majority of individuals are able to handle this amount with no effect on mood, some experience increased anxiety. People who are prone to feeling stress have reported that they experience increased anxiety from small amounts of caffeine. With long-term use, caffeine has been linked with anxiety and depression. Discontinuation of caffeine intake may be warranted in patients with anxiety.¹⁵

Alcohol

With long-term use, alcohol has been found to diminish levels of serotonin and catecholamine. Discontinuation of alcohol consumption may therefore be warranted in cases of anxiety.¹⁶

Omega-3 Fatty Acids

Epidemiologic data indicate that omega-3 fatty acid deficiency or imbalance between the ratio of dietary omega-6 and omega-3 fatty acids are associated with increased anxiety and depression. Animal studies have demonstrated that levels of polyunsaturated fats and cholesterol metabolism influence neuronal tissue synthesis, membrane fluidity, and serotonin metabolism.¹⁷ Primarily indirect evidence, particularly in depression, suggests that correction of the ratio of omega-6 to omega-3 consumption may improve mood. Given the evidence concerning neuronal tissue synthesis and serotonin metabolism, increased supplementation with omega-3 fatty acids may be beneficial in patients with depression.¹⁸ Recommending consumption of cold water fish (sardines, mackerel, tuna, salmon, herring) at least two or three times a week, flaxseed oil (1000 to 2000 mg/day), or freshly ground flaxseed (2 tablespoons daily), may also be appropriate in such patients (see [Chapter 88](#)).

Supplements

B Vitamins

Nutrient deficiencies may alter brain function and therefore lead to anxiety. Deficiency of certain vitamins, including the B vitamins, has been linked with mood disorders. The B vitamins, including B₆ (pyridoxine) and B₁₂, are linked with the synthesis of S-adenosylmethionine (SAME), which carries and donates methyl molecules to many chemicals in the brain including neurotransmitters. Vitamin B₆ is essential for the production of serotonin and has been linked with improvement in various mood disorders including anxiety when administered as a supplement.¹⁹ Although large-scale clinical studies are lacking, a trial of a B-complex supplement appears warranted, particularly in older individuals or those taking medications that may deplete B vitamins, for example, oral contraceptives or replacement estrogen (Premarin).²⁰

Dosage

Vitamin B₆ is administered as a B-complex vitamin supplement.

Folic Acid

Studies have shown that folic acid supplementation has benefit in individuals with depression (see section on folic acid use in [Chapter 5](#)). Patients with low levels of folic acid reportedly respond less well to selective serotonin reuptake inhibitors (SSRIs).²¹ Serum vitamin B₁₂ levels should be checked in patients receiving folic acid supplementation, particularly if megaloblastic anemia is noted in laboratory tests because vitamin B₁₂ deficiency can be masked by folic acid supplementation.

Dosage

The recommended dose of folic acid for supplementation is 400 to 1000 mcg per day.

Precautions

High doses of folic acid have been reported to cause altered sleep patterns, exacerbation of seizure frequency, gastrointestinal

disturbances, and a bitter taste in the mouth.

5-Hydroxytryptophan

5-Hydroxytryptophan (5-HTP) is an amino acid precursor used in the formation of serotonin. 5-HTP has been used as an oral supplement alternative to boost serotonin.²² It has been shown in studies to improve depression, but only preliminary evidence is available suggesting that 5-HTP also may improve anxiety. L-Tryptophan, another amino acid found to improve mood, is converted to 5-HTP and then to serotonin. 5-HTP readily crosses the blood–brain barrier. The metabolism of 5-HTP by monoamine oxidase and aldehyde dehydrogenase forms 5-indoleacetic acid, which is excreted in the urine.

Dosage

For anxiety or depression, the dose is 150 to 800 mg daily.

Precautions

Anyone using conventional medications for depression or anxiety, particularly those agents that boost serotonin, should discuss the use of 5-HTP with his or her health care practitioner before initiating supplementation to avoid excessively elevated levels of serotonin. 5-HTP can cause gastrointestinal side effects such as nausea, belching, and heartburn.

Caution

Some concern exists that 5-HTP, like L-tryptophan, can cause a condition known as eosinophilia myalgia syndrome. The suspected culprit is a group of contaminants identified from the peak X family. However, current evidence is insufficient to suggest that this element is consistently responsible. Case reports have been sporadic.^{23,24}

Pharmaceuticals

Conventional options for initial therapy in GAD are based on various factors and drug side effect profiles. Depression frequently coexists with GAD, so antidepressants are often considered. Several of the SSRIs can be

considered (paroxetine, sertraline, citalopram, escitalopram, fluoxetine, fluvoxamine) for the treatment of GAD, although some agents have been approved for panic disorder, social phobia, and PTSD. Because less cardiotoxicity is associated with SSRIs than with tricyclic antidepressants, an SSRI may be a better choice for patients with heart disease. Other conventional options for treatment of GAD involve the use of multiple receptor agents. Serotonin norepinephrine reuptake inhibitors (e.g., venlafaxine (Effexor) and duloxetine (Cymbalta)) are also approved for GAD. The use of tricyclic antidepressants has always been a consideration, but the difficulty in using these medications is that they can have anticholinergic and cardiovascular side effects, as well as a more pronounced sedative effect. Most experts recommend a trial of at least 4 to 6 weeks to determine efficacy.

TABLE 6.2**Supplement and Drug Recommendations for Treatment of Anxiety**

Drug/Supplement	Initial Dose (Range)	Frequency
Vitamin B complex 100	1 tablet	Daily
Folic acid	400–800 mcg	Daily
Kava	50–70 mg (of kava lactones)	tid
Valerian root	150–300 mg every AM and 300–600 mg at bedtime	
5-Hydroxytryptophan	150–300 mg	Daily
Selective Serotonin Reuptake Inhibitors and Mixed Reuptake Blockers		
Fluoxetine (Prozac)	10–20 mg (10–80)	Daily
Fluvoxamine (Luvox)	50 mg (50–300)	Daily
Paroxetine (Paxil)	10 mg (10–60)	Daily
Sertraline (Zoloft)	50 mg (50–200)	Daily
Escitalopram (Lexapro)	10 mg (10–20 mg)	Daily
Citalopram (Celexa)	20 mg (20–40 mg)	Daily
Others		
Venlafaxine (Effexor)	75 mg (37.5–75 mg)	bid
Nefazodone (Serzone)	200 mg (100–300 mg)	bid
Bupropion (Wellbutrin)	100 mg (50–125 mg)	bid
Duloxetine (Cymbalta)	60 mg (30–120 mg)	Daily
Azapirones		
Buspirone (BuSpar)	5 mg (15–30 mg)	bid

bid, Twice daily; tid, three times daily.

For short-term treatment of GAD, the use of anxiolytics, especially benzodiazepines, has always been a consideration. However, the risk of abuse and habituation has made most primary care practitioners cautious about prescribing these medications. The nonbenzodiazepine anxiolytic buspirone (BuSpar) may be a conventional alternative lacking the problematic issue of drug dependence and excessive sedation.

Dosage

See [Table 6.2](#).

Botanicals

Kava (*Piper methysticum*)

In the field of botanical pharmaceuticals, kava has become known as a botanical option for the treatment of GAD in the United States and Europe. It is derived from the pulverized lateral roots of a subspecies of pepper plant, *Piper methysticum*, and is indigenous to many Pacific Island cultures. In Europe, kava is recognized by health authorities as a relatively safe remedy for anxiety.²⁴ A recent meta-analysis of six of the eleven published randomized clinical trials evaluated the efficacy of kava in GAD,²⁵ with kava found to be superior to placebo in the symptomatic treatment of GAD.

The constituents of kava considered to be most pharmacologically active are lactones, which have a chemical structure similar to that of myristicin, found in nutmeg.²⁶ Kava lactone structures are lipophilic and are present in the highest concentration in the lateral roots. Of the 15 isolated kava lactone structures, 6 are concentrated maximally in the root and vary depending on the variety of *Piper methysticum*.²⁷ The mechanism of action of kava in GAD has yet to be completely elucidated, although the action appears to be similar to that of benzodiazepines. However, conflicting results have been reported in studies in rats and cats.

Benzodiazepines exert their actions by binding to the gamma-aminobutyric acid (GABA) site and benzodiazepine receptors in the brain. Animal studies analyzing the anxiolytic activity of kava, however, have demonstrated mixed and minor effects at both sites. Other studies indicate that kava constituents produce anxiolytic effects by altering the limbic system, particularly at the amygdala and hippocampus.²⁸ Other documented uses of kava have been as a muscle relaxant, an anticonvulsant, an anesthetic, and an antiinflammatory agent.

Indication

Mild to moderate GAD.

Dosage

Kava is taken for anxiety at a dose of 50 to 70 mg (purified extract, kava

lactones) three times daily.

Precautions

Anecdotal reports have noted excessive sedation when kava is combined with other sedative medications.²⁹ Extrapiramidal side effects were reported in four patients using two different preparations of kava. Thus, kava should be avoided in patients with Parkinson syndrome.³⁰ The effects were reported to diminish once the extract was discontinued. A yellow, ichthyosiform condition of the skin, known as kava dermatopathy, has been observed in patients with heavy kava consumption. This condition is reversible with discontinuation of kava.³¹ The overdose potential of kava appears to be low. In many cases, skin rash, ataxia, redness of the eyes, visual accommodation difficulties, and yellowing of the skin have been reported in studies from Australia and the Pacific region after ingestion of up to 13 liters per day, equivalent to 300 to 400 g of dried root per week. This amount of kava represents a dose 100 times that of the recommended therapeutic dose.³²

Caution

There are insufficient data to determine the teratogenicity of kava. For this reason, it is wise to avoid the use of kava during pregnancy. Kava is present in the milk of lactating mothers and its use is therefore discouraged during breast-feeding.³³ The use of kava with other sedative medications should be avoided.

Kava has been reported to cause idiopathic hepatotoxic hepatitis. To date, all case reports (a total of 31) have been in patients from Europe who used concentrated extracts manufactured in Germany or Switzerland. The exact cause of the observed effects are currently under investigation. Kava should not be used in individuals who have liver problems, nor should it be used concomitantly in patients who are taking multiple medications that are metabolized by the liver or in individuals who drink alcohol on a daily basis.³⁴ Liver tests should be routinely performed in individuals who use kava on a daily basis, and patients should be counseled regarding the signs and symptoms of hepatotoxicity (jaundice, malaise, and nausea). Furthermore, daily use of kava should be discontinued after approximately 4 months.

Valerian (*Valeriana officinalis*)

Valerian represents a botanical alternative for the treatment of GAD. The clinical efficacy of valerian has predominantly been evaluated in the treatment of treating sleep disturbances, with fewer clinical studies assessing its use in anxiety available and mixed reports regarding efficacy. Nevertheless, valerian has been used in Europe for more than a thousand years as a tranquilizer and calmative.³⁵ The use of valerian in combination with either passionflower (*Passiflora incarnata*) or St. John's wort (*Hypericum perforatum*) for anxiety has been studied in small clinical trials. One study evaluated valerian root in combination with passionflower (100 mg of valerian root with 6.5 mg of passionflower extract) compared with chlorpromazine hydrochloride (Thorazine, 40 mg daily) over a period of 16 weeks. In this study, 20 patients were randomly assigned to the two treatment groups after being identified as suffering from irritation, unrest, depression, or insomnia. Electroencephalographic changes in both groups consistent with relaxation were comparable, with the use of two psychological scales demonstrating scores consistent with reduced anxiety.³⁶ A further study evaluated anxiety in 100 anxious individuals receiving either a combination of 50 mg of valerian root plus 90 to 100 mg of standardized St. John's wort for 14 days or 2 mg of diazepam (Valium) twice daily in the first week and up to 2 capsules twice daily in the second week. The results of this study demonstrated reduced anxiety in the phytomedicine treatment group compared to healthy individuals. Patients in the diazepam treatment group continued to have significant anxiety scores after treatment.³⁷

Indication

Mild to moderate anxiety.

Dosage

For adults with anxiety, a dose of 300 to 450 mg daily in three divided doses. Combinations with lemon balm and hops (*Humulus lupulus*) may be considered. These additions are based on herbal traditions and empirical medicine, with no clinical trials demonstrating their efficacy currently available.^{38,39}

Precautions

Valerian root is not suitable for the treatment of acute insomnia or anxiety as it takes several weeks before a beneficial effect is obtained. An alternative treatment that provides a more rapid response should be considered from the time of valerian root treatment initiation.³⁸ Adverse effects are rare with products that do not contain valpotriates. Occasional reports have noted headache and gastrointestinal complaints following valerian root use.

Contrary to common belief, valerian is not suitable for short-term treatment of anxiety or insomnia, with several weeks required to observe a beneficial effect.

Mind-Body Therapy

Psychotherapy

Psychotherapy has been shown to be effective as a therapeutic option in the treatment of GAD with or without medical intervention. Two clinically proven forms are frequently used: behavioral therapy and cognitive-behavioral therapy. Behavioral therapy focuses on changing specific unwanted actions by using several techniques to stop the undesired behavior. In addition, both behavioral therapy and cognitive-behavioral therapy help patients to understand and change their thinking patterns so that they can react differently to their anxiety.

Relaxation Techniques

Relaxation training, stress reduction techniques, and breath work are of proven benefit. In fact, imaginal exposure is used as a tactic for repeated exposure to induce anxiety (in a gradual way). Patients learn to cope with and manage their anxiety through repeated exposure rather than to eliminate it. Relaxation training paired with interceptive therapy is often useful. Patients who admit to their anxiety are often willing to confront and learn to cope despite an inability to relax completely. Depending on patient preference, patients should choose a relaxation technique that reinforces a sense of calm. Therapies that can be used for this purpose are massage, sound therapy, aromatherapy, guided interactive imagery, and

hypnosis. Because many patients have somatic sensations that accompany their anxiety, a complementary therapy that imparts a “remembrance” of a deeply relaxed state (see [Chapter 94](#)) should also be used to reinforce on a more somatic-kinesthetic level.

Therapies to Consider

Traditional medical systems, such as acupuncture and Ayurvedic medicine, may provide other options for the treatment of anxiety.⁴⁰⁻⁴² Several small trials assessing relaxation in an anxious state have reported reduction of anxiety in psychologically normal patient populations through the use of auricular acupuncture.^{41,42} Although the mechanisms underlying the efficacy of these treatment are not well elucidated, such systems may have beneficial effects on autonomic nervous system balance.

Prevention Prescription

- Maximize nutrition to include foods rich in omega 3-fatty acids, B vitamins, and folic acid.
- Follow a regular exercise routine (even walking with tracking using a pedometer).
- Institute a daily mind-body exercise program to enhance the relaxation response.
- Keep a journal to develop a “feeling inventory” and enhance self-awareness.
- Limit the use of personal digital assistants, cellphones, and BlackBerry devices. Do not access these devices during meals and special times with family and friends. Turn to “off” at 10 p.m. and “on” at 6 to 7 a.m. Do not recharge these devices next to your bed!
- Get enough sleep to feel refreshed.

Therapeutic Review

The following four steps are recommended for initial management of patients with generalized anxiety disorder (GAD).

1. Remove exacerbating factors. Review current medications and supplements that could contribute to anxiety (particularly botanical

supplements, such as ephedra, and over-the-counter stimulant preparation). Supplements that are unnecessary should be discontinued.

2. Screen for diseases that mimic anxiety. Screening should be performed for underlying medical conditions that produce anxiety, such as hyperthyroidism or withdrawal syndrome.
3. Improve nutrition. Nutritional support is recommended, such as with omega-3 fatty acid supplementation (two to three servings of cold water fish per week, or flaxseed oil 2 tablespoons a day or 1000 mg of flaxseed oil in a capsule). In addition, caffeine and alcohol consumption should be avoided. 
4. Institute physical activity. Physical activity (aerobic or anaerobic) at least 5 days out of 7 should be encouraged. To ensure long-term compliance, an activity that is enjoyable to the patient is important. Furthermore, adherence to a regular exercise regimen and setting realistic short-term goals may require emphasis. Increases in exercise level and intensity should be gradual (see [Chapter 91](#)). 

Supplements

- Vitamin B6 included in a vitamin B 100 complex preparation with the addition of folic acid (400 mcg daily) should be considered. 
- Folic acid 
- 5-Hydroxytryptophan (150 to 300 mg daily) may be considered as a serotonin boosting alternative; however, close monitoring should be undertaken to screen for eosinophilia myalgia syndrome. 

Botanicals

- Kava can be administered at 50 to 70 mg three times a day (purified kava lactones). Choose a standardized product with either 30% or 50%–55% kava lactone concentration.
- If no improvement is observed after 4 to 6 weeks, consider valerian, a valerian combination, or a pharmaceutical anxiolytic (use for at least 6 weeks before evaluating efficacy) 
- Concurrent psychotherapy is highly recommended if this approach is

acceptable to the patient.

Mind-Body Therapy

- Psychotherapy: The combination of psychotherapy in conjunction with supplements, botanicals, or a pharmaceutical anxiolytic or antidepressant is highly recommended, particularly in GAD. An integrative therapeutic approach is associated with higher success rates in cases of severe anxiety. Often, psychotherapy can provide the patient with skills for coping with anxiety, as opposed to extinguishing the symptoms. Primary care physicians are able to monitor lifestyle modification, dietary and supplement interventions, and drug therapy. However, referral to a psychotherapist is advised.

- Relaxation training: Patients are educated in relaxation techniques, allowing control of anxiety symptoms when required.

Traditional Medical Systems

- Use of traditional medicine systems (TMSs) is problematic as TMSs have historically been used to provide primary care for a variety of medical ailments (including anxiety). In allopathic medicine, TMSs are generally used as an adjunctive modality. However, the use of a TMS (e.g., Chinese medicine or Ayurvedic medicine) may represent an appropriate primary therapeutic option in patients with strong feelings regarding the use of singular botanical preparations (predominantly as being insufficient for treatment) or whose medical conditions appear mild, as long as the well-being of the patient is not in jeopardy.

Pharmaceuticals

- The use of a pharmaceutical anxiolytic or antidepressant should be considered if no improvement is obtained with lifestyle measures, dietary measures, or supplement interventions in conjunction with botanical supplements. Depending on the severity of the anxiety and the degree of lifestyle impairment, a conventional prescriptive option with dietary and lifestyle interventions in combination with complementary therapy (e.g., acupuncture, mind-body therapy) may

be used to induce a sense of relaxation before reduction of the prescriptive treatment (often a couple of months later). Depending on the severity of the disorder, botanical supplements (e.g., kava) may also be useful. 

- Different clinical responses may be obtained with various anxiolytics (and selective serotonin reuptake inhibitors). Optimal management may require a change of medication according to patient symptoms. For long-term therapy, the use of benzodiazepines should be limited due to the risk of tolerance and dependence.
- Referral to a psychiatrist should be considered if the patient remains refractory to treatment, is suicidal or psychotic, or requires psychiatric stabilization in a hospital unit.

Key Web Resources

<p>Dartmouth-Hanover Institute for Mind-Body Medicine. http://www.mindbodyinstitute.org/bbi/.</p>	<p>The Institute was founded in 1988 as a nonprofit scientific and educational organization building on the work of Herbert Benson at Harvard Medical School on the relaxation response. The website covers research, education, training programs, clinical programs, books, videotapes, audiotapes, and more.</p>

CHAPTER 7

Attention Deficit Disorder

Anju Sawani, MD, FAAP, FSAHM, and Kathi J. Kemper, MD, MPH

Definitions, Epidemiology, and Pathophysiology

Attention-deficit/hyperactivity disorder (ADHD) is one of the most commonly diagnosed and costly neurodevelopmental disorders affecting school-aged children in the United States. ADHD is characterized by symptoms of developmentally inappropriate levels of inattention and/or hyperactivity-impulsivity for which there is no other explanation. ADHD may also lead to significant impairment of academic or work performance. ADHD is a lifelong condition with 60% to 80% of children reported to have ADHD symptoms that persist into adulthood,^{1,2} with the prevalence of ADHD in adults estimated at 4.4%.³

Current data indicate ADHD is diagnosed in 3%–11% of children between 4 and 17 years of age (depending on age, gender, and community), with rates increasing in the past 10 years from 3%–5% per year.³ ADHD is diagnosed more commonly in boys than girls (3:1 ratio), with a peak age of diagnosis between 8 and 10 years. Drugs used to treat ADHD, such as methylphenidate (Concerta), atomoxetine (Strattera), and a combination of amphetamine and dextroamphetamine (Adderall), are three of the top five (ranked by spending) treatments for children younger than 18 years in the United States. Unlike acute bacterial infection, ADHD is a chronic condition requiring ongoing management.

The classic presentation of ADHD is that of an energetic boy who is easily distracted, talks a lot, interrupts others, acts as if driven by a motor, fidgets and squirms, has a messy room, acts impulsively, has trouble following rules, and often breaks or loses things, and often admonished to sit still, pay attention, and clean up his room. The quiet

girl who daydreams and is inattentive in class represents a second presentation of ADHD (ADHD without hyperactivity). The diagnosis is based on the most recent edition of the *Diagnostic and Statistical Manual* (DSM-5),⁴ characterized by an age of onset less than 12 years and consistent perceptions of a particular pattern of behavior, such as the following:

- Persistence of symptoms (at least 6 months).
- Pervasive (present in at least two settings) patterns of inattention and/or hyperactivity-impulsivity (at least six symptoms up to the age 17 and five symptoms at age 17 and older).
- Symptoms are inappropriate for developmental level and disrupt age-appropriate academic, social, or occupational functioning.

Knowledge of normal child development is essential in making a diagnosis of ADHD, as normal behavior for a 2 year old includes impulsivity and a short attention span that would be abnormal in an 8 year old.

The majority of clinicians use behavioral checklists, such as the Vanderbilt Parent and Teacher Rating Scales, to diagnose ADHD and monitor treatment progress. No laboratory or imaging modalities have demonstrated utility in confirming the diagnosis of ADHD, although clinicians often use laboratory or neuropsychological tests to rule out contributory problems, such as hearing or vision problems, anemia, hypothyroidism, absence seizures, reading or math learning disabilities, and short-term memory impairment.

Common comorbidities include oppositional defiant disorder (ODD) and conduct disorders (CD) (30% to 50%), mood or anxiety disorders (15% to 30%), learning disabilities (20% to 25%), sleep problems (25% to 50%), and tic disorders such as Tourette syndrome (10% to 60%).^{2,5,6} Strengths often include creativity, imagination, sociability, flexible attention, interest in the environment, energy, vitality, enthusiasm, adaptability, confidence, exuberance, spontaneity, and desire to please others.⁷ A strengths-based, specific behavioral goal-oriented approach is popular in the management of ADHD.

Consequences of persistent, poorly treated ADHD include: an increased risk of injuries; increased cost of medical care; an increased risk of addiction to tobacco, alcohol, and illicit drugs; an increased risk of incarceration; and a diminished ability to maintain employment or relationships.^{8,9}

Although a single pathophysiological mechanism underlying ADHD has yet to be described, genetic associations, multiple environmental

agents, and psychosocial characteristics (e.g., poverty, stressed parents and households, families with mental health or substance abuse challenges, difficulty setting limits, disorganized routines) affect the risk of developing or being labeled with ADHD. Genes found to be significantly associated with ADHD include *DRD4*, *DRD5*, *DAT*, *DBH*, *5-HTT*, *HTR1B*, and *SNAP-25*. Other risk factors for ADHD include male gender, maternal tobacco use during pregnancy or early childhood, intrauterine growth retardation, excessive exposure to television, and exposure to certain pesticides.¹⁰⁻¹² Of the 358 industrial chemicals, pesticides, and pollutants found in studies of the umbilical cord blood of infants in the United States, more than 200 are known to be toxic to the brain. Multiple brain regions, including the prefrontal cortex, frontostriatal networks, and cerebellum, and neurotransmitters, particularly dopamine and norepinephrine, appear to be involved in ADHD deficits.¹³⁻¹⁶

In summary, ADHD is a common clinical diagnosis in both children and increasingly in adults, and has multiple genetic, environmental, and psychosocial effects on several neurotransmitter systems and regions of the brain.

Integrative Therapy

Integrative therapy focuses on the goals of the patient and family in the context of values, culture, and community. Goals for treating ADHD may include improvements in the ability to focus or pay attention and in following directions, greater persistence in the presence of difficulty, improved ability to delay gratification, more consistent anticipation of consequences, improving grades, better organizational skills, better short-term memory, greater neatness, less procrastination, improved social relationships, greater obedience, better sleep, and fewer injuries, among other goals. Each of these goals requires a complex interaction of specific skills and resources.

Requirements for learning to manage attention are as follows:

1. *Motivation* (it is easier to pay attention to things that interest us)
2. The ability to *perceive* sensory data, such as sounds (as words) and symbols (written words or gestures), accurately and to *process* these data into meaningful information
3. *Tuning out of irrelevant* sensory information (e.g., ignoring music or conversation in the background while reading a book) while being *flexibly responsive* to changing priorities (a fire by a smoke detector, a cry

for help, or ringing telephone)

4. *Monitoring* of one's own attention ("Oh, was I listening to the music instead of focusing on the words? How many times have I read this sentence?")

5. *Redirection* of attention (let us get back to the book)

In addition to managing attention, learning to *follow directions* also requires certain abilities:

1. Understanding the meaning of the request

2. Recognizing the tools and skills needed to complete it

3. Assessing the availability of these tools and skills

4. Using available resources and asking for help when needed

5. Monitoring performance

The choice of specific therapies depends, to some extent, on individual-specific goals; however, general mental and physical health can always be supported by appropriate attention to the fundamentals: *healthy habits in a healthy habitat*. Four fundamental healthy habits have been identified: exercise, balanced with optimal sleep; nutrition and avoidance of toxins in the diet; management of stress and emotions; and establishment of healthy communication and supportive, rewarding social relationships.¹⁷ A healthy habitat includes both the physical and psychosocial environment ([Fig. 7.1](#)).

Lifestyle

Exercise

A minimum of 30 to 60 minutes of aerobic activity daily is necessary for general physical and mental health.¹⁸ A study conducted in 2009 of children with developmental coordination disorder found that regularly playing table tennis was beneficial for both coordination and ability to sustain focus.¹⁹ Exercise outdoors in nature is even better than exercise in a gym or urban setting.²⁰ Exercise increases brain-derived neurotrophic factor levels and enhances neurogenesis, thereby promoting overall cognitive function, including attention and memory, which are both required for academic achievement.^{21,22} Cerebellar dysfunction has been implicated in ADHD.²³ This has led to growing interest in activities that build balance and coordination such as yoga, juggling, cross-midline exercises, the Interactive Metronome method, and Brain Gym. Quiet, mindful exercises, such as tai chi and yoga, encourage focus on body movements and can thereby improve ability to focus and allow

individuals to be more deliberate and less impulsive.²⁴ Martial arts training promotes discipline. Dr. David Katz of Yale University in Connecticut recommends the ABCs: Activity Bursts in the Classroom (or Corporation).²⁵

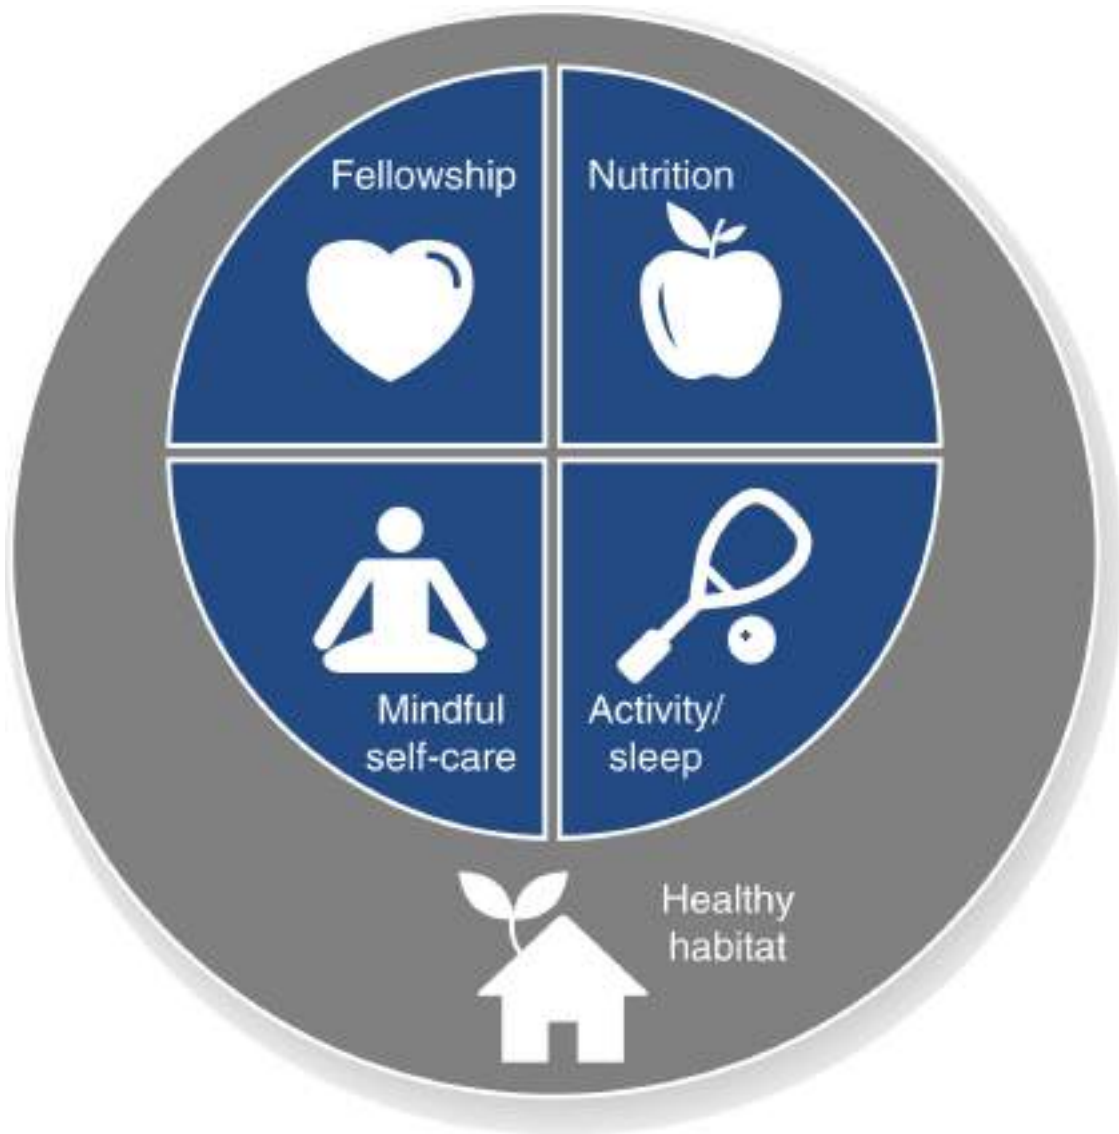

FIG. 7.1 Healthy habits in a healthy habitat.

A minimum of 30 to 60 minutes of aerobic activity daily is necessary for general physical and mental health.

Safety

Impulsive, distracted people are prone to injuries. Encourage appropriate use of bike and ski helmets in addition to protective padding for skateboarding. Encourage enrollment in organized sports or lessons with small classes with close supervision and low student-teacher ratios (karate, tae kwon do, tai chi, or yoga) to help develop body awareness and self-discipline. Counsel the patient to avoid overuse injuries.

Sleep

Sleep deprivation impairs focus, organizational skills, diligence, and self-discipline during boring tasks. Inadequate sleep and poor sleep quality impair attention and judgment, increase fidgeting, lower performance, and lead to more mistakes, automobile collisions, and injuries. Although many patients with ADHD report sleep problems, even before starting treatment, stimulant medications may contribute to insomnia. Improved sleep may lead to improvements in daytime focus on behavior. Clinicians should routinely inquire about sleep and recommend sleep hygiene measures (e.g., cool, quiet, dark room; comfortable bedding; avoidance of television in the bedroom or exercise late in the day; routine bedtime) to promote optimal sleep. Even a brief behavioral intervention to improve sleep hygiene may improve quality of life and overall functioning in addition to sleep quality.²⁶

Nutrition

Despite weighing less than 5% of total body weight, the brain uses approximately 20% of the body's energy supply. To function well, the brain requires a steady supply of high-quality fuel ([Table 7.1](#)). Accordingly, regular meals supplying optimal amounts of essential fatty acids for cell membranes, amino acids for the production of neurotransmitters, vitamin and mineral cofactors for neurotransmitter production and metabolism, and a steady supply of glucose are required to meet whole-body energy needs. Optimally, nutrients are ingested in the diet; however, supplements may be required in patients with a poor diet. Children with ADHD are at increased risk of deficiencies of several essential nutrients, including vitamin D, iron, magnesium, and zinc.²⁷

Omega-3 Fatty Acids

Low levels of omega-3 fatty acids are associated with ADHD and behavioral problems in both adults and children.^{28,29} Supplementation with fish oils (which are rich sources of omega-3 fatty acids) can alleviate ADHD symptoms and decrease depression, anger, anxiety, impulsivity, and aggression, in addition to improving academic achievement.³⁰⁻³⁶ Although flaxseed, walnuts, and green leafy vegetables contain the omega-3 fatty acid *linolenic acid*, humans convert only 5% to 10% of linolenic acid to useful *eicosapentaenoic acid* (EPA) and *docosahexaenoic acid* (DHA). Patients should be encouraged to eat either sardines, salmon, or mackerel twice weekly, consume 1 to 2 tablespoons of flaxseeds daily, or consider a supplement containing between 500 and 2000 mg of combined EPA and DHA.

Amino Acids

The results of two small studies indicate *carnitine* supplements may help improve attention and behavior in children and adults with ADHD, particularly the inattentive type.^{37,38} Additional studies are required to determine optimal dosing, frequency, and duration, particularly for patients with varying intake of foods rich in amino acids.

Minerals

Iron deficiency interferes with memory, concentration, behavior, and both physical and mental performance. Correcting iron deficiencies (indicated by low ferritin levels) has been shown to have utility in improving attention and restlessness.³⁹⁻⁴⁴ *Magnesium* supplements have benefit in children with ADHD who are excitable, easily stressed, or worriers, as well as those who also suffer from constipation.⁴⁵ *Zinc* supplements has been shown to improve behavior in individuals deficient in zinc.^{46,47} The best dietary sources of essential minerals are considered to be plants and animals raised on mineral-rich soils.

TABLE 7.1
Dietary Essentials for Optimal Attention

Dietary Essentials	Foods Sources
Amino acids	Soy, tofu, beans, lentils Seeds and nuts Milk, cheese, eggs Fish, fowl, meat
Essential fatty acids (omega-3 fatty acids: EPA,	Fish (tuna, salmon, sardines, and mackerel) Flax seeds, walnuts

DHA, and linolenic acid)	Dark green leafy vegetables Animals raised on eaten omega-3-rich diets (e.g., eggs from chickens fed flaxseed; pasture-raised and grass finished beef; lamb; bison; wild game)
B vitamins, including folate and B12	Beans, lentils, nuts and seeds Leafy green vegetables, asparagus Oranges and other citrus fruits and juices Whole grains Yeast (e.g., brewer's), dairy, eggs, meat, poultry, fish, and shellfish
Minerals: iron, magnesium, zinc	Peas, beans, lentils, peanuts, peanut butter Leafy green vegetables: spinach, kale Avocado Raisins Whole grains, brown rice, wheat bran and germ Nuts: almonds, cashews Dairy, eggs Meat, fish, poultry, oysters

DHA, docosahexaenoic acid; EPA, eicosapentaenoic acid.

Vitamins

The B vitamins function as essential cofactors in the production of neurotransmitters. Many children who avoid leafy green vegetables consume insufficient amounts of folate. Those who are strict vegans may benefit from vitamin B₁₂ supplements. For picky eaters or those who eat poor-quality diets, multivitamin and mineral supplementation may be beneficial; however, megadoses have not been shown to have efficacy and are associated with side effects.⁴⁸

Water

Dehydration may impair attention and mood.⁴⁹ In a small study of first graders, ingestion of water prior to a test led to increased attention and greater happiness.⁵⁰

Sugar

At least a dozen double-blind studies have demonstrated that sugar does not cause hyperactivity. However, eating simple sugars can cause blood sugar swings that impair mental and emotional stability. Calories should be consumed in the form of complex carbohydrates, such as whole grains, rather than simple sugars.⁵¹ Furthermore, many sweet, processed food products also contain artificial colors and preservatives that may contribute to behavior problems.

Feingold Diet, Artificial Colors, Flavors, and Preservatives

The Feingold diet does not exclude sugar but does eliminate salicylates (at least initially before slowly reintroducing fruits containing them),

several synthetic food additives, and certain synthetic sweeteners:

- Artificial colors (petroleum-based certified FD&C and D&C colors)
- Artificial flavors
- BHA, BHT, TBHQ (preservatives)
- The artificial sweeteners Aspartame (now called Truvia), Neotame, and Alitame

Artificial food colors significantly worsen hyperactivity in many cases.⁵² The Center for Science in the Public Interest (CSPI) has called on the U.S. Food and Drug Administration (FDA) to ban dyes linked to hyperactivity and behavior problems. The colorings the CSPI would like to see banned are as follows:

- Blues 1 and 2
- Green 3
- Orange 8
- Reds 3 and 40
- Yellows 5 and 6

In studies of children with ADHD who received the Feingold diet, 73% had improved behavior.^{53,54} Studies involving more than 1800 children have reported significant improvements in hyperactive behavior in participants consuming a diet free of benzoate preservatives and artificial colors and flavors.^{55,56} Some families find diets free of artificial colors, flavors, and preservatives difficult to follow. When families focus on healthy foods, use supplements wisely, and avoid exposure to artificial ingredients and environmental toxins, they often see remarkable improvements in mood, attention, and behavior, with a proportion of patients able to reduce reliance on stimulant medications.

Coffee and Other Caffeine-Containing Foods

Caffeine has demonstrated greater efficacy in improving attention than placebos but has not been shown to be as potent as prescription medications.⁵⁷⁻⁶⁰ Some families find caffeine a useful substitute for stimulant medications. In addition to caffeine, green tea contains the amino acid theanine, which leads to a feeling of calm that can counteract the jitteriness a proportion of individuals experience with coffee.⁶¹ Coffee and tea contain variable amounts of caffeine depending on growing conditions and preparation techniques. Side effects of caffeine include insomnia, jitteriness, anxiety, palpitations, panic attacks, and dehydration. Coffee can be addictive, and withdrawal symptoms include headaches and feeling irritable, sleepy, depressed, anxious, or fatigued. Withdrawal symptoms can occur with as little as 1 to 2 cups daily.

Caffeinated sodas and energy drinks often contain artificial flavors, colors, and preservatives and are considered less appropriate choices than coffee or tea. Caffeine should not be used as a substitute for regular high-quality sleep.

Food Sensitivities

Approximately 6% to 10% of children have allergies or sensitivities to foods. In addition to classic allergies, a significant proportion of individuals are lactose intolerant and approximately 1% of individuals are sensitive to gluten. The most common food sensitivities are to wheat, corn, soy, milk products, eggs, tree nuts, shellfish, citrus, and peanuts. If sensitivities are suspected, families should be encouraged to keep a careful *food diary*. Blood testing, skin testing, biopsies (for gluten sensitivity), and elimination diets may be useful in some cases. However, allergy test results may be negative even in affected individuals because many reactions are not true allergies. Some studies have posited that the use of few foods or oligoantigenic diets may improve symptoms in more than half of children with ADHD.⁶² An elimination diet typically removes all foods and artificial ingredients that commonly cause problems for at least 2 weeks before slowly reintroducing specific foods one at a time every 3 to 4 days while monitoring symptoms. Nutritional counseling to avoid deficiencies should be recommended if families pursue this option.

Organic or Not?

Products that contain the highest levels of pesticide contamination include apples, bell peppers, celery, cherries, imported grapes, nectarines, peaches, pears, potatoes, raspberries, spinach, and strawberries. Organic crops contain lower levels of pesticides and other agrochemical residues than nonorganic crops.⁶³ Children who regularly eat organic produce have lower levels of toxic pesticide chemicals than children who eat nonorganic produce.⁶⁴ As historical farming practices waned, mineral levels in fruits, vegetables, meat, and milk fell by up to 76% between 1940 and 1991.⁶⁵ Organic crops contain significantly more minerals and antioxidants than crops raised with petroleum-derived (so-called conventional) fertilizers.^{66,67} Milk from cows that graze on grass (botanically diverse pasture) has higher levels of the essential omega-3 fatty acids than milk from cows fed grains such as corn.^{60,68}

Mind-Body Therapies

Know Thy Self

Several studies have reported that children with ADHD tend to have deficits in central executive function and short-term working memory.^{69,70} Accordingly, training in cognitive function and short-term memory may be useful for patients with ADHD.⁷¹ A meta-analysis of 16 randomized controlled trials of cognitive training for children and adolescents with ADHD demonstrated significant improvements in working memory but not necessarily in other symptoms.⁷²

Managing Stress and Emotional Self-Regulation

Learning to manage stress is an important lifelong skill. Major pediatric stressors include physical or sexual abuse; divorce; moving; parental loss of a job or house; serious health challenges; war; neighborhood violence; exposure to domestic violence; parental addiction, incarceration, deployment, or depression; and loss of a loved one. Stress interferes with concentration and self-discipline. Numerous successful strategies for managing stress are available and may be common sense or require training and practice or professional counseling.

Common Sense Stress Management

Common sense strategies include preventive strategies, such as practicing gratitude (counting blessings), and in-the-moment strategies, such as taking a deep breath and counting to 10 before reacting impulsively. Learning to understand one's own triggers, strengths, and weaknesses is also helpful in proactively planning how to manage stressful situations, such as tests, conflicts, running late, or losing something. Rehearsing an anticipated event can help decrease the stress of the actual experience ([Table 7.2](#)). For example, at a calm time, a parent and child may imagine how to handle a situation in which a teacher asks the child to hand in homework and the child is unable to find it in his backpack. What can he do to *prevent* this from happening? If it does happen, how can he *handle* it in a way that is respectful to him, his teacher, his classmates, and his parents? Learning how to anticipate and manage problems proactively is a critical skill that requires practice and effective coaching. *Timing* in training and problem-solving is important, too. Night owls may wish to save perplexing problems until later in the

day, whereas morning people (larks) may wish to get up earlier to tackle challenging tasks. *Reflecting* on the day's events after the heat of the moment can also help children learn to identify negative patterns and create opportunities for meeting challenges.

TABLE 7.2

Stress Management Strategies

Common Sense

Gratitude. Develop the habit of listing three things you are grateful for before meals or bed.

Count on it. Count to 10 before reacting.

Identify your early warning signs: tight muscles, faster breathing, red face, clenched hands, and tight jaw.

Know yourself. Plan activities based on whether you are a morning person or a night owl and a visual or auditory learner.

Plan ahead. Being organized and consistent reduces stress.

Reflect. Develop the daily practice of reflecting on what went well and what could be improved.

Rehearse. Anticipate difficult situations and rehearse or role play before the situation.

Formal Practices, Often Learned with a Teacher or Trainer

Sitting meditation (concentration or mindfulness types)

Moving meditation (e.g., yoga, tai chi, qi gong)

Other Practices, Often Best Learned with Professional Coaching

Biofeedback

Autogenic training, guided imagery

Meditation

Meditation improves attention, stability, creativity, and mental clarity

and reduces errors, aggressiveness, anxiety, and depression, particularly in the presence of stress or distractions. Meditation leads to calm coherence with more focused electroencephalographic (EEG) patterns.^{73,74} Regular meditation practice changes cortical blood flow and increases the size of areas dealing with attention, focus, planning, emotional self-regulation, and mood.⁷⁵⁻⁸⁰

Just as many forms of sport improve physical fitness, many kinds of meditation improve attention and reduce stress reactivity. Just as some kinds of sports involve rackets, bats, or balls, meditation can be performed with eyes open or closed, while sitting still or moving, in silence or not, while visualizing or not, and alone or in groups. *Concentration-based* meditation practices involve focusing on a word, sound, object, idea, emotion (e.g., gratitude), or movement. When other thoughts, sensations, or emotions arise, they are gently placed aside and the mind returns to its object of concentration. Students who practice concentration-types of meditation reportedly have fewer problems with absenteeism and suspension for behavioral problems,⁸¹ less distractibility and better creativity,⁸² and better cognitive function and grades.^{83,84} *Mindfulness* meditation is the moment-to-moment practice of nonjudgmental awareness of sensations, thoughts, emotions, and experiences; when the mind wanders to past or future concerns, it is also gently returned to the present. Studies in school settings have demonstrated that mindfulness-based meditation training can improve attention, emotions, and behavior, with students having fewer fights and improved grades.⁸⁵⁻⁹¹ For hyperactive patients, types of meditation that involve movement, such as yoga, tai chi, or qi gong, may be more appropriate than sitting meditation.^{24,92} Regular practice reduces test anxiety and improves academic achievement, with those who practice the most reaping the greatest rewards.^{93,94}

Regular meditation practice changes cortical blood flow and increases the size of cortical regions dealing with attention, focus, planning, emotional self-regulation, and mood.

The need for formal training and the intensity, duration, and frequency of practice vary. Some clinicians undertake specific training and certification to provide specific kinds of meditation training (e.g., mindfulness-based stress reduction, mindfulness-based cognitive-behavioral therapy, or dialectical behavior therapy). Nevertheless, it is

prudent to ask about a provider's training and experience in case of the absence of consistent state or national certification for mind-body training. As with other clinicians, look for those who are welcoming, warm, empathetic, and show genuine interest in people, not just in their favorite techniques. The most effective teachers and trainers offer steadfast acceptance and positive regard. They also create an atmosphere of safety and trust while fostering independence and acknowledging the strengths and capacities of students.

Just as national guidelines recommend 30 to 60 minutes daily of physical exercise to maintain physical health, recommendations for meditation practice typically range from just a few minutes for young children to 10 minutes twice daily for school-age children to 40 to 60 minutes daily for older adolescents and adults.

Biofeedback

EEG biofeedback (neurofeedback) has been shown to significantly improve behavior, attention, and intelligence quotient (IQ) scores.⁹⁵⁻¹⁰⁴ In fact, neurofeedback can be as effective as standard therapies, even for children with Asperger's syndrome and those with mental retardation.^{100,105-109} The majority of studies provided at least 20 to 40 EEG biofeedback training sessions with a professional trainer. EEG biofeedback training develops a particular skill. Unlike medications, whose effects stop when the pills stop, EEG biofeedback training benefits can be expected to persist if the skill is mastered and practice continues.

Typical costs range from \$75 to \$200 per session; however, insurance reimbursement for neurofeedback varies. The majority of professionals who offer EEG biofeedback are psychologists, therefore, their professional services may be covered by insurance. Despite promising preliminary evidence, neurofeedback remains controversial.¹¹⁰

Neurofeedback shows promising results as an active treatment where the child learns skills rather than relying on medications or supplements that are passive and whose effects disappear on treatment cessation.

Professional Counseling

The results of large studies indicate that, at least in the short term, the most effective treatment for children with ADHD is an integrated

strategy including both behavioral therapy and stimulant medication.^{2,111,112} Cognitive-behavioral therapy can be particularly useful in helping patients learn to question assumptions and thoughts underlying negative emotions. Given all the negative feedback patients with ADHD commonly receive regarding their behavior and academic performance, it is not surprising that they frequently internalize many of these messages and develop low self-esteem. Negative self-labels are occasionally projected onto others, thus leading to blaming and oppositional behavior. By recognizing, questioning, and transforming negative self-talk, one can build confidence, self-esteem, and problem-solving capacities. Professional counseling may also be helpful for those who have comorbidities, such as anxiety, depression, ODD, or CD, or for chaotic families where parents may not be effective role models. Psychological or neuropsychological testing has utility in identifying children with specific learning disabilities, thus allowing specific educational accommodations in school. For adults with ADHD, “metacognitive” therapy can help teach skills, such as time management, organization, and planning. This type of training promotes significant improvements in daily life skills and job performance.¹¹³ Although professional counseling takes more time to be effective compared to medication, the skills learned in behavioral therapy can provide long-term and lasting benefits.¹¹⁴

Social Relationships

Effective communication is key to developing positive social relationships. Most children want to win the approval of their parents and teachers, and receiving frequent criticism, punishment, and negative feedback can be very disheartening. Parents are also often frustrated, confused, discouraged, angry, feel helpless, or consider themselves ineffective parents. This can generate a cycle of maladaptive patterns with high levels of criticism, negative expectations, and negative emotions. Helping families break this cycle can be one of the most beneficial treatments for ADHD. Several common sense steps to do so are summarized in *Transforming the Difficult Child: The Nurtured Heart Approach* by Howard Glasser and Jennifer Easley.¹¹⁵

1. Take a strengths-based approach to communication. Recognize the child’s strengths and where possible, reframe negative labels or challenges as positive opportunities or gifts ([Table 7.3](#)).
2. Identify clear, specific rules with achievable, measurable behaviors and

clear time-linked consequences. In behavioral pediatrics, this is referred to as a SMART plan: Specific, Measurable, Achievable, Relevant, and Timely. For example, “start to get ready for bed by brushing your teeth at 8 pm” is more specific, measurable, and timely than “go to bed soon.” “Spend 15 minutes studying spelling words before 4 pm” is more timely than, “you’ll have to work harder on homework.”

TABLE 7.3
Reframing Labels

Negative Label	Reframed as a Positive
Hyper	Exuberant, vigorous
Distractible	Aware of details that others miss
Spacey	Rich inner life
Driven by a motor	Energetic
Off task	Creative
Impulsive	Eager, enthusiastic, willing
Inattentive	Listening to a different drummer
Poor concentration	Flexibly aware of changes in the environment
Accident-prone	Fearless

3. Frame rules in positive terms. For example, “please play with your toys in your bedroom,” is more positive than “don’t leave your toys in the kitchen.”

4. Make accommodations for learning challenges. If it’s easier for the child to pay attention when sitting in front of the classroom, ask for those seating arrangements. If the child cannot remember to bring books home, ask for a second set of books for home. If the child has learning problems, ask for educational accommodations such as more time for tests. If he or she forgets his or her assignments, ask that the teacher communicate them directly to the parent. Recognize that children with ADHD are generally trying their best and make accommodations to help them succeed.¹¹⁶ These can be part of a standard 504 educational plan.

5. Break it down. Rather than asking a young child to “set the table” or “put plates, silverware, glasses, and napkins out,” start with just one request, such as “put a plate at each person’s place at the kitchen table.” When that task is done, give positive feedback and then say, “Thank you! That’s so helpful. Now put out the forks.” As the child’s memory and capacity improve, you can increase the number of steps or the complexity of the request.

6. Anticipate that the child will test the rules. Testing rules and limits is how children establish a sense of cause and effect, trust, and reliability.

This is normal and can be expected. For example, if you ask a child who dislikes peas to “eat his peas,” he may well leave a few (or many) on the plate to find out exactly what you mean. Or he may bargain (“what if I eat all the carrots and leave some peas?”), rationalize (“I shouldn’t have to eat peas since I had a salad”) compare (“Suzy didn’t eat all of HER peas”), distract (“look at Dad” while feeding peas to the dog), or sabotage (roughly reaching for something and spilling the plate on the floor). It may be helpful to practice or rehearse a few of these scenarios in clinic in a playful way to help families anticipate how to handle these common situations when they arise in the heat of the moment.

7. Give positive feedback frequently and negative feedback neutrally. This practice will help counter the pattern of criticism and sense of failure that are all too common among families confronted with ADHD. “Catch them being good” is a cornerstone of behavioral pediatrics. It is easy to pick on the faults, failures, and lapses. This is not to say that problems should be ignored, but instead make sure there is a balance of at least three praises for every one correction. Help parents rehearse corrective language, too. “We all make mistakes. How do you imagine handling it next time Johnny forgets his homework?”

The benefits of nurturing behavioral strategies can be more profound and long-lasting than medications. For example, when the Tolson School in Tucson began applying this approach, they found a sharp decline in discipline problems, improved test scores, and a decrease in the number of students requiring special education (from 31 students to 7 students), with just 2 out of 519 students requiring medications for ADHD.¹¹⁶

Social support is useful for most families managing chronic conditions such as ADHD. National support groups usually have local chapters with ongoing support and local resources. See Key Web Resources for the URL of key social support groups that include *All Kinds of Minds (AKOM)*, *The National Federation of Families of Children’s Mental Health*, *Learning Disabilities Association of America (LDA)*, and *Mental Health America*.

Alliance With Schools

Clinicians should help teachers and school administrators recognize the child’s unique gifts and challenges. Families should schedule regular meetings with their child’s teachers to monitor progress and advocate for seating arrangements that put the child near the front of the classroom. Encourage families to advocate for the child to receive the public services to which he or she is legally entitled. According to the 1999 addendum to

the U.S. Individuals with Disability Education Act (IDEA), children and youth whose disabilities adversely affect their educational performance should receive special services or accommodations that address their problem (i.e., ADHD) and its effects. Section 504 of the U.S. Vocational Rehabilitation Act prohibits discrimination against any person with a disability. Under Section 504, students may receive services such as a smaller class sizes, tutoring, modification of homework assignments, help with organizing, and other assistance.

If the patient has not received sufficient services or accommodation within 6 months of asking the teacher or principal, write to the school district's director or chairperson for special educational services. The letter should specifically request an evaluation for specific learning disabilities and a functional assessment to determine how the disabilities are affecting the child's classroom performance. These evaluations are required to develop an Individual Educational Plan (IEP) or a 504 Accommodation Plan. Middle school and high school students diagnosed with ADHD are also entitled to these evaluations and, if appropriate, an IEP or accommodation plan. With an IEP, the child may qualify for extra help, special classes, extra time for tests or projects, an extra set of books for home study, permission to take notes on a computer keyboard rather than by hand, extra breaks in the day, fewer classes, and other accommodations, such as support teachers and administrators who offer creative, effective strategies to promote children's strengths.

Encourage parents to try other activities that explore the child's interests, talents, and possible lifelong passions or vocations. When choosing activities, consider the adult-child ratio. Music, art, tutoring, and individual language lessons may offer more individual attention than soccer leagues. Look for consistency. A class that meets every Tuesday is easier to schedule and attend than a sports team that has inconsistent practice and game schedules requiring frequent changes in the family driving routine.

Environment

Increasing time in nature may help soothe irritable children and adults, allow room for exploratory and creative play, and build on innate strengths and skills. Encourage families to reduce electronic screen time to less than 2 hours daily. Ask, advise, and assist families in reducing or eliminating exposure to tobacco smoke and help adults learn to be better

role models when managing stress (i.e., not using alcohol or drugs). Remind families to use proper safety equipment (e.g., seat belts, helmets). Reduce the use of pesticides at home and in schools. Consider using music as a way of reinforcing positive behavior, a learning strategy (songs with rhymes to assist in memorization), and a way to influence the environment subtly to cue wake up times and bedtimes. Encourage families to use calendars and posted schedules to promote structure and predictability for the day, week, and month ([Table 7.4](#)).

Biochemical Therapies

Botanicals & Dietary Supplements

Melatonin

Melatonin does not improve daytime symptoms of ADHD but can help improve sleep, particularly for shift workers and those with delayed sleep phase syndrome.¹¹⁷⁻¹²⁰ The typical adult dose of melatonin is 0.3 to 5 mg taken 1 hour before the desired bedtime. However, melatonin is not a substitute for a healthy sleep routine. One study followed children with ADHD who had started taking melatonin as part of a clinical trial on sleep. At nearly 4 years later, more than two thirds of children were still using melatonin as they reported it helpful with no serious side effects.¹²¹

Calming Herbs

Historically, certain varieties of herbs have been used to promote calm and decrease agitation; however, none can replace a healthy lifestyle. Calming herbs, such as chamomile, hops, kava, lavender, lemon balm, passionflower, and valerian, may promote sleep but are not usually helpful for calming daytime hyperactivity, inattentiveness, or impulsivity.¹²²

TABLE 7.4

Environmental Dos and Don'ts

Do

Spend more time in nature.

Be more mindful of use of music to calm, focus, and reinforce behavior.

Use clocks, calendars, and lists to organize time.
Post schedules, chore charts, and other tools to organize activities and expectations.
Use proper safety equipment (e.g., bike helmets and seat belts).

Don't

Spend more than 2 hours in front of electronic devices daily.
Spend time around tobacco smoke.
Model the use of alcohol or drugs as skillful stress management strategies.

Other Herbs

Coffee and tea containing caffeine are natural stimulants. Green tea also contains theanine, which can be calming and thereby offset some of the unpleasant side effects of caffeine.¹²³⁻¹²⁵ Caffeine helps enhance attention and promotes positive cognitive performance in both children and adults.¹²⁶⁻¹²⁹ To minimize the risk of insomnia due to caffeine, caffeinated beverages should not be consumed within 6 hours of the planned bedtime. No controlled trials have demonstrated significant benefits for other commonly used stimulant herbs, such as ginseng, for ADHD. A pilot study from Italy indicated that ginkgo may help improve ADD symptoms.¹³⁰ A Canadian product (AD-fX) that combines ginseng and ginkgo benefitted patients with ADHD or dyslexia in one manufacturer-sponsored study.¹³¹ Similarly, pycnogenol or European pine bark extract was significantly better than placebo in improving concentration and decreasing hyperactivity in children in several European studies funded in part by pycnogenol producers.¹³²⁻¹³⁴ Neither evening primrose oil (which contains gamma-linoleic acid, GLA) nor St. John's wort supplements have greater efficacy than placebo in treating ADHD. Variations in the quality of herbal products and the paucity of research studies indicate further studies and product standardization are required before the routine administration of these products ([Table 7.5](#)).

Pharmaceuticals

In the United States, stimulant medications combined with behavioral therapy comprise the first-line treatment for young individuals with ADHD, although the long-term effectiveness of this therapeutic regime remains unclear.^{2,112,135,136} The British National Institute for Health and Clinical Excellence (NICE) guidelines for treating ADHD recommend stimulant medications as a first-line therapy for adults with ADHD, but only for children with severe symptoms and not mild or moderate ADHD.¹³⁷ Initially, stimulants (which are classified as controlled substances) benefit approximately two thirds of patients. Stimulant medications typically do not improve oppositional or defiant behaviors, or overall quality of life; however, their adverse effects on appetite, sleep, and growth require ongoing monitoring. Research conducted by scientists without conflicts of interest (unlike previous studies in which investigators occasionally received payments from pharmaceutical companies) have reported that stimulants have limited additional efficacy compared to placebo.¹³⁸

TABLE 7.5

Herbs as Additional Therapy

Calming Herbs

Tea: chamomile, hops, lemon balm, passionflower

Valerian: tincture, glycerite, or capsule

Aromatherapy: chamomile, lavender

Avoid kava because of concerns about hepatotoxicity

Stimulant Herbs

Coffee

Tea: black and green

Ginseng or ginseng/ginkgo combination

Other Herbs

Pycnogenol (pine bark extract, also known as OPC): benefits shown in small, industry-funded studies

Evening primrose oil: ineffective in a randomized controlled trial

St. John's wort: ineffective in a randomized controlled trial

The National Institute of Clinical Excellence (NICE) recommends stimulant medications only for children with severe symptoms and not those with mild to moderate ADHD.

Stimulant medications include short-acting (3 to 6 hours), medium-acting (4 to 8 hours), and long-acting (more than 8 hours) methylphenidates (Ritalin, Methylin, Metadate, Concerta, and Quillivant), dexamethylphenidate (Focalin), methylphenidate transdermal patches (Daytrana), and amphetamines (Adderall, Dexedrine, and Vyvanse). As with coffee, the effects of the majority of stimulants are observed after approximately 20 minutes ([Table 7.6](#)).

Nonstimulant medications used to treat ADHD include atomoxetine (Strattera), clonidine (Catapres, extended-release Kapvay), guanfacine (Tenex and extended-release Intuniv), bupropion (Wellbutrin), and other antihypertensives and antidepressants. Atomoxetine is the most commonly prescribed nonstimulant medication for ADHD and has been shown to be significantly superior to placebo in improving the ability to focus, to be organized, and to regulate attention and emotions, in addition to enhancing short-term memory in adults.¹³⁹ Atomoxetine has also been shown to be beneficial in children with ADHD; however, side effects such as sleepiness and decreased appetite have limited its wider use.¹⁴⁰ In addition to having limited efficacy in a proportion of patients, stimulant medications have several limitations:

1. *Side effects.* The most common side effects of stimulant medications are decreased appetite, poor growth, and insomnia. Less common side effects include nausea, headaches, stomachaches, sweating, jitteriness, tics, dizziness, a racing heart, and, paradoxically, drowsiness. Of greater concern, stimulant use may be linked to psychosis, hallucinations, heart arrhythmias, and sudden death.^{141,142}
2. *Failure to work when not taken.* Medications do not represent a cure for ADHD. Medications will not work when a dose is missed or if patients stop taking their medication. More than half of patients with ADHD stop taking stimulant medication without being advised to do so by their physician.^{143,144}
3. *Reliance on medications.* Patients may rely on these agents instead of making healthy changes in lifestyle and environment.
4. *Long-term costs.* Continuous dependence on medications is costly for individuals and society. An estimated 3.5% of U.S. children received stimulant medication in 2008, up from 2.4% in 1996. Over the period of 1996 to 2008, stimulant use increased consistently at an overall annual

growth rate of 3.4%.¹⁴⁵ In terms of the overall costs of medications, of the top five drugs prescribed for children, three were medications for ADHD.

5. *Long-term effects.* The effects of long-term medication use or of the concurrent use of multiple medications are unknown. Although stimulant medications have been used for decades, no long-term studies have evaluated the developmental impact of using these medications daily for 30 years. Short-term use has been evaluated for one drug at a time; however, the impact of taking multiple medications simultaneously remains unknown.

TABLE 7.6

Short-, Medium-, and Long-Acting Stimulant Medications for Attention Deficit Hyperactivity Disorder

Short (3–6 hours)	Medium (4–8 hours)	Long (>8 hours)
Ritalin (methylphenidate) 5, 10, 20 mg bid or tid	Ritalin LA (methylphenidate long acting) 10, 20, 30, 40, 60 mg daily	Concerta (methylphenidate) 18, 27, 36, 54 mg daily
Methylin (methylphenidate) 2.5, 5, 10 mg, or 5, 10 mg/5 mL bid or tid		Focalin XR (dexmethylphenidate extended release) 5, 10, 15, 20, 25, 30, 35, 40 mg daily
Focalin (dexmethylphenidate) 2.5, 5, 10 mg bid	Metadate CD (methylphenidate extended release) 10, 20, 30, 40, 50, 60 mg daily	Daytrana (methylphenidate patch) 10, 15, 20, 30 mg daily
	Metadate ER (methylphenidate extended release) 20 mg daily to bid	Adderall XR (amphetamine/dexamphetamine extended release) 5, 10, 15, 20, 25, 30 mg daily
Adderall (amphetamine/dexamphetamine) 5, 7.5, 10, 12.5, 15, 20, 30 mg daily to bid		Quillivant XR (methylphenidate-liquid) 5 mg/mL
		Vyvanse (lisdexamfetamine) 10, 20, 30, 40, 50, 60, 70 mg daily

bid, twice daily; tid, three times daily.

Misuse, diversion, and abuse. As the number of prescriptions for stimulant medications has grown, so has the number of reports that these drugs are being diverted or sold to people who do not have ADHD. A 2009 study reported a 76% increase in the number of calls to Poison Control Centers related to adolescent abuse of prescription ADHD medications.¹⁴⁶

Given these concerns regarding stimulant medications, many pediatricians do not provide prescriptions for stimulant medications without first conducting N-of-1 trials to determine the short-term benefits and risks for individual patients. Such trials can be repeated annually to assess the ongoing need for such medications.

Therapies to Consider

Massage, Chiropractic, Acupuncture, and Osteopathy

Scientific studies support the regular use of massage for improving ADHD symptoms.¹⁴⁷⁻¹⁴⁹ Massage affects blood flow and neurotransmitters involved in focus and clarity.^{150,151} Massage also reduces stress, improves mood, decreases pain, and alleviates anxiety, all of which can improve concentration, deliberation, and self-discipline.¹⁵²⁻¹⁵⁴ Even a 15-minute chair massage has been shown to improve speed and accuracy on standard tests.¹⁵⁵ Additional studies are required to determine the best type of massage, the duration and frequency of treatments, and whether massage provided by friends or family members has similar effectiveness to care provided by a licensed professional.

Aside from case reports, there are few studies evaluating the effectiveness of chiropractic adjustments in improving ADHD symptoms. There are insufficient studies to recommend chiropractic as a front-line treatment for ADHD.¹⁵⁶ There is also insufficient data to recommend acupuncture as a proven strategy to address ADHD.¹⁵⁷ The results of one small study in 2014 indicated osteopathic manipulative therapy may improve some test scores in children with ADHD compared to standard treatment.¹⁵⁸

Massage is safe when common sense precautions are used, such as avoiding massage over rashes, infections, bruises, or burns. Do not force massage therapy on patients who have suffered physical or sexual abuse or who are particularly shy. The wishes of adolescents for privacy should also be respected. In the United States, massage therapists are licensed or certified as health professionals in 40 states and licensed by cities or counties elsewhere. Licensed professionals in the United States can be found through the American Massage Therapy Association's Locator Service.

Prevention Prescription

- Advise pregnant women to stop smoking and avoid drinking alcohol.
- Advise parents not to smoke around their children and to limit exposure to television and pesticides.
- Encourage families to live a healthy lifestyle focusing on the following: a whole foods diet that limits intake of artificial colors,

flavors, sweeteners, and preservatives and foods that cause sensitivity reactions and that avoids deficiencies of essential omega-3 fatty acids, amino acids, vitamins, and minerals; daily physical activity, preferably outdoors in natural surroundings; adequate sleep; effective stress and emotional self-management; strength-based communication skills and participation in supportive community networks; and a safe, structured, well-organized environment.

Therapeutic Review

Accurate Diagnosis

Use standard rating scales, such as the Vanderbilt Parent and Teacher Rating Scales, to assess ADHD symptoms and response to interventions. 

Rule out medical and neuropsychological conditions that impair attention and self-discipline, such as hypothyroidism and vision, hearing, and specific learning deficits. Consider requesting a neuropsychological examination to assess IQ and learning difficulties. 

Encouraging Healthy Habits in a Healthy Habitat

Dietary

Assess diet and correct nutritional deficiencies with an improved diet or dietary supplements. 

Encourage patients to maintain a steady blood glucose level by eating regular meals with low glycemic index foods. Foods containing artificial colors, sweeteners, flavors, and preservatives should be avoided, as should foods with heavy contamination with pesticides.

Instruct patients to avoid dehydration. 

Consider recommending coffee or tea as mild dietary stimulants and monitoring for insomnia and other common side effects. 

Sleep and Activity

Promote adequate sleep with sleep hygiene. Consider melatonin (0.3 to 3 mg an hour before bed) or sedative herbal remedies (a cup of chamomile tea or lavender aromatherapy) as a first-line approach to improving sleep. 

Encourage vigorous daily activity, at least 30 minutes daily of activity vigorous enough to break a sweat or make it difficult to talk and move at the same time. 

Stress Management and Emotional Self-Management Skills

Assess stress management and emotional self-management skills.

Counsel families regarding stress management.

Consider referral for meditation training, including moving meditation practices such as yoga and tai chi. Consider referral for effective counseling and cognitive-behavioral therapy. 

Social Support

Refer families to support networks of other families such as Children and Adults with Attention Deficit Hyperactivity Disorder (CHADD).

Encourage positive family communication, focusing on goals rather than problems. Help families view overall long-term goals in terms of short-term achievable objectives and learn to make specific, measurable, achievable, relevant, time-specific (SMART) plans, including ways to celebrate success.

Consider referring families for additional support for parenting, strengths-based communication, and discipline skills, as well as time management and organizational skill development.

Healthy Environment

Advocate for appropriate testing and learning accommodations at school.

Referral for Additional Professional Assistance

Consider referral to a psychologist for neurofeedback. 

Consider a referral for massage therapy. 

Pharmaceutical Management

Remember that 65% of individuals do respond to stimulant medication, at least initially.

Consider recommending an *N*-of-1 trial of a stimulant medication, comparing a low dose (e.g., 2.5 to 5 mg methylphenidate twice daily) and a middle dose (5 to 10 mg twice daily) with placebo for 1 week each.

If patients report improvement, consider switching to a longer-acting medication to reduce the number of pills or doses required daily. 

Monitor and Support Families With Regular Follow-up Every 3 to 4 Months

CHAPTER 8

Autism Spectrum Disorder

John W. Harrington, MD, and Samudragupta Bora, PhD

Autism spectrum disorder (ASD) and autism are now used interchangeably in research literature; however, ASD emphasizes that this disorder is based on a continuum of neurodevelopmental problems characterized by deficits in social communication and interactions in addition to restrictive and repetitive patterns of behaviors, interests, and activities.¹ Recently published data from the Centers for Disease Control and Prevention (CDC) demonstrate that autism continues to increase in prevalence, with 1 in 68 children now affected. Because boys are more commonly affected than girls, at a ratio of 4:1, this translates to 1:42 boys and 1:189 girls diagnosed with an ASD by age 8 in the United States of America.² Recent estimates from the United States and the United Kingdom suggest that the average lifetime costs associated with ASD are remarkably high (\$1.4 million–\$2.4 million in 2011), not accounting for the hidden costs to families.³ With approximately 1%–2% of the population being affected by ASD, clinicians, public health, and research experts agree that understanding of the factors underlying the increased prevalence of ASD is an urgent matter. Three major hypotheses still prevail to some extent: a true increase in prevalence; heightened awareness and therefore earlier diagnosis; and the criteria used to define autism are too subjective, leading to “diagnostic substitution” with other disorders. This final hypothesis was possibly ameliorated with the release of the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* in May of 2013.⁴ The DSM-5 merges communication and social interaction behaviors into one symptom category and increases the importance of repetitive and restrictive behavior regarding the requirements for a diagnosis of an ASD ([Table 8.1](#)). In addition, unlike the DSM-IV, the DSM-5 allows the diagnosis of co-occurring diagnoses, such as attention-deficit/hyperactivity disorder (ADHD), with ASD. The impact of these changes on the diagnostic criteria for ASD has not been

fully realized, making it difficult to predict the potential effect on the incidence of ASD over time. Some experts believe the new criteria will exert a downward pressure on the prevalence of ASD⁵; however, new prevalence data from the CDC monitoring networks, which review data from both schools and clinicians, may provide better information regarding the true incidence of ASD and is expected to be reported again in 2016.

Prevalence, Characteristics, and Guidelines for Complementary and Alternative Medicine Therapies in Autism

More than 3000 patients in the autism treatment network completed a complementary and alternative medicine (CAM) usage survey, with 28% of patients reported to use CAM and 17% using special diets overall.⁶ Rates of CAM usage were higher in children with more severe ASD, those diagnosed at an earlier age, and those with seizures or gastrointestinal symptoms.⁶ In a separate study by Akins et al., no significant difference in CAM use was observed between ASD and developmental disability.⁷ However, a higher level of parental education was associated with increased CAM usage, and families who used > 20 hours per week of conventional services were more likely to use CAM. Clinicians should be aware that families who use CAM are likely to use more than one CAM treatment, and children using CAM should be monitored for possible treatment interactions.⁸ Interestingly, CAM treatments are viewed as safe by parents because they are perceived as natural.⁹ Unfortunately, while the search for a consistent etiology or cure for autism continues, therapies that extend beyond educational and behavioral interventions are readily contemplated by parents hoping to help their child with autism. In addition, because many comorbidities are associated with ASD, children are often referred to CAM for the treatment of ADHD, oppositional defiant disorder, repetitive and restricted behaviors, depression, and anxiety.

It is important for parents and practitioners to have a framework from which to work from when considering and discussing the safety of CAM therapies. Following is a table that highlights the guidelines parents should review ([Table 8.2](#)). [Table 8.3](#) provides an ethics and advice table first produced by Cohen et al.¹⁰ that may inform practitioners and health

care providers when counseling parents regarding the use of a CAM therapy.

Pathophysiology

Genetic/Environmental/Epigenetics

Many genetic disorders and syndromes have been shown to have strong associations with autism, including Angelman, Down, Fragile X, and Williams syndromes in addition to tuberous sclerosis and neurofibromatosis.¹¹ In addition, increasingly refined genetic techniques, such as comparative genomic hybridization microarrays, whole genome linkage, and gene association studies, have allowed researchers to identify numerous chromosomal regions with specific single nucleotide polymorphisms or copy number variants that may be associated with autism.¹² However, even with these developments in genetic testing, the likelihood that a primary care provider will be able to test and uncover a significant genetic finding reportedly remains less than 20%.¹³ The vast majority of cases of ASD are presumed to be caused by an underlying genetic predisposition and interplay between the genetic code and environmental factors, referred to as the *epigenetics of autism*.^{14,15} One of the largest, longitudinal, population-based studies to date, involving 1.6 million families, revealed that genetic and environmental factors contribute equally to the development of ASD, with the relative risk of autism directly correlated with increasing genetic relatedness.¹⁶ There are currently multiple studies being conducted evaluating these environmental risks: the Study to Explore Early Development (SEED),¹⁷ the Childhood Autism Risk Factors from Genetics and Environment (CHARGE) study,¹⁸ the Early Autism Risk Longitudinal Investigation (EARLI),¹⁹ and the Early Markers for Autism study (EMA).²⁰ Results from these studies have demonstrated factors that increase the risk of autism include prematurity, twins or multiple pregnancies, advanced maternal and paternal age at conception and that folic acid supplementation in mothers may have a protective affect against having a child with autism.^{18,19}

TABLE 8.1

Comparison of Changes Between the DSM-IV and DSM-5 for ASD

DSM-IV for Autism	DSM-5 Changes for ASD
1. Rett disorder	1. Rett disorder is removed as it is considered a genetic disorder
2. Pervasive developmental disorder-not otherwise specified, Asperger disorder, and childhood disintegrative disorder	2. These three disorders will now officially be termed autism spectrum disorder
3. Unusual sensory behaviors not part of the criteria	3. Unusual sensory behaviors will be added to the criteria
4. 3 symptom categories (impairment in social interaction, impairment in communication, and repetitive and restricted behaviors)	4. Two symptom categories (difficulties in social communication and social interaction combined, repetitive and restrictive behaviors) but more criteria required per category

ASD, autism spectrum disorder; DSM-IV, Diagnostic and Statistical Manual of Mental Disorders, 4th edition; DSM-5, Diagnostic and Statistical Manual of Mental Disorders, 5th edition.

TABLE 8.2

Guidelines for Parents Interested in Starting CAM Therapies

1. Research the medication or therapy and try and find out safety and efficacy
2. Isolate the behavior you hope to improve in your child
3. Start only one new treatment at a time
4. Understand that all children with autism will improve in their development over time
5. Children may naturally have good and bad weeks regardless of treatment
6. Observe other confounding factors that may affect outcome (life transitions, new infant, vacation, etc.)
7. Assess poor sleep and improve sleep hygiene before CAM trial if possible

CAM, complementary and alternative medicine.

Safe Effective		
	Yes	No
Yes	Use/recommend	Tolerate
No	Monitor closely	Advise against

Reproduced from Cohen MH, Kemper KJ, Stevens L, Hashimoto D, Gilmour J. Pediatric use of complementary therapies: ethical and policy choices. *Pediatrics*. 2005;116(4):e568-575.

The vast majority of ASD is presumed to be caused by an underlying genetic predisposition and the interplay between the genetic code with environmental factors, referred to as the *epigenetics of autism*.

Unfortunately, without a consistent genetic or biologic marker for autism, common procedures and practices, such as vaccines, were wrongly considered to have a causal link with autism. Several hundred studies have since proven that autism and vaccines have only a temporal association with no causal link with autism demonstrated. The recent outbreak of measles at Disneyland in 2015, affecting predominately unvaccinated or undervaccinated children, clearly highlights the problems that can be wrought in public health when parents neglect the immunization of their child and clinicians, along with media, fail to practice according to evidenced-based guidelines.

Neuroimaging Findings

Autism remains a disorder defined by its clinical presentation. However, there is growing information from postmortem and neuroimaging studies highlighting the role of brain abnormalities in the pathogenesis of ASD, although a clear description of the phenotypic neuropathology remains lacking. Alterations in brain structural development, primarily in the frontal and temporal lobes, cerebellum, amygdala, and hippocampus, have consistently been reported. A recent meta-analysis of 16 whole-brain voxel-based morphometric studies, pooling data from 277 ASD patients and 307 healthy controls, found alterations in the lateral occipital lobe, pericentral region, medial temporal lobe, basal ganglia, and the insula/parietal operculum in ASD patients.²¹ Similarly, a

separate meta-analysis of 20 studies, comprising 497 patients with ASD and 471 healthy controls, confirmed alterations of brain structures related to social cognition in patients with autism.²² Although no statistically significant difference in global gray matter volumes between ASD patients and controls was observed in this meta-analysis, regional alterations with markedly lower gray matter volumes were observed in the amygdala-hippocampus complex and the precuneus. Altered development and functioning of brain areas involved in face processing, verbal and nonverbal communication, and social interaction have been consistently reported by previous studies, although the nature of these alterations has yet to be elucidated. The discrepancies in the findings of these studies may be attributable to various factors, including small sample size, methodological differences in data acquisition and analysis across neuroimaging studies, effects of medication status, and heterogeneity among ASD patients in terms of etiology and symptom manifestation. Consistent with reported neuroimaging findings, postmortem studies of ASD patients have demonstrated focal cortical dysplasia and reduced gamma-aminobutyric acid-B (GABA_B) receptors in the cingulate cortex and fusiform gyrus, providing additional evidence indicating neuroanatomical alterations are associated with autism.^{23,24} Finally, in addition to alterations in specific brain structures, abnormal brain size and volume has been observed in autism. Despite inconsistent findings between studies, a meta-analysis published in 2005 including all published studies at that time using a range of methodologies to estimate brain size from birth to age 65 years demonstrated early brain overgrowth during infancy and toddler years in children with ASD, followed by age-related decline in brain size.²⁵

While the pathophysiology of ASD remains unknown, in addition to neuroanatomical abnormalities, studies have demonstrated metabolic abnormalities, including neurotransmitter, hormonal, and immune imbalance, in patients with autism. These changes will be briefly discussed in the following sections.

Integrative Therapy

Intensive Behavioral Therapy

Early diagnosis is the most important aspect of interventional therapy because every published study has demonstrated that earlier interventions in patients with autism are associated with improved

outcomes. Intensive behavioral therapy, referred to as applied behavioral analysis or ABA, represents the only conventional therapy proven through evidence-based methods to marginally treat the core disorder of ASD.^{26,27} ABA is a behavioral treatment approach designed to increase socially appropriate behavior and decrease the severity and/or emergence of challenging behaviors.²⁸ ABA focuses on teaching specific behaviors in a systematic manner in the context of repeated trials. ABA has utility in improving communication, social relatedness, and decreasing repetitive behaviors.²⁹ The ABA framework is used in other treatment modalities, such as Pivotal Response Training, Treatment and Education of Autistic and Related Communication Handicapped Children (TEACCH), and Developmental, Individual-Difference, Relationship based model (DIR)/Floortime³⁰⁻³² (see [Key Web Resources](#)). Many children with autism also receive conventional services, such as speech and language therapy, to address expressive and receptive language deficits and occupational therapy to address sensory integration issues commonly seen in autism. The use of additional or CAM therapies is common in autism and requires an understanding of their genesis.

Understanding the Theoretical Gastrointestinal Link to Autism

Due to the frequency of gastrointestinal problems in autism, it is important for clinicians involved in the treatment of ASD to understand theories related to immune function and gut-brain theory, intestinal permeability, and dysbiosis.^{33,34} The reported prevalence of gastrointestinal problems in children with autism ranges from 9%–91%, with abdominal pain and discomfort, constipation, diarrhea, and chronic diarrhea the most common complaints.³⁵⁻⁴³ Because two-thirds of the human immune system is composed of gastrointestinal mucosal cells, this further implies immune dysfunction is associated with the documented inflammation in gastrointestinal biopsies from children with autism.³⁶ There have also been multiple reports of altered immune function in terms of cytokine function, T-cell abnormalities, and an augmented immune response in patients with autism.^{44,45} Familial histories of autoimmune disorders have been reported in patients with autism,⁴⁶ along with maternal increases in autoantibodies directed at central nervous system proteins (an extension of the gut-brain theory) of

their child with autism.⁴⁷⁻⁴⁹

Leaky Gut

Altered intestinal permeability (“leaky gut”), possibly in response to allergy or inflammatory response, may play a pathogenic role in autism. There have been several studies reporting impaired intestinal barrier function in autism.⁵⁰ In addition, Altieri et al. reported elevated levels of a bacterial product (p-cresol) in the urine of young children with autism versus controls.⁵¹ Other studies have also shown that children with autism have higher concentrations of *Clostridia*, *Bacteroidetes*, and *Firmicutes* than controls.^{52,53} This dysbiosis, or abnormalities of gastrointestinal microflora, is thought to be interrelated with intestinal permeability.⁵⁴ Nutritional factors may be inhibited from effective transport through the gastrointestinal tract and, in addition, interstitial permeability may allow active neuropeptides to move from the gastrointestinal tract into the bloodstream, have an end-organ effect on the brain, and contribute to the core symptoms of autism and possibly anxiety.^{43,55}

Dietary/Lifestyle Treatments

Probiotics

The theoretical pathogenic model of ASD described previously endorses the use of probiotics to aid digestion and improve immune function. Probiotics have been found to influence the composition of microbiota, potentially improving intestinal barrier function and mucosal immune responses in children with autism. The restoration of the gut microbiota to normal levels using probiotics may have utility in reducing inflammation, restoring epithelial barrier function, and improving behavioral symptoms in children with ASD.⁵⁶ A recent study of plasma myeloperoxidase (MPO) levels in children with autism found probiotics decreased MPO levels and may affect the overall absorption properties of the gastrointestinal tract.⁵⁷ Unfortunately, no studies have conclusively demonstrated the benefits or dose response of probiotics that would allow practitioners to make standard recommendations for their use.⁵⁸ However, the use of probiotics has not been shown to have harmful effects, other than occasional diarrhea, and therefore are likely to be well-tolerated if parents agree with their use.⁵⁹ The most commonly used

probiotics are *Lactobacillus rhamnosus* GG and *Saccharomyces boulardii*. These probiotics are provided at many concentrations that range between 1 and 10 billion cells per oral daily dose.⁶⁰

Gluten-Free, Casein-Free Diet

One of the most popular dietary treatments tried by parents is the combination of a gluten-free / casein-free diet (GFCF). The premise of this diet is centered on the theory of the “leaky gut,” as previously described, whereby increased intestinal permeability allows gluten and casein peptides to leak from the gut and promote opioid activity resulting in ASD behaviors.⁶¹ Interestingly, there does not appear to be an increased rate of celiac disease in patients with autism, nor has any consistent increase in opioids been observed in the urine of children with autism.^{62,63} The most recent systematic review of studies including children with autism using the GFCF diet published between 1970 and 2013 concluded that there was no convincing evidence of benefit.⁶⁴ Although previous studies have reported mixed results, there is consensus that the potential risks related to maintaining a GFCF diet include low intake of calcium, vitamin D, and amino acids in addition to decreased bone density.⁶⁴ There were additional concerns regarding rice milk, almond milk, and potato milk as poor sources of protein. Previous studies have also reported high dropout rates and a significant proportion of participants being unable to maintain the diet, highlighting the difficulty in adhering to such a strict diet in children who already have restrictive dietary behaviors. At the population level, the GFCF diet may not have a beneficial effect; however, the majority of previously reported studies were not adequately powered to detect significant benefit effects on gastrointestinal disease between subgroups of children. If parents do wish to try their child or family on the GFCF diet, we suggest the following: consultation with a dietician to limit the risks of decreased protein and calcium intake; listing of current dietary and behavioral problems they wish to monitor; and setting a clear start and stop date, usually 60–90 days, to help verify any observed changes.

Exercise

Exercise has been found to be beneficial for several psychiatric and developmental disorders.⁶⁵ The mechanisms underlying the beneficial effects of exercise in reducing hyperactive and repetitive behaviors by children with autism may be through stimulation of the release of

neurotransmitters such as acetylcholine and beta-endorphins.⁶⁶ In a systematic review published in 2010, the vast majority of previously reported studies of antecedent aerobic exercise (6–20 minutes) found a decrease in self-stimulatory behaviors and an improvement in academic performance.⁶⁷ Although a proportion of these studies had significant limitations, exercise is cheap, safe, and easy to adhere to for children, with benefits that include improved sport skills, improved physical fitness, and increased control of obesity. Aerobic activities that may be performed in groups but do not require strict rules, such as running, swimming, and treadmill or biking exercise, are generally recommended.

Pharmaceuticals

It must be stressed that there are currently no medications known to treat the core symptoms of autism. Children with autism generally have other common medical problems, such as sleep disorders, constipation, and food limitations, which may be treated with conventional or, in some cases, complementary therapies. However, pharmaceutical treatments based on previous studies should be considered as adjuncts to robust behavioral or counseling programs in patients with emotional and behavioral disturbances that commonly co-occur with autism, such as anxiety, ADHD, compulsions and repetitive behaviors, depression, irritability, and aggression.

Stimulants

When using an inclusive definition of all types of ADHD (inattention, hyperactivity, and combined), ADHD may be apparent in up to one-half of patients with autism.⁶⁸ Occasionally, children are diagnosed and treated for ADHD before a diagnosis of autism is made.⁶⁹ Some studies have even suggested that ADHD may be part of a continuum with autism.⁷⁰ Regardless, it is important to understand that the very few randomized, double-blind, placebo-controlled studies that have been published limits the evidence supporting the treatment of inattentiveness and hyperactivity with stimulants (methylphenidate and amphetamines).⁷¹ Anecdotally, children with autism tend to be more sensitive to stimulants and may have an increased incidence of common adverse effects, such as increased irritability, heightened emotionality, decreased appetite, and insomnia.^{1,71} As a result of these side effects, the

mantra for most pharmaceutical medications, particularly in autism, is “start low, and go slow.”^{1,58} Therefore, a half tablet of a 5 mg short-acting methylphenidate is typically trialed initially. When using amphetamine, which tends to be twice as potent as methylphenidate, one should consider a half tablet of a 2.5 mg amphetamine drug. If the stimulant does not prove helpful or has side effects that make continuing the stimulant difficult (tics or hyperemotionality), an alpha agonist, such as guanfacine or clonidine, should be used either alone or as an adjunctive therapy; however, there have been very few clinical trials to validate the efficacy of this treatment approach.⁷² Once no side effects are noted with a short-acting alpha agonist, the use of a long-acting guanfacine (such as Intuniv) at 1 to 2 mg daily is recommended.

When considering a nonstimulant medication for inattentiveness and hyperactivity, recent studies have demonstrated the efficacy of the norepinephrine reuptake inhibitors Atomoxetine or Strattera in decreasing hyperactivity and stereotypic behaviors.^{73,74} These medication are titrated at an initial dose of 0.4 mg/kg for several days and can be increased to approximately 1.2 mg/kg daily as a single dose. The norepinephrine reuptake inhibitors appear to have significantly less side effects than stimulants. The benefits of norepinephrine reuptake inhibitors may take six to eight weeks to be fully realized, and this should be explained to the parent and child.

Antipsychotics

The antipsychotics risperidone and aripiprazole are the only medicines with FDA approval for use in autism for irritability and explosive behaviors.⁷⁵ Risperidone continues to be used as the first-line medication and its use has significantly increased over the last several years in children with autism.⁷⁶ Common side effects with risperidone include rapid weight gain precipitated by a voracious appetite, drowsiness, and hypertriglyceridemia with early signs of diabetes.^{75,76} In addition, patients should be monitored for extrapyramidal symptoms (EPS), including tremors, dyskinesia, and rigidity. Liquid preparations (1 mg/mL) should be used with caution as parents have been known to accidentally overdose children via decimal point confusion (5.0 mL versus 0.5 mL).⁷⁷

Aripiprazole may also be used for managing severe irritability and aggression in ASD. Aripiprazole has a similar side effect profile to risperidone (increased appetite, weight gain, drowsiness, and EPS)

despite initially being marketed as causing fewer side effects.⁷⁶ Aripiprazole, as with other antipsychotics, requires blood monitoring for neutropenia, electrocardiography if prolonged QT syndrome is suspected, and monitoring for suicidal ideation.⁷⁸ Generally, liquid aripiprazole (1 mg/mL) is initially administered at 1 mL two times a day and increased by 1–2 mL per week to a total of 5 mL or 5 mg two times per day.

Serotonin Reuptake Inhibitors and Selective Serotonin Reuptake Inhibitors

SRI and SSRI may be used to treat anxiety, phobias, and compulsions in children, adolescents, and adults with autism; however, the results of previous studies of the efficacy of these treatment have been mixed.⁷⁹ Citalopram, escitalopram, and fluoxetine have been the most commonly studied drugs in randomized controlled trials.⁸⁰ Fluoxetine is preferred in children and adolescent groups using a liquid preparation (4 mg/mL) for titration, because low doses tend to be tolerated better for anxiety and compulsions than the higher doses used for depression.⁸¹ Fluoxetine administration should be initiated at 1 mL/4 mg/week and titrated up by 1 mL/4 mg/week until effect or to 5 mL/20 mg because doses above 20 mg are associated with increased side effects.⁸² The main side effects of SRI and SSRIs are agitation, increased energy, and poor sleep.⁸² Overall, the side effect profile and limited efficacy in children have led the Cochrane Database report to support only very limited use of these medications in children with autism.⁸⁰

Newer Pharmacological Agents

Many pilot or trial studies of nonconventional pharmacological agents have recently been reported in children with autism aimed at manipulating specific receptor-associated channels and neurotransmitters in the brain related or sensitive to glutamate, glutamine, glycine, Gamma-amino-butyric acid (GABA), N-methyl D-aspartic acid (NMDA), nicotinic, or opioids. There is hope that these pharmacological agents may target the core symptoms of autism, with N-acetylcysteine (NAC), memantine, D-cycloserine, naltrexone, and oxytocin demonstrating utility in improving comorbid symptoms or as potential subgroup treatments for core symptoms. All of these therapies

are currently in the research phase and require validation by further clinical trials before their use in children with ASD is fully endorsed.

NAC is a glutamate modulator administered orally at 900 mg 1–3 times a day. NAC has demonstrated benefit in decreasing irritability either alone or in conjunction with risperidone.⁸³⁻⁸⁵

Memantine was originally developed to treat Alzheimer's disease. A connection between Alzheimer's and autism was hypothesized several years ago following results from Fragile X studies.⁸⁶ Memantine modulates glutamate neurotransmission and is administered at 10–20 mg doses daily. In a systematic review, memantine therapy was associated with improvements in the core symptoms of autism in eight of nine studies, including one double-blind, placebo-controlled study.⁸⁷

D-Cycloserine acts on the NMDA receptor, which is thought to have effects on improving sociability.⁸⁸ Two recent studies have been done by the same authors, using a randomized, double-blind trial and assessing dosage of 50 mg of D-cycloserine daily versus weekly, which show improvements in both the Social Responsiveness Scale and the Aberrant Behavior Checklist.^{89,90}

Naltrexone, an opioid antagonist, has been trialed in children with autism in several studies to determine its utility in treating the core symptoms of autism. A recent systematic review of previous literature concluded that naltrexone provided some improvement in hyperactivity and restlessness but had no discernible effect on the core symptoms of autism.⁹¹ Reported dosages were between 0.5 mg/kg and 2.0 mg/kg, with an onset of action of 30 minutes and peak effect at 6–12 hours. The most common side effect of naltrexone therapy was weight loss.⁹¹

Oxytocin is a naturally occurring peptide in the brain that increases socialization and promotes parental nurturing and social bonds. It has been developed into an intranasal medicine and trialed in autism in the hope that it will improve social cognition and reciprocity.⁹² Currently, there are numerous studies underway ([ClinicalTrials.gov](https://www.clinicaltrials.gov)); however, early results are mixed with some studies reporting modest improvements in social engagements and others reporting nonmeasurable affects.⁹³ The dosage of intranasal oxytocin is 0.4 IU/kg/dose and appears to be safe in short trials.^{92,93}

Older Unproven or Disproven Pharmacological Treatments and Agents

The use of antifungal medications (fluconazole or nystatin) and/or antibiotics as a treatment for autism remains popular and based on the unproven hypothesis that there is an overgrowth of yeast and/or intestinal microbes in the gastrointestinal systems of children with autism. There is currently no evidence to support the efficacy or safety of any antifungal agents or bacterial treatments, and there have been no studies of the effectiveness of antiviral therapies.⁹⁴ A trial of the use of minocycline to modulate neurotrophic growth factors demonstrated no effect on the clinical symptoms of regressive autism.⁹⁵

Chelation

Chelation is a process of administering a medication to remove heavy metals from the blood. The most commonly used medications are ethylene diamine tetra-acetic acid (EDTA), 2,3-dimercaptosuccinic acid (DMSA), and 2,3-dimercaptopropane-1-sulfonate (DMPS). Chelation has been used in children with autism based on the theory that ASD is caused by heavy metal poisoning, specifically with mercury. Mercury and other heavy metals are thought to accumulate due to increased exposure or an inability to clear toxins due to metabolic dysfunction, or a combination of both. Chelation is occasionally referred to under the larger umbrella of detoxification, where patients initially have their gastrointestinal tract prepared by removing dysbiotic flora and the addition of essential nutrients before the initiation of a course of chelation. This theory also relies on monitoring urine after chelation to determine treatment response. This process was utilized in two related studies published involving 65 children with autism and chelation that reported treatment responses in 49 children with elevated urinary excretion of heavy metals.^{96,97} These 49 children were randomly assigned to receive 6 more rounds of DMSA or placebo treatment. Although a small but significant difference in language, cognition, and sociability was reported by this study, the side effect profile of the chelating agents was considered to be unacceptably high and is likely to prevent further studies due to substantial renal and hepatic toxicity and a reported death due to hypocalcemia.^{98,99}

Although slight improvements in autism symptoms have been reported with chelation therapy, the side effects, including hepatotoxicity and one reported death, outweigh any minimal

potential benefits.

Secretin

Secretin is a gastrointestinal hormone that inhibits intestinal motility and the release of gastric acid, and stimulates the secretion of pancreatic fluid. There are anecdotal reports that secretin has benefit in children with autism and gastrointestinal problems. These reports culminated in a special feature on *60 Minutes*, a CBS news program, where a small study of injectable secretin was followed and debunked on an episode aired on February 20, 1994, and recounted in Paul Offit's novel.¹⁰⁰ Since that time, more than 900 children with autism have been evaluated in double-blind, placebo-controlled trials, with no behavioral benefit of secretin observed.⁹⁴

Immunotherapy

Immunotherapy for children with autism is based on the hypothesis that early fetal brain development is sensitive to the prenatal immune response.¹⁰¹ Although this hypothesis concerning an epigenetic immune phenomenon has been supported by recent studies of biological markers,^{102,103} the successful development of therapeutic treatments with intravenous immunoglobulin (IVIG) or oral immunoglobulin is not currently supported by published data.^{104,105}

There does not appear to be any ongoing clinical trials or any FDA-approved clinical use of an immunomodulatory treatment for autism. The potential adverse effects of IVIG and other immune therapies include transmission of blood-borne pathogens and transfusion reactions.

Supplements

Folic Acid

Folic acid may be considered in patients with autism for several reasons. There were initial concerns that children and mothers with methylenetetrahydrofolate reductase (MTHFR) deficiency were at risk of autism or having a child with autism¹⁰⁶ (see [Chapter 38](#)). Open trials of folic acid and B12 supplementation in children with autism have reported improvements in language both expressive and receptive.¹⁰⁷ In

recent studies, the risk of women near conception having a child with autism was significantly reduced by supplementation with folic acid at levels above the recommended requirements (600–800 mcg rather than 400 mcg).¹⁸

Methyl B12 Injections

Methyl B12 is a vital cofactor for the regeneration of methionine from homocysteine by providing methyl groups for the transmethylation and transsulfuration metabolic pathways. Methyl B12 deficiency causes reduced synthesis of transsulfuration pathway products, specifically glutathione and cysteine, which are important antioxidants responsible for controlling macromolecular damage produced by oxidative stress.¹⁰⁸ However, there is currently only one reported double-blind, placebo-controlled, randomized crossover trial using subcutaneous injection of methyl B12 at 65–75 mcg/kg every 2–3 days.¹⁰⁹ The results were mixed with no statistical significance observed in behaviors between the two groups, but a subgroup of approximately a third of all patients had some improvements in language and social interaction. Although injections were well tolerated in this study, methyl B12 injections do not appear to be a viable option for many families of children with autism due to the frequency of visits required and as yet unproven benefits.

Amino Acid Therapy

Glutamine, taurine, and carnosine are all amino acids that have been hypothesized to have a neuroprotective effect in children with autism. It is thought that the metabolism of these amino acids, as well as many others, is impaired in children with autism and supplementations may have a positive neurological effect. Previous studies of amino acid therapy have proven inconclusive, with no current therapy presently having sufficient evidence to be recommended.

Dimethylglycine and Trimethylglycine

Dimethylglycine (DMG) and trimethylglycine (TMG) are both derivatives of the amino acid glycine and have been posited to reduce lactic acid, enhance oxygen use, and reduce seizure activity during times of stress.¹¹⁰ The use of DMG and TMG is based on the theory that metabolic derangements contribute to the development of autism. There

has been very little research on the use of DMG and TMG, with only 2 studies reporting essentially no benefits of the use of DMG in patients with autism.^{110,111}

Vitamin B6 and Magnesium

Vitamin B6 (Pyridoxine) and magnesium represent some of the oldest therapies used for children with mental health disorders and have subsequently been trialed for children with autism.¹¹² A systematic review of more than 25 studies reported the evidence for treatment with B6 and magnesium to be inconclusive and equivocal.¹¹² The main concern with vitamin B6 and magnesium therapy is that high dose of vitamin B6 (>100 mg/day) may cause neuropathy and magnesium may cause diarrhea.

Melatonin

Melatonin is a hormone produced by the pineal gland in response to decreasing levels of light and is involved in the regulation of sleep by inducing drowsiness. Melatonin is synthesized from serotonin, and abnormalities in these pathways have been reported in children with autism.¹¹³ Sleep problems have been reported in children with autism 50%–80% of the time.¹¹⁴ Several studies have demonstrated abnormally low levels of melatonin in children with autism and other developmental disabilities.¹¹⁵ Therapy with melatonin at doses ranging from 1–10 mg at bedtime have been shown to improve the overall amount of sleep and shorten sleep latency in the majority of studies involving children with autism.^{116,117} Melatonin is available in many different preparations and dosages. The 3-mg pills are preferred because this dose tends to work well as an initial dose and allows easy titration to 6 and 9 mg. For children with autism that are unable to swallow pills, melatonin is available in a 1 mg/mL solution, which can be initiated at doses of 1 mL to 3 mL at one to two hours before bedtime.

Omega-3 Fatty Acids

Omega-3 fatty acids (FA) are essential for brain function and development. Omega-3 FA are nutrients that primarily function at the cell membrane and aid in synaptic plasticity and neuroprotection.¹¹⁸ The two omega-3 FA of primary interest for the treatment of autism are

eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Low levels of omega-3 FA have been reported in children with autism.¹¹⁹ The use of omega-3 FA in children with autism has become ubiquitous in primary care practices despite surprisingly little evidence regarding their efficacy in the treatment of the core symptoms of ASD.⁹⁴ However, that practitioners may be using omega-3 FA to treat comorbidities, such as ADHD and depression, where omega-3 FA have also been posited to have utility despite a current lack of evidence.^{120,121} The initial dose of omega-3 FA is typically approximately 600 mg (equal amounts of DHA and EPA) daily as a trial dose for treatment before titration up to 2 g. Doses can be reduced in patients that develop diarrhea while receiving higher doses.

Multivitamins and Minerals

Studies of multivitamin and mineral supplementation, along with specific vitamin and mineral therapies, have reported mixed results.⁹⁴ Previous multivitamin and mineral studies have had significant methodological flaws that have made the interpretation of their results difficult. Previous literature supports supplementation with vitamins A, C, and D3 for the prevention of nutritional deficiencies, such as scurvy and rickets, that may occur in children with autism due to restricted diets or stressed maternal environments.^{122,123} Several important metal minerals have also been linked to the expression of autism, including iron, zinc, and copper.^{124,125} These metals are critical in synaptic transmission and deficiencies in these metals may have significant cognitive, behavioral, and neurodegenerative consequences.^{126,127} The strongest research to date indicate both low maternal iron stores and low infant or child stores of iron are potential risk factors for the development of autism. Further, there is good evidence to indicate that deficiencies in either prenatal mothers or infants and children should be treated with iron supplementation.^{128,129}

The most important mineral deficiency to screen for and treat in individuals with autism is iron.

Botanicals and Herbal

There is a lack of studies of botanicals and herbal remedies for the treatment of children with ASD.

Mind-Body Medicine

Biofeedback and Neurofeedback

Biofeedback and neurofeedback therapies were initially considered as a treatment for autism because it was noted that children with autism had abnormal electroencephalogram (EEG) patterns compared to controls.¹³⁰⁻¹³² Teaching participants with ASD to regulate these patterns reportedly improves social interactions, verbal and nonverbal communication skills, and executive function.¹³³⁻¹³⁵ The underlying mechanism remains unknown; however, current research is focusing on mechanisms responsible for a proportion of children with autism responding better than others and the utility of this method in improving cognitive flexibility.¹³⁶

Music Therapy

Music therapy for children with ASD refers to musical experiences and the relationships that develop through music that enable communication and expression and help to improve the core symptoms of autism such as joint attention, communication, expression, and engagement.¹³⁷ Music therapies involve structured and unstructured individual and group sessions with and without a leader that include playing and/or listening to music. A recent Cochrane database review concluded that music therapy has benefits for children with autism in the areas of social interaction, verbal communication, initiating behaviors, and social-emotional reciprocity.¹³⁸ Additional studies with larger sample sizes and longitudinal followup are required to determine if the effects of music therapy are reproducible and enduring.

Yoga

Yoga involves breathing, positioning, and relaxation exercises that can easily be taught to children with autism. Unfortunately, very few studies evaluating the utility of yoga as a therapy for autism have been reported. In one study, yoga was combined with dance and was found to result in

significant changes in the behavioral and cognitive areas of the Behavioral Assessment System for Children (BASC).¹³⁹ A separate study of a 16-week program in school reported significant improvements in maladaptive behaviors of children with autism compared to controls.¹⁴⁰

Body-Based Practices, Energy Medicine

Acupuncture

Acupuncture involves the systemic insertion of needles or pressure to specific points on the body and is widely used in traditional Chinese medicine. Previous studies have reported that acupuncture increases levels of beta-endorphins, serotonin, and noradrenaline, which may reduce the symptoms of depression or anxiety.¹⁴¹ The majority of studies of acupuncture in children with autism has been performed in China and are thus difficult to review. A systematic review published in 2011 by Lee et al. concluded that acupuncture is safe but with conflicting results across the 11 studies they were able to review.¹⁴² A more recent review by Yang et al. evaluating all uses of acupuncture in children found unclear benefits of acupuncture in children with autism.¹⁴³

Auditory Integrative Training

Auditory integration training was developed as a technique for improving abnormal sound sensitivity in children and individuals with behavioral disorders, specifically ASD. Sound therapies that use these principals include the Tomatis Method and Samonas Therapy. Studies of this therapy with controls, such as waiting lists, usual therapy, and sham placebo, found no benefits and no evidence to support the use of auditory integrative training in children with autism.¹⁴⁴ Accordingly, auditory integration training and sound therapies are not currently recommended or supported by research literature.

Transcranial Magnetic Stimulation

Transcranial magnetic stimulation (TMS) or neuromodulation is an energy-based therapy that has been posited to work through electromagnetic induction, thereby modifying neuroexcitability. TMS uses noninvasive focal cortical stimulation, involving small, variable intracranial electrical currents generated by a rapidly fluctuating extracranial magnetic field.¹⁴⁵ This is a new field of research in autism

with very few randomized control trials reported; however, preliminary work is intriguing. The use of low frequency TMS has been shown to include improvements in EEG indices that correspond to attention and information processing, and improvements in repetitive behaviors.¹⁴⁶ In addition, the use of high frequency stimulation has been shown to improve self-reported social relating and social anxiety.¹⁴⁷

Hippotherapy

Hippotherapy (therapeutic horseback riding) for children with ASD is based upon the hypothesis that riding a horse stimulates multiple areas of functioning for children, including cognitive, social, and gross motor functioning.¹⁴⁸ Several very small and nonrandomized trials have reported improvements in parent-reported emotional and social functioning, improvements in adaptive behaviors, and dose-response benefits.¹⁴⁹⁻¹⁵¹ Despite the potential benefits, the cost and risk of injury associated with hippotherapy should be considered before recommending this therapy. The use of a helmet and appropriately trained supervision should also be strongly advised.

Massage and Qigong

Qigong is a Chinese movement therapy that, along with massage therapy alone, has gained increasing popularity with the recognition and addition of sensory abnormalities to the diagnostic criteria of ASD in the DSM-5. Abnormalities in tactile sensation may delay early self-regulation milestones and social development in young children with ASD. Parents are best positioned to promote more tactile stimulation through therapeutic massage protocols that may improve developmental outcomes.¹⁵² Several small studies have reported the benefits of qigong in improving parental perceptions and decreasing parental stress, with children benefiting from decreases in tactile impairment and improved self-regulation.¹⁵² Qigong represents an extremely low risk therapy with potential benefits.

Other

Hyperbaric Oxygen Therapy

Hyperbaric oxygen therapy (HBOT) has been posited to enhance oxygen delivery to potentially damaged areas of the brain, reduce swelling, and

promote brain recovery in children with autism.¹⁵³ A multicenter, randomized control trial published in 2009 including 62 children with autism between the ages of 2 and 7 years reported potential benefits with the use of low pressure and low oxygen levels.¹⁵⁴ The results of this study included improvements in overall function, receptive language, social interaction, eye contact, and sensory/cognitive awareness.¹⁵⁴ Unfortunately, this study was limited by a short follow up and a period of strong placebo effect. The results of this study have never been reproduced but retain strong support in the autism community.¹⁵⁵ The reported side effects of HBOT include ear barotrauma, reversible myopia, pulmonary barotrauma, pulmonary oxygen toxicity, and seizures.^{156,157} However, these side effects are typically seen at higher atmospheric pressures rather than the lower pressures used in the previous studies. Overall, the number of dives required for HBOT (40 dives in total) and high cost (\$100–\$200/dive) may make this therapy prohibitive for many families. Accordingly, it may be difficult to recommend such an expensive and unproven therapy in most cases of autism.

Therapies to Consider

There is a lack of studies on healing touch therapy, reiki, and prayer, as well as evidence to support their use in children with autism; however, all are safe and seem reasonable to recommend.

There is also a lack of studies on the potential efficacy of craniosacral manipulation/therapy, chiropractic, and homeopathy in children with autism; however, such therapies may compete with other validated therapies for limited time and resources and may therefore be difficult to support.

Prevention Prescription

No definitive strategies exist for the prevention of autism. The results of recent epigenetic studies suggest the following:

- Women of childbearing age should receive folic acid supplementation at > 400 mcg to 600 mcg–800 mcg daily and iron supplements to maintain normal hemoglobin and ferritin levels.
- Births should be spaced by at least 2 years if possible, and mothers should be encouraged to have children before the age of 35.

- Avoid pesticide exposure where possible.
- Supplementation of the child's daily intake with a multivitamin is advisable; however, mega-doses of any individual vitamin or mineral may confer little to no benefit.
- The avoidance of immunizations will put the child and other children who cannot be immunized at risk of vaccine-preventable diseases.
- Prevent exposure of pregnant women and infants to any toxic household cleaning products or insecticides.

Therapeutic Review

Nutrition

A 60-day trial of a gluten-free/casein-free diet (GF/CF; strongly consider consultation with a nutritionist or dietician). 

Exercise

Aerobic exercise, 20 minutes daily. 

Supplements

- Folic acid (>400 mcg daily) in children and preconception females. 
- Probiotics containing lactobacilli, bacteroidetes, and saccharomyces (1–10 billion cells daily). 
- Omega 3 fatty acids (EPA + DHA; 500–2000 mg). 
- Iron (3–6 mg/kg daily if deficient and 1–3 mg/kg for supplementation) in children and preconception females. 
- Melatonin (1–9 mg taken one or two hours before bedtime). 

Mind-Body

- Intensive behavioral therapy (ABA, TEACCH, DIR/Floortime, see [web resources](#) for more information). 
- Music therapy. 

Pharmaceuticals

- Oxytocin (0.4 IU/kg/dose) 1–2 doses daily. 
- Memantine (10–20 mg daily). 
- Methyl B12 injections (65–75 mcg/kg every 2–3 days). 

Others

- Qigong/massage. 
- Transcranial magnetic stimulation (TMS). 
- Hippotherapy (horseback riding). 
- Hyperbaric oxygen therapy (HBOT). 

Key Web Resources

Research Autism has updated data on recent research studies of many of the complementary and alternative therapies discussed in a searchable database.	http://www.researchautism.net/interactions
Much of the genetic and environmental research is being performed through the MIND (Medical Investigation of Neurodevelopmental Disorders) Institute at the University of California, Davis.	http://www.ucdavis.edu/mindinstitute/
Autism Science Foundation has evidence-based information.	http://www.autism-science.org/
Interactive Autism Network (IAN) is headed from the Kennedy Krieger Institute and offers families a register for research.	http://www.IANresearch.org/
Intensive Behavioral Therapy Resources Applied Behavioral Analysis	http://www.centerforautism.com/iba-therapy.aspx
TEACCH stands for Treatment and Education of students and related Communication Handicapped Children.	http://teacch.com/about-teacch-in-4000/
DIR/Floortime, DIR stands for Developmental, Individual-Differences, Relationship-Based and uses a developmental intervention approach integrating psychodynamic and cognitive learning principles.	http://www.intentionalrelationships.com/section/teaching-floortime

CHAPTER 9

Insomnia

Rubin Naiman, PhD

Insomnia is prevalent, associated with a broad range of illnesses, and presents a significant medical, social, and economic burden. Largely undiagnosed and untreated despite the existence of effective interventions, insomnia has been described as “unremitting, disabling, costly, pervasive, and pernicious.”¹ Because it is strongly linked to lifestyle and mind-body dynamics and is resistant to conventional medical treatment, insomnia deserves much greater consideration from integrative medicine researchers and practitioners. In fact, a National Health Interview Survey reported that 1.6 million adults already use complementary and alternative medicine (CAM) to treat insomnia.²

The National Institutes of Health reports that 60 million adults in the United States struggle with insomnia annually.³ Depending on definition, the prevalence of insomnia among adults ranges from 10% to 30% and increases with age and in female gender, as well as with a broad range of medical and psychiatric comorbidities.⁴

Patients with insomnia are at increased risk for comorbid medical disorders, including chronic pain, cardiovascular disease, cancer, neurological and gastrointestinal disorders,^{5,6} obesity,⁷ and diabetes.⁸⁻¹⁰ Sleep loss has been associated with insulin dysregulation,^{9,10} disruptions of cortisol rhythms,^{11,12} and immune function and inflammatory markers.¹³⁻¹⁶

Psychiatric illness, especially depression or anxiety,¹⁷ is the most common comorbidity linked to insomnia.^{18,19} Approximately 40% of adults with insomnia have a psychiatric illness, most commonly depression.^{18,19} Persistent insomnia significantly increases the risk of clinical depression, anxiety disorders, and substance abuse.^{20,21} The traditional presumption that insomnia is secondary to psychiatric illness has been challenged by several findings that suggest insomnia more

often precedes, and is likely a significant risk factor for, mood disorders.²²⁻²⁵

Although psychiatric illness,¹⁸ medical disorders,²⁶ and shift work²⁷ significantly increase the risk for insomnia, they are not causal but precipitating factors in patients already predisposed to the disorder.²⁸ Primary sleep and circadian rhythm disorders, such as restless legs syndrome,²⁹ periodic limb movement disorders, delayed sleep phase, and sleep-related breathing disorders, are also frequently associated with insomnia.³⁰

Insomnia is associated with significant impairment in quality of life,³¹⁻³³ increased risk of accidents,³⁴ and decrements in work productivity.³⁵ The economic burden of insomnia in the United States has been estimated to be as high as \$63.2 billion annually.³⁶

Although conventional sleep medicine has clearly made advances in understanding and evaluating sleep and sleep disorders, one can argue that it lags in terms of developing effective treatment and prevention strategies for insomnia. Despite their serious limitations, hypnotic agents remain the primary focus of conventional insomnia treatment. Advances in cognitive-behavioral therapy for insomnia (CBT-I) challenge the conventional emphasis on medication and are associated with a chasm between conventional and behavioral sleep medicine. Among the most significant limitations of conventional approaches to insomnia is a widespread tendency to “treat the chart” that offers remarkably limited regard for subjective experiences of the patient.

An integrative medicine approach to understanding and managing insomnia (1) restores the place of subjectivity, as is evident in CBT-I; (2) emphasizes the promotion of sleep health, as opposed to symptom suppression; (3) acknowledges the important social and relational context of sleep; (4) underscores the critical role of natural rhythms in life and health; and (5) strongly emphasizes the role of lifestyle. An integrative approach to insomnia also calls for personalization of treatment based on a thorough evaluation.

Definitions

Insomnia disorder refers to difficulties with initiating or maintaining sleep, as well as nonrestorative sleep that is associated with excessive sleepiness or fatigue and with functional decrements for at least 4 weeks. Primary insomnia is not attributable to medical or psychiatric causes,

whereas secondary insomnia has historically been viewed as a symptom of a primary disorder that would resolve with treatment.²⁸ A National Institutes of Health (NIH) State of the Science Conference⁵ recommended that secondary insomnia be considered *comorbid insomnia* to encourage its direct treatment. Insomnia is frequently comorbid with other conditions, most commonly primary sleep disorders ([Box 9.1](#)), chronic pain syndromes, and psychiatric disorders, especially depression and substance abuse.

Etiology

The etiology of insomnia is commonly understood in terms of a “Three P” model,^{37,38} including predisposing, precipitating, and perpetuating factors. Predisposing factors comprise a broad range of biomedical, psychological, and lifestyle factors that increase the risk of developing insomnia. These include (1) dependence on substances such as alcohol, caffeine, nicotine, and other drugs; (2) the long-term use of stimulant, sedating, or circadian rhythm–disrupting medications; (3) illnesses associated with nocturnal pain or discomfort; (4) primary sleep disorders, such as restless legs syndrome, periodic limb movements in sleep, gastroesophageal reflux disease, and obstructive sleep apnea; and (5) circadian rhythm disorders associated with shift work, jet lag, and advanced or delayed sleep-phase syndromes.

BOX 9.1 Comorbid Primary Sleep Disorders

- Restless legs syndrome (RLS)
- Periodic limb movements in sleep (PLMS)
- Gastroesophageal reflux disease (GERD)
- Sleep-phase disorders
- Narcolepsy
- Obstructive sleep apnea (OSA)
- Nocturia

Precipitating factors in insomnia commonly include stress associated with family, occupation, or health challenges. These factors are usually negative challenges, such as divorce, death of a loved one, or illness, but they can also involve stress associated with positive events, such as the birth of a child or retirement.^{37,38}

Perpetuating factors in insomnia refer to behaviors intended to manage or compensate for sleeplessness that inadvertently exacerbate the condition. Examples include (1) excessive waking time spent in bed; (2) an irregular sleep–wake schedule including napping and dozing; (3) excessive use of caffeine, alcohol, and other drugs; and (4) anxiety associated with attempts at controlling sleep, as well as the daytime consequences of sleeplessness. Dependence, habituation, and rebound effects associated with sedative-hypnotics can also perpetuate insomnia.

The common practice of spending excessive time in bed to compensate for lost sleep results in conditioned insomnia, a negative association of the bed with wakefulness that significantly perpetuates the problem.

Conditioned insomnia is measured in terms of *sleep efficiency*, the ratio of total time spent asleep to the amount of time spent in bed. A sleep efficiency below 85% is considered problematic.^{37,38}

Additional biomedical factors that can predispose to, precipitate, or perpetuate insomnia include iatrogenic influences of extended hospitalizations, as well as a broad range of medications that interfere with sleep, such as analgesics, benzodiazepines, antidepressants, and anticholinergic medications. Beta blockers, calcium channel blockers, diuretics, and other medications may also suppress melatonin (MT) and interfere with sleep. [Box 9.2](#) provides a more extensive listing of medications that can interfere with sleep.

Exposure to ordinary room light before bedtime suppresses MT onset and duration in humans,³⁹ potentially disrupting sleep and circadian rhythms. Other environmental factors, including sound, temperature, and air and bedding quality, can also predispose one to precipitate or perpetuate insomnia, although these factors have not received the attention they warrant.

BOX 9.2 Medications That Can Interfere With Deep or Rapid Eye Movement Sleep

- Alcohol
- Antiarrhythmics
- Anticonvulsants
- Antihistamines

- Appetite suppressants
- Benzodiazepines
- Bronchodilators
- Caffeine
- Carbidopa/levodopa
- Corticosteroids
- Diuretics
- Decongestants
- Estrogen
- Lipophilic beta blockers
- Monoamine oxidase inhibitors
- Nicotine
- Pseudoephedrine
- Selective serotonin reuptake inhibitors
- Sedatives
- Statins
- Sympathomimetics
- Tetrahydrozoline
- Thyroid hormones
- Tricyclic antidepressants

Pathophysiology

The most compelling pathophysiological model for insomnia suggests a strong association with chronic cognitive-emotional hyperarousal, which may be a premorbid characteristic of the disorder.⁴⁰⁻⁴² Compared with controls, patients with insomnia have elevated heart rates,^{43,44} increased body and brain metabolic rates,^{45,46} elevated core body temperature,⁴⁷ increased beta and gamma electroencephalography, and neuroendocrine dysregulation including elevated nighttime cortisol and decreased serum MT.⁴⁸⁻⁵¹ Insomnia has also been linked to nocturnal sympathetic activation and overactivation of the hypothalamic-pituitary-adrenal axis.^{52,53}

Chronic cognitive-emotional hyperarousal associated with elevated metabolic rate, sympathetic overactivation, and chronic inflammation

is a common substrate of insomnia.

Insomnia appears to be bidirectionally associated with chronic inflammation. A single night of sleep deprivation in human subjects can alter cellular immune responses⁵⁴ and increase levels of inflammatory markers.⁵⁵⁻⁵⁸ Inflammatory conditions have been shown to disrupt sleep by increasing pain, anxiety, and depression.^{59,60} Chronic inflammation is fundamentally a process of immune system overactivation, which can be understood as yet another expression of hyperarousal.

Sleepiness and sleep propensity appear to be strongly influenced by circadian core body temperature rhythms. Specific types of insomnia have been linked to specific patterns of disrupted temperature rhythms. Sleep onset difficulties have been associated with a delayed circadian temperature rhythm, early morning awakenings with an advanced circadian temperature rhythm, sleep maintenance insomnia with a nocturnally elevated core body temperature, and mixed insomnia with a 24-hour elevation of core body temperature, consistent with the hyperarousal model.⁶¹

Hyperarousal can be further elucidated by the widely accepted dual-process model of sleep regulation,⁶² which views sleep in terms of a dynamic interaction between homeostatic and circadian processes. As the homeostatic sleep drive gradually increases through the waking day, the circadian pacemaker exerts an equal but opposite force to maintain alertness. The potential for sleep normally occurs with the nightly, rhythmic release of circadian alertness.

As a consequence of their 24-hour hyperarousal, insomnia patients are generally less sleepy during the day than normal sleepers. However, they may be significantly more fatigued (a construct independent of sleepiness)^{63,64}—a condition strongly associated with major depression.⁶⁵ Theoretically, fatigue, which draws one toward rest, and hyperarousal, which encourages activity, can result in a state of chronic isometric tension that characterizes the insomnia–depression complex. Suspended in a limbic zone between fatigue and hyperarousal, neither a healthy descent into sleep nor a passionate ascension into waking are possible.⁶⁶

Modern lifestyles are associated with the widespread suppression of rapid eye movement (REM) sleep and dreaming. Excessive alcohol consumption, most sleep medications, and many psychiatric medications suppress REM sleep. Sleep maintenance insomnia, early morning awakenings (including those caused by an alarm clock), obstructive sleep apnea, and short sleeping can further limit REM sleep and dreaming.⁶⁷

Human and animal studies confirm that the selective deprivation of REM sleep results in its rebound in the form of a reduced REM latency and disrupted deep sleep. This same pattern characterizes the sleep of depressed patients.⁶⁸ The classic psychodynamic notion that depression is “a loss of one’s dreams” appears to have a literal underpinning.

Hyperarousal may be understood as circadian alertness (wakefulness) that has gone awry and overrides both normal sleep drive and the excessive daytime sleepiness one would expect with chronic insomnia.

Evaluating Insomnia

The scope of an insomnia evaluation should be comprehensive, including any and all biomedical, psychological, and environmental factors potentially affecting sleep. [Box 9.3](#) provides a list of essential clinical interview and history topics.

Subjective measures, including the clinical interview and history, are the most critical components of the evaluation of insomnia.

BOX 9.3 Clinical Interview and History

1. The presenting complaint
2. The sleep–wake routine
3. Daytime functioning and symptoms
4. Sleep conditions and routines
5. Previous treatment effects
6. Other sleep disorder symptoms
7. Comorbid medical conditions
8. Psychiatric conditions and stressors
9. Medication and substance use
10. Relevant family history

Adapted from Mai E, Buysse DJ. Insomnia: prevalence, impact, pathogenesis, differential diagnosis, and evaluation. *Sleep Med Clin.* 2008;3:167-174.

The adage that as important as knowing which disease the patient has is knowing which patient has the disease is most pertinent here. It is

critical to elicit each patient's personal sleep *and dream* story. Evidence from a study of bad dreams and nightmares suggests that patients may respond to these dreams with sleep avoidant behaviors.⁶⁸ Eliciting the patient's basic posture toward sleep and dreams is a critical component of the insomnia evaluation. In addition to providing essential diagnostic information, doing so can engage the patient more deeply, strengthen the therapeutic alliance, and improve treatment adherence. The patient's story should be complemented with information gathered through personalized sleep logs or diaries, which should be recorded over a period of 1–2 weeks. Sleep logs and diaries (see [Key Web Resources](#)) provide data about sleep patterns, habits, and daytime effects as well as related cognitive, affective, and behavior patterns. Interviewing available bed partners may also be helpful to corroborate information about snoring and movement disorders.

Self-Report Scales

Self-report scales can be useful for the assessment of sleepiness, fatigue, and hyperarousal. Empirically supported tools include the Pittsburgh Insomnia Rating Scale,⁶⁹ the Athens Insomnia Scale,⁷⁰ and the Bergen Insomnia Scale.⁷¹ The Epworth Sleepiness Scale⁷² is a brief, public domain questionnaire that provides an effective measure of current sleepiness (see [Key Web Resources](#)). Although the Epworth Sleepiness Scale is helpful as a screening device, it does not provide useful discriminative information for insomnia; however, it may have value in screening for comorbid sleep apnea, narcolepsy, or other sleep disorders. Also in popular use, the Stanford Sleepiness Scale⁷³ offers sensitivity to patterns of daytime wakefulness. Finally, the Insomnia Severity Index⁷⁴ is a self-report scale that assesses insomnia type, severity, and impact on daily life.

Objective Measures ([Fig. 9.1](#))

Polysomnography (PSG), as its name implies, measures multiple sleep parameters including indices of respiration, electroencephalography, and movement and muscle tone. Widely considered the gold standard of sleep evaluation, PSG is not, however, routinely indicated for insomnia because it provides little information useful for diagnosis or treatment.

FIG. 9.1 Stages of Sleep.

PSG may be necessary to rule out periodic limb movements in sleep, obstructive sleep apnea, or other conditions underlying persistent insomnia.²⁵ With advances in remote monitoring technologies, home-based PSG is increasingly being used. Other home use devices, such as actigraphy, allow for longitudinal studies that can reveal useful information about circadian rhythms and other sleep parameters.⁵

Integrative Therapy

“The best cure for insomnia,” said W.C. Fields, “is sleep.” A common temptation among both patients and practitioners is to oversimplify the causes and treatment of insomnia. As suggested earlier, treatment of insomnia calls for lifestyle change. Promoting general health with proper nutrition, exercise, and psychological well-being provides an essential backdrop to the comprehensive integrative treatment of insomnia. There are no magic bullets. Treatment typically entails multicomponent interventions that address all three P factors contributing to the noise of hyperarousal, including comorbid medical and psychiatric conditions. Ongoing monitoring and evaluation using subjective reports and objective measures should be an integral part of treatment.

If there is a secret to a good night’s sleep, it is a good day’s waking.

From the patient's perspective, interventions for insomnia can be classified in terms of two basic approaches: *taking something to sleep* and *letting go of something to sleep*. Patients who struggle with insomnia are inclined to consume sleeping medication, alcohol, warm milk, herbal teas, MT, botanicals, nutraceuticals, a wide range of comfort foods, and more. The fundamental belief underlying this approach is that insomnia results from *insufficient sleepiness* that can be ramped up with sleep-promoting ingestibles.

Sleep Promotion: Principles of Taking Something to Sleep

Both conventional and CAM approaches offer a wide array of options for *taking something to sleep* when indicated by psychological or medical crises. Short-term use of safe alternatives minimize the risk of dependence and the erosion of sleep self-efficacy. With the possible exception of MT, which regulates circadian rhythms, both conventional and alternative sleep aids do little to address the underlying “noise” of hyperarousal.

Most chronic insomnia results not from insufficient sleepiness, but from excessive wakefulness. *Letting go of something to sleep* refers to an approach concerned with reducing the noise of this excessive wakefulness.

Pharmaceuticals and Substances

Epidemiological studies suggest that alcohol, cannabis, OTC antihistamines, and prescription sedative-hypnotics are the most common treatments used by insomnia patients. Data suggesting that sedative-hypnotics can be effective in ameliorating insomnia raise serious questions about pharmaceutical industry influence and bias. At best, positive outcomes are negligible, and harmful side effects are substantial.⁷⁶

[Box 9.4](#) provides a list of the most common U.S. Food and Drug Administration–approved and off-label medications used to treat insomnia. Long-term use of most of these medications is associated with serious side effects ([Box 9.5](#)). Additional studies have raised concerns

that the hypnotic agents may increase the risk of cancer.^{77,78} Other findings revealed a 10%–15% increase in mortality among occasional users of sleeping pills and a 25% increase in mortality among nightly users of these drugs.⁷⁹

In the end, most sleep medications do little more than temporarily suppressing the neurophysiological symptoms of hyperarousal—and they do so with risk.

Despite these concerns, an unprecedented surge in the use of sleep medications has been underway since 2000.⁸⁰ This trend is certainly a factor in the rising tide of psychiatric polypharmacy.⁸¹

Supplements

Numerous botanical sleep aids have been in use around the globe for centuries. In contrast to conventional sleep medications, CAM sleep aids, including botanical medicines as well as nutraceuticals, generally provide less of a knockout and more of a gentle assist to sleep with significantly fewer adverse effects. Although L-tryptophan and 5-hydroxytryptophan (5-HTP), precursors to serotonin and MT, are widely used, reports about the effectiveness of these agents in treating insomnia are mixed. Kava has empirical support for use in treating insomnia; however, controversial findings have raised serious questions about its safety.⁸² More rigorous research into such alternatives has been hindered by limited financial incentives, conventional sleep medicine biases, and the natural complexity of many botanicals. Of the many alternatives to conventional sleep medications available, MT, valerian, hops, l-theanine, and lemon balm have been reviewed in greater detail, are in common use, and are generally regarded as safe.

BOX 9.4 Common Medications for Insomnia

Over-the-Counter Agents

- Diphenhydramine
- Doxylamine
- Benzodiazepines
- Estazolam

- Flurazepam
- Quazepam
- Temazepam
- Triazolam

Nonbenzodiazepine Hypnotics

- Eszopiclone
- Zaleplon
- Zolpidem
- Melatonin receptor agonists
- Ramelteon

Antidepressants (Tricyclic or Tetracyclic Antidepressants)

- Amitriptyline
- Doxepin
- Trazodone
- Mirtazapine

Other Agents

- Clonidine
- Gabapentin
- Quetiapine
- Sodium oxybate (gamma-hydroxybutyric acid sodium salt [GHB])

BOX 9.5 Common Side Effects of Sedative-Hypnotics

- Dependence
- Tolerance
- Damaged sleep architecture
- Diminished deep sleep
- Rapid eye movement suppression
- Parasomnias
- Anterograde amnesia
- Morning hangover
- Undermined self-efficacy
- Rebound insomnia with discontinuation
- Increased risk of falls

- Cognitive impairment
- Symptom suppression
- Increased mortality

Melatonin

Synthesized from tryptophan via 5-HTP and serotonin, MT is a neurohormone found in most living organisms. MT production is normally inhibited during the day by exposure to the blue wavelength of light and is disinhibited by dim light and darkness.⁸³ In addition to regulating circadian rhythms; MT mediates sleep and dreaming; decreases nocturnal body temperature; and has antiinflammatory, immune-modulating, and free-radical scavenging effects.⁸⁴ The suppression of endogenous MT through overexposure to light at night,⁸⁵⁻⁸⁷ in advancing age,⁸⁸ and by common substances and medications (e.g., caffeine, nicotine, alcohol, beta blockers, diuretics, calcium channel blockers, and over-the-counter analgesics⁸⁹) may be a factor in the development of insomnia, depression, and cancer. A growing number of animal, human, and population studies suggest that MT may have oncostatic properties.^{90,91} Other findings suggest that high doses of MT may actually disrupt sleep.⁹² Anecdotal reports suggest that MT may heighten awareness of dreams. Doses as high as 50 mg can dramatically increase REM sleep and dreams. Certain psychoactive drugs, including cannabis and lysergic acid diethylamide (LSD), increase MT synthesis and may emulate MT activity in the waking state as a “waking dream.”⁹³ Although an Agency for Healthcare Research and Quality report suggested that MT had limited effectiveness in treating insomnia,⁹⁴ a more recent meta-analysis of the effects of exogenous MT confirmed its beneficial effects on sleep-onset latency, total sleep time, and sleep efficiency.⁹⁵

Preparations

MT is available in oral, sublingual, and transdermal immediate or sustained-release formulations. Sublingual MT can avoid first-pass liver metabolism, thereby resulting in more reliable serum levels. Given its short half-life (approximately 0.5–2 hours), sustained-release formulations administered at or near bedtime are more likely to maintain effective levels throughout the sleep period, while immediate-release sublingual formulations administered at awakening may be more

effective in treating sleep maintenance insomnia and early morning awakenings.

Dosage

The recommended dose of MT is 0.3–0.5 mg for adults.⁹⁵ A sustained-release formulation more closely approximates the natural pattern of release. Although anecdotal data suggests higher doses may be effective for some, they can also disrupt sleep.

Precautions

MT generally has a good safety profile; however, it is contraindicated in pregnancy, and concerns about it exacerbating autoimmune illness have been raised. One meta-analysis found adverse effects to be uncommon and more likely with high doses.^{96,97}

Valerian Root (*Valeriana officinalis*)

Valerian is a sedating botanical with purported anxiolytic and hypnotic properties. In contrast to prescription sedative-hypnotics, valerian does not impair psychomotor or cognitive performance.^{98,99} One review concluded that valerian was safe but did not have significant effects on sleep.¹⁰⁰ A second study concluded that valerian appeared effective for mild to moderate insomnia.¹⁰¹ Valerian is nonaddictive, resulting in no withdrawal symptoms on discontinuation. Valerian may sometimes require weeks of nightly use before producing an effect.¹⁰²

Preparation

Valerian is available as whole powdered root and an aqueous or ethanolic extract standardized to 0.8% valerenic acids. High-quality products have an unpleasant odor, which confirms potency.

Dosage

For adults: 300–900 mg standardized extract of 0.8% valerenic acid or as a tea of 2–3 g of dried root steeped for 10–15 minutes and taken 30–120 minutes before bedtime for 2–4 weeks to assess effectiveness

Precautions

Valerian has a good safety profile.¹⁰⁰ Possible herb-drug interactions can increase sedation or alter drug metabolism. Caution should be exercised during pregnancy or in patients with a history of liver disease.

Hops (*Humulus lupulus*)

Hops refers to the flower clusters atop the *Humulus lupulus*. Best known for its use in beer, hops has also been used in traditional preparations to treat a broad range of conditions, including insomnia. The German Commission E Monographs listed hops as an approved remedy for insomnia.¹⁰² More recent findings have shown a modest hypnotic effect of a valerian-hops combination in treating adult insomnia.¹⁰³ Hops are believed to have antispasmodic properties that can help reduce muscle tension and promote relaxation.¹⁰⁴ Additional evidence suggests that hops may be beneficial in alleviating hot flashes and other menopausal symptoms.¹⁰⁵

Dosage

Prescribe 5:1 ethanolic extract, one-half to one dropper full, 30–60 minutes before bedtime.

Precautions

Although no evidence indicates toxicity at medicinal dosages, avoiding the use of hops in pregnancy may be advisable.

L-theanine

L-theanine is a unique amino acid commonly found in green and black tea. Although human research is limited, animal studies and anecdotal experience suggest that l-theanine may be useful in managing anxiety, hypertension, the stimulant effects of caffeine, and sleeplessness.¹⁰⁶

Dosage

There is limited data supporting l-theanine dosages for insomnia.

Typical recommendations range from 50 to 400 mg taken 30–60 minutes before bedtime.

Precautions

Although theanine is generally regarded as safe by the FDA, it is not recommended for pregnant or lactating women. Theanine can have an antihypertensive effect, so it should be used with caution when combined with antihypertensive medications. Avoid supplements that contain extracts of D-theanine.

Lemon Balm (*Melissa officinalis*)

Lemon balm leaves have been used medicinally for centuries to address insomnia. Available in capsules, teas, and essential oil, lemon balm is frequently combined with other sedating botanicals or nutraceuticals, such as valerian, hops, or l-theanine, to promote sleep. Lemon balm has an uplifting lemon-like fragrance and can be an effective aromatherapy agent.¹⁰⁷

Dosage

Capsules of dried leaf: 300–500 mg, or as a tincture: 60 drops

Precautions

Lemon balm should not be used by pregnant or lactating women.

Cannabis

The recent legalization of recreational and medical marijuana use in many states has sparked interest in cannabis as a potential sleep aid. Tetrahydrocannabinol (THC) has been shown to cause a 400-fold increase in endogenous MT.¹⁰⁸ Existing research suggests that cannabis does impact sleep, including REM sleep, but there are striking contradictions and inconsistencies in these findings. Older research relied on marijuana that was relatively weak in potency compared to the array of high potency hybrid products available today. Because rigorous, well-controlled studies are still lacking, the impact of cannabis on sleep likely depends on the specific kind utilized, the characteristics of the user, and the setting in which it is used.¹⁰⁹

Numerous additional botanical and nutraceuticals supplements are available to promote sleep. Proprietary blends that include a number of ingredients run the risk of providing too little of any one of them. It goes without saying that healthy nutrition is essential for sleep and a range of nutrient deficiencies can contribute to insomnia. The role of vitamin D in promoting healthy sleep, for example, is now receiving substantial attention.^{110,111}

Although it is beyond the scope of this chapter, a number of aromatherapeutic agents have also shown promise in promoting healthy sleep. Most notably, the effects of jasmine were found to be comparable to a benzodiazepine in a recent trial.¹¹²

Mind-Body Therapy

The Noise Reduction Approach for Insomnia

The breadth of an integrative approach to insomnia treatment can overwhelm patients. Too often, the misguided temptation is to reduce sophisticated integrative strategies that support a shift in consciousness and lifestyle to a simple sleep hygiene checklist. The Noise Reduction Approach for Insomnia (NRAI)¹¹³ provides a comprehensive and face valid framework for patients by organizing complex and numerous etiological and therapeutic recommendations into an understandable and manageable system. More specifically, the NRAI uses a *body, mind, and bed* framework in which *body* refers to biomedical factors, *mind* refers to psychological factors, and *bed* refers to sleep environmental factors.

The NRAI conceptualizes healthy sleep in terms of a *sleepiness-to-noise ratio* in which *sleepiness* refers to the propensity to sleep and *noise* refers to any kind of stimulation that interferes with sleep. Noise is used to denote the subjective experience of hyperarousal. Both sleepiness and noise can derive from body, mind, or bed factors. Although insomnia can result from insufficient sleepiness caused by daytime sleep or dozing, inadequate activity, sedating medications, and circadian rhythm disorders, it usually results from excessive noise.

Noise resulting from body, mind, or bed factors is cumulative. For example, the stimulating effects of ordinary work stress, two cups of coffee, or minor reflux alone may not interfere with sleep; however, their cumulative effect may well reach a threshold that does. Insomnia occurs when an individual's noise level exceeds their sleepiness, whereas sleep occurs when noise levels fall below the threshold of sleepiness. Because

the propensity to sleep is our natural default, the NRAI is less concerned with promoting sleepiness and more concerned with the identification and management of factors that produce noise.

Reducing Body Noise

The essential focus of body noise reduction is decreasing physiological manifestations of hyperarousal. In addition to the importance of promoting basic health through exercise, nutrition, and stress management, reducing body noise involves attending to a range of biomedical and lifestyle factors that commonly disrupt sleep. [Box 9.6](#) summarizes the major components of body noise reduction.

Simultaneously addressing all comorbid disorders is essential. This is especially true for depression, primary sleep disorders, and disorders characterized by pain and discomfort. The reasonable assumption is that doing so may have a synergistic effect. For example, reducing pain will obviously improve sleep, but improving deep and REM sleep can raise pain thresholds by 60% and 200%, respectively.¹¹⁴

Managing the sleep-disruptive side effects of medications and substances (see [Box 9.2](#)), as well as managing caffeine and alcohol, is essential to reducing body noise. Although individual variations exist, the half-life of caffeine is approximately 5 hours and can range from 2 hours for tobacco smokers to more than 10 hours for women who are pregnant or using oral contraceptives. Consuming two 8-ounce cups of drip coffee within an hour of morning awakening will leave approximately 35 mg of caffeine, the amount found in a cola drink, in one's system near bedtime. "Energy drinks," which contain 2–500 mg of caffeine per serving, have soared in popularity. Because the depressant effects of alcohol can facilitate sleep onset, it is widely used as a sleep aid. Insomnia increases the risk of relapse in patients recovering from alcoholism.¹¹⁵ Alcohol, especially if consumed without food or near bedtime, commonly compromises sleep quality and results in subsequent arousals.

BOX 9.6 Reducing Body Noise

- Manage all comorbid conditions, especially other sleep disorders, depression, and chronic pain.
- Manage the sleep side effects of medications.
- Manage alcohol and caffeine use.

- Manage symptoms of women’s health issues (e.g., premenstrual dysphoric disorder, menopause).

Common women’s health concerns, including premenstrual syndrome and premenstrual dysphoric disorder,¹¹⁶ pregnancy,¹¹⁷ and menopause,¹¹⁸ are strongly linked to insomnia. These conditions and any associated insomnia are most effectively addressed independently. Additionally, MT may be helpful in managing premenstrual syndrome and premenstrual dysphoric disorder,^{119,120} possibly through regulating rhythmic features of the disorder. Menopausal symptoms, particularly hot flashes, are commonly blamed for repeated awakenings. Disrupted sleep, however, is not a likely consequence of menopause.¹²¹

Menopause neither causes nor exacerbates sleep problems for most women.

Reducing Mind Noise

The basic goal of mind noise reduction is decreasing psychological and behavioral expressions of hyperarousal. This is largely achieved through CBT-I (cognitive-behavioral therapy for insomnia). CBT-I combines cognitive restructuring, which addresses insomnia-related dysfunctional thoughts and beliefs, with behavioral interventions including sleep hygiene education, stimulus control therapy (SCT), sleep restriction therapy (SRT), and relaxation practices. CBT-I also addresses common maladaptive coping reactions to insomnia that function as perpetuating factors. In addition to the treatment of individuals, CBT-I can be used in group settings, as well as through automated and web-based formats. [Box 9.7](#) provides a list of mind noise reduction therapies. This list primarily contains CBT-I components, but it is expanded to include dream health, which is not typically addressed in conventional treatment.

BOX 9.7 Mind Noise Reduction (Cognitive-Behavioral Therapy for Insomnia)

- Sleep hygiene education
- Cognitive restructuring
- Stimulus control therapy

- Sleep restriction therapy
- Relaxation practices
- Restoring dream health

Compelling evidence indicates the effectiveness of CBT-I for primary insomnia,^{5,122,123} and support for CBT-I in comorbid insomnia is growing.²² CBT-I has been shown to be at least as effective as prescription medications in the short-term treatment of chronic insomnia, with beneficial effects extending well beyond the completion of treatment and no evidence of adverse effects.¹²⁴ Patients with insomnia who were treated with CBT-I experienced greater increases in deep sleep and decreases in wake time than those treated with zopiclone (Canadian hypnotic with similar action to eszopiclone). These benefits were still present at a 6-month follow-up in contrast to patients treated with zopiclone who showed no ongoing benefits of treatment.¹²⁵ CBT-I alone was also found to be no less effective than CBT-I paired with zolpidem.¹²⁶ CBT-I has also been shown to enhance depression outcomes for patients with comorbid insomnia.¹²⁷

Sleep Hygiene

Sleep hygiene refers to a list of basic behavioral and environmental recommendations that promote healthy sleep. These can include most of the suggestions reviewed earlier, such as managing substances, regulating one's sleep-wake schedule, obtaining adequate exercise, and creating an environment conducive to sleep. Sleep hygiene has not been demonstrated effective as a stand-alone intervention, although most sleep specialists believe that it can be an effective aid to a multicomponent treatment approach.¹²⁸

Cognitive Restructuring

Cognitive restructuring techniques systematically review, reconsider, and replace thoughts and beliefs that trigger sleep-disruptive anxiety and rumination. [Box 9.8](#) provides examples of common dysfunctional thoughts about sleep. These thoughts are dysfunctional because they distort the truth, set up unrealistic expectations, and inevitably trigger anxiety. For example, the belief that "I can and must get myself to sleep" is nearly ubiquitous among patients with insomnia. Because it implies that falling asleep is under one's conscious control, this belief leads to excessive sleep effort, which then backfires by increasing arousal.

Similarly, the common belief that “I should always sleep through the night” sets the stage for a reflexive reaction of frustration, disappointment, and even self-recrimination with wakefulness after sleep onset. In reality, what wakes one up is not necessarily what keeps one awake. Frequently, our strong reaction to the awakening, which is based on a dysfunctional belief, is the real problem. Similar cycles of disappointment, frustration, arousal, and anxiety can ensue from comparable dysfunctional thoughts and beliefs, and their effects can be cumulative.

BOX 9.8 Dysfunctional Thoughts About Sleep

- I should sleep at least 8 hours every night.
- I should fall asleep quickly.
- I should always sleep through the night.
- I can and must get myself to sleep.
- I should just rest in bed if I cannot sleep.
- I will have a terrible day if I do not sleep well.

BOX 9.9 Stimulus Control Therapy Instructions

1. Get into bed with the intention to sleep only when sleepy.
2. Use the bed and bedroom only for sleep and sexual activity.
3. Do not watch the clock.
4. If awake after approximately 15 minutes, leave the bedroom, engage in restful activity, and return to bed when sleepy. Repeat as needed.
5. Keep a fixed morning rising time irrespective of the amount of sleep obtained.
6. Avoid napping until nighttime sleep is normal.

Stimulus Control and Sleep Restriction Therapies

Both SCT and SRT are effective behavioral interventions for managing conditioned insomnia and reducing sleep efficiency.^{129,130} Both approaches systematically minimize the amount of waking time spent in bed in an effort to increase sleep efficiency. SCT does so through self-monitoring and staying out of bed when sleepless. [Box 9.9](#) provides basic SCT instructions.

SRT requires patients to limit the amount of time in bed to their

average total sleep time established at baseline. Time in bed is then gradually increased as sleep efficiency improves. The administration of SRT is challenging to both patients and clinicians and should be used only by professionals trained in this intervention. Both SCT and SRT may be contraindicated in patients with sleep apnea, mania, epilepsy, and parasomnias and those at risk of falling.

Relaxation Practices

Relaxation practices, which have been included under the rubric of CBT-I, are useful in reducing sympathetic tone, decreasing mind noise, and familiarizing patients with the waking state of rest that serves as a transition to sleep. A myriad of effective techniques are available and should be matched to patients' interests and personalities. Breathing exercises are among the easiest and most portable practices.¹³¹ Early research combining mindfulness meditation and CBT-I showed a reduction in sleep-related arousals¹³² (see [Chapter 94](#)).

Restoring Dream Health

In contrast to conventional approaches, integrative therapies for insomnia are concerned with the restoration of dream health. From antiquity through recent times, dreams have been revered as rich sources of psychological insight, healing, and spirituality. Healthy REM sleep and dreaming are critical to the consolidation of procedural memory, as well as to the processing of emotion.¹³³

BOX 9.10 Promoting Healthy Dreaming

- Identify and manage dream thieves
- Arise slowly in the morning to enhance recall
- Journal or talk about dreams
- Join a dream circle or support group
- Note dreamlike aspects of waking life

Trying to promote healthy sleep without considering dreams is like trying to promote healthy nutrition without regard for the taste of food.

Given the frequency of bad dreams and the common belief that high-

quality sleep is devoid of dreaming, it is not surprising when patients with insomnia state that they would prefer not to dream at all. Dream avoidance, evident in Hamlet's classic remark, "To sleep, perchance to dream...",⁶⁸ is clearly seen in patients with frequent nightmares and can result in sleep avoidance and arousals.⁶⁸

[Box 9.10](#) offers recommendations for promoting healthy dreaming. Simply asking patients whether they have dream recall can be an essential first step in sensitizing them to the importance of dreaming. In addition to avoiding dream thieves—REM-suppressant drugs, substances, and activities—it may be useful to intentionally recall and attend to one's dreams.¹³⁴ Because we usually awaken from dreams, arising slowly in the morning with a receptive attitude can improve recall. Bridging dream experiences to waking life through journaling, discussion, and noting the "waking dream," dreamlike aspects of ordinary waking life, can also be helpful.

Reducing Bed Noise

Although the sleep environment can have a critical impact on sleep, it has not yet received the attention it warrants. Recognizing the bedroom as not only a physical location, but also a temporal and psychological space, the goals of bed noise reduction include the following: (1) minimizing the toxic burden of the physical environment, (2) regulating circadian rhythms through entrainment with light and darkness, and (3) creating a sense of sanctuary that is free of ordinary waking life stimulation.

A Healthy Sleep Environment

Sensitivities or allergies to bedroom irritants or toxins can be pronounced or subtle. Awareness is increasing, as reflected in the growth of the natural mattress industry, of the importance of an environmentally friendly and toxin-free bedroom. In addition to recommendations to keep the bedroom quiet and cool (68°F or lower), compelling arguments have been made on behalf of "green" (organic) beds and bedding as well as clean bedroom air.^{134,135} [Box 9.11](#) lists common sources of bedroom toxicity that should be evaluated and addressed to improve sleep. Bedroom air quality can be improved with high-efficiency particulate air (HEPA) filtration systems as well as with varieties of ordinary houseplants. Because electromagnetic fields can suppress endogenous MT,¹³⁶ it is advisable to clear them from the sleep area.

BOX 9.11 Common Sources of Bedroom Toxicity

- Pesticide-laden fabrics in bed and bedding
- Synthetic materials in mattresses and pillows
- Outgassing from furnishings, floors, walls, or carpeting
- Polluted indoor air
- Electromagnetic fields

BOX 9.12 Regulating Circadian Rhythms

- Use phototherapy, with timed exposure to light and darkness.
- Maintain a regular sleep-wake pattern.
- Simulate dusk by dimming the lights or using blue blocker technology 1–2 hours before sleep.
- Supplement with melatonin.
- Sleep in total darkness.

Regulation of Circadian Rhythms

Time can be conceptualized in two distinct ways. Ordinary waking life is structured by linear or clock time. However, human biology, including sleep–wake cycles, operates on cyclic time, most evident in circadian rhythms. Nature’s darkness may invite us to sleep, whereas culture, with its vast array of evening distractions, encourages us to stay awake.⁷⁰

Sleep disorders, in part, are chronic skirmishes between nature and culture—between linear and cyclic time.

Zeitgebers (from the German, “time giver”) refer to environmental and behavioral factors that regulate circadian rhythms. These include temporal patterns of feeding, activity or exercise, socialization, and, most importantly, the timing of exposure to light and darkness. Bright light signals the start of morning, whereas dim light or darkness conveys a sense of night to the brain’s circadian pacemaker. Sleep-phase disorders, most commonly advanced or delayed sleep-phase syndromes, are common predisposing factors in insomnia. These disorders can be effectively treated by systematically manipulating exposure to light and darkness to restructure the position of the patient’s sleep phase within their circadian cycles.

Regulating circadian rhythms ([Box 9.12](#)) is a critical component of treating insomnia. Maintaining a regular sleep–wake pattern 7 days per week is essential in promoting a healthy sleep rhythm. Bright light exposure for approximately 30–45 minutes shortly after morning arising is a most potent Zeitgeber¹³⁷ as well as a potential antidepressant.¹³⁸ When natural light is not an option, light boxes that provide comparable lux levels are commercially available. Exposure to higher lux levels of natural light throughout the waking day may also reduce daytime sleepiness.¹³⁹

Given the relentless demands of daily living, dusk simulation practices—dimming lights for 2 to 3 hours before bedtime—are particularly challenging. Dim light diminishes the blue wavelength of light prominent in natural daylight, artificial lighting, and computer and television screens. The blue wavelength of light has been shown to signal the brain to suppress MT production, thus delaying the start of the sleep phase.¹⁴⁰ Newer blue light filtration technology in the form of goggles and light bulbs can provide illumination without suppressing MT (see [Key Web Resources](#)) and can minimize the negative impact of reading or watching television.

BOX 9.13 [Creating a Sense of Sanctuary](#)

- Establish the bedroom as a stress-free and work-free zone.
- Limit exposure to stressful imagery from books, television, and radio.
- Conceal ready access to clocks.
- Establish a sense of personal safety.
- Maintain peace with your sleep partner.

Because even small amounts of light can trickle across closed eyelids and suppress MT, sleeping in total darkness or with a sleep mask is ideal.

Creating a Sense of Sanctuary

For many who struggle with insomnia, the bedroom is a place of work, entertainment, and other activities that may be antagonistic to sleep. Reimagining the bedroom as a sanctuary ([Box 9.13](#)), a place of retreat from the world of waking, is helpful. To do so, the bedroom should be a

work-free, stress-free, and clock-free zone. Exposure to stressful imagery from reading material, television, or radio should be avoided. Clock watching is a common compulsion among patients with insomnia and serves only to exacerbate sleeplessness by tethering them to the waking world of linear time. Establishing a deep sense of personal or psychological safety in the bedroom is also important. For some patients, this may mean installing a security system, whereas for others it may mean keeping a religious icon on the bed stand.

The percentage of couples sleeping apart, largely as a result of sleep disorders, has increased dramatically and now stands at 23%.¹⁴¹ Sleeping apart is associated with negative effects on the relationship.¹⁴² Addressing sleep symptoms (e.g., snoring or periodic limb movements in sleep) that may provoke one's sleep partner is essential. Differing sleep environment preferences can also be negotiated. Creating a sense of sanctuary in the bedroom encourages an essential shift from waking to *night consciousness*.⁷⁰

Fundamentally, insomnia is associated with inadvertently smuggling waking consciousness into the world of night and sleep.

Behavioral Sleep Medicine Specialists

Although some components of CBT-I can be implemented by patients on their own, this complex therapy generally requires specialized training. The stepped care model for CBT-I recommends a hierarchy of five increasing levels of interventions associated with clinician expertise and patient needs (Fig. 9.2). Behavioral sleep medicine specialists, formally trained and certified in the use of CBT-I, are a small but steadily growing and key professional resource in this model (see [Key Web Resources](#)).

A Basic Primary Care Intervention

Due to the shortage of behavioral sleep medicine specialists, practical implementation of CBT-I has been lagging. Today, the majority of insomnia patients rarely, if ever, see a behavioral sleep medicine specialist. Given that primary care is the front-line contact for most insomnia patients, providers need to be educated in their diagnosis and treatment. New research suggests that insomnia patients may be effectively treated by primary care providers with a brief, single-session

of sleep restriction therapy.¹⁴³

Prevention Prescription

Preventing insomnia by intentionally maintaining healthy sleep is considerably less daunting than treating it.

- Recognize the value and joy of sleep.
- Attend to and journal dreams.
- Engage in relaxation practices daily.
- Perform adequate regular exercise.
- Obtain daily exposure to morning light.
- Limit the use of stimulants and sedatives.
- Maintain a regular sleep–wake schedule.
- Dim lights or use blue blocker tools 1–2 hours before sleep.
- Sleep in total darkness or use a sleep mask.
- Sleep in a cool environment
- Consider low-dose melatonin replacement therapy.

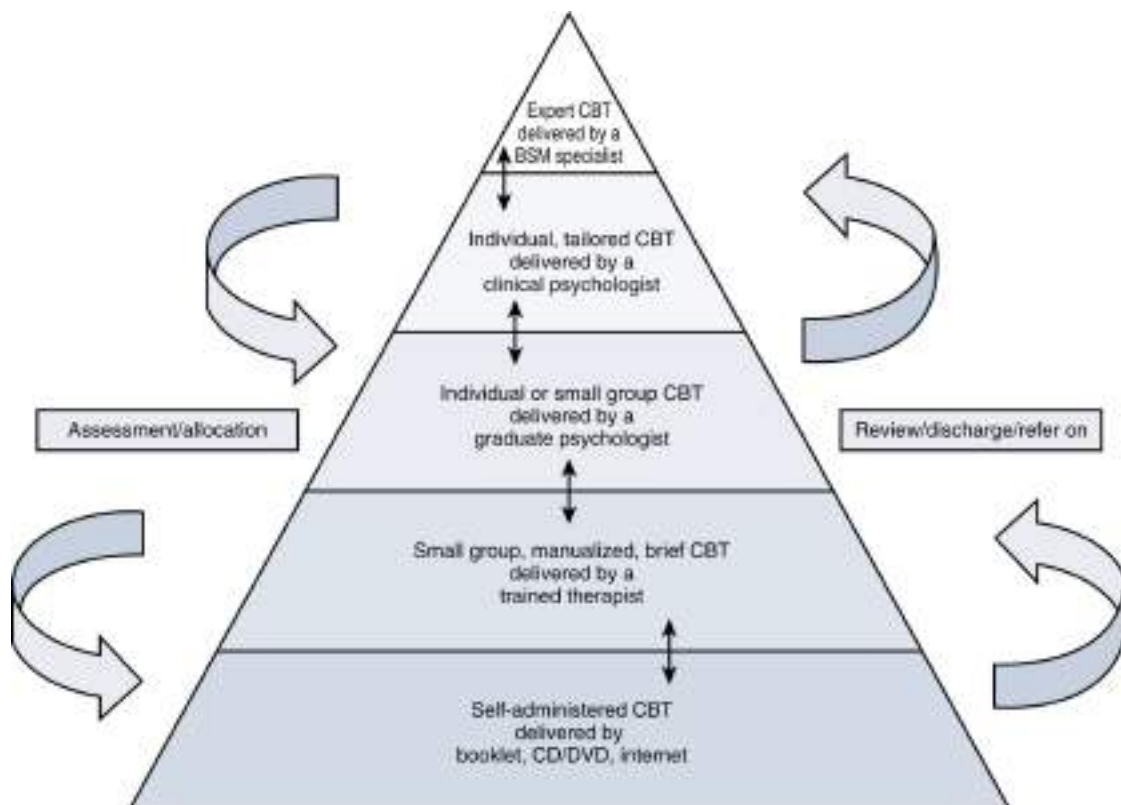

FIG. 9.2 A Stepped Care Model for Cognitive-Behavioral Therapy for Insomnia (CBT-I).

This evidence-based model for CBT illustrates how patients may be allocated to resources. *Arrows* represent referral movements. BSM, behavioral sleep medicine. (From Espie CA. "Stepped care": a health technology solution for delivering cognitive behavioral therapy as a first line insomnia treatment. *Sleep*. 2009;32:1549-1558).

Therapeutic Review

Reduce Body Noise

- Directly address all comorbid conditions, especially primary sleep disorders, depression, chronic pain, and women's health issues. Evaluate and manage sleep side effects of all medications (see [Box 9.2](#)). Evaluate and manage alcohol, caffeine, and other stimulant use. 
- Melatonin: 0.3–0.5 mg at bedtime, especially if the patient may have an associated circadian rhythm disorder 
- Avoid sedative-hypnotics ₂, and use complementary and alternative medicine sleep aids as needed, preferably on a short-term (2- to 4-week) basis. Consider one or a combination of the following:
 - Valerian, for adults: 300 to 900 mg standardized extract of 0.8% valerenic acid or as a tea of 2–3 g of dried root steeped for 10–15 minutes and taken 30–120 minutes before bedtime for 2–4 weeks to assess effectiveness ₂
 - Hops: in a 5:1 ethanolic extract, ½; to one dropper full, 30–60 minutes before bedtime ₁
 - L-theanine: 50–400 mg taken 30–60 minutes before bedtime. ₁
 - Lemon balm: 300–500 mg or 60 drops of tincture; can be used in blends with valerian, l-theanine, or other soporifics. ₁

Reduce Mind Noise

- Encourage patients to select and engage in a daily relaxation practice.

 The 4-7-8 relaxing breath exercise ([Box 9.14](#)) is an easy and effective option.

- Use stimulus control therapy for sleep efficiency lower than 85%. 
- Consider sleep restriction therapy as a standalone intervention in lieu of sedative-hypnotics.
- Evaluate and discuss basic dysfunctional beliefs and thoughts about sleep. Refer the patient to a behavioral sleep medicine specialist for more elaborate cognitive restructuring therapy as needed. 
Encourage dream recall by limiting “dream thieves,” and promote daily dream journaling and participation in dream support groups. Refer patients with chronic nightmares to a behavioral sleep specialist for image rehearsal therapy. 

Reduce Bed Noise

- Recommend reduction of bedroom toxicity from beds, bedding, and furnishings, as well as air filtration with high-efficiency particulate air (HEPA) filters or houseplants. Encourage evaluation of and protection from electromagnetic fields. 
- Urge the patient to maintain a regular sleep–wake schedule, including on weekends. The patient should simulate dusk by dimming lights or using blue blocker technology (see [Key Web Resources](#)) 1–2 hours before sleep, and sleep in total darkness. Exposure to morning light is important. 
- Encourage patients to create a sense of sanctuary by establishing the bedroom as a stress-free and work-free zone, limiting exposure to stressful imagery and clocks, ensuring a sense of personal safety, and maintaining peace with bed partners. 

BOX 9.14 4-7-8 Relaxing Breath Exercise

1. Place the tip of your tongue against the ridge behind your front teeth and exhale completely through your mouth.
2. Inhale through your nose for a count of 4.
3. Hold your breath for a count of 7.

4. Exhale through your mouth with a swooshing sound to the count of 8.
5. Repeat this cycle three more times for a total of four breaths.

The ratio of 4:7:8 is key, not the actual time spent on each breath cycle. Practice at least twice daily, beginning with no more than four breath cycles at one time for the first month and increasing to eight breath cycles afterward if desired. This exercise can be used to increase presleep relaxation and to facilitate sleep onset in bed.

CHAPTER 10

Posttraumatic Stress Disorder (PTSD)

David J. Kearney, MD, Michelle E. Martinez, MPH, and Tracy L. Simpson, PhD

Definition and Diagnostic Criteria

Posttraumatic stress disorder (PTSD) is a common consequence of trauma that, without treatment, can persist for decades.¹ The lifetime risk of developing PTSD is estimated to be 6.8%, with women more likely to be affected than men.² The clinical hallmarks of PTSD include recurrent, intrusive recollections or reexperiencing of a traumatic event, avoidance of external or internal trauma reminders, negative changes in cognitions and mood, and changes in arousal and reactivity.³ PTSD has been shown to have a greater impact on quality of life than major depression and obsessive-compulsive disorder, and it is estimated that the typical person with PTSD experiences active symptoms for at least two decades over their lifespan.¹ PTSD is also significantly associated with an increased lifetime risk of suicide, with a stronger association with suicidality than any other anxiety disorder.⁴ PTSD often results in severe reductions in quality of life, including disruptions in interpersonal relationships and ability to work in addition to increased risk of mood and substance/alcohol use disorders.^{5,6} PTSD is also associated with an increased risk of developing physical conditions, including arthritis, coronary artery disease, metabolic syndrome, chronic pain syndromes, and asthma, after adjusting for other risk factors.^{7,8}

A number of different types of treatments for PTSD have been evaluated, including pharmacological, traditional cognitive-behavioral (CBT) interventions, and complementary and alternative (CAM) interventions. In this chapter, we provide a brief overview of these treatments, with particular emphasis on various CAM approaches for

PTSD. Where possible, we have used comprehensive systematic reviews and meta-analyses as guides, with greater weighting given to the results of randomized clinical trials (RCTs) than open trials or case studies. We begin by describing the least invasive approaches before providing an overview of psychotherapeutic approaches and conclude with an overview of current psychopharmacology literature.

Integrative Therapy

Exercise

Previous studies have demonstrated that exercise is effective in reducing anxiety and reactivity,⁹ which are prominent components of PTSD symptoms. Three PTSD studies were identified in a review of research exploring the anxiety-reducing effect of exercise on a range of anxiety disorders.⁹ Each of these studies used aerobic exercises (rather than weight lifting or circuit training) as the intervention, and the length and frequency of exercise varied between the studies. In a pre–post open trial involving a sample of adolescent females, an exercise routine of 40-minute sessions three times a week for 8 weeks led to a reduction in PTSD symptoms, depression, and anxiety.¹⁰ A separate open trial of adolescent females reported the efficacy of 5 weeks of 3 weekly sessions of aerobic exercise in treating PTSD. Heart rates were measured at the conclusion of the 12th minute of moderate-intensity exercise to ensure rates had decreased to between 60%–90% of the maximum calculated heart rate. The intervention resulted in significant reductions in PTSD symptoms at posttreatment for 90% of participants, and general anxiety was significantly reduced in >50% of participants.¹¹ Significant reductions in the symptoms of PTSD, anxiety, and depression were observed posttreatment in an open trial of adults who participated in a program involving twelve 40-minute sessions of exercise that maintained 60%–80% of their calculated maximum heart rate.¹² In all three studies, symptom improvement was maintained at 1-month followup.⁹ Although these findings provide encouraging preliminary evidence, future studies in this area should use larger sample sizes and appropriate control groups to strengthen the evidence base for aerobic exercise as a treatment option for PTSD.

Encouraging exercise may have utility in reducing PTSD symptoms,

anxiety, and depression. Exercise is also posited to lead to reductions in coping-oriented alcohol use without patients making specific efforts to cut back on alcohol consumption.

There is preliminary evidence that exercise may be associated with a decreased risk of symptoms that commonly co-occur with PTSD, including suicidal ideation and use of alcohol as a coping strategy. For example, veterans in inpatient PTSD treatment who reported engaging in relatively more exercise were found to be at decreased risk of suicide and depression, and to have improved sleep patterns.¹³ In a separate correlational study, vigorous-intensity exercise (≥ 6 resting metabolic equivalents) was found to be inversely correlated with alcohol use as a coping strategy among individuals who had experienced trauma, indicating that encouraging exercise may lead to reductions in coping-oriented alcohol use without any special efforts to cut back on alcohol consumption.¹⁴

Mind-Body

In the interest of providing patients with increased options for treatment, there has been increasing interest in CAM modalities for the treatment of PTSD. Further, the Institute of Medicine (IOM) has called for more research in these areas.¹⁵ The following overview of the literature pertaining to CAM and mind-body interventions for PTSD is an extension of the comprehensive systematic review published by Helané Wahbeh et al. in 2014.¹⁶ We have provided summaries of their findings along with information about relevant studies that have been published since 2013 when their literature search concluded.

Meditation

Meditation can be considered a broad term that encompasses a wide variety of practices involving attention and mental focus.^{17,18} Mindfulness practice may involve techniques that run counter to tendencies to suppress or avoid painful emotions and thoughts, as is characteristic of PTSD. A small body of literature suggests that meditation may have benefit in cases of PTSD. In their systematic review of CAM for PTSD, Wahbeh et al. reported on 9 studies of meditation (5 RCTs and 4 pre-post studies).¹⁶ Of note, all pre-post studies showed positive outcomes and

the majority of RCTs (which were of variable quality) reported favorable outcomes for meditation compared to waitlist controls.¹⁶ Because there are a wide variety of techniques for practicing meditation, which differ according to how mental focus is cultivated,¹⁸ we review specific meditation practices that have been postulated to be effective in the treatment of PTSD in this section.¹⁸ These include mindfulness meditation, mantra repetition meditation, and compassion-based meditation.¹⁸

Mindfulness practice may involve techniques that run counter to tendencies to suppress or avoid painful emotions and thoughts, as is characteristic of PTSD.

Mindfulness Meditation

Mindfulness is defined as “the awareness that emerges by way of paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience moment by moment.”¹⁹ In mindfulness-based interventions, individuals are taught to pay attention to experiences with an attitude of curiosity, openness, acceptance, and kindness. In this way, mindfulness practice runs counter to tendencies to suppress or avoid painful emotions and thoughts, as is characteristic of PTSD.²⁰ Mindfulness practice is postulated to represent a form of exposure therapy.²¹

Two of the most widely available clinical programs for teaching mindfulness meditation are an 8-week class series called Mindfulness-Based Stress Reduction (MBSR) and Mindfulness-Based Cognitive Therapy (MBCT). A well-designed RCT (n = 116) compared MBSR to an active control condition and found that patients randomized to MBSR had greater improvements in PTSD symptom severity, depression, and quality of life at 2-month followup.²² In addition, a significantly greater proportion of patients randomized to MBSR experienced clinically significant improvements in PTSD symptoms compared to the control condition (49% vs. 28%; $P = 0.03$).²² These findings corroborate the results of two before-and-after studies of MBSR in individuals with a high prevalence of PTSD, which both reported significant improvements in symptoms of PTSD, depression, and quality of life over time.^{23,24} A separate small trial comparing MBCT to usual care for veterans with PTSD reported greater PTSD symptom reductions after MBCT.²⁵ Other

studies of mindfulness-based interventions have indicated the benefit of a telehealth mindfulness intervention²⁶ and a mindfulness-based stretching and deep breathing exercise program²⁷ in improving PTSD symptoms. Further definitive trials of mindfulness-based intervention for PTSD are required and are currently ongoing.

Mantra Meditation

A mantra is a sacred word or phrase that is repeated silently over the course of the day as a means of training attention with the intent of bringing about a sense of peace and relaxation.¹⁸ As noted in the review by Wahbeh et al.,¹⁶ both a before-and-after study²⁸ and an RCT (compared with a waitlist control)²⁹ evaluating mantram repetition reported that participation in the intervention was associated with significant reductions in PTSD. More recent research on a mantram repetition program (not included in the Wahbeh review)¹⁶ include an RCT (n = 146) comparing this intervention (6-week duration, 90 min per week) to usual care for military veterans with PTSD and observed an associated with significantly greater reductions in PTSD symptoms and depression than treatment as usual alone.³⁰ In this study, reductions in PTSD symptoms were mediated by enhanced existential spiritual wellbeing³¹ and mindfulness.³² Transcendental meditation (TM) is another type of mantra meditation practice in which one's attention is placed on a mantra as an object of attention. TM is generally practiced with eyes closed for 15–20 minutes, twice per day. The evidence supporting the use of TM for PTSD is limited. However, a small RCT comparing TM to psychotherapy among Vietnam veterans³³ and a before-and-after study involving Operation Iraqi Freedom/Operation Enduring Freedom veterans³⁴ (included in the Wahbeh review)¹⁶ both found that TM was associated with reductions in PTSD. A moderate-sized RCT comparing TM to no intervention among Congolese refugees.³⁵ TM is hypothesized to reduce hyperarousal by effects on the autonomic nervous system.¹⁸

Loving-Kindness/Compassion Meditation

Loving-kindness and compassion meditation practices are intended to enhance one's capacity for kindness and compassion to self and others. Self-compassion is associated with healthy psychological functioning and negatively associated with self-criticism, rumination, thought suppression, and depression,³⁶ which are phenomena frequently

associated with PTSD.³⁷ Loving-kindness and compassion practices are theorized to represent an innovative approach to address emotional numbing, which is common in chronic PTSD. In loving-kindness meditation, individuals silently repeat a series of phrases that invoke the desire for safety, happiness, health, and ease or peace for self and others. Two studies evaluating this approach were not included in the Wahbeh review. A before-and-after study of veterans with PTSD (n = 42) reported improvements in symptoms of PTSD and depression, as well as increases in self-compassion and pleasant emotions over time.^{38,39} Another self-compassion intervention, “Compassionate mind training,” appeared promising for people with a history of trauma in a small open trial⁴⁰ (see [Chapter 100](#)).

Relaxation Exercises

There is little evidence to support relaxation training as an effective treatment modality for PTSD. Relaxation, which typically involves teaching patients various scripted exercises, has been studied primarily as a control condition in trials of PTSD treatment. In the systematic review by Wahbeh et al., four trials that assessed relaxation techniques for PTSD (two randomized controlled trials, one before-and-after, and one crossover) were described.¹⁶ The studies were all limited by significant methodological shortcomings and reported mixed or negative results (see [Chapter 94](#)).

Visualization and Guided Imagery

Visualization or imagery-based therapies for PTSD have predominantly focused on addressing chronic nightmares, as opposed to the full range of symptoms. These therapies include imaginal confrontation with nightmare contents (ICNC), imagery rescripting and rehearsal (IRR), imagery rehearsal therapy (IRT), and imagery rescripting and exposure therapy (IRET). In a meta-analytic review of 20 studies of treatments incorporating IRR or ICNC for PTSD nightmares, in addition to sleep quality, depression, anxiety, and PTSD severity, both IRR and ICNC were found to be effective. However, the quality of this evidence has been called into question. In a review of 16 trials that used a range of imagery rehearsal approaches for PTSD, Harb et al. found that most had low methodological quality due to a lack of details regarding treatment delivery (which inhibits replication of the treatment in a future trial) and

poor descriptions of sample populations.⁴¹ Research investigating the impact of visualization on the full range of PTSD symptoms (rather than nightmares alone) is also lacking. A recent randomized controlled trial described in the Wahbeh review¹⁶ incorporated guided imagery into its treatment arm; however, this was coupled with healing touch, which limited the ability of the study to determine which treatment was responsible for the improvements observed.⁴² Currently, the evidence base for visualization treatments is too underdeveloped to determine its clinical value as a PTSD treatment method, although it may have utility as a supplement to an evidence-based approach due to its apparent safety (see [Chapter 97](#)).

Yoga

Yoga is a practice that typically includes physical postures, breathing exercises, and meditation, with the relative emphasis on each of these components varying according to the style of yoga practiced.⁴³ Yoga also involves paying attention to emotional and physical stimuli. In this way, yoga can be considered a form of mindfulness practice.^{43,44} Yoga has been hypothesized to influence pathways that may favorably impact PTSD, including upregulation of the parasympathetic nervous system, downregulation of the sympathetic nervous system, and decreased basal cortisol and catecholamine levels.⁴⁴ In addition, practicing yoga may represent a form of behavioral activation⁴³ and may encourage grounding in the body, both of which may counter PTSD-related avoidance and hyperarousal symptoms.

There is growing evidence indicating a beneficial effect of yoga for PTSD, with four of five comparative trials reporting benefit. A nonrandomized trial (n = 183; included in the Wahbeh review)¹⁶ compared a yoga breath intervention for tsunami survivors to a yoga breath intervention plus exposure therapy or a waitlist control. A similar level of symptom reduction was observed with the two interventions such that exposure therapy component did not confer additional benefit; however, both active interventions were found to be superior to the waitlist control.⁴⁵ In a recent, well-designed RCT (n = 60; published since the Wahbeh review)¹⁶ that compared a 10-week duration (one hour per week) yoga intervention to an active control (supportive health education), yoga was associated with significantly greater improvements in PTSD symptoms compared to the active control and was well tolerated.⁴⁶ Two smaller randomized trials (n = 38 and n = 22; not

included in the Wahbeh review)¹⁶ reported conflicting results regarding PTSD outcomes as compared to control groups that did not receive treatment.^{44,47} Larger randomized controlled trials are required to clarify the effectiveness of yoga practice in reducing PTSD symptoms and improving quality of life; however, the current small body of evidence indicates the benefit of yoga in treating PTSD symptoms.⁴⁸

Emotional Freedom Technique and Thought Field Therapy

Thought field therapy (TFT) and emotional freedom technique (EFT) are similar methods that use a combination of exposure through visualization and acupoint tapping to address emotional disturbances. In these treatments, PTSD is conceptualized as an emotional disturbance resulting from conflicts in the body's energy field (also known as the meridian system) or thought fields.⁴⁹ EFT or TFT involves eliciting the imagery, narrative, and physiological arousal associated with a traumatic memory while tapping on the ends of one's energy meridians located at certain points on the body in a specific sequence. This process is theorized to release energy blockages that create the negative emotions associated with the disturbing memory.

There is some preliminary evidence that TFT and EFT may be effective treatments for PTSD. An open trial of participants receiving TFT found that posttreatment total scores and symptom subgroupings of the DSM criteria for PTSD dropped significantly from pretreatment scores.⁵⁰ In a small RCT (n = 46), individuals with PTSD were assigned to EFT or eye movement desensitization and reprocessing (EMDR) and assessed 3 months later. Results showed similar therapeutic gains for both interventions.⁴⁹ A more recent before-and-after study provided male veterans and their spouses with a multimodal intervention that involved EFT and other energy / psychology methods that was associated with significant decreases in PTSD symptoms, which were maintained through followup.⁵¹ Finally, a more recent randomized controlled trial compared 6-hour-long sessions of EFT and standard care to a waitlist group (standard care only) and observed significant decreases in psychological distress and PTSD symptom levels in EFT subjects, with 90% of those receiving EFT no longer meeting PTSD criteria at the end of the study (compared to 4% in the standard care / waitlist group).⁵² Though these studies are encouraging, validation by further studies is

required due to high drop-out rates⁴⁹ and a lack of control arms in open trials^{50,51} (see [Chapter 103](#)).

Hypnotherapy

As a treatment for PTSD, hypnosis provides guided, controlled access to traumatic memories that may be kept out of normal consciousness.⁵³ Hypnotherapists can help patients access and experience traumatic memories and then assist in reshaping these experiences. More specific forms of hypnotherapy can also be employed. For example, hypnotherapeutic olfactory conditioning may be used to treat resistant olfactory-induced flashbacks.⁵⁴

Wahbeh et al. reviewed two RCTs comparing hypnosis to an active control arm.¹⁶ In a study using cognitive behavioral therapy as the active control, hypnotherapy was found to be associated with comparable outcomes to CBT at 3-year followup.⁵⁵ The other study focused on PTSD-related insomnia and used Zolpidem as a pharmaceutical active control.⁵⁶ The hypnotherapy group had significantly better outcomes compared to patients treated with Zolpidem with regard to improved insomnia and other symptoms; however, Zolpidem was not expected to improve PTSD symptoms unrelated to sleep.

Abreactive Ego State Therapy

Abreactive ego state therapy (AEST) is a form of hypnosis based on the psychodynamic view of personality being comprised of several “ego states.” In the framework of AEST, it is believed that the underlying pathology of PTSD results from memory encodings specific to the traumatic event and tied to particular ego states, which are treatable through hypnosis-guided emotional catharsis. Abreactive hypnosis activates expression of the trauma-related ego state to release affect through subcortical processes. Therapists provide support, encouragement, and foster adaptive communication among patient ego states, thereby altering attitudes and emotional reactions related to trauma at subcortical (subconscious) levels.⁵⁷

Ego state therapy has been internationally embraced for a range of trauma disorders, but it is not as commonly used in the United States. However, there is preliminary evidence that supports it as a treatment for PTSD. Barabasz et al. conducted two recent studies of AEST for PTSD (neither of which were included in the Wahbeh review)¹⁶ comparing a

single five- to six-hour session of AEST with a 3-phase active placebo involving an informational video about PTSD and an introduction to the “counting method.”⁵⁸⁻⁶⁰ Both treatment arms led to significant improvements in common measures of PTSD symptoms at posttreatment; however, the effect sizes within the placebo group were markedly smaller than those in the AEST group. Additionally, improvements following AEST continued through follow-up measures, whereas the therapeutic impact observed in the placebo groups had disappeared by the first follow-up visit. This was true for both studies. Although these results are encouraging, further high-quality studies are required.

Psychotherapy

Psychotherapies for PTSD and other psychiatric disorders emphasize the reduction of painful thoughts and feelings and seek to achieve this through a variety of means, including skill building to cope more effectively with trauma cues and stressors, desensitization and habituation through repeated or prolonged exposure to imaginal and in vivo trauma cues, and restructuring maladaptive thoughts and beliefs pertaining to traumatic events. Stress inoculation treatment (SIT), prolonged exposure (PE), eye movement desensitization and reprocessing (EMDR), and cognitive processing therapy (CPT) all have been evaluated in multiple RCTs and are considered empirically supported treatments for PTSD (EST).⁶¹

Psychotherapies for PTSD can generally be categorized as trauma-focused therapies and nontrauma-focused therapies.

Trauma-focused therapies are forms of cognitive behavioral therapy that address memories, thoughts, emotions, and beliefs associated with the traumatic event(s), and include cognitive processing therapy (CPT), prolonged exposure therapy (PE), and eye movement desensitization and reprocessing therapy (EMDR).

Nontrauma-focused interventions emphasize the development of skills (e.g., stress management, relaxation, or problem-solving) and provide instructions regarding the application of these skills in daily life, such as reminders of the trauma, relationship difficulties, and daily stressors. In contrast to trauma-focused therapies, nontrauma-focused approaches do not directly attempt to address trauma-related beliefs, emotions, or memories. Present centered therapy (PCT) is a nontrauma-focused intervention that facilitates the use of patients’ own coping strategies and

has recently been found to have results that are only marginally inferior to trauma-focused CBT and superior with regard to treatment retention.^{62,63}

Narrative exposure therapies, which involve individuals constructing a story of their lives that they then tell another person either directly or through an interpreter, have been found to be effective in reducing PTSD and trauma symptoms among refugees, particularly when administered by counselors who themselves are refugees.⁶⁴

The literature base regarding psychological interventions for children and adolescents with PTSD is far more limited than for adults. To date, CBT has most consistently been found to be effective at reducing PTSD symptoms,⁶⁵ with trauma-focused variants possibly the most efficacious.⁶⁶ EMDR has not been found to outperform conventional treatment in children with regard to overall PTSD symptoms, and narrative therapy has been shown to be associated with short-term but not longer-term gains.⁶⁵

There is even more limited research on psychological approaches for preventing PTSD. Early efforts evaluating single-session critical incident debriefing strategies were found to not be helpful and to actually be harmful such that those who underwent them were over two and a half times more likely to meet diagnostic criteria for PTSD at follow-up than those in the no-treatment control conditions.⁶⁷ More recently, a meta-analysis of multiple session interventions for preventing PTSD also failed to find these approaches helpful and noted a trend toward increased PTSD symptoms at follow-up in patients who received active interventions compared to formal intervention.⁶⁸ In contrast, brief trauma-focused CBT has been found to be helpful in reducing acute traumatic stress symptoms in a number of studies. Acute traumatic stress is defined as meeting the diagnostic criteria for PTSD when less than 1 month has elapsed posttrauma.⁶⁹

Cognitive behavior therapy is recommended for the treatment of children and adolescents with PTSD because CBT has the most substantial evidence base for reducing PTSD symptoms in this population.

Acupuncture

There is growing evidence that acupuncture may be an effective treatment for PTSD, particularly as a supplement to other forms of treatment. Three RCTs have provided evidence that acupuncture or acupoint stimulation significantly improves PTSD symptoms compared to control conditions, two of which were included in the Wahbeh review.¹⁶ In the first, acupuncture and CBT were compared to waitlist control, with both found to be significantly more effective than the control and similar to each other.⁷⁰ The other found that a combination of acupoint stimulation and CBT was more effective than CBT alone.⁷¹ In a more recent study, 55 service members were randomized to acupuncture (eight 60-minute sessions of acupuncture twice weekly) or treatment as usual. Patients in the acupuncture group reported significant improvements in PTSD severity as well as depression, pain, and physical and mental health functioning compared to the treatment as usual group.⁷² A meta-analysis of two RCTs compared acupuncture plus moxibustion to SSRIs and concluded the results favored acupuncture plus moxibustion for PTSD symptoms, depression, and anxiety.⁷³

Acupuncture is a reasonable treatment approach for patients with PTSD who do not wish to pursue traditional psychotherapeutic options.

Although these outcomes are encouraging, additional placebo or sham-controlled trials are warranted. Side effects of acupuncture are uncommon but include dizziness, nausea and vomiting, pain, fainting, and infection of needle insertion points. Acupuncture may be appropriate for patients whose preference is to not engage in more conventional therapies.

Repetitive Transcranial Magnetic Stimulation

Repetitive transcranial magnetic stimulation (rTMS) is a multisession treatment that uses magnetic fields to stimulate nerve cells associated with mood control and depression, reaching no more than 5–6 cm into the right dorsolateral prefrontal cortex of the brain. rTMS is a noninvasive procedure, and side effects are rare but may include seizures (rTMS is not recommended for patients with epilepsy), pain at the

stimulation site, muscle twitching during treatment, posttreatment headache, and toothache. It is primarily used to treat medication-resistant major depression; however, there is emerging evidence of its efficacy in treating PTSD. A systematic review¹⁶ and meta-analysis⁷⁴ of three RCT trials applying rTMS to subjects with PTSD have indicated significant differences favoring rTMS for improvement in PTSD symptoms, overall anxiety, and depressive symptoms. Additional studies are required. Also, rTMS is not widely available, which currently limits its utility in clinical practice.

Pharmacotherapies

The U.S. Food and Drug Administration (FDA) has approved the use of the selective serotonin reuptake inhibitor (SSRI) antidepressant medications, sertraline and paroxetine, based on a series of positive RCTs favoring these medications.⁷⁵⁻⁷⁸ Although a recent large meta-analysis of medications for PTSD supported the use of paroxetine in adults, sertraline was not found to consistently outperform placebo treatments.⁷⁹ This meta-analysis also found that two additional SSRIs, fluoxetine and venlafaxine, outperformed placebo on both clinician and self-rated symptoms of PTSD.⁷⁹ Because SSRIs typically have limited effects on PTSD, with significant symptom reduction observed in approximately 60% of patients and full remission in only 30%, the use of the atypical antipsychotic medications, such as risperidone and olanzapine, has also been evaluated in adults.⁸⁰ A recent meta-analysis of the use of atypical antipsychotics for PTSD based on eight RCTs found that they both outperformed placebo and, importantly, were well-tolerated.⁸¹

Other types of medications have also been subjected to double-blind tests of efficacy for the treatment of PTSD among adults, including prazosin, an alpha-1 adrenergic receptor antagonist, and nabilone, a synthetic cannabinoid. Prazosin has been found to ameliorate PTSD-related nightmares and sleep disturbance and improve overall clinical status in several trials.⁸²⁻⁸⁵ In a small crossover double-blind trial of nabilone, the active medication was found to reduce nightmares and improve global functioning relative to placebo;⁸⁶ however, further studies of nabilone are required before its adoption into clinical practice.

Pharmacotherapies have only recently begun to be evaluated among children and young adults, with the majority of available information based on small open trials.⁸⁷ Thus far, double-blind RCTs involving

children and youth have not found sertraline to outperform placebo.^{88,89} Small open label-trial studies involving children and/or young adults indicate the noradrenergic agent, guanfacine, along with propranolol, respiridone, and the mood stabilizer carbamazepine may be worthy of further study.⁹⁰

Pharmacological approaches have also been evaluated for the prevention of PTSD following exposure to trauma in adults. Pharmacological agents have been studied due to their potential to inhibit the formation of trauma memories. A recent Cochrane review of nine relevant RCTs concluded that there is moderate quality evidence (based on four trials) supporting the use of hydrocortisone (relative risk, 0.17), but no support for propranolol, escitalopram, temazepam, or gabapentin (the final three medications have only been tested in one RCT each), in preventing PTSD. Although results regarding the efficacy of hydrocortisone in preventing PTSD in adults are promising, the authors concluded that there is not sufficient evidence to endorse hydrocortisone use in routine clinical practice.⁹¹

Therapies to Consider

Biofeedback

Biofeedback uses electronic instruments to provide immediate information to patients so that they can learn to control physiological functions. For PTSD, biofeedback attempts to teach patients techniques for detecting and controlling physiological changes associated with increased arousal, which in turn is theorized to lead to reductions in symptoms.^{92,93} Heart rate variability (HRV), a marker of parasympathetic nervous system function, is typically the physiological parameter monitored. Patients are trained to control their breathing pattern in order to increase HRV. However, literature regarding biofeedback for PTSD remains very limited. There have been four trials conducted of biofeedback for PTSD (two RCTs, one nonrandomized controlled trial, and one before-and-after study),¹⁶ with the controlled trials reporting mixed results.⁹²⁻⁹⁴ Further research on biofeedback for PTSD is warranted (see [Chapter 96](#)).

Natural Products

The clinical efficacy of natural products for PTSD is not well-studied. Wahbeh et al.¹⁶ reviewed a small double-blind crossover trial (n = 13)

that compared the efficacy of inositol, a carbohydrate chemical compound found in fruits such as cantaloupe and oranges, to placebo in reducing PTSD core symptoms.⁹⁵ Although depression was lowered in the inositol group, core symptoms of intrusion and avoidance were unaffected. A separate study compared ginkgo biloba to placebo and reported significant improvements in PTSD in the ginkgo biloba group.⁹⁶

Prevention Prescription

PTSD prevention is a complex topic and, as noted in the psychotherapy section, is not without pitfalls (e.g., critical incident debriefing strategies and multiple session interventions have been shown to increase the risk of developing PTSD rather than prevent PTSD, whereas brief trauma-focused CBT has been shown to reduce the risk of developing PTSD; see [psychotherapy](#) section previously). From a societal perspective, attempts to reduce trauma exposure (e.g., through public safety laws) may be expected to reduce the risk of PTSD. For example, lower speed limits and the required use of seatbelts have reduced the incidence of severe traffic accidents and injuries. However, exposure to potentially life-threatening traumatic events (e.g., natural disasters, interpersonal violence, motor vehicle accidents) remains common over the course of an individual's life. Although the majority of individuals recover from traumatic events without lasting adverse psychological consequences, a small proportion will develop PTSD. Below are factors that may serve to prevent trauma exposure, minimize the negative psychological effects of trauma, or bolster natural recovery:

- **Physical fitness and safety:** Participating in regular aerobic exercise and avoiding unsafe, high-risk behaviors.
- **Social support^{97,98}:** Social support reduces the likelihood of developing PTSD. Maintenance of social support networks provides an avenue for individuals who have sustained trauma to share their experience, which appears to play a role in natural recovery.
- **Adjusting negative cognitive biases:** A negative attributional style, a tendency to ruminate and appraise situations negatively, and fear of one's own emotions increases vulnerability to PTSD. Conversely, learning to view things in a less negative way and to become

emotionally aware and accepting may protect against PTSD.⁹⁹

- Cognitive flexibility: The ability to “reframe, redefine, re-story” and to use alternative thinking to identify benefits and solve problems is a characteristic of resilient individuals.¹⁰⁰ Participation in programs or approaches that develop these abilities, such as psychotherapy, may help to foster resilience and mitigate the effects of trauma.
- Experiencing positive emotions and accepting / tolerating negative emotions: People who are realistically optimistic, laugh often (and can laugh at themselves), hopeful, and have positive self-image are more resilient,¹⁰⁰ whereas those who fear and avoid their emotions are at increased risk of PTSD. Participation in programs or activities that build emotional awareness and acceptance (e.g., meditation practices or psychotherapy) may help with emotional clarity and regulation.
- Spirituality and “meaning making”^{98,100}: Having a sense of meaning and purpose in life enhances resilience and reduces the risk of developing PTSD after trauma. For many individuals, the ability to find meaning in difficult experiences is assisted by faith or spirituality; however, it can also be supported by any value system that provides a moral compass and sense of altruism.

For people whose risk of traumatic exposure is especially high due to occupation or environment (e.g., military personnel, first responders, firefighters, female college students, etc.), resiliency programs may be offered to help bolster the qualities and capacities listed previously. For example, mindfulness-based mind fitness (MMFT)¹⁰¹ and stress resilience in virtual environments (STRIVE)¹⁰² have been used to promote predeployment resiliency in the military as a way of preventing the development of combat-related PTSD. Further, mindfulness-based resilience training (MBRT)¹⁰³ has received initial support as a method of building resiliency among police officers.

Therapeutic Review

A broad range of approaches have been studied for PTSD including exercise, CAM interventions, and psychotherapy. We briefly summarize the findings pertaining to different modalities that have some evidence for successfully treating PTSD, noting strengths and

limitations of the extant literatures.

Exercise

- Uncontrolled trials and correlational studies indicate regular aerobic exercise (up to 60%–90% of maximal heart rate) is associated with improvements in PTSD symptoms, anxiety, and depression. 

Mind Body

- Meditation
 - Mindfulness-based stress reduction (MBSR) 
 - Mindfulness-based cognitive therapy (MBCT) 
 - Mantram repetition 
 - Loving-kindness meditation 
- Yoga
 - Hatha yoga 
- Tapping: thought field therapy and emotional freedom technique 
- Hypnotherapy 
- Abreactive ego state therapy (AEST) 
- Psychotherapy
 - Stress inoculation treatment (SIT) 
 - Prolonged exposure (PE) 
 - Eye movement desensitization and reprocessing (EMDR) 
 - Cognitive processing therapy (CPT) 

Acupuncture

- Eight 60-min sessions of acupuncture twice weekly are associated with improvements in PTSD severity in addition to depression, pain, and physical and mental health functioning. [72](#)

Pharmacotherapies

Selective serotonin reuptake inhibitor (SSRIs) and serotonin

norepinephrine reuptake inhibitors (SNRIs) with the best evidence for benefit in treating PTSD include:

- Paroxetine 20–60 mg daily 
- Fluoxetine 10–60 mg daily 
- Venlafaxine 37.5–300 mg daily 

Alpha-1 adrenergic receptor agonists have been found to reduce nightmares and sleep disturbance but may cause hypotension.

- Prazosin 1 mg at bedtime. Titrate to a maximum of 15 mg at bedtime until nightmares are controlled. ⁸⁴

CHAPTER 11

Alzheimer Disease

Mikhail Kogan, MD, and Hwee Soo Jeong, MD

Alzheimer disease (AD) presents as a progressive cognitive decline affecting an individual's memory, language, and social functioning. Later stages lead to complete dependency for basic activities of daily life and premature death.

An estimated 44 million people have AD worldwide, including more than 5 million people in the United States alone. Approximately 500,000 people die of AD every year in the United States. AD is the most common form of dementia comprising 70%–90% of all cases. The annual cost of dementia care in the United States is thought to be between \$150 and \$215 billion. In 2010, Alzheimer's Disease International estimated the global cost of dementia care, including informal care from family and caregivers, at \$600 billion. Care costs in Europe and North America accounted for 70% of this burden.^{1,2}

For decades, dementia has been one of the most expensive diseases in the United States in terms of total costs to the economy; the annual cost of formal dementia care exceeds the direct health care expenditures for heart disease or cancer.³ It is projected that by 2040, nearly 10 million Americans will have dementia, including 50% of those aged more than 80.

Pathophysiology

Scientists have long understood that AD is caused by brain lesions known as *plaques*—beta-amyloid clusters that build up between nerve cells. As plaques accumulate, they block cell-to-cell signaling and trigger an inflammatory response from the brain's immune system that kills nerve cells. Twisted strands of dead nerve cells, known as *tangles*, also provide stimuli for inflammation. Inflammation is clearly an important

contributor to the pathological process of AD. A seminal paper entitled, “Inflammation and Alzheimer’s Disease,” describes a complex web of interacting inflammatory mediators in the periphery and in the AD brain.⁴ High plasma levels of C-reactive protein (CRP) in mid-life and elevated interleukin-6 in old age are strong predictors of AD risk.⁵⁻⁷ Neurons contain large amounts of metabolically active mitochondria, and synaptic activity depends on good mitochondrial function. A recent theory proposes that accumulation of beta-amyloid damage may cause mitochondrial dysfunction and memory loss in AD^{8,9} (see [Table 11.1](#) and [Table 11.2](#) for a summary of risk factors).

Methylation and Homocysteine

One of the key steps of methylation is the final step of the folate cycle that is regulated by methylenetetrahydrofolate reductase (*MTHFR*). *MTHFR* single nucleotide polymorphisms (SNPs) (mostly C677T and A1298C) slow down conversion of folic acid or dietary folate into 5-methyltetrahydrofolate (5MTHF), a step regulating the homocysteine cycle, glutathione and neurotransmitters production, and the general availability of the methyl group for a variety of biochemical reactions. While elevated homocysteine is considered by many to be an independent risk factor for dementia,^{10,11} lowering homocysteine with synthetic forms of B vitamins (e.g., folic acid) has not been shown to slow dementia progression.¹² The data linking *MTHFR* polymorphism to AD risk is conflicting. A few studies have suggested that the *MTHFR* C677TT mutation is three times more prevalent in AD patients than in controls, while other studies have found no relationship between *MTHFR* genotype and impaired cognition.^{13,13a,13b} This suggests we have a lot more to learn about the methylation cycle and its complexities. The associations between methylation defects and dementia may be illuminated by genome-wide SNP analysis as it becomes more widely available and affordable (see [Chapter 38](#)).

Chronic Exposure to Toxins

Environmental exposures that have been proposed—though not proven—to increase AD risk include those to aluminum, lead, mercury, organophosphate pesticides, and extremely-low-frequency electromagnetic fields.¹⁴⁻¹⁷

Case Study

A 91-year-old man was brought by his wife to the author's clinic with a chief complaint of progressive memory loss during the past several years. Upon initial assessment we learned that the patient was a strong and physically healthy 3-war veteran. He lacked a number of important AD risk factors such as cardiac disease and family history of AD; however, he had been eating swordfish at least twice weekly for many decades. The patient's Mini-Mental State Examination (MMSE) score was 23/30. Mercury Tri-Test (blood, urine, and hair testing) was ordered based on a clinical suspicion of mercury toxicity.¹⁸ The results revealed a total mercury level nearly 10 times higher than the Centers for Disease Control's average level for healthy individuals, with predominance of methylmercury, an organic form found in fish. The patient's wife removed swordfish and other high-mercury fish from his diet, and the author prescribed comprehensive nutritional detoxification support consisting of alpha-lipoic acid, methylated B vitamins, N-acetyl-cysteine, zinc, and other nutrients. Repeat Mercury Tri-Test showed an 80% reduction in the patient's total mercury level six month later and normal mercury levels four months after that. At a follow-up visit one month after the last mercury test, the patient's wife reported substantial memory improvement and his MMSE score was 27/30.

TABLE 11.1
Risk Factors of Alzheimer Disease (AD)

Risk Factor	Comments
Advanced Age	Advanced age is the most important risk factor in AD. 18% of persons who are 65 years old develop AD. The incidence at 85 years is as high as 50%. ¹⁰³
APoE4 ε4	Individuals with two ε4 alleles are at least eight times more likely to develop AD. The ε4 allele gene seems to exert a protective effect on people in their 60s. ¹⁰⁴
Body Weight	U-shaped risk distribution—obesity likely due to inflammatory and insulin resistance factors and underweight due to poor nutritional factors. ^{105,106}
Cardiovascular Disease (CVD)	Hypertension leads to subcortical dysfunction and neuronal death. ¹⁰⁷
Diabetes and Insulin Resistance	In AD, brain glucose utilization and energy production are impaired. ¹⁰⁸ Diabetes is a risk factor not only for strokes and vascular dementia but also for AD. ¹⁰⁹
Family History of AD	There is three-fold increased AD risk among those with first-degree relatives with the disease. ¹¹⁰
Education	Higher education is associated with lower risk of AD later in life. ¹¹¹
Cholinesterase (ChE) low	Postmortem studies have shown low neuronal ChE level in patients with AD. ¹¹²
Dysmetabolism	Nonketotic acidosis, leukoencephalopathy, and AD risk. ^{113,114}
Hormonal Imbalance	<ul style="list-style-type: none"> • Low estrogen¹¹⁵ • Cortisol dysregulation¹¹⁶ • Low DHEA and progesterone are associated in AD patients • Hypothyroid and Cushing's disease-like symptoms
Methylation Defects	MTHFR mutations and high homocysteine levels—see text
Mitochondrial Cognitive Impairment (MCI)	30%–12% will progress to dementia. Patients with MCI function normally in daily activities requiring complex cognitive abilities such as thinking, calculating, and decision making. ¹¹⁷
Sleep Apnea	One of the more recently found factors, likely due to nocturnal hypoxia. ¹¹⁸
Smoking	Surprisingly, a great deal of findings indicate that heavy smokers may have protective effect on smoking-associated AD cases. ¹¹⁹
Chronic Stress	See text
Toxicities	Mercury, lead, organophosphates, and others—see text
Transient Brain Injury (TBI)	AD risk is doubled in patients who have experienced TBI early in life.

TABLE 11.2**Nutritional and Minerals/Vitamins Risk Factors of Alzheimer Disease (AD)**

Consuming High Glycemic Index Diets	High glycemic foods are well known to have proinflammatory effects; this is addressed in detail in a separate chapter.
Low Omega-3 Dietary Content	See text for details.
Low B12 and B6	Well-known risk factors clearly associated with AD risk. ¹³
Niacin (B1) Deficiency	Causes Wernicke–Korsakoff: dementia, sight and muscular coordination problems, confabulations, and hallucinations
Thiamine (B3) Deficiency	Causes pellagra: dementia, diarrhea, and dermatitis
Selenium Deficiency	Studies have suggested that low selenium levels increase AD risk. ^{179,180} One study demonstrated a direct correlation between plasma selenium concentration and cognitive function. ¹⁸¹
Vitamin E Insufficiency	Numerous studies have associated low Vitamin E levels with AD, but the data is mixed. ^{182,183}
Copper Excess	Studies have shown free copper, not bound to ceruloplasmin, is increased in patients with AD and correlates negatively with cognition. ^{184,185} Dietary copper is in organic form and is processed by the liver to bind to ceruloplasmin. In contrast, inorganic copper from supplements and from unfiltered drinking water in areas where copper pipes are used can bypass the liver and enter metabolism as free copper readily delivered to and deposited in the brain. ¹⁸⁶
Zinc Insufficiency	Zinc intake has been thought to decrease available copper and may therefore have a protective role. In a recent systematic review, low zinc intake was attributed to AD risk. ¹⁸⁷
Vitamin D Deficiency	A meta-analysis of 37 studies found that adults with low serum vitamin D concentrations (<50 nmol/L) had poorer cognitive function and greater risk of AD than adults with higher vitamin D concentrations; AD patients have lower vitamin D concentrations than controls. ¹⁸⁸ More recently, a large cohort study found an increased risk of all-cause dementia and AD among elderly adults with low serum Vitamin D concentrations. ¹⁸⁹

Differentiating Normal Aging From Mild Cognitive Impairment or Alzheimer Disease

As the mature brain ages, its short-term ability to keep and use information normally declines. This results in cognitive changes such as forgetfulness, distractibility, and reduced efficiency in carrying out tasks.¹⁹ Distinguishing cognitive changes of normal aging from mild cognitive impairment (MCI) or AD is best achieved with specialized screening questionnaires. Screening takes time and skill, and is not routinely performed in busy primary care practices. As a result, an AD diagnosis is frequently delayed by several years until symptoms worsen.

Early diagnosis is also delayed because the presenting complaint is rarely “I am losing my memory,” even though family members may have this observation. Patients who personally complain of memory loss are not likely to have AD, although they may have MCI. MCI is different from AD in two critical aspects: patients with MCI have (1) normal overall cognition and (2) normal functioning per measures of Activities of Daily Living (ADL).

Most of patients are first seen for memory complaints by primary care providers. However, establishing a diagnosis of MCI or AD requires a comprehensive mental assessment and is better done in a memory clinic.

Screening

Due to the high prevalence of AD, regular screening is recommended for all adults aged more than 65 years,²⁰ although a screening frequency has not been defined. Several screening methods exist and as no data supports the superiority of one method over another, the choice may be determined by the operator’s comfort with each tool and the available time. The Mini-Mental State Examination (MMSE) has been the most popular; however, due to copyright issues, it can no longer be used without obtaining rights from the publisher, Psychological Assessment Resources (PAR). PAR claims that the various free, online versions of the MMSE are all derivatives of the original and thus copyrighted. The MMSE cannot be used to screen for MCI as its sensitivity for MCI is only 18%.²¹

The authors recommend having familiarity with two methods: Mini-Cog and Montreal Cognitive Assessment (MoCa). An abnormal score on either test signifies cognitive impairment and suggests a high probability of MCI or AD diagnosis.

Mini-Cog takes less than 5 minutes to implement. The test consists of three items, recall, and a clock draw. Scoring is either pass or fail; patients who miss two or more recall items or make any mistake on the clock draw are considered to have failed and should be referred for a more detailed cognitive assessment.

MoCa is a 30-point, 10–15-minute test somewhat similar to the MMSE, but it can be used for diagnosing both MCI and early AD. The patient’s total score can be tracked longitudinally as a measure of disease progression. MoCa was validated against the MMSE in 2005.²¹ A normal score is considered to be 26/30 or above; one point is added for patients with 12 or less years of education. Before initiating use of the MoCa with

patients, a practitioner should have a detailed understanding of the test's instructions and, ideally, have observed its administration by an experienced clinician several times.

Diagnosis

As with any other illness, diagnosis begins with the patient's story. If a comprehensive clinical query and the results of memory or neuropsychological testing provide suspicion of AD, they should be followed by physical examination, laboratory studies, and possibly neuroimaging to rule out reversible causes and to prepare an AD treatment plan.

Physical examination may reveal evidence of stroke, making vascular dementia more likely. While a physical exam is often unrevealing, functional assessment of the tongue, skin, and nails may reveal subtle evidence of vitamin and essential fatty acid deficiencies. Routine laboratory studies should include complete blood count, comprehensive metabolic panel, vitamin B12, folate, thyroid panel, and testing for syphilis and human immunodeficiency virus (HIV). Beyond these, the integrative practitioner may consider investigations for fasting glucose; hemoglobin A1c (HbA1c); free zinc and copper; high sensitivity C-reactive proteins; serum levels of pregnenolone, dehydroepiandrosterone (DHEA), and testosterone in both sexes; and a comprehensive nutritional assessment that may include an oxidative panel and fatty acid analysis. Patients with AD often have hormonal and nutritional abnormalities, as well as increased oxidative stress. There are a number of oxidative stress assays available. The authors prefer assessing reduced glutathione (GSH), lipid peroxides, coenzyme Q10, 8-hydroxydeoxyguanosine (8-OHdG), cysteine/cystine ratio, and superoxide dismutase (SOD). Total body lead or mercury is assessed only upon suspicion of toxicity from history, examination (i.e., multiple amalgams), or elevated oxidative stress. Testing for heavy metals using serum levels alone is likely to miss cases due to rapid sequestration from blood into tissues.²² Screening patients for the APOE4 gene remains controversial. Knowledge of a positive APOE4 status can provide motivation to make early lifestyle changes, but it may also cause psychological distress due to the high likelihood of developing AD.

Neuroimaging has become an adjunct tool for AD diagnosis despite the lack of clarity as to which tests should be done. Some prefer special positron emission tomography (PET) scans, others believe magnetic

resonance imaging (MRI) scans are more useful, and a combination of these has also been proposed ([Fig. 11.1](#)). Authors have not yet embraced routine neuroimaging. National Institute on Aging provides information on new genetic, laboratory, and imaging strategies for AD diagnosis.²³

FIG. 11.1 A, Longitudinal serial coronal magnetic resonance imaging (MRI) in patient with bvFTD, demonstrating increasing frontal and temporal atrophy after 1 year of symptoms; B, after three years of symptoms; C, after 7 years of symptoms; D, after 9 years of symptoms. *bvFTD*, Behavioral variant frontotemporal dementia. (From Peterson R, Graff-Radford J. Alzheimer disease and other dementias. In: Daroff RB, Jankovic J, Mazziotta JC, Pomeroy SL, eds. *Bradley's neurology in clinical practice* . 7th ed. Philadelphia, PA: Elsevier; 2016:1380-1421. Courtesy Bradley Boeve.)

Clinical Course

AD progresses slowly with an average life expectancy of 8–10 years from onset. However, since most patients are diagnosed several years into the disease, the time from diagnosis to death is often much shorter. After confirming the AD diagnosis and ruling out possibly reversible conditions, clinicians should focus on arresting or slowing down the decline, anticipating and palliating dementia-associated symptoms, and providing assistance to family and caregivers to help alleviate caregiver stress.

A number of rating scales have been designed to characterize a patient's level of dementia, predict life expectancy, and improve coordination among providers and caregivers. Clinical Dementia Rating (CDR) is a 5-point scale used to characterize six cognitive and functional areas, including memory, orientation, and personal care. The CDR requires substantial time to administer, yet it is reliable and increasingly

used in research and clinical settings.²⁴

The Reisberg Functional Assessment Staging Test (FAST) is a validated measure of AD course that is easy to use in clinical settings despite its complex scoring system.²⁵ The FAST scale is also used to assess eligibility for hospice. Hospice eligibility criteria require patients to have a life expectancy of 6 months or less; however, estimating how long AD patients will survive is challenging. The current AD hospice eligibility criteria (available at <http://alzonline.phhp.ufl.edu/en/reading/hospice.php>) has been criticized; some clinicians recommend referral for hospice evaluation when the patient's goals are consistent with those of hospice and their symptoms can no longer be adequately managed by caregivers.²⁶

Integrative Therapy

Given the numerous pathophysiologic factors of AD, it is not surprising that no monotherapy has been proven effective in stopping AD progression. A combination of therapies, however, may have important disease-modifying effects, according to anecdotal evidence. In a recently published case series, Bredesen describes a novel “therapeutic system” of diet and lifestyle changes which he prescribed to 10 patients (median age, 68 years) who had been diagnosed with AD, MCI, or subjective cognitive impairment. Nine patients experienced a halting and reversal of memory loss symptoms that had been progressing during the past 1–12 years. Six patients were able to return to work. The program consisted of 25 interventions—not all of which were followed by every patient—addressing key, scientifically based pathogenic mechanisms, for example, personalized stress reduction plans, an inflammation-minimizing diet, and fasting for at least 12 hours at night to enhance autophagy, known to reduce intracellular A β secretion. Approximately half of the interventions involved nutritional supplementation. These findings illustrate the potential for comprehensive AD treatment targeting multiple pathophysiological pathways, although they remain to be confirmed via clinical trials.²⁷

While no single treatment has been proven to halt AD progression, multidimensional therapies show promise for disease modifying effects.

Lifestyle Factors

Exercise

Aerobic exercise training has been associated with modest improvements in memory, executive function, attention, and processing speed in nondemented individuals.²⁸ In AD patients, exercise programs had a positive effect on cognition and ADL.²⁹

There are several proposed mechanisms for the effect of exercise on cognition. Exercise increased the gene expression of synaptic plasticity and mitochondria³⁰⁻³² and reduced extracellular amyloid proteins in the hippocampus and frontal cortex.³³ AD comorbidities such as hypertension and diabetes are better controlled with exercise. Exercise prescription for early AD should include a combination of aerobic, balance, strength, and stretching exercises practiced for 30–60 minutes per day four to five times per week. As the disease progresses, exercise should focus on balance and strength to prevent falls, sarcopenia, and contractures.

Cognitive Exercise

Cognitive exercises may slow cognitive decline or reduce the risk of dementia. A computerized mental activity training program including games improved cognition in older adults with cognitive complaints.³⁴⁻³⁶ Leisure activities including reading and playing board games or musical instruments also decreased dementia risk in the elderly.³⁷ There is no clear mechanism, but these activities might affect perceptual speed, accuracy, and attention. The amount or frequency of activity may be more strongly associated with cognitive improvement than the type of exercise.^{34,37}

Yoga and Tai Chi

Yoga and tai chi are mind-body practices that combine physical and cognitive exercises for stress-reducing effects. Healthy, elderly individuals who practiced yoga daily for 1 month and weekly for 3 months improved their immediate and delayed recall.³⁸ Among AD patients residing in a long-term care facility, yoga had no impact on cognitive function but improved physical health and reduced the symptoms of depression and agitation.³⁹

The series of slowly flowing circular movements, known as *tai chi*, is a martial art form that has been practiced for general health and well-being

in China.⁴⁰ A few studies have shown a decreased risk of cognitive decline and increased brain volume among tai chi practitioners.^{41,42} Tai Chi can be practiced alone or in groups. Like yoga, tai chi is reasonably safe when taught by experienced teachers, requires minimal equipment or space, and is inexpensive when offered in group format.

Optimizing Vascular Disease Risk Factors

A number of longitudinal studies in the elderly support the idea that reducing cardiovascular risk factors may also lower the risk of cognitive decline. In both the Honolulu Asia Aging Study (n = 6000 men) and an osteoporotic fractures study cohort (n = 9704 women), the risk of cognitive decline was relatively lower in individuals without diabetes, hypertension, smoking, excessive alcohol consumption, and poor social networks.^{43,44} Poorly managed hypertension in midlife increases the risk of subsequent dementia.⁴⁵⁻⁴⁷ Results of a large cohort study suggested that use of antihypertensive medications to control hypertension was associated with reduced dementia risk.⁴⁸

Optimizing Gut Health

Increased intestinal permeability is thought to be a common cause of systemic inflammation.⁴⁹ In addition, unhealthy changes in intestinal microbial flora, called *dysbiosis*, appear to be an independent factor contributing to inflammation.⁵⁰ While research linking these factors to AD has not yet been established, leading clinicians have proposed that optimizing gut health could improve brain function.^{51,52} The importance of gut flora in human health will grow quickly, especially with the help of the National Institute of Health (NIH) Human Microbiome Project.

Nutrition

A recent randomized clinical trial (RCT) compared a plant-based, low-fat diet with an antioxidant-rich Mediterranean diet that included mixed nuts (30 g per day) or olive oil (1 L per week) in 447 healthy, elderly volunteers. Over 3 years, those on the poly- and monounsaturated fat-supplemented diet experienced improved memory, frontal functions, and global cognition.⁵³ Like the antiinflammatory diet (see [Chapter 88](#)), a Mediterranean diet is thought to inhibit inflammation. Another recent trial evaluated the MIND diet—a hybrid of the Mediterranean and DASH (see [Chapter 89](#)) diets—in 900 elderly participants. Those who

followed a MIND diet had a 53% lower risk of developing AD. The Mediterranean diet also had a modest protective effect.⁵⁴ The MIND diet is relatively simple, allows a limited intake of animal-based food, and specifies consumption of berries and leafy greens, which have neuroprotective benefits according to animal and human studies ([Table 11.3](#)).

Intermittent Fasting

In addition to the aforementioned diets, authors advocate regular intermittent fasting. In recent years, studies have demonstrated that intermittent fasting has a number of beneficial effects of reducing oxidative damage and inflammation, optimizing energy metabolism and bolstering cellular protection. In AD animal models, regular caloric restriction has resulted in an improved clinical and pathological picture.⁵⁵ An easy way to practice intermittent fasting is to eat the last meal of the day 3 hours before bedtime, resulting in a 12-hour nighttime fast. If this results in patient waking up at night due to hypoglycemia, then mealtime may be gradually adjusted, allowing the patient to adapt to hypoglycemia and shift to ketogenesis, which is thought to be neuroprotective. Ketogenesis may also be enhanced by medium-chain triglycerides in form of 1 to 2 tablespoons daily of coconut oil or Axona medical food (described in the following section).

Omega-3 Fatty Acids

Omega-3 long-chain polyunsaturated fatty acids, including α -linolenic acid (ALA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA) play essential roles in cell membrane viscosity and in antiinflammatory processes. Humans can synthesize DHA and EPA from ALA. While EPA is antiinflammatory and modulates membrane fluidity and neuronal synaptic plasticity, DHA is the most abundant membrane lipid.⁵⁶ Most epidemiological data clearly demonstrates that increased fish intake lowers the risk for AD development.⁵⁷ However, randomized trials of fish oil supplementation have generally failed to produce positive effects on AD prevention or progression.^{58,59} Similarly, studies of isolated high-dose DHA (2 g per day) have not shown a benefit.⁶⁰ In healthy adults > 65 years, a higher dietary intake of omega-3 polyunsaturated fatty acid was associated with a lower level of plasma amyloid beta ($A\beta$) 42, which is linked with a reduced AD risk.⁶¹

TABLE 11.3**Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) Diet**

Foods to Consume More of	Foods to Avoid or Decrease
Whole grains at least three servings per day	Red meats and red meat products less than four times per week
Green leafy vegetables at least six times per week	Fast/fried food less than once per week
Other vegetable at least one per day (red-orange vegetables preferred)	Butter, margarine less than 1 tablespoon a day
Berries at least twice a week	Cheese once per week or less
Fish at least once a week	Pastries and sweets less than five times per week
Poultry at least two times per week	
Beans at least three times per week	
Nuts at least five times per week	
Olive oil as your primary oil	
Alcohol/wine once per day	

Key components of diet for AD prevention and treatment include the following:

1. Low-glycemic index diet.
2. Reduction of proinflammatory foods such as red meat, dairy, and sugar.
3. High amounts of fresh fruits and vegetables including high antioxidant foods such as berries, turmeric, and green tea.
4. High amounts of foods rich in omega-3 fatty acids.
5. Overnight fasting to promote ketogenesis.

Mind-Body Techniques

Chronic Stress

Persistent stress is thought to be a cause of many chronic diseases. Memory function is influenced by stress too. Acute or temporal stress may positively affect stimulus-induced neuroplasticity, while persistent stress impairs synaptic activity.⁶² The hypothalamic-pituitary-adrenal (HPA) axis is a central system in stress-mediated processes. Activation of the HPA axis by stress triggers rapid secretion of corticotrophin releasing hormone (CRH) from the paraventricular nucleus (PVN) of the hypothalamus. This influences the release of adrenocorticotrophic hormone (ACTH) from the anterior pituitary, which induces the adrenal

gland to release cortisol (see [Chapter 94](#)). Cortisol induces stress adaptation in many organs. It also provides negative feedback inhibition to the HPA axis via activation of glucocorticoid receptors in the PVN, amygdala, and hippocampus.⁶² HPA axis dysfunction has been shown to contribute to AD risk in many studies; however, a clinically measurable link, for example with cortisol levels, has failed to produce clear results and is generally not used in practice. A large population-based cohort study showed no relationship between morning serum cortisol levels and cognitive function and annual cognitive decline.^{63,64} The dexamethasone suppression test was assessed but not found clinically useful for AD.^{65,66} Salivary cortisol level changes from morning to evening were associated with AD and smaller hippocampal volumes.^{67,68} It has been proposed that persistently elevated cortisol is directly involved in memory impairment by irreversible hippocampal damage. Decreased hippocampal volume has been observed in patients with Cushing disease, and in one study, hippocampal volume increased after successful treatment of that disease.^{69,70} Cortisol blocks glutamate uptake by the glial cell, causing increased accumulation of glutamate in the synapses and activating N-methyl-D-aspartate (NMDA) receptors, resulting in an influx of calcium into the postsynaptic neuron. Excessive cytosolic calcium increases oxidative stress thought to cause neuronal death.⁷¹

Meditation

Clinical trials have suggested the benefits of meditation as nonmedical intervention for dementia treatment. Transcendental meditation and mindfulness training, practiced twice daily for 20 minutes, improved cognitive flexibility, memory, and verbal fluency in elderly subjects at 12 weeks.⁷² In a small, nonrandomized study, 8 weeks of a meditation practice called *kirtan kriya* was shown to improve cognitive function and cerebral blood flow in patients with MCI. Kirtan kriya takes about 12 minutes and consists of breathing, finger movement, and the chanting of primal sounds.^{73,74} Tibetan sound meditation daily for 6 weeks improved verbal memory, short-term memory, and processing speed in adults suffering drug-induced cognitive impairment.⁷⁵ Mindfulness-based stress reduction programs have not been studied in AD, but may be well-suited for prevention given their success for stress reduction. The choice of mind-body modality will likely be based on local resources and the preferences of the patient and practitioner (see [Chapter 100](#)).

Sleep

Seven to eight hours of good quality sleep is recommended for AD patients. Sleep apnea should be excluded or treated. Melatonin use (described in the following section) can be helpful for AD patients with insomnia.

Vitamins and Minerals

B Vitamins

Frank deficiency of vitamin B12 can cause pseudodementia or pseudodepression and is common in the elderly. We recommend a serum level above 500 pg/mL. Alternatively, intracellular B12 levels may be assessed by some functional labs such as Genova and Spectrocell.

While there are no clear guidelines regarding B vitamin and dementia, the authors advocate the use of activated forms of B12 and folate: methylcobalamin and 5-methyltetrahydrofolate (5MTHF) often called *L-methylfolate*. One strategy is to use a therapeutic B complex with high doses of activated B12 and 5MTHF.

Dosage

The authors usually use 1000 mcg of methyl B12 and L-methylfolate per day, with doses ranging between 200 mcg and 10,000 mcg of each.

Precautions

When supplemented with methylcobalamin, patients with COMT SNPs are at increased risk of side effects of anxiety or agitation due to higher levels of dopamine and norepinephrine. This can often be mitigated with hydroxy or adeno B12 or decreasing dose of methyl B12. B complex is better taken in the morning to avoid sleep disruptions in sensitive patients. In addition to prescribing activated B vitamins, the authors recommend avoiding synthetic folic acid in patients with dementia unless a negative MTHFR status is reported. Data supporting the negative effects of unmetabolized folic acid is slowly growing.⁷⁶

Consider testing all AD or MCI patients for MTHFR SNPs and if positive for either A1289C or C677T use methylfolate (1–10 mg) and avoid synthetic folic acid.

Vitamin E and C

Investigation of vitamin E as a treatment for AD has produced conflicting results. While some trials found cognitive and functional benefits with high dose synthetic α -tocopherol (2000 IU per day), a meta-analysis and Cochrane Review each concluded that there is no clear clinical benefit of high-dose vitamin E and that it should not be used for AD or MCI.⁷⁷⁻⁸¹

Unless nutritional testing indicates vitamin C or E deficiency, we recommend that patients obtain adequate doses from dietary sources including fruits, nuts, and vegetables.

Interactions of different phytochemicals with vitamin C and E and other antioxidants likely provide additional beneficial effects.^{82,83} A multivitamin or antioxidant formula should provide mixed tocopherols to contain all eight natural isoforms (instead of synthetic α -tocopherol) with a daily dose of 200–400 IU of vitamin E and 500–1000 mg of vitamin C.

Vitamin D

We recommend assessing vitamin D status in all patients with AD and optimizing and maintaining serum Vitamin D 25 OH levels at 40–60 ng/mL.⁸⁴ Vitamin D supplementation (of at least 800 IU) has been shown to reduce the risk of falls.⁸⁵

Selenium

Brazil nuts have a high concentration of selenium (Se), and two Brazil nuts daily are the recommended source.^{86,87} Since the levels of selenium in Brazil nuts can vary from 8–83 mcg/g, overdose is possible and patients should be advised accordingly. A typical supplemental dose of selenium is 100–200 mcg.

Zinc and Copper

We recommend free zinc and copper assessment for all patients with AD. In the case of zinc, targeted high normal range is reasonable, which may require supplemental doses of 15–50 mg per day. With copper the reverse is true, and the aim is to keep patients at a low normal or even just under normal levels by removing all supplemental forms of copper, filtering water, or using high-dose zinc and alpha-lipoic acid in an attempt to lower the copper level. There is no need to limit copper rich foods as organic forms of copper contribute little to elevate free copper

levels.

Multivitamins in Alzheimer Disease

For supplementation of patients with a poor diet or documented nutritional deficiencies, follow these guidelines:

- No additional copper and iron
- Natural forms of vitamin E 200–400 IU—mixed tocopherols
- Methylated forms of folate—at least 400 mcg
- Activated forms of B12—methyl, hydroxy, or adeno B12—at least 500 mcg
- Zinc at least 15 mg
- Selenium 100–200 mcg

Supplements

Acetyl-L-Carnitine

Acetyl-L-carnitine (ALCAR) is synthesized in the human brain, liver, and kidney; it facilitates fatty acid oxidation, enhances acetylcholine production, and stimulates protein and membrane phospholipid synthesis.⁸⁸ In mild cognitive impairment and mild AD patients, the result of a meta-analysis revealed a significant advantage for ALCAR compared to placebo in daily doses of 1.5–3.0 g.⁸⁹ However, a Cochrane Review has not found it to be effective.⁹⁰ ALCAR appears to increase nerve growth factor (NGF), which is thought to be important for neuronal survival.⁹¹

Dosage

Typical daily dose is 2–3 g.

Precautions

Side effects are uncommon, but it can include bloating, abdominal cramps, and particular body odor.

Omega-3 and Fish Oil

Unless a diet is very high in oily fish, the authors recommend supplementation with omega-3 fatty acids. Fish oil appears to be the easiest to obtain, and as long as purification is adequate, it should remove most of contaminants, including mercury. Fatty acid analysis is currently available, and its utilization for patients with AD could be useful; the authors have found that identifying patients with decreased Delta 6 desaturase activity can help balance fatty acids by increasing intake of gamma-linolenic acid through usage of borage, evening primrose, or black current oils. One long-term strategy could be providing a 4:1 Omega-6:3 balanced supplement with at least 1 g of DHA/EPA.

Dosage

The typical dose is 1–3 g per day of combined DHA/EPA, and at least 50% should be DHA. We often use a 2:1 DHA:EPA ratio.

Precautions

Doses greater than 4 g per day may have a prooxidant effect.

Coenzyme Q10

Coenzyme Q10, a powerful neuroprotective agent, works as a dynamic antioxidant. It is present throughout the brain cell membrane and mitochondria, where it is involved in the production of high-energy phosphate compounds.⁹²

Dosage

Conversion of ubiquinone to ubiquinol is not universal and thus we prefer use of ubiquinol at 100–200 mg daily.

Precautions

Mild gastrointestinal symptoms can occur with 300 mg per day. It can also elevate serum aminotransferase level.

Alpha-Lipoic Acid

Alpha-lipoic acid (ALA) is a natural compound synthesized in the mitochondria.⁹³ It is believed to induce the oxidative stress response rather than directly act as a free radical scavenger.⁹⁴ In addition to inducing the antioxidant system, ALA has been shown to improve glucose handling, increase eNOS activity, and activate Phase II detoxification via the transcription factor Nrf2. ALA also has been proposed to have a chelation effect in the brain on iron and copper.

Dosage

Taking 600 mg ALA daily for 2 years or a combination of omega-3 and ALA for 1 year slowed down progression of cognitive decline in AD patients.⁹⁵ We routinely use 600 mg 5 days a week, taken with food.

Precautions

Because ALA is rather acidic, it can irritate gastric mucosa and should be taken with food.

N-Acetylcysteine and Glutathione

As a glutathione (GSH) precursor, N-acetylcysteine (NAC) has been recently proposed to have an important role in prevention and treatment of AD. Thus it plays an essential role in antioxidant defense and detoxification.⁹⁶ NAC does not require an active transporter and can easily cross cell membranes leading to intracellular GSH production.⁹⁷ The capacity of NAC to cross the blood-brain barrier has been debated for years, but more recent data seems to suggest that it can indeed cross.⁹⁸ A number of studies have shown low neuronal GSH levels in patients with AD.⁹⁹⁻¹⁰¹ In addition to a number of animal model studies, one human RCT showed a possible positive effect on patients with AD.¹⁰² In addition, NAC is a component of several medical foods discussed in the following section, which are trending towards overall benefit. NAC has been used safely in traditional settings, for example, in acute acetaminophen overdose. Intravenous use of NAC or GSH is safe, but expensive and inconvenient. In the past, oral forms of GSH have not been shown to be well absorbed and able to reach the brain. This has been recently changing since introduction of liposomal and other more bioavailable oral and topical forms.

Dosage

The authors recommend using NAC at 500–1000 mg per day taken 5 days a week.

Precautions

NAC is well tolerated with occasional intestinal side effects.

Botanicals

Huperzine A

Huperzine A is a natural anticholinesterase inhibitor derived from Chinese club moss. A recent meta-analysis, which included 20 RCTs and almost 2000 patients showed positive results on cognitive function and ADLs in patients with AD; however, most of the studies were of poor methodological quality.¹⁰³ One recent U.S. based RCT showed slower cognitive decline in patients with AD, but only with the higher dose of 400 mcg twice daily.⁴⁶ In addition to anticholinesterase inhibition, huperzine A may have neuroprotective effects that are, as of yet, not well characterized. In 1994, huperzine A was approved by State Food and Drug Administration of China for AD therapy.¹⁰⁴

Dosage

The authors favor the use of huperzine A in patients who would like to try anticholinesterase inhibitor medications but have developed side effects. The dose is 100–400 mcg twice daily.

Precautions

Generally, Huperzine A is better tolerated than anticholinesterase inhibitor drugs, but side effects increase proportionally to dose, with intestinal symptoms being most common. It is important to note the relative contraindication of combining Huperzine A with any anticholinesterase inhibitor medications due to a higher risk of side effects.

Turmeric and Green Tea

Both turmeric and green tea are food-based antioxidants and are consumed in variable amounts in different populations; they have been suggested as possible therapeutic agents for AD. While a number of epidemiological studies show lower risk of dementia in populations consuming high doses of turmeric or green tea, clinical studies are lacking. Given that both foods are recommended as part of an antiinflammatory diet, the authors recommend using them in liberal amounts as foods. Drug interactions at food-based dosages are not common, and both herbs are typically well tolerated; although they can trigger intestinal irritation if taken in larger amounts.^{105,106} While epidemiological data for turmeric and green tea being linked to a lower risk of dementia is clear, data on black tea or coffee consumption has provided mixed results.^{107,108} Matcha, a powdered form of green tea, is more potent, does not require steeping, and can be mixed with hot or cold water or with other foods. The authors recommend one teaspoon daily in divided doses. Dietary turmeric should be cooked with an oil to enhance absorption. Recipe books on cooking turmeric to maximize its health benefits are available.

Hormones

Dehydroepiandrosterone and Pregnenolone

The adrenal prohormone dehydroepiandrosterone (DHEA) may provide anticortisol effects against the hypercortisolism observed in AD patients.¹⁰⁹ Hippocampal perfusion had a positive correlation with plasma DHEA.¹¹⁰ However, in a clinical trial of patients with AD using a high DHEA dose, 50 mg twice daily for 6 months, improved cognitive performance was not reported.¹¹¹ The same result was observed in healthy elderly women who took 50 mg per day oral DHEA for 1 year.¹¹²

Dosage

Usual doses of DHEA and pregnenolone are 10–100 mg per day.

Precautions

While routine supplementation is not warranted, the authors recommend assessing DHEA and pregnenolone levels, and using appropriate supplementation if needed. Side effects are not expected if

levels are maintained within normal range.

Melatonin

Low nocturnal melatonin levels and disturbed circadian melatonin rhythms were observed in MCI and AD patients.¹¹³ In healthy elderly, a 1-mg melatonin supplement improved cognitive function and sleep.¹¹⁴ Cognitive function was improved in AD patients who took melatonin 3 mg per day for 4 weeks.¹¹⁵ Prolonged-release 2-mg melatonin supplement for 6 months improved cognitive function and insomnia in mild to moderate AD patients.¹¹⁶ Recently, a meta-analysis of AD patients reported that melatonin (up to 10 mg) nightly over 4 weeks prolonged total sleep time and sleep efficacy, but did not improve cognitive function.¹¹⁷ Melatonin improved agitation symptoms in dementia patients through the reduction of circadian rhythm disturbance.¹¹⁸

Dosage

Typical bedtime dose ranges from 0.5–10 mg.

Precautions

To avoid the most common side effect, that is, excessive daytime sleepiness, the authors usually recommend starting with low dose of 0.5–1 mg and increasing gradually.

Therapies to Consider

Medications (Table 11.4)

Four FDA-approved medications are prescribed to treat the cognitive symptoms of AD. All have neurotransmitter-based effects by either boosting available acetylcholine via acetylcholinesterase inhibition or by antagonizing NMDA-dampening excitatory neurotransmitters.

Long-term use of medications with anticholinergic side effects (lower acetylcholine) have been associated with an elevated risk of dementia.^{123,124}

Data on the effectiveness of these medications is limited. While all agents had a statistically significantly delayed symptom progression in 6-month trials, the effects were small—about 2 or 3 points on the ADAS-Cog Scale (the scale range is 0–70; a higher number indicates a greater cognitive impairment)—and of questionable clinical significance.^{125,126} Donepezil is the only FDA-approved medication shown to be effective at 12 months, and patients did not show improvement after 12 months.¹²⁷

The authors prescribe medications only in some cases after detailed discussion with the patient or family. The new high-dose formulation of donepezil (23 mg nightly) has been gaining momentum; however, side effects appear to be more frequent than with the lower dose (10 mg nightly or daily).¹²⁸ Fortunately, there appear to be few clinically significant interactions between commonly used AD nutritional supplements and medications. Alkalinizing agents that increase urine pH may decrease clearance of memantine and lead to drug overdose. Ginkgo, commonly used for memory loss, has a theoretical interaction with liver-metabolized cholinesterase inhibitors, but in a randomized controlled trial of 96 subjects with AD, the combination of donepezil and ginkgo had fewer side effects than donepezil alone.¹²⁹

TABLE 11.4
Medications

Category	Name (Brand)	Approved for (Stage)	Major Side Effects	Comments
Acetylcholinesterase inhibitors	Donepezil (Aricept)	All stages	Bradycardia/heart block, gastrointestinal bleeding, syncope, nausea, diarrhea, headache	5–10 mg once daily
	Rivastigmine (Exelon)	Mild to moderate		9–12 mg PO or patch
	Galantamine (Razadyne)	Mild to moderate		10–24 mg once daily
N-methyl-D-aspartate (NMDA) antagonist	Memantine (Namenda)	Moderate to severe	Dizziness, headache, fatigue, diarrhea, constipation, usually well tolerated	5–10 mg twice daily

In addition to Alzheimer-specific medications, most dementia patients with moderate to severe disease are eventually prescribed several medications to manage psychological and behavioral problems including depression, anxiety, agitation, and altered circadian rhythm. Selective serotonin reuptake inhibitors (SSRI) antidepressants are among the most common. The most concerning class of medications used frequently in patients with AD is antipsychotics, both older ones such as haloperidol and newer such as risperidone. While these medications can control agitation, they have severe side effects such as delirium and increased mortality.^{130,131} Therefore the authors recommend the following integrative approaches as a first line of treatment for psychological and behavioral problems in patients with AD.

Role of Integrative Therapies for Management of Behavioral Problems

Music

Music is a beneficial intervention in stress-related disorders. Music has been shown to reduce cortisol levels in salivary samples.¹³² In dementia patients, music has potential positive effects on agitation and anxiety.^{133,134} Music therapy combined with physical exercise or recreational activity also showed a positive synergistic effect in patients with AD.^{135,136}

Animal-Assisted Therapy

Animal-assisted therapy (AAT) has been getting attention as a stress-reducing intervention that enhances well-being.¹³⁷ In a pilot study, AAT for 3 weeks reduced agitation and increased social interactions in patients with AD.¹³⁸ Similarly to music, AAT has been increasingly utilized in nursing homes and assisted living facilities. There is hope that this will translate to lower use of medications.

Reiki

Reiki offers light touch to patients and is believed to reduce stress and stimulate self-healing by optimizing autonomic nervous system and HPA axis. Reiki appears to reduce stress, anxiety, and pain in dementia patients.¹³⁹ Caregivers can be easily taught delivering Reiki to patients. One of the authors (MK) assisted in implementing longitudinal Reiki program at a local retirement community, where an integrative team provides Reiki sessions and teaches self-Reiki to staff and residents. A number of treated residents had AD. The program has been well accepted, and our unpublished data showed that some patients and staff members had less anxiety and better life satisfaction. However, we did not assess cognition or observed any functional improvements.

Assisting Caregivers

Dr. Elizabeth Cobbs, one of the most distinguished geriatricians stated, "Supporting and guiding the caregiver may be one of the most powerful 'treatments' we have." If despite the most aggressive care measures, a patient with AD continues to decline, caregiving needs are likely to escalate. Chronic caregiving burden results in poor quality of life,

increased risk of acute myocardial infarction, and death.¹⁴⁰⁻¹⁴³

Creating an effective assistance program has proven to be a difficult task, with numerous systematic approaches attempted.¹⁴⁴ While no good answers on the best strategy exist, it is clear that integrative practitioners are well positioned to advocate and teach caregivers self-care. Assuring good sleep, regular exercise, good nutrition, and ongoing social interactions is critical as often all these get disrupted. Logistical support can consist of number of things, including coordinating short-term respite care and covered benefit under hospice so that caregiver can take time off. Educating about AD progression and steps that should be taken at each stage is critical and best started as early as possible. Mind-body approaches such as yoga, meditation, and a Mindfulness-Based StressReduction (MBSR) program recently have been shown to be effective for decreasing caregiver stress and improving mental health.^{145,146}

Spirituality

In the prior edition of this chapter, Dr. Dharma Singh Khalsa elegantly summarized the importance of spirituality below.

“Beyond reported improvements in memory, concentration, learning ability, and activities of daily living, patients enrolled in an integrative medical program for cognitive enhancement also note positive changes in what can be described as personal awareness. This awareness sometimes appears as a sense of increased self-knowledge or what many people call spirituality and leads to a feeling of connectedness. Some patients report that this spiritual connection leads to a profound level of wisdom: the combination of age, intelligence, and experience. This wisdom, or maturity, brings greater life satisfaction. These changes are consistent with the work of Benson, Larson, and Matthews, who established that an integrative medical program, including mind-body interactions, enhances spirituality. Spirituality was expressed as experiencing the close presence of a higher power. A preliminary study presented by Dr. Yaku Kaufmann at the 2005 American Academy of Neurology meeting demonstrated that patients with AD who lived a rewarding spiritual lifestyle had slower progression of their illness. This lifestyle was defined as being connected with a spiritual presence in life, whether it took the shape of a family member, close friend, support network, meditation, yoga, or prayer.”

Medical Foods

Over the last decade, numerous medical foods claiming efficacy in dementia have appeared. These are Axona, CerefolinNAC, and Souvenaid.¹¹⁹ Each works differently and all require prescription. Axona and CeferolinNAC are available in United States, but not Souvenaid.

Axona is a form of medium-chain triglycerides (MCT) made of glycerin and caprylic acid. Like all other MCTs, Axona is thought to induce ketogenesis providing ketone bodies to the brain, which is thought to represent a better energy source for the brain as compared to glucose, leading to optimized mitochondrial electron transport. Axona manufacturer, *Accera* has published a single phase II, double-blind, randomized trial of 152 patients showing statistically significant positive result of clinically borderline significance.¹²⁰ Axona is taken once daily as a powder mixed with water. Intestinal side effects, mostly gas and diarrhea, are common. The cost of Axona is about \$120 per month.

CerefolinNAC is a combination of methylcobalamin 2 mg (B12), L-methylfolate 6 mg and N-acetylcysteine (NAC) 600 mg. It is approved by the U.S. Food and Drug Administration (FDA) for the treatment or prevention of vitamin deficiencies associated with memory loss. The main advantage of CerefolinNAC is once daily dosing in one tablet; however, it does not offer flexibility in dosing of the previously listed nutrients. The cost of CerefolinNAC is about \$120 per month. The total cost of each ingredient is a less than that of CerefolinNAC, but the dosages are different.

Souvenaid is designed to promote synaptic formation and function.^{121,122} Souvenaid contains uridine monophosphate; choline; phospholipids; EPA; DHA, vitamins E, C, B12, and B6; folic acid; and selenium. It is the most comprehensive formula targeting acetylcholine deficiency, integrity of neuronal membranes, resistance to oxidative stress, and optimal metabolic activity in the brain.^{121,122} Several recent clinical trials have shown conflicting results.^{121,122} It is not currently available in the United States.

Ginkgo biloba

Although *Ginkgo biloba* has been previously advocated for use in dementia, recent studies reported negative outcomes.¹⁴⁷⁻¹⁴⁹ Despite these negative results, ginkgo clearly has a role in improving microvascular circulation and scavenging free radicals.¹⁵⁰ Authors do not routinely recommend using ginkgo. It may have benefits for patients with a vascular component with history of heart disease, diabetes, transient ischemic attacks, or strokes. Theoretically, ginkgo's risk of increased

bleeding in patients taking Coumadin is probably not clinically significant; however, caution is advised by close monitoring of INR.

Magnesium-L-Threonate

In animal experiments, oral magnesium-L-threonate supplements elevated brain magnesium levels and produced synaptoprotective effects in the hippocampus, including upregulated NMDA receptor signaling and inhibition of TNF- α overexpression. The supplement enhanced short-term synaptic facilitation and long-term potentiation in normal rats and restored deficits in short-term memory and LTP in rats with spared nerve injury.^{151,152} In a mouse model of AD, oral magnesium-L-threonate prevented NMDA receptor downregulation, synapse loss, and memory decline.¹⁵³ Compared to controls, rats treated with the supplement had an improved ability to distinguish between fear contexts and reduced generalization of fear.¹⁵⁴

L-Alpha-Glycerolphosphorylcholine, Cytidine 5'-Diphosphocholine, and Phosphatidylcholine

Numerous studies have clearly demonstrated the critical importance of adequate dietary choline consumption and that low dietary choline consumption in childhood negatively affects brain development.¹⁵⁵ Phosphatidylcholine (PC), a phospholipid integral to cell membranes, has been more recently tapped as a possible agent for enhancing memory and treating dementia by enhancing a generation of new synapses. Several recent studies have shown that PC improves memory in subjects without memory impairments.^{156,157} More recently, novel forms of PC analogues, such as L-Alpha-glycerolphosphorylcholine (alpha GPC) and cytidine 5'-diphosphocholine (CDP-choline), have become available. In contrast to PC, these are water-soluble and have a faster rate of absorption.

Alpha GPC is an actual PC metabolite that in addition to being excellent source of choline, boosts acetylcholine production as well. Daily intake of 1200 mg of semisynthetic derivative of PC alpha GPC has been shown in one RCT to improve all studied measures including MMSE over course of 3 and 6 months. No significant side effects have been reported.¹⁵⁸

CDP-choline, an endogenous molecule and direct PC precursor, with all benefits on PC and additional protective effect on dopaminergic neurons, is approved for strokes, Parkinson's disease, and other

neurological disorders in Japan and Europe, where it is sold under brand name Citicoline. Multiple RCTs using CDP-choline were performed, mostly for vascular dementia. A 2005 Cochrane Review concluded that there is some evidence for positive effect despite mostly short-term and heterogeneous studies.¹⁵⁹

PC, alpha GPC, and CDP-choline have not been compared side to side or tried in combinations, making it impossible to evaluate which, if any, of these products are preferred. A 2009 Cochrane Systematic Review concluded that there is no obvious benefit of lecithin or PC choline precursors in patients with AD, but due to one study showing strong results, the review concluded that larger studies are needed and moderate benefit can indeed exist.¹⁶⁰

Intravenous Immunoglobulin Therapy

Intravenous immunoglobulin therapy (IVIG) is a mix of antibodies derived from plasma of healthy donors. IVIG has been used to treat diseases for more than 30 years. It is FDA approved for use in treating several disorders. IVIG is administered intravenously every 2–4 weeks. The initial interest regarding this treatment for use in AD surfaced in 2003 when decreased levels of free antibodies against beta-amyloid in the blood of patients with AD were found.¹⁶¹ Findings from a recent large phase III trial were disappointing. Primary outcomes were not statistically different from the placebo arm, despite some positive secondary outcomes in some subgroups.¹⁶² Side effects have been described, mostly mild, but have included hypertensive crisis and even stroke, presumably due to increased blood viscosity.

Prevention Prescription

- Antiinflammatory, Mediterranean, or MIND diets, high in omega-3, with a low glycemic index
- Regular high intake of high antioxidant foods such as green leafy vegetables, turmeric, berries, and green tea
- Patients who prefer a low-fat diet can choose to take oil supplements such as olive, sunflower, safflower, or fish oil.
- Mind-body practices to manage stress, 15–30 min per day
- Regular physical and cognitive exercises
- Advocate building strong social support system to avoid isolation

later in life.

- Optimize vascular risk factors: avoid smoking, excessive alcohol use, obesity, prevent or if not possible control hypertension and diabetes.
- Consider high-quality methylated B vitamin complex supplementation for patients aged more than 65 years.

Therapeutic Review

Address Systemic Issues

- Chronic stress 
- Insulin resistance
- Nutritional deficiencies or insufficiencies
- Methylation defects
- Oxidative stress and inflammation
- Increased intestinal permeability and dysbiosis
- Sleep apnea
- Toxic exposures
- Cardiovascular comorbidities such as hypertension

Nutrition

- Antiinflammatory, Mediterranean, or MIND diets, high in omega-3 with a low glycemic index 
- Regular high-intake of high antioxidant foods such as green leafy vegetables , turmeric,  blueberries and other berries , and matcha green tea 
- One to two tablespoons daily of high-quality coconut oil 
- Night time 12-hour fasting 

Exercise

- Recommend exercise regardless of disease stage 
- For early stages—combination of physical and cognitive exercises (e.g., yoga, tai chi) 

- Aggressive physical therapy for later stages 

Mind-Body and Behavioral

- Meditation: kirtan kriya , Tibetan sound meditation, , and other mind-body methods
- Recommend, regardless of disease stage—late stages use music , pet therapy , and Reiki 

Supplements

- Acetyl-L-carnitine: 2–3 g per day
- Alpha-lipoic acid: 300–600 mg per day 
- N-acetyl cysteine: 500–100 mg per day 
- Fish oil: 1–3 g per day of combined DHA/EPA, at least 50% should be DHA 
- Huperzine A: 100–400 mcg per day in twice daily dosing. Do not combine with cholinesterase inhibitors. 
- Methylated B complex: once per day (unless part of multivitamin) 
- Multiantioxidant (could be multivitamin) if poor diet, see Note Box. 
- Vitamin D (to maintain serum level of 40–60 ng/mL) 
- Ubiquinol (activated coenzyme Q10) 50–100 mg per day 

Hormones

- Assess DHEA and pregnenolone levels and if low use the following:
 - DHEA: 10–100 mg per day 
 - Pregnenolone: 10–100 mg per day 
- Melatonin: 0.5–10 mg at bedtime. It can help with both sleep and nighttime agitation 

Medications

- Discuss risks and benefits—if decision is to proceed, monitor for side

effects

- Memantine: start with 5 mg in the morning and slowly increase to 10 mg twice daily 
- Donepezil: start with 5 mg every night and increase to 10 mg every night in 4–6 weeks. 

Team Building

- Hospices and home care agencies
- Therapists providing physical therapy and occupational therapy, yoga instructors, and tai chi teachers
- Geriatric case managers
- Medical house calls programs at <http://www.aahcm.org>.

CHAPTER 12

Headache

Remy R. Coeytaux, MD, PhD, and John Douglas Mann, MD

Headache is one of the most common complaints that brings a patient to the attention of health care providers.¹ Ninety percent of all headaches are either migraine, with or without aura; tension-type headache (TTH); or a mixture of the two. Sixteen percent of adult women and 6% of men suffer from migraine.² The remaining 10% of headaches seen by caregivers are secondary to disorders of the tissues of the head and neck, including the cervical spine, sinuses, temporomandibular joints, and dental structures and soft tissue trauma and posttrauma, with primary tumors, infection, and metastatic cancers constituting a small fraction of the possible causes.

“Red flag” symptoms of life-threatening disorders include early morning headaches that awaken the patient; visual dimming or double vision; headaches that are increasing in frequency or severity over weeks to months; headaches made significantly worse by postural changes; explosive onset of new, severe head pain; and headaches associated with mental status changes, focal motor or sensory deficits, syncope, seizures, fever, or stiff neck. Headaches in the setting of systemic illness, weight loss, human immunodeficiency virus (HIV), or known malignancy clearly require thorough investigation. Findings on examination that prompt further diagnostic workup include focal neurological signs, evidence of head or neck trauma, temporal artery tenderness, papilledema, nuchal rigidity, fever, and physical evidence of local or systemic infection or malignancy.

Clinical guidelines are available for pharmacological prevention and treatment of migraine³⁻⁵ and tension-type headache.⁶ The emphasis in this chapter is on nonpharmacological, behavioral, nutritional, and complementary therapies that are effective in the treatment or prevention of migraine and tension-type headache.

Migraine Pathophysiology

Characteristics typical of migraine include subacute onset of throbbing head pain (unilateral or bilateral) associated with nausea and vomiting, photophobia, and sonophobia. Headaches are heralded by visual or other nonpain premonitory symptoms (auras) in about 20% of those with migraine. The duration is usually more than 4 hours and may last up to 72 hours with fluctuating intensity.⁷ The precipitating factors can include menses, specific foods, stress or letdown following stress, changes in the weather, infection, fatigue, and bright sunlight.

While the origin of migraine pain is not fully understood, recent evidence points to a role for potent vasodilators, such as substance P and calcitonin gene-related peptide (CGRP), released by peripheral nerve endings of cranial nerve V on blood vessels in the scalp and meninges⁸ (Fig. 12.1). This leads to sterile inflammation and edema of blood vessels, with increased sensitivity to mechanical stimulation, resulting in pain. Glutamate, nitric oxide, and vanilloid receptors are also implicated in migraine. Translation of this information to therapy is very active. For instance, CGRP receptor antagonists are currently in phase III clinical trials.^{9,10} In the periphery, release of serotonin by platelets in the early stages seems to increase pain and prolong the headache. Centrally, the presence of a “headache generator” in the midbrain and pons is supported by findings from positron emission tomographic studies obtained during migraine attacks. Genetic influences are evident in a majority of patients with one or more family members experiencing migraine. Although the individual attacks of migraine are often stereotypic, variation is not uncommon and comorbid TTH is frequent.

Patients with migraine often suffer from tension-type headaches (TTH) and other forms of headache. A carefully recorded history of headache symptom characteristics helps establish criteria that lead to diagnoses and helps highlight distinctions that guide specific therapies.

The following sections describe complementary approaches that are potentially useful for integration with conventional therapies in the treatment of migraine (Table 12.1). Conventional approaches rely heavily on pharmaceutical interventions to prevent or abort headaches and are usually prescribed with analgesics and antiemetics. Although these measures are by themselves generally effective in the management of

symptoms, they are often expensive; come with significant side effects; and do not address the underlying physical, psychological, and energetic issues that lead to headache. Patients with headache currently use a variety of alternative and complementary therapies,¹¹ many of which will be reviewed in this chapter.

Integrative Therapy

Lifestyle

Effective management of migraine requires a careful assessment of lifestyle issues related to sleep, nutrition, exercise, stress management, and relationships. Regularizing meal times, developing an exercise routine, and correcting poor sleep can significantly reduce the frequency of migraine.^{12,13} Sleep hygiene guidelines are readily available, easy to implement, and often lead to a decrease in both duration and frequency of migraine.¹⁴

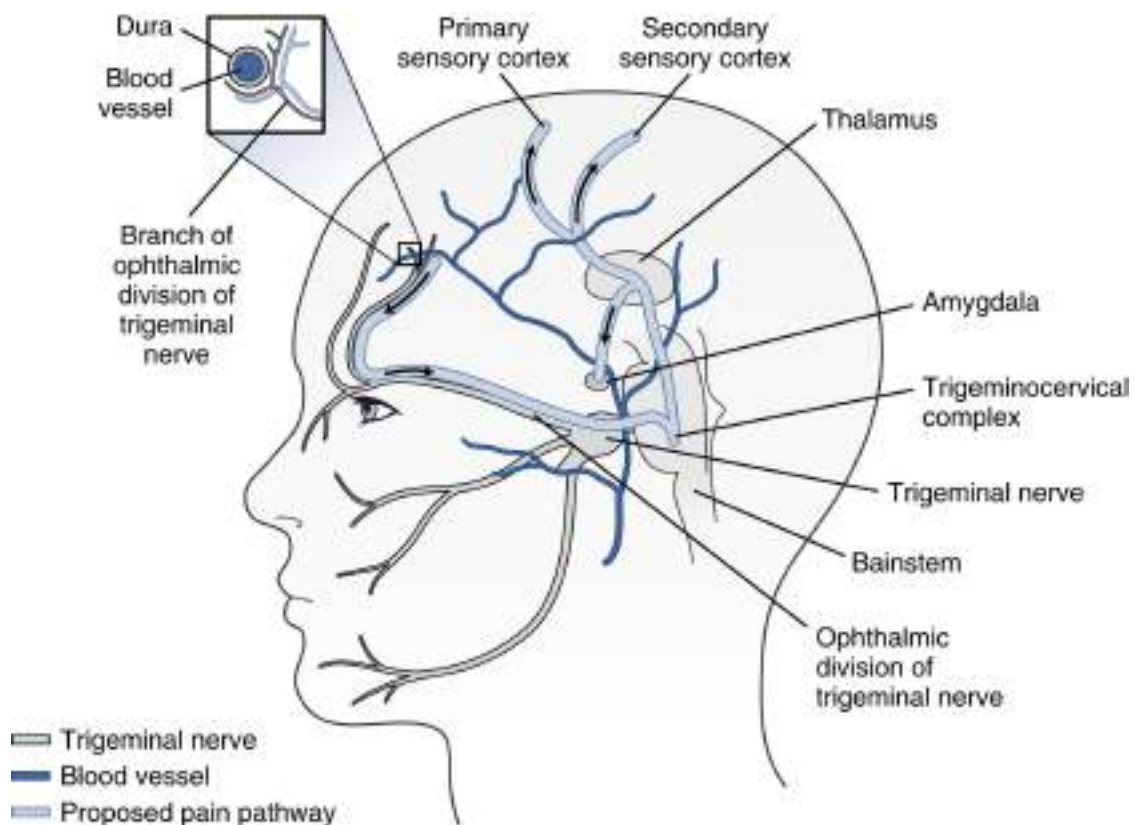

FIG. 12.1 Pathophysiology of headaches. (From Nicolson Stephen E. *Massachusetts General Hospital comprehensive clinical psychiatry*. 4th ed. Philadelphia, Elsevier Inc; 2016:78, 839-851)

TABLE 12.1
Summary of Migraine Therapies

Type of Therapy	Specific Examples/Comments
Preventive	
Lifestyle	Sleep hygiene, exercise, stress management
Neutram supplements—botanicals	Elimination of “food triggers,” consideration of food allergy, maintenance of good hydration. Magnesium, riboflavin, coenzyme Q10, omega-3 fatty acids, meloxic acid
	Ferrous, pyridox, melatonin, and lobelia root (plant), ginger root (herb)
Pharmaceuticals	Tricyclic antidepressants, beta-blockers, calcium channel blockers, anticonvulsants, NSAIDs, botulinum toxin, reduction of the risk of analgesic rebound headache by addressing analgesic polypharmacy

Mind-Body Techniques	
Biofeedback	Motivation required to practice and use as a life skill
Relaxation	Progressive muscle relaxation, focused breathing exercises, guided imagery
Cognitive-behavior therapy	Modification of maladaptive thoughts and reactions to feelings and sensations
Neurolinguistic programming	Alteration of the subjective experience of pain and modification of expectations
Self-hypnosis	Use for both headache prevention and pain control
Mindfulness meditation	Improvements in mood, coping, blood pressure, muscle tone, pain control, and pain perception
Body work	Craniosacral therapy and chiropractic
Bioenergetics	Effectiveness in both preventing and treating migraine

Abortive and Acute	
Pharmaceuticals	NSAIDs, ergot alkaloids, isometheptene, intranasal lidocaine, triptans, valproate, magnesium, narcotics, antiemetics (ginger)
Chiropractic, massage	Use especially for headaches associated with neck discomfort
Acupuncture	Use for severe acute attacks

NSAIDs, nonsteroidal antiinflammatory drugs.

Nutrition

Dietary choices clearly influence migraine, and exploration of diet is an important therapeutic avenue for improving migraine outcomes¹⁵; regularity in the diet may be the key to migraine control.¹⁶ Dietary triggers are found in 8%–20% of patients with migraine.¹⁷ Red wines, dark beers, aged cheese, some nuts, onions, chocolate, aspartame, and processed meats containing nitrates (such as hot dogs and pepperoni) are common offenders. Specific mechanisms may include direct effects of

ingested substances on neuronal receptors governing headache or allergic responses to foods such as gluten and dairy products. A thorough history and testing for specific food allergies are key in the management of recurrent and chronic headache. Patients often know which foods they should avoid, but it is important to raise the possibility of dietary triggers with patients as these sometimes go unnoticed until they are brought up and discussed. Caffeine is a dietary factor that is particularly important. Caffeine withdrawal can temporarily exacerbate migraine or TTHs, whereas caffeine taken during a migraine can reduce pain in some patients, possibly due to its vasoconstrictive effects on the scalp and meningeal vessels. However, caffeine excess (more than five cups of coffee per day) can contribute to maintaining chronic daily headache, especially when combined with medication excess (see [Chapters 31](#) and [86](#)).

Diets that contain large quantities of omega-6 fatty acids are generally proinflammatory and are likely to aggravate migraine and chronic TTH. In a study of 65 adults with chronic daily headache, of which 85% had chronic migraine, there was significant improvement in headache severity and frequency in those on a high omega-3, low omega-6 fatty acid diet compared to baseline and compared to those on a low omega-6 fatty acid diet alone.¹⁸ The dietary interventions lasted 12 weeks. Food was provided, and all subjects received regular dietary counseling throughout the intervention. Fatty acid supplements were not given. Clinical benefits were most pronounced in the last 4 weeks of the intervention. Most striking were the correlations between clinical improvement and levels of omega-3–derived antiinflammatory lipid mediators. Biochemical endpoints correlated closely with clinical improvement in pain and psychological distress¹⁹ (see [Chapter 88](#)).

Obesity and metabolic syndrome have also been found to be associated with migraine and chronic headache, perhaps related to the proinflammatory state associated with these conditions.²⁰⁻²² Inflammatory bowel disorders also have a higher incidence of migraine.²³ Treatment implications for migraine in these conditions, while not fully defined, favor integration of dietary choices with other forms of treatment.

Specific nutrients and supplements that have shown promise in headache management are reviewed in the following text.

Supplements

Magnesium

Levels of ionized tissue magnesium are often low in migraine, especially in individuals with menstrual migraine.²⁴⁻²⁶ There is limited evidence that suggests that oral supplementation with magnesium may be effective in the prevention of migraine.²⁷ The mechanisms leading to improvement with magnesium supplementation may include reduction in cerebral cortical neuronal excitability or alteration in magnesium-dependent circadian regulatory mechanisms that are frequently disturbed in migraine.²⁸⁻³⁰ One study showed that oral magnesium dicitrate 600 mg given once a day significantly reduced the frequency of migraine compared to placebo.³¹ In another study, oral administration of 360 mg of pyrrolidine carboxylic acid magnesium daily for 2 months was associated with greater pain relief than placebo in women with menstrual migraine.³² Patients with menstrual migraine should continue magnesium for at least 3 months to determine the effectiveness because beneficial effects may be delayed for several cycles.

Preventive benefit can be achieved with oral potassium magnesium aspartate (500–1000 mg / day at bedtime). Magnesium oxide is more readily available and cheaper than other forms, but it is poorly absorbed, especially when combined with calcium, zinc, or iron. Magnesium may cause diarrhea, particularly in those with irritable bowel syndrome, a common comorbid condition. For acute treatment of migraine, 2 g in 100 mL of saline given IV over 30 min appears to be effective and safe in an outpatient setting,³³⁻³⁵ but the U.S. Food and Drug Administration (FDA) issued a warning in 2013 about potential harm to the fetus associated with prolonged use of IV magnesium sulfate during pregnancy.³⁶

Dosage

For prevention: potassium magnesium aspartate 500–1000 mg at bedtime

Precautions

May cause diarrhea; consider magnesium gluconate as an alternate form

Riboflavin (Vitamin B₂)

Patients with migraine have been shown to have reduced phosphorylation potential in brain and muscles, suggesting a

mitochondrial defect in electron transport.³⁷ Riboflavin is a precursor for two coenzymes involved in electron transfer for redox reactions. One hypothesis for the mechanism of action of riboflavin is that it improves mitochondrial energy reserves without changing neuronal excitability.³⁸ In several clinical studies of riboflavin as a supplement in migraineurs, there were significant preventive effects.^{39,40} It may have synergistic preventive effects when used concurrently with a beta-blocker.³⁸ There are no head-to-head studies comparing riboflavin with other preventive measures. Results in children with migraine are mixed.^{41,42}

Dosage

The recommended dose of riboflavin is 200 mg twice daily with meals.

Precautions

Riboflavin is well tolerated and does not influence metabolism of other agents. Patients may notice that color of their urine turns to intense yellow with daily use. It is safe in pregnancy.

Coenzyme Q₁₀

The rationale for studying coenzyme Q₁₀ relates to lower phosphorylation potentials found in patients with a variety of chronic disorders including migraine.⁴³ The findings of an open-label trial showing reduction in headache frequency at 3 months with daily dosing of 150 mg of coenzyme Q₁₀ were confirmed in a double-blind, placebo-controlled, randomized trial in 42 patients with migraine.^{44,45} The oral coenzyme Q₁₀, 100 mg three times a day, resulted in a reduction in attack frequency by 47.6% compared to 14.4% in the controls at 3 months. The number of days with headache was also significantly reduced. Like riboflavin, there was no change in headache intensity or duration once a headache occurred. Another clinical trial published in 2011 demonstrated early (but not sustained) benefits associated with coenzyme Q supplementation for the prevention of migraine in children and adolescents.⁴⁶ There have been no major recent studies.

Dosage

Coenzyme Q₁₀, 150 to 300 mg/day; minimum 3-month trial based on research of Sandor and associates.²⁴

Precautions

Well tolerated with rare gastrointestinal side effects, is relatively expensive, and safe in pregnancy.

Fish Oil

Rationale for the use of omega-3 fatty acids in migraine prevention includes their antiinflammatory properties, vascular relaxation effects, and inhibition of serotonin release from platelets. Only two studies in the last 15 years specifically address the role of omega-3 supplements in migraine. The American Academy of Neurology (AAN) Guidelines for Headache (2013) ranked the evidence as insufficient to make recommendations.

One study of fish oil capsules for migraine prevention used a randomized crossover design in 27 adolescents with migraine; it compared daily omega-3 fatty acids vs an olive oil control, both given as capsules, with no change in the diet. Each arm was 2 months with a 2-week washout. Both olive oil and omega-3 were associated with a striking reduction in headache frequency compared to baseline and washout frequencies.⁴⁷ There were no measures of compliance or biochemical endpoints and no follow-up.

Another study of fish oil capsules in 96 adults with migraine showed no benefit.⁴⁸ The dosing ranged between 2 and 6 g/day, and there was no recommendation to change the usual diet of subjects. Side effects included nausea and symptoms of gastric reflux.

A recent diet-only study of adults with chronic migraine on omega-3-enriched diet for 12 weeks, without supplements, showed significant benefits in headache by week 9 of the intervention, which increased further during the last 3 weeks, compared to a reduced omega-6 diet.¹⁸ It is safe during pregnancy.

Dosage

According to the available literature, it is best to increase omega-3 fatty acid levels through nutrition rather than taking it as a supplement.

Daily use of a compound containing 400 mg of riboflavin, 300 mg of magnesium, and 100 mg of feverfew has been shown to be effective in reducing the frequency of migraine in adults.⁴⁹

Botanicals

Feverfew (*Tanacetum parthenium* Leaf)

Johnson et al. reported a significant increase in migraine severity and frequency when feverfew was stopped in a small group of migraineurs taking it for prevention.⁵⁰ In one well-designed study, a 70% reduction in headache frequency and severity was shown in 270 patients with migraine.⁵¹ Variations in the standardization of the dried leaf constituents confound replication studies of this herb. A reproducibly manufactured extract of feverfew has shown preventive efficacy in a double-blind randomized controlled trial (RCT).⁵² There are no long-term studies documenting safety and no head-to-head trials with other preventive medications. The mechanism of action in migraine may be related to its inhibiting effects on platelet aggregation and inflammatory promoters, such as serotonin and prostaglandins, or possibly its effect in dampening vascular reactivity to amine regulators of blood flow.

Dosage

Oral administration of feverfew up to 125 mg/day of the dried leaf standardized to a minimum of 0.2% parthenolide. Beneficial effects may take weeks to develop.

Precautions

Aphthous ulcers and gastrointestinal irritation develop in 5%–15% of users. Abrupt cessation of feverfew occasionally results in agitation and increased headache. It is not recommended during pregnancy due to prolongation of bleeding times.

Butterbur (*Petasites hybridus* Root)

In a large, three-arm, dose-finding RCT of a standardized extract of the root of this perennial shrub, it was found that migraine attack frequency

was reduced by almost 50%. Among those on the highest dose, 68% had a 50% or greater reduction in headache frequency.⁵³ This effect continued for at least 4 months. One smaller study showed similar results,⁵⁴ and another study in 108 children and adolescents with migraine was also positive.⁵⁵ One study that compared butterbur root extract to both music therapy and placebo in the prevention of migraine in children had mixed findings, with butterbur demonstrating efficacy compared to placebo in the long-term, but not short-term, follow-up.⁵⁶ A systematic review of the published literature on the effectiveness of *P. hybridus* revealed that higher dose extracts (150 mg) were associated with a lower frequency of migraine attacks after 3–4 months compared to a lower dose and placebo.⁵⁷ The extract is commonly standardized to 15% of the marker molecule (petasins) and known carcinogens are removed. Drug–herb interactions have not been studied.

Dosage

Butterbur, 50 mg three times a day for 1 month; then 50 mg twice a day

Precautions

Unknown effects in pregnancy; excessive belching as a side effect

Supplements for Sleep

Sleep management is a major therapeutic strategy in helping patients gain control over their headaches. Melatonin and valerian root can be used on a temporary basis to improve sleep.

Melatonin

Melatonin is used in the management of migraine to improve sleep and circadian rhythms. Sleep maintenance, as opposed to sleep induction, is improved with melatonin. Melatonin is recommended every night for 4–6 weeks and then tapered off. During that period, a sleep hygiene program can be put into place to reduce the need for the supplement. There are few side effects. Leone and coworkers demonstrated that a daily intake of 10 mg of melatonin for 14 days significantly reduced cluster headache frequency.⁵⁸ Others have shown beneficial effects of melatonin in migraine and other types of headache, including migraine

prevention in children.⁵⁹⁻⁶¹ However, a recently published, double-blind, placebo-controlled, crossover study comparing extended-release melatonin at a dose of 2 mg 1 hour before bedtime did not demonstrate improvement in migraine frequency compared to placebo.⁶²

Dosage

Melatonin, 2–12 mg; start at 2 mg and titrate up every 4 days as needed for sleep. Lower doses are needed if taken each evening for several weeks. Higher doses (>15 mg) are needed to acutely induce sleep over several days (jet lag).

Precautions

Fatigue, drowsiness, dizziness, abdominal cramps, and irritability

Valerian (*Valeriana officinalis* Root)

When taken at night for sleep, valerian rarely results in residual drowsiness on awakening. It is nonaddictive and useful as an anxiolytic when given during the daytime (up to 250 mg three times per day). It does not impair psychomotor or cognitive performance.⁶³ The mechanism of action includes stimulation of the central nervous system gamma-aminobutyric acid (GABA) receptors along with enhanced release and inhibition of reuptake of GABA. In clinical trials, including the use for sleep and anxiety, it has been judged to be safe.⁶³⁻⁶⁶ Gastrointestinal irritation is the most common side effect (15%).

Dosage

Valerian, 100–300 mg of the extract standardized to 0.8% valerenate at bedtime or 250 mg every 6 hours for anxiety

Precautions

Very unpleasant smell that may aggravate nausea during migraine. It may cause worsening of tension headache if taken regularly for more than 3 months. It should not be used during pregnancy.

Magnesium aspartate, in contrast to magnesium oxide, is easily absorbed and rarely causes diarrhea when used for migraine prevention. Avoid giving either preparation at the same time as calcium, zinc, or iron. Dosage: 500–1000 mg each night.

Pharmaceuticals

There is no inherent difficulty in the integration of conventional and complementary approaches in the treatment of headache. Conventional pharmacological therapy includes use of preventive and abortive medications. The pharmaceutical approaches discussed here are the ones for which there is greatest evidence of efficacy and clinical usefulness.³⁻⁵

Preventive Pharmaceutical Therapies

Application of preventive pharmacological therapies in practice is typically organized around classes of medications, including tricyclic antidepressants, selective serotonin reuptake inhibitors, beta-blockers, calcium channel blockers, anticonvulsants, and other miscellaneous agents. The goals are reduction in headache frequency and severity, improved function, and increased responsiveness to abortive and analgesic agents.

The decision to start preventive therapy is based on the following: (1) headache frequency of more than two per month or more than 3 days per month lost to headache, (2) willingness of the patient to take a medication or supplement daily for at least 3 months, and (3) ability to maintain a headache diary. Medications for prevention are administered according to the half-life and a schedule that minimizes side effects. Effectiveness is best measured by having the patient maintain a headache diary, noting headache frequency and intensity as well as significant life events, such as stressful circumstances, menses, vacations, and major changes. Patients may respond to any of several beta-blockers (e.g., propranolol, atenolol, metoprolol, or timolol), making the choice of an agent highly individualized. It is not possible to predict who will respond to a given agent in advance, although the history of a family member who achieved effective prevention with a given agent may guide initial choices. Comorbid depression, a history of active asthma, and thyroid disease limits the use of beta-blockers, whereas obesity limits the use of tricyclic antidepressants and valproate.

Medications and supplements are prescribed one at a time and tapered

up to a maximum dose or until satisfactory benefit is realized at lower doses. Most drugs are started at less than half the predicted maximum dose. Often, patients achieve satisfactory results at doses well below the maximum, particularly with the tricyclic antidepressants. On the other hand, verapamil usually has to be given at doses of at least 320 mg/day for benefit to occur. Magnesium, vitamin B₂, coenzyme Q₁₀, and daily aspirin mix well with conventional preventive agents.

Once improvement is achieved, the medication combination is continued for a period of 3–6 months with periodic gradual reductions in one or more agents to determine the minimum effective dose. Effective preventive agents allow time for patients to work on lifestyle issues, including management of stress, sleep, nutrition, and exercise, as well as to develop life skills, such as relaxation, biofeedback, and self-hypnosis. Preventive agents are also chosen to facilitate the treatment of comorbid depression and sleep dysfunction. As patients improve, diaries that focus on pain are discontinued.

Tricyclic Antidepressants

Amitriptyline, in doses of up to 150 mg at bedtime, starting as low as 10 mg, is effective for prevention. A few patients do well on very low doses such as 10 mg at night. Other useful medications in this group include nortriptyline, up to 100 mg at bedtime. Sleep is often improved, which reduces migraine frequency. Dry mouth, morning drowsiness, and constipation are significant side effects.

Beta-Blockers

Medications in this class that have been shown to be effective for migraine include propranolol, nadolol, timolol, atenolol, and metoprolol. Long-acting formulations have not been formally studied. Side effects include fatigue, depression, insomnia, dizziness, and nausea. Rebound headaches may occur if beta-blockers are suddenly withdrawn. Dosing of propranolol for migraine prevention ranges between 80 and 240 mg/day in two or three divided doses.

Calcium Channel Blockers

Calcium channel blockers shown to be effective include verapamil, nimodipine, flunarizine, and nifedipine. Delayed onset (weeks) of effectiveness is typical, and side effects such as abdominal pain, bloating, weight gain, constipation, and even headache are not uncommon. A

typical dose of verapamil is 180 mg twice daily.

Anticonvulsants

The major members of this group prescribed for migraine are sodium valproate, gabapentin (Neurontin), topiramate (Topamax), zonisamide (Zonegran), and levetiracetam (Keppra).^{67,68} A typical adult dose of sodium valproate for prevention is 1500 mg/day, with a starting dose of 250 mg twice daily. Side effects include weight gain, alopecia, tremor, and nausea. Sodium valproate is available in 125-, 250-, 500-mg, and sustained-release formulations. Topiramate is the most consistently effective of the four most commonly used drugs in this class, but cognitive side effects and nausea can be limiting. Levetiracetam and zonisamide have the fewest side effects.

Nonsteroidal Antiinflammatory Drugs

Trends toward reduction in migraine frequency have been seen with daily use of aspirin, naproxen, ketoprofen, and tolfenamic acid. Gastric side effects are common, and patient compliance is poor. Dosages include naproxen 500 mg twice daily, aspirin 350–975 mg/day, and ketoprofen 150 mg/day. These drugs are not safe in pregnancy.

Botulinum Toxin

Botulinum toxin has been found to prevent migraine when injected in small quantities at multiple sites into the muscles of the forehead, temples, posterior neck, and the trapezius muscle.⁶⁹⁻⁷³ The early Phase III REsearch Evaluating Migraine Prophylaxis Therapy (PREEMPT) studies showing efficacy have been confirmed.⁷⁴⁻⁷⁶ The FDA has approved it for treatment of chronic migraine (>15 headache days per month). The positive response rate in those with chronic migraine is more than 60%. The frequency of chronic migraine is reduced significantly, whereas headache intensity remains largely unchanged. Effects last an average of 2–4 months. There is limited evidence on its efficacy in TTH. Side effects are few and can include transient weakness of injected muscles. Dosing is 100–200 units total per injection session. It is injected with a 27-gauge needle over 15–25 sites (~2–10 units per site).

Abortive Pharmaceutical Therapies

The following is a list of medications that, when taken early in the course

of migraine, can abort further development of the headache.

Nonsteroidal Antiinflammatory Drugs

Ibuprofen (800 mg) and naproxen sodium (200–400 mg) can block headache progression when given during the first few hours when the headache is building. Ibuprofen in liquid form (200–400 mg) is recommended when nausea occurs early in the headache. Individual variation in responsiveness to nonsteroidal antiinflammatory drugs (NSAIDs) is high; thus, it is worth trying several different agents from this class early in the headache.

Ergot Alkaloids

Now largely supplanted by the triptans, ergot alkaloids can be useful in those who cannot tolerate other abortive methods. A typical dose is ergotamine tartrate, 1 mg orally, 2 mg sublingually, or dihydroergotamine (DHE-45) 2 mg subcutaneously (self-injection) every 4 hours for up to three doses. A nasal inhalational form is also available.

Isometheptene

Isometheptene (Midrin) has a low side-effect profile and modest cost. It is a weak vasoconstrictor of scalp vessels. The dosing is two or three capsules at the start of a headache, then one every 45 minutes for three more doses as needed within 24 hours.

Intranasal Lidocaine

Intranasal lidocaine is effective for most forms of migraine and is particularly useful when given during the aura and when nausea and vomiting are prominent early in the headache.⁷⁷ The mechanism may relate to the anesthetizing effects of lidocaine on sphenopalatine ganglia. Lidocaine (4% liquid) is applied with a dropper, 0.25–0.50 mL up each nostril, with the patient supine and the head hyperextended. Side effects include a mild transient burning sensation in the nasal passages and occasional transient numbness in the throat. The nasal spray form of lidocaine is generally ineffective. Repeat dosing can be done hourly for 4–6 hours. Intranasal ketorolac has also shown promise for the acute treatment of migraine.⁷⁸

Triptans (5-Hydroxytryptamine Receptor 1B/1D Agonists)

The triptans, on average, are the most effective agents available for aborting migraine.⁷⁹⁻⁸² They act by blocking the release of inflammatory cytokines from the distal nerve endings of the trigeminal system onto the scalp and meningeal vessels and by their vasoconstrictive effects on scalp vessels. Multiple products are available by prescription, including tablet or melt forms, self-injection kits, and nasal sprays. Efficacy of a single dose is 60%–80% for pain and nausea relief, with a 25%–30% recurrence rate necessitating a second dose. The choice of a triptan depends on patient response, side-effect profile, and preferred route of administration. Long-acting forms, including naratriptan (Amerge) and frovatriptan (Frova), can be effective when recurrence rates are noted with the more rapidly acting triptans. Oral melt formulations and nasal sprays are useful when nausea is prominent early in the headache.

Usual dosing is at 2-hour intervals, if necessary, for a maximum of three doses in 24 hours.

- Sumatriptan (Imitrex): 25-, 50-, and 100-mg tablets; 20-mg nasal spray; and 6- and 4-mg/0.5 mL injection kits
- Naratriptan (Amerge): 1- or 2.5-mg tablets
- Rizatriptan (Maxalt): 5- or 10-mg tablets or melt tablets
- Zolmitriptan (Zomig): 2.5- or 5-mg tablets or melt tablets
- Almotriptan (Axert): 12.5-mg tablets
- Frovatriptan (Frova): 2.5-mg tablets
- Eletriptan (Relpax): 40-mg tablets

Triptans are contraindicated in pregnancy, cardiovascular disease, complex migraine, and poorly controlled hypertension. Cost is a major factor. Rebound headache can occur with daily use. Side effects include transient pressure sensations in the chest, neck, and head. It is ineffective in TTH and occasionally effective in cluster headache. Insurance coverage varies widely.

Mind-Body Techniques

Biofeedback

Biofeedback has demonstrated effectiveness in treating both migraine and TTH without major side effects or adverse interactions with other therapies. Thermal biofeedback, in which patients learn to increase the temperature of their hands through guided imagery and relaxation training, and/or electromyography (EMG) biofeedback, wherein patients learn to relax targeted skeletal muscle groups, have been shown to significantly improve migraine symptoms.^{83,84} A meta-analysis of 25

studies showed that biofeedback is comparable to preventive pharmacotherapy,⁸⁵ and another meta-analysis of 55 studies revealed that migraine headache frequency and perceived self-efficacy showed strongest improvements in biofeedback patients. Migraine patients experienced significant reductions in headache frequency, intensity, and headache-related disability as well as reductions in interictal symptoms, such as irritation and anxiety, in a study combining thermal and EMG biofeedback and relaxation training.⁸⁴ Biofeedback, however, did not appear to provide additional benefit in a study involving 64 patients randomized to relaxation training vs relaxation training plus biofeedback.⁸⁶ Multiple studies showed a reduction in medication use and health service utilization for both migraine and TTH patients when using biofeedback techniques.^{87,88} Biofeedback may also enhance the effectiveness of preventive, abortive, and rescue migraine medications.⁸⁹

There are no criteria for predicting benefit from biofeedback, and the training requires a significant time commitment (10- to 15-hour-long sessions plus home practice). Pharmacotherapy combined with biofeedback may have variable results. This is an important point because vascular reactivity (a major target in biofeedback training) may be modified by medications used for headache prevention (e.g., beta-blockers), potentially limiting the effects of training. On the other hand, biofeedback could be favorably synergistic with magnesium or topiramate.⁹⁰ Biofeedback is indicated in patients intolerant to medications, those oriented toward self-efficacy in pain management, pregnancy, and is especially suited for those willing to regularly practice the techniques.

Relaxation

The category of relaxation includes progressive muscular relaxation, focused breathing exercises, and guided imagery. Holroyd and Penzien reported that these techniques are as effective as biofeedback.⁵⁵

Treatment effects were enhanced by beta-blockers and other preventive agents, making integration both feasible and effective. Some patients are able to identify the early stages of a headache in time to deploy focused relaxation or guided imagery to abort the full development of pain.

D'Souza et al. demonstrated that relaxation training improved headache frequency and disability associated with migraines among college students compared to written emotional disclosure or a neutral writing group control.⁹¹ These techniques can be taught in groups and then practiced individually using audiotapes. Relaxation appeals to those with

an internal locus of control and above-average motivation (see [Chapter 94](#)).

Cognitive-Behavioral Therapy

Cognitive-behavioral therapy is a stress-management approach designed to help patients identify maladaptive thought patterns (e.g., self-blame, hopelessness, helplessness, worthlessness, and catastrophizing) as well as emotional states such as anger and anxiety that can precipitate and amplify headaches. Acknowledgment of present-moment and historical emotional states, shifting of habitual thought patterns, and modification of physiological responses are the key steps in this approach. It has been shown to be effective, alone or in combination, with other behavioral therapies for headache.⁹² Combining cognitive-behavioral and biofeedback therapies is effective.

Hypnosis

Hypnosis has been shown to reduce the number of headache days and decrease headache intensity among patients with chronic TTH.⁹³ For abortive therapy, hypnosis is useful in helping patients identify the early stages of migraine so that they can initiate relaxation or self-hypnosis routines. Patient motivation and regular practice is a vital part of this strategy. Self-hypnosis can also be useful in resetting expectations about future successes with treatment, reducing rumination about the past and future, and modifying patterns of negative thought (see [Chapter 95](#)).

Mindfulness Meditation

Meditation has been shown to have positive effects on mood, cardiac function, blood pressure, and muscle tone when regularly practiced. Effects are believed to be mediated by the development of nonjudgmental awareness of feelings, thoughts, and sensations combined with a sense of gratitude while optimizing the sympathetic and parasympathetic nervous system balance. Group instruction is based on the work of Jon Kabat-Zinn^{94,95} and is taught as an 8-week course, including 2–3 hours of formal training each week, combined with daily practice of at least half an hour of meditation. Patients report improved sleep and less anticipatory anxiety relating to headache as well as reduction in headache intensity.⁹⁶ Home practice is important in maintaining benefits.⁹⁷

Feasibility studies indicate that mindfulness training, specifically

Kabat-Zinn's 8-week mindfulness-based stress reduction program, is effective for reducing headache severity in migraine and TTH patients.^{98,99} One study of migraine patients also showed reductions in levels of anxiety and migraine-related disability after the 8-week course.⁹⁸ Headache-specific mindfulness training may improve outcomes^{100,101} (see [Chapter 100](#)).

Biomechanical Techniques

Physical Therapy

Physical therapy alone does not appear to be effective in the treatment of migraine, but it can be useful as an adjunct to biofeedback and relaxation training when there is significant reactive muscle tension in the upper body with limitation of head and neck movement.

Spinal Manipulation

Chiropractic and osteopathic manipulation approaches are often used for patients whose migraines have a cervicogenic or musculoskeletal component. One study of 218 patients demonstrated comparable results in reduction of migraine headache frequency and intensity in a prospective, randomized, parallel-group comparison of amitriptyline, spinal manipulation, and their combination.^{102,103} A systematic review of manual therapies for the treatment of migraine included four RCTs, each of which suggested that chiropractic spinal manipulation may have prophylactic effectiveness similar to that of propranolol and topiramate.¹⁰⁴ However, many of the studies lacked methodological rigor, necessitating future research. Another review published in the same year found that spinal manipulation, whether performed by a chiropractor, physician, or physical therapist, was not effective as a replacement drug therapy for reducing migraine duration but may be an appropriate adjuvant therapy.¹⁰⁵ A review of 21 articles found evidence in support of effectiveness of spinal manipulation for episodic and chronic migraine but not TTH.¹⁰⁶

Bioenergetics

Acupuncture

Findings from a systematic review and meta-analysis of acupuncture for

migraine prophylaxis involving 22 trials with 4419 participants suggest that acupuncture is more effective than routine care only, but not more effective than sham acupuncture, and that acupuncture is associated with better outcomes and fewer adverse effects than prophylactic drug treatment.¹⁰⁷ A more recent patient-level data meta-analysis of acupuncture for the management of chronic headache (including chronic migraine) concluded that acupuncture is superior to sham acupuncture and medication therapy in decreasing headache intensity and frequency and in improving response rate to treatment.¹⁰⁸ A recently published sham-controlled randomized trial reported similar findings among patients with frequent migraine.¹⁰⁹ The current evidence clearly suggests that acupuncture is effective as an adjunct to usual care in the treatment of migraine, but the degree to which placebo effects contribute to this efficacy is unknown.

Homeopathy for Headache Prevention

There are few prospective studies that have evaluated the effectiveness of homeopathy for migraine treatment or prevention. A systematic review of four RCTs and two observational studies found varying results. The observational studies showed significant improvements in homeopathically treated patients with regard to headache intensity, medication usage, and health service utilization.⁷⁵ Three of the four RCTs produced equivocal results, while the remaining RCT showed significant reduction in headache frequency in the homeopathy group.⁷⁵ A 2010 study found that patients seeking homeopathic treatment for migraine maintained positive results in terms of headache frequency, quality of life, medication use, and health services utilization for 24 months after study completion.⁷⁶ The first prospective pediatric homeopathy study with 159 children in 12 countries showed significant decrease in the frequency, severity, and duration of migraine attacks and reduced absenteeism from school during 6 months of treatment.¹¹⁰

Therapies to Consider

Formal evidence of effectiveness of the following treatments in migraine is anecdotal, largely theoretical, empirical, limited, or nonexistent. However, some patients respond favorably to them. Based on their overall safety, they may be considered in an integrated treatment plan. For prevention, consider the following: naturopathy, probiotics,

ginkgolide B, tai chi, yoga, craniosacral therapy, and ayurvedic medicine. For acute therapy, consider the following: aromatherapy, Reiki, and therapeutic touch; sleep induction with an oral hypnotic; and lorazepam with haloperidol IV; methylprednisolone IV; and valproic acid.

Prevention Prescription—Migraine

- Identify and avoid environmental factors that consistently lead to headache, e.g., allergens, fluorescent lights, loud noises, fumes, and dust.
- Implement a sleep hygiene program using a prebedtime routine that signals a time leading to restorative sleep. Avoid excessive as well as inadequate sleep.
- Eliminate foods that lower the threshold for migraine, that is, chocolate, aged and yellow cheese, caffeine, red wine, dark beer, shellfish, and meats processed with nitrates.
- Water/fluid intake should be a minimum of 40–60 oz per day for an adult.
- Maintain an exercise program: aerobic level activity, minimum 30 minutes, three times a week.
- Regularize meals, sleep, exercise, and use of medications for prevention.
- Maintain a diary documenting headache frequency and intensity, response to medications, association with major life changes, stress, and changes in physiological states, such as menses, pregnancy, and illness. Share the diary information with caregivers.

Therapeutic Review

Migraine Prevention

Lifestyle

- Regular meals and sleep, sleep hygiene, aerobic exercise three times a week, headache calendar, stress management, and avoiding environmental triggers 
- Consider discontinuation of hormonal birth control method if

menstrual migraine is evident or the history is suggestive of cause and effect. Consider nonhormonal birth control such as a copper intrauterine device.

Nutrition

- Elimination of food triggers: wine, aged cheese, cashews, chocolate, processed meats, caffeine 

Biochemical Supplements

- Magnesium aspartate, 500-1000 mg qhs 
- Riboflavin, 200 mg bid 
- Coenzyme Q₁₀, 150 mg daily 

Botanicals

- Feverfew, 125 mg up to tid 
- Butterbur, 50 mg tid 
- For sleep: valerian root extract, 100-300 mg qhs ; melatonin, 6-10 mg qhs 

Pharmaceuticals

- Aspirin, 325 mg daily 
- Amitriptyline, 10-150 mg qhs 
- Propranolol, 60-180 mg daily 
- Gabapentin, 300-600 qid 
- Topiramate, 100-200 mg qhs 
- Verapamil, 180-480 mg daily 
- Valproate, 500 mg tid 
- Botulinum toxin, subcutaneous 100 units q3 mo 

Mind-Body

- Biofeedback 10 sessions 

- Cognitive behavioral therapy 
- Hypnosis 
- Mindfulness meditation 8-wk course 

Biomechanical

Consider in cases where muscle tension in the jaw, neck, or shoulder is prominent:

- Chiropractic 
- Massage 

Bioenergetics

- Acupuncture, 6–8 sessions over 8 weeks, repeat as needed 

Acute Migraine Treatment

- Use of specific abortive measures depends on efficacy, cost, side effects, and ease of administration. Use of narcotics and antiemetics is not covered.

Lifestyle

- Darkened, quiet environment, maintain hydration, meals if possible, sleep

Biochemical Supplements and Herbs

- Magnesium sulfate, 2 g IV in 100 mL saline over 30 min 
- Ginger tea for nausea, 8 oz q3 h 
- Aromatherapy (peppermint) 

Pharmaceuticals

- Naproxen sodium, 250–500 mg q4 h 
- Ibuprofen liquid, 200–400 mg q2 h 
- Lidocaine 4% liquid, 0.25 mL in each nostril q1 h 
- Isometheptene (Midrin) 2 tablets at onset, then 1 tablet q45 min × three 

- Triptans. Many available. Dosing routines identical: initial dose at the onset of head pain, followed no sooner than 2 hours by a second dose if necessary. Limit 3 doses in 24 hours 
- Valproate, 1 g IV over 1 h 
- DHE-45, 1.5 mg IV over 30 min preceded by promethazine (Phenergan) 20 mg IV 

Mind-Body

- Self-hypnosis training 
- Practiced biofeedback routine 
- Relaxation 

Biomechanical

- Massage, slow stretch 

Bioenergetic

- Acupuncture 

Tension-Type Headache

TTH may exist in a spectrum with migraine, as shown by positive responses to antimigraine agents in some patients, with or without coexisting migraine. History and physical examination suggest intermittent muscle traction of pain-sensitive tendons and connective tissues of the head and neck. Pain is typically bilateral, nonthrobbing, and band-like, with trigger points at the base of the skull, temples, masseters, and forehead. The pain is typically slow in onset and intermittent with little or no nausea or sensory sensitivity. Positive responses to NSAIDs suggest that inflammatory and myofascial influences dominate, with modest secondary contributions from vascular structures.

Certain pericranial conditions (e.g., brain tumor and central nervous system infection) can present with features of TTH and little else. It is rare for a vascular headache pattern to be the presenting complaint for such conditions. Warning symptoms and signs that suggest the need for

head imaging and other studies are reviewed in the first section of this chapter.

Integrative Therapy

There is considerable overlap with migraine in an integrated treatment approach to TTH. Lifestyle issues surrounding stress, sleep, exercise, and diet are central to effective management and all need to be reviewed carefully for both the work and home environments. It is important to remember that individuals with baseline TTH may develop conditions that abruptly amplify the pain. Examples include sinus and dental infections, head trauma, refractive errors, glaucoma, cervical disk disease, depression, and occult hypertension.

A thorough physical examination may lead to discovery of tender areas and trigger points in the head, neck, or shoulders that promote or sustain head pain. Observation of the patient while sitting, walking, and lying down can provide useful clues to musculoskeletal imbalances. Examination of temporomandibular joints is important in all patients because daytime clenching, nocturnal bruxism, and joint disease can all contribute to the pain of TTH.

Patient education in ergonomics, posture, and breathing is often useful in treating TTH. Mind-body approaches can be usefully integrated with conventional therapies. Hypnosis has been shown to reduce the number of headache days and decrease headache intensity among patients with TTH.^{111,112} One study of 98 patients with TTH found that when given a choice between medication treatment with amitriptyline or hypnotic relaxation, more participants chose hypnotic relaxation and stayed with their choice when given repeated opportunities to switch to amitriptyline therapy. Seventy-four percent (74%) of patients in the hypnotic relaxation group and 58% of patients in the medication group had a 50% reduction in the frequency of headaches. TTH patients demonstrated decreased headache frequency after a twice-weekly 6-week mindfulness course.¹⁰¹

A combination of sleep hygiene and regularization of daily schedules is effective in reducing pain in motivated and compliant patients. The botanicals for sleep previously described for migraine can be equally effective for those with TTH. Patients should be strongly encouraged to reduce consumption of sugar, caffeine, and red meat along with increasing omega-3 fatty acids to reduce the sympathetic nervous system activity and to enhance the production of antiinflammatory prostaglandins. Detoxification from unneeded drugs is part of effective

TTH management. One often overlooked area is dehydration. Poorly hydrated muscles tend to cramp and contract painfully.

Pharmaceuticals have a limited role because of the risk of rebound headache and the tendency to reduce motivation to attend to needed lifestyle adjustments. NSAIDs should be medium- to long-acting and strictly limited to less than 20 doses per week. Muscle relaxants provide limited short-term benefit and tend to lead to psychological dependence and rebound headache. Triptans are rarely effective in TTH.

When TTH occurs daily or almost daily without evidence of an underlying organic condition, analgesic rebound headache is likely, especially when there is use of more than a total of 20 doses of analgesics (NSAIDs and opiates), decongestants, muscle relaxants, and caffeine per week. Caffeine consumption, when greater than three drinks a day, should be tapered slowly over 2–3 weeks along with short-acting analgesics. Pain is managed with patient education, biofeedback, relaxation, slow-stretch exercises, massage, heat, long-acting NSAIDs, and low-dose tricyclic antidepressants given at night (10–50 mg amitriptyline or equivalent).

Chiropractic

There are few older studies of chiropractic or osteopathic manipulation in TTH. Hoyt et al. reported a 50% reduction in headache severity after a single, 10-minute cervical manipulation session.¹¹³ In another study of patients with posttraumatic headache, a 57% reduction in pain intensity and a 64% reduction in analgesic use over a 2-week period was found after two cervical spine manipulation treatments compared with treatment with ice packs.¹¹⁴ Another group found no difference between chiropractic manipulation vs daily amitriptyline at the end of a 6-week course of treatment in patients with chronic TTH. However, patients who received chiropractic manipulation had fewer headaches on follow-up 6 weeks after the end of treatment.¹¹⁵ Finally, an RCT comparing soft tissue therapy plus spinal manipulation vs soft tissue therapy plus placebo laser treatment for episodic TTH did not show a statistical difference in outcomes between the two arms.¹¹⁶ Credible recent studies are lacking.

Acupuncture

A three-arm, randomized controlled trial involving 270 patients with TTH demonstrated that a course of up to 12 acupuncture treatments over

8 weeks was associated with significantly improved clinical outcomes compared to no acupuncture but not when compared to a sham-acupuncture comparison group.¹¹⁷

A systematic review that included a meta-analysis of data from five trials that compared acupuncture with a sham acupuncture control demonstrated small but statistically significant benefits for treatment response and other clinical outcomes. The authors of the systematic review concluded that “acupuncture could be a valuable nonpharmacological tool in patients with frequent episodic or chronic tension-type headaches.”¹¹⁸

Therapies to Consider—TTH

Therapies that promote awareness of mind-body healing connections have the greatest potential for reducing TTH pain. Although evidence supporting the following approaches is sparse, they have proven to be useful in some patients: mindfulness meditation, naturopathy, Reiki, healing touch, magnet therapy, aromatherapy, prolotherapy, tai chi, yoga, traditional Chinese medicine and ayurvedic medicine.

Prevention Prescription—TTH

- Notice physiological reactions to stressful situations in the home and workplace, especially muscle contraction in the neck and shoulders, breathing patterns, chest sensations, and gastrointestinal responses such as nausea, pain, and diarrhea.
- Develop a daily relaxation routine that focuses attention on posture and muscles of the head and neck.
- Maintain adequate sleep, regular aerobic exercise, and adequate hydration.
- Modify the diet to ensure regular consumption or supplementation of omega-3 fatty acids.
- Be alert to conditions that may contribute to or intensify muscular head pain, such as sinus or dental infection, jaw clenching, tooth grinding, head thrusting, anxiety, and depression.
- Be checked for hypertension at least twice a year.
- Consult a physician if symptoms of weakness, loss of sensation, poor coordination, difficulty with speech, fever, or syncope occur with

TTH.

Therapeutic Review—TTH

Tension-Type Headache

- Emphasis is placed on lifestyle and mind-body techniques and reduced reliance on medication.

Lifestyle

- Stress management, sleep hygiene, nutritional choices, ergonomic awareness, regular aerobic exercise 

Nutrition

- Increase omega-3 fatty acid per diet or supplements. Reduce sugar, caffeine, red meats, tobacco, alcohol 

Sleep and Exercise

- Sleep hygiene 
- Aerobic exercise, 30 minutes, three times per week 

Supplements and Herbals

- Melatonin, 6–10 mg qhs 
- Valerian root, 100–300 mg qhs 

Pharmaceuticals

- Time-contingent NSAIDs 
- Limit total of NSAIDs, decongestants, and caffeine to less than 20 doses per week 

Mind-Body

- Biofeedback and relaxation training 
- Stress management, cognitive-behavioral therapy, mindfulness meditation

Biomechanical

- Manipulative therapy, massage, craniosacral therapy 

Bioenergetic

- Acupuncture, 6–10 weekly sessions with follow-up as needed

CHAPTER 13

Peripheral Neuropathy

Sunil T. Pai, MD

Pathophysiology

Peripheral neuropathy or peripheral neuritis is a common neurological disorder that results from damage to the peripheral nerves. It may be caused by diseases of the nerves or may be the result of systemic illnesses. It has various causes, including toxic trauma ([Table 13.1](#)), certain prescription medications and chemotherapeutic agents ([Table 13.2](#)), and mechanical injury that causes compression or entrapment, for example, carpal tunnel syndrome (see [Chapter 70](#)). Even simple pressure on superficial nerves, such as that from the prolonged use of crutches or sitting in the same position for too long, can lead to the disorder. Nutritional deficiencies can cause peripheral neuropathy, as seen in vitamin B deficiency (i.e., from alcoholism, pernicious anemia, isoniazid-induced pyridoxine deficiency, or malabsorption syndromes). Other causes include viral and bacterial infections and other infectious diseases (e.g., human immunodeficiency virus [HIV] infection, Lyme disease), autoimmune reactions (e.g., Guillain-Barre syndrome, chronic inflammatory demyelinating polyneuropathy, multifocal motor neuropathy), cancer (e.g., lymphoma, multiple myeloma), collagen-vascular disorders (e.g., systemic lupus erythematosus, rheumatoid arthritis, polyarteritis nodosa, Sjogren syndrome), endocrinopathies (e.g., hypothyroidism, acromegaly), and rare inherited genetic abnormalities (e.g., hereditary sensory neuropathy types I, II, III, and IV; Krabbe disease; Charcot-Marie-Tooth disease). Despite a thorough history and physical examination, the origin remains a mystery in approximately 50% of cases.¹

One of the most common causes is diabetes. Peripheral neuropathy is estimated to be present in approximately 40%–60% of individuals with

diabetes of 25 years or more in duration.² Diabetic neuropathy is now thought to be the most common form of peripheral neuropathy in humans,³ and the incidence significantly increases with age.⁴ Although the exact pathophysiology of diabetic neuropathy has not yet been clearly identified, the origin is multifactorial. Persistent hyperglycemia, oxidative stress, and inflammatory, autoimmune, and microvascular mechanisms are important factors.

Persistent hyperglycemia is the most common primary factor responsible for the development of diabetic neuropathy. It is thought to increase oxidative-nitrosative stress. Oxidative-nitrosative stress activates the polyol pathway, which results in the intraneural accumulation of fructose and sorbitol, and thereby damages the nerves.⁵ This polyol pathway hyperactivity is pathogenic because it increases the turnover of cofactors, such as NADPH and NAD⁺, leading to a reduction of glutathione. It also increases the production of advanced glycation end products (AGEs), activation of diacylglycerol and protein kinase C (PKC) isoforms, and overactivity of the hexosamine pathway.^{6,7,8} Depletion of glutathione may be the fundamental cause of oxidative stress and be related to the accumulation of toxic elements.⁹

Oxidative-nitrosative stress not only activates the above but also instigates and amplifies neuroinflammation. This coupling between oxidative-nitrosative stress and inflammation is because of the activation of TNF-alpha, NF-kappaB along with numerous other interleukins, AP-1 an inhibition of Nrf2, peroxynitrite mediate endothelial dysfunction, altered NO levels, and macrophage migration. These all create proinflammatory cytokines, which are responsible for tissue damage, and debilitating and painful neuropathy.¹⁰⁻¹⁴

Hyperglycemia alone, however, cannot account for the development of nerve damage because diabetic neuropathy also occurs in patients with well-controlled disease, while other patients with poorly controlled disease have no evidence of neuropathy.²

Immunological mechanisms also play a role in the development of diabetic neuropathy. This damage is caused by antineural autoantibodies that circulate in the serum of some diabetic patients. Antiphospholipid antibodies may also be present and may contribute to nerve damage in combination with vascular abnormalities.¹⁵

Finally, endoneural vascular insufficiency, resulting from decreased nitric oxide or impaired endothelial function, impaired sodium/potassium-adenosine triphosphatase (Na⁺/K⁺-ATPase) activity, and homocysteinemia, has been found to be a primary cause of diabetic

neuropathy.¹⁵⁻¹⁸ Investigators have postulated that ischemia related to endoneural and epineural vascular changes causes nerve damage by thickening the blood vessel wall. Eventually, occlusion of the vessel may occur, leading to vascular permeability, compromise of endoneural blood flow (Fig. 13.1), and microvascular impairment.^{19,20} Preclinical and clinical studies have shown a reduction of peripheral perfusion not only in the nervous tissue^{21,22} but also in the skin,^{23,24} indicating microvascular changes.^{24,25}

Other multifactorial mechanisms that are implicated in the development of diabetic neuropathy are body habitus, environmental factors (e.g., alcohol, smoking, exposure to heavy metals), and genetic predisposition.

By these mechanisms, the sensory, autonomic, and motor nerves may all be affected, beginning with the distal lower extremities and spreading to involve the upper extremities as the diabetes progresses.³ Diabetic neuropathy usually manifests in a “stocking-and-glove” distribution, with sensory loss, dysesthesias, and painful paresthesias, most commonly in the lower extremities. Common symptoms include the following: tingling, prickling, or numbness; burning or freezing pain; sharp, stabbing, or electric pain; extreme sensitivity to touch; muscle weakness; and loss of balance and coordination. However, pain intensity is not always associated with the severity of the neuropathy and can occur even without nerve injury.^{26,27}

TABLE 13.1
Agents Causing Symptoms Associated With Toxic Neuropathy

Acrylamide (truncal ataxia)
Alcohol
Allyl chloride
Arsenic
Buckthorn toxin
Carbon disulfide
Cyanide
Dichlorophenoxyacetic acid
Dimethylaminopropionitrile (urinary complaints)
Biologic toxin in diphtheritic neuropathy (pharyngeal)

neuropathy)
Ethylene oxide
Germanium
Hexacarbon (n-hexane) (glue-sniffing; occupational exposure to solvents, glue, or glue thinner)
Lead (wrist drop, abdominal colic)
Lucel-7 (cataracts)
Mercury
Methylbromide
Mold (in water-damaged buildings)
Nitrous oxide inhalation
Organophosphorus esters (triorthocresyl phosphate, leptophos, mipafox, trichlorphon) (cholinergic symptoms, neuropathy of delayed onset)
Polychlorinated biphenyls
Tetrachlorobiphenyl
Thallium (pain, alopecia, Mees lines)
Trichloroethylene (trigeminal neuralgia)
Vacor

Modified from Wyngaarden JB, Smith LH Jr, Bennett JC, eds. *Cecil textbook of medicine*. 19th ed. Philadelphia: Saunders; 1992:2246.

TABLE 13.2

Pharmaceutical Agents Associated With Generalized Neuropathy

5-Azacytidine
5-Fluorouracil
Amiodarone
Antiretrovirals
Aurothioglucose
Chloramphenicol
Clioquinol

Cytarabine
Dapsone*
Disulfiram
Ethambutol
Ethionamide
Etoposide
Gemcitabine
Gold
Glutethimide
Hexamethylmelamine
Hydralazine
Ifosfamide
Isoniazid†
Metronidazole, misonidazole
Nitrofurantoin*
Penicillamine
Perhexiline
Phenytoin
Pyridoxine† (in excessive amounts)
Platinum† (cisplatin, oxaliplatin)
Sodium cyanate
Statins
Stilbamidine
Suramin
Taxoids (paclitaxel, docetaxel)
Thalidomide†
Vinblastine
Vincristine
VM-26

* Predominantly motor (neuropathy).

† Predominantly sensory (neuropathy).

Modified from Wyngaarden JB, Smith LH Jr, Bennett JC, eds. *Cecil textbook of medicine*. 19th ed. Philadelphia: Saunders; 1992:2247.

FIG. 13.1 Pathophysiological factors in diabetic neuropathy. ATPase, adenosine triphosphatase; K⁺, potassium; Na⁺, sodium. (From Head K. Peripheral neuropathy: pathological mechanisms and alternative therapies. *Altern Med Rev* . 2006;11:295.)

Integrative Therapy

Because diabetic neuropathy is the most common peripheral neuropathy that is encountered in clinical practice, and its symptoms consist primarily of pain, the management of neuropathy involves not only prevention and control of the underlying disease, for example, diabetes, but also alleviation of the resultant painful symptoms. In addition, because the worldwide rise in cancer over the next 20 years has been projected to be 57%,²⁹ there will be an increase in chemotherapy-induced neuropathy, which is a side effect of such treatments. Although the neuropathological mechanisms are in the end similar, studies are underway on the utilization of natural and adjunctive therapies to lower the incidence and side effects from chemotherapy.

Lifestyle

Nutrition

Good diabetic control can be one of the best preventive measures for peripheral neuropathy. The benefits of near normoglycemia on nerve function in the Diabetes Control and Complications Trial adequately demonstrated that strict glycemic control may reduce the incidence of diabetic neuropathy by up to 64%.³⁰

In addition, multiple studies have shown that following a whole-foods, low-fat, high-fiber, plant-based diet combined with exercise can decrease type 1 diabetic medications by up to 40%³¹ or eliminate them completely in type 2 diabetes.³²⁻³⁵ Furthermore, there is growing evidence that oxidative stress due to the previously described mechanisms creates deficits in antioxidant defense, which play a major role in diabetic neuropathy,^{6,36} and, therefore, a plant-based diet, which is rich in antioxidants, phytonutrients, and fiber, is vitally important. Plant-based diets are associated with improved glycemic control, lower lipid levels and oxidative stress, and improvement in other physiological and cognitive health factors in type 2 diabetics, and produce better glycemic control compared to a standard ADA diet.³⁷⁻⁴¹ Maintaining diabetic control and avoiding environmental toxins, such as heavy metals, cigarettes, alcohol, and pollution, are of the utmost importance.

Exercise

Regular exercise, that is, walking for a minimum of 30 minutes three times a week, should be implemented. An optimal regimen consists of daily walks for 30 minutes to 1 hour as tolerated (see [Chapter 91](#)).

Although there is inadequate evidence to evaluate the effect of exercise on functional ability in patients with peripheral neuropathy,⁴² some evidence indicates that strengthening exercises improve muscle strength in peripheral neuropathy. Most of the studies involved conventional exercises such as cycling, running, and walking. However, patients may be fearful that exercise may exacerbate their symptoms, as well as increase the possibility of injury.⁴² Physical limitations of their current state of health can lead to decreased compliance, and, therefore, proper guidance and support must be given.

Movement Therapies: Tai Chi, Yoga

Studies have shown that as little as 6 weeks to 6 months of performing tai chi can improve motor performance (e.g., 6-minute walk, leg strength, timed up-and-go), enhance balance (the greatest improvements are seen in patients with large sensory losses), improve plantar sensation, decrease glycated hemoglobin (HbA1c), and improve peripheral nerve conduction velocities.⁶²⁻⁶⁶ Tai chi can be used as a safe and effective intervention for patients with peripheral neuropathy.

Movement therapies, such as yoga and tai chi, are usually gentler and less strenuous and, as such, may lead to better compliance. With proper instruction and supervision, these techniques may be valuable lifestyle behaviors to help patients who may not be able to exercise using conventional modalities.

Mind-Body Therapy

Biofeedback

Biofeedback may be used to reduce stress and improve coping skills, which may aid in improving compliance, thereby promoting better glycemic control and reducing the pain associated with diabetic neuropathy.^{23,67} Biofeedback has been shown to reduce HbA1c directly and to increase blood flow in the extremities, which, in turn, decreases neuropathic pain, reduces stress levels, improves psychological health, and enhances quality of life.⁶⁸⁻⁷² The patient should be referred to a behavioral therapist or a psychologist who teaches biofeedback

techniques. The recommendation is a minimum of six 1-hour biofeedback sessions at approximately 1-week intervals. Usually, the treatments include sessions of guided imagery or relaxation techniques (see [Chapters 94](#) and [97](#)). During these sessions, the patient wears a biofeedback device that indicates physiological responses, such as electromyographic or electrodermal responses, and a vital sign monitor typically for blood pressure, pulse, or oxygen saturation. The monitoring enables patients to conceptualize how emotion, anxiety, stress, and pain can affect their physiological status.

Once patients gain the ability to alter their physiological state, they are taught to perform the relaxation biofeedback techniques at home, at work, or on the go with the use of biofeedback home-use computer, tablet, or smartphone programs⁷² (e.g., emWave Pro, emWave,² Innerbalance [HeartMath Institute, Boulder Creek, CA]), audio CDs, DVDs, or guided imagery exercises 10–20 minutes each day, in order to attain the same result without the monitoring equipment (see [Chapter 96](#)). Therefore biofeedback is a tool that the patient can use to control certain physiological parameters during times of stress or pain in order to help alleviate symptoms.

Bioelectromagnetics

Physical Vascular Therapy

Pulsed electromagnetic frequency (PEMF) devices have rapidly emerged worldwide as a technology used by both physicians and patients. Physical vascular therapy is the new classification of a patented waveform of the next generation of pulsed electromagnetic therapy (PEMF) devices from a company called BEMER, which holds the patent on this technology and has supported most of the research. With all research, the reader should use caution when the majority of the data come from the makers of a device, drug, or supplement. Although PEMF devices are very popular for commercial use, there are few published studies apart from those on BEMER's patented device, which has been used for over 15 years in Europe. When physical vascular technology is applied via a mat, improvements in microcirculatory characteristics, such as capillary perfusion, venular outflow, or oxygen utilization, can occur.⁸²

Increase in microcirculation can improve the transport of cellular and humoral factors of the immune system, leading to decreased pain and increased healing responses. Various case-controlled, pilot, and placebo-controlled studies have shown that the benefits of improving

microcirculation include improved blood glucose response and utilization in organ tissue, improved immune response, increased physical rehabilitation response, improved wound healing, decreased pain and neuropathy, and increased pain-free walking due to peripheral arterial disease.

Increasing microcirculation may improve penetration and increase the efficacy of the medications used to treat peripheral neuropathy.⁸³⁻⁹⁰

In one study of 165 patients with difficult peripheral neuropathic pain that was not controlled adequately with medications, daily use of the device for 2–5 weeks for 25 to 30 minutes was associated with a 61% decrease in pain on a visual analogue scale (VAS). In addition, there was improvement in motor performance (25%), elimination of somatic complaints (5%), elimination of psychological complaints and associated depression (32%), and a significant improvement in the quality of life (75%).⁹¹ Another randomized placebo-controlled study using BEMER vascular technology demonstrated clinically significant improvements in diabetic polyneuropathy and trophic skin lesions of approximately 3 cm² in area. Patients were treated with the BEMER vascular therapy mat for 10 minutes twice daily at level 3 (10.5 = microtesla) for 30 days.⁹² Furthermore, it has been shown to significantly improve sleep and quality of life and lower pain and fatigue.⁹³⁻⁹⁵ BEMER has been shown to have positive effects on neuropathic pain and diabetic complications and can be used safely as an adjunctive therapy.

Bioenergetics

Acupuncture

Acupuncture and electroacupuncture have been found to be useful for neuropathic pain. Because beta endorphins are involved in the pathogenesis of both painful and painless neuropathy,⁹⁸ acupuncture may exert its well-known effect by stimulating the production of endorphins in the central nervous system.⁹⁹ Although acupuncture cannot easily be explained by known neurophysiological mechanisms, several studies have examined the effects of acupuncture in the treatment of various types of peripheral neuropathy, including diabetic, HIV-associated, chemotherapy-induced, and neuropathy of mixed origin.¹⁰⁰⁻¹⁰⁶ In randomized controlled studies, case series, and sham studies, acupuncture was shown to improve nerve conduction velocity, decrease numbness and pain (66%–87%), and improve symptoms more effectively

than conventional medical treatment in peripheral neuropathy induced by chemotherapeutic drugs (66% vs. 40%), especially in moderate and severe sensory nerve disorders.¹⁰⁷⁻¹¹³ In some cases (67%), patients were able to reduce or stop their pain medications.¹¹⁴

Neuroacupuncture has a positive effect on neuropathic pain and often results in the ability to reduce or stop pain medications.

Patients can receive six courses of classical acupuncture analgesia^{115,116} to both lower limbs over a 10-week period. In addition to classical acupuncture, a small, clinical, pilot study of biweekly electroacupuncture treatments for 4 weeks demonstrated a reduction in continuous pain from 32.9% to 15.9% and a decrease in the intensity of pain attacks from 59% to 44%.¹¹⁷ Electroacupuncture may have a positive influence on nerve conduction velocity and may also relieve neuropathic pain.¹¹⁵ Electroacupuncture is performed in two cycles of five sittings each (10 sessions) at 2-day intervals. Most clinical studies provided one to two treatments per week for 10–20 weeks.

There is clinical evidence that an acupuncture subspecialty called neuroacupuncture (Chinese scalp acupuncture) has remarkable effects on central nervous systems disorders.¹¹⁸ A more comprehensive mixture of body acupuncture and neuroacupuncture (with or without electrical stimulation) can improve clinical outcomes by using the following protocol. In my clinical experience, this works very well.

Neuroacupuncture points are the upper one-fifth sensory area (S 1/5) for the lower limbs, middle two-fifths sensory area (S 2/5) for the upper limbs, and foot motor and sensory areas; ear points: ShenMen, sympathetic, foot; body points: GB-40, GB-34, SP-10, SP-6, ST-44, LR-3, and Bafeng (extra point). Electrical stimulation can be used for the ear and body points at a frequency of 100 Hz at low intensity for 10–15 minutes in order to achieve an enhanced response.¹¹⁹

Before such therapies can be recommended, a constitutional evaluation by a practitioner who is trained in acupuncture, or more specifically neuroacupuncture, should be considered because each modality is prescribed on the basis of the unique symptoms and physical characteristics of the patient. A comprehensive review of medical acupuncture and scalp acupuncture for physicians may be found in the various texts by Dr. Joseph Helms¹²⁰ and Dr. Jason Hao.¹¹⁹

Botanical Medicine

Diabetes, diabetic neuropathy, and its complications all have inflammatory triggers and components, as previously described. Many herbs are used for diabetes (see [Chapter 33](#)); however, a few Ayurvedic herbs, such as curcumin,^{121-139,141-150} boswellia,¹⁵¹⁻¹⁶⁹ ginger,¹⁷⁰⁻¹⁸⁹ and black pepper,¹⁹⁰⁻²⁰⁰ are used to treat the pain of diabetic neuropathy and the other complications and comorbidities associated with diabetes.

Curcumin

Curcumin is the active ingredient found in turmeric at a concentration between 3% and 5%. It is widely used as a spice and food colorant throughout India. For more than 4000 years, curcumin has been used in traditional Ayurvedic medicine to treat a wide variety of ailments. It is one of the most researched natural medicines to date, with more than 7000 published studies.

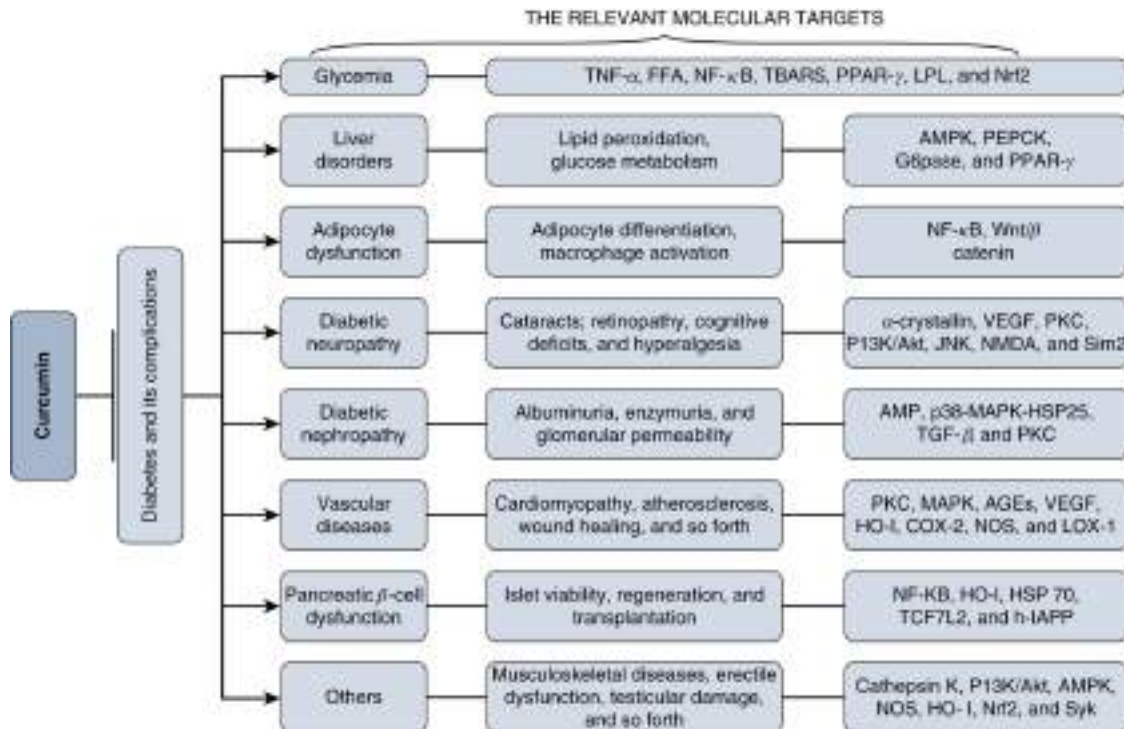

FIG. 13.2 The relevant molecular targets of diabetes and the complications that are modulated by curcumin.

Curcumin has been shown to be beneficial in treating many different

inflammatory diseases, including diabetes and its complications, for example, diabetic neuropathy²⁰¹ (Fig. 13.2). It reduces inflammation through more than¹⁶¹ one biological mechanism, including nuclear factor-kappaB (NF-kB), C-reactive protein, cyclooxygenase-2 (COX-2), 5-lipoxygenase (5-LOX), interleukin (IL)-1beta, IL-6, IL-10, IL-12, tumor necrosis factor-alpha (TNF-alpha), interferon-gamma, activator protein-1, macrophage inflammatory protein (MIP), matrix metalloproteinase (MMPs), human leukocyte elastase (HLE), several types of protein kinases, adhesion molecules, and genes involved in inflammation.^{137-139,141,142,148} In addition, curcumin has been shown to improve endothelial function,^{143,144} reduce vascular inflammation,^{145,146} down-regulate adipokines, including resistin, leptin, and monocyte chemoattractant protein-1, and minimize osmotic stress by regulating the polyol pathway.^{137,202}

Furthermore, it downregulates the p300/CBP HAT activity-mediated gene expression of BDNF and COX-2 in neuropathic pain.²⁰³

Curcumin also demonstrates antinociceptive activity by attenuating diabetic and chemotherapy-induced neuropathic pain,^{147,204-206} and has been shown to provide other benefits for diabetic complications in *in vitro*, animal, and human studies.^{139,207} In addition, curcumin not only helps with pain but has also been shown to have neuroprotective benefits through the following actions:

- Suppression of β -amyloid oligomer-induced phosphorylation of tau and degradation of insulin receptor substrate via c-Jun N-terminal kinase (JNK) signaling. This is beneficial in improving cognitive deficits and insulin signaling in Alzheimer's disease.^{208,205}
- Effects on malondialdehyde and glutathione, oxidative stress index, total antioxidant state, and nitric oxide levels in the brain and sciatic tissue.²⁰⁹⁻²¹¹ This is mediated through regulation of TNF-alpha and TNF-alpha receptors.^{148,212-214} Curcumin is an effective oral TNF-alpha and NF-kB blocker along with other pro-inflammatory markers in diabetes.^{212,213}
- Finally, curcumin may act upon the opioid system for alleviation of diabetic peripheral neuropathic pain.²¹⁴

Therefore, curcumin can be used as a safe analgesic for neuropathic pain while assisting in reversal of insulin resistance, hyperglycemia, hyperlipidemia, obesity, and neurodegenerative disorders, which are common in diabetic patients as well as in the general population.^{137,215}

Dosage

Curcumin 500 mg four times daily or 1000 mg twice daily is commonly used. Absorption can be enhanced by combining curcumin with black pepper. Many combination products are available, such as Bosmeric-SR [a sustained-release formulation that combines patented Curcumin C3 Complex, Boswellin PS, and gingerols (20%) along with Bioperine (black pepper) to enhance absorption], two caplets orally twice daily.

Precautions

Although curcumin is nontoxic to human subjects at high doses,¹³⁸ many curcumin supplements may contain contaminants, such as lead, and are not standardized to the curcuminoids that provide health benefits. Curcumin C3 complex is a patented form of curcumin that is standardized to 95% curcuminoids, including curcumin (70%–80%), bidehydroxycurcumin (2.5%–6.5%), and demethoxycurcumin (15%–25%). Curcumin C3 complex has the most research in human studies at major hospitals and universities and thus is a safe and effective form to be recommended.

Cannabinoids

Through the growing changes in the legalization of cannabis and the use of medical cannabis for chronic pain syndromes, one must start to look at the importance of cannabinoid medicine as part of an integrative medicine approach. Two primary types of cannabinoid receptors (CB1 and CB2) exist on cells throughout the body. These receptors are most abundant in the brain (CNS) and peripheral tissues, respectively. Medical cannabis contains both THC (delta-9 tetrahydrocannabinol), the part that is psychogenic, and CBD (cannabidiols), the part that is not. Both have numerous health benefits in diabetes and its complications.²¹⁶

Cannabinoids represent a new class of therapeutic agents for the treatment of chronic pain and other diseases that involve glycine receptor dysfunction.²¹⁷ In addition to alleviating pain, studies on the benefits of cannabinoids have included improvement of quality of life and sleep.²¹⁸

Randomized placebo-controlled trials (RCTs) involving cannabis and cannabinoids have been used in different populations of chronic neuropathic pain patients to provide effective analgesia in conditions that are refractory to other treatments.²¹⁹

Although currently not available in the US (due to its THC content), a prescription medication called *Sativex*, which contains THC:CBD in an approximate 1:1 ratio, has been investigated. Multicenter, randomized controlled trials, along with double-blind, randomized, placebo-controlled trials, used the THC:CBD oral spray and demonstrated a significant reduction in pain by 30%.²²⁰⁻²²² Current applications are pending with the FDA for the indication for treatment of peripheral neuropathy with this oral spray. However, with this combination THC:CBD formulation, tolerability of increasing doses of THC in lieu of adequate analgesia was the most common side effect and depression was also a confounding factor.²²⁰⁻²²⁶

Newer sources of CBD, which are derived from industrial hemp, containing CBD and traces of THC, are currently available. Therefore, without the psychogenic component and without accessibility being an issue, as it is currently legal and available in all 50 states, these are a great alternative option for patients regardless of the federal and state restrictions that may be in place for medical cannabis.²²⁷ With this opportunity available, CBD has now been studied on its own.

Cannabidiol (CBD) decreases inflammation and neuropathic pain in preclinical models of diabetes. CBD exposure enhances the ability of arteries to relax via enhanced production of vasodilatory COX-1/2-derived products acting at EP4 receptors.²²⁸ CBD decreases the autoimmune inflammatory phenotype,²²⁹ is an inhibitor of NF-kappaB and interferon-beta/STAT pro-inflammatory pathways,²³⁰ and exhibits analgesic^{231,232} and antiinflammatory actions^{233,234} in chronic diseases and cancer. CBD also has been shown to lower inflammation in oxidative stress,²³⁸ and may be used to modify the development of the neuropathic pain state by restricting the elevation of microglial density and phosphorylated p38 MAPK.²³⁹ Furthermore, CBD has been shown to inhibit paclitaxel-induced neuropathic pain without diminishing nervous system function or chemotherapy efficacy.²⁴⁰

A patient's perception of cannabis and CBD extracts depends greatly on their age, their socioeconomic and cultural beliefs, the location and atmosphere of the dispensary, and federal and state restrictions. Many of my patients are simply afraid to try medical cannabis for one or a combination of these reasons, and, therefore, I preferentially use CBD products to provide health benefits without the other issues related to medical cannabis.

CBD is nontoxic in nontransformed cells, does not induce changes in food intake, does not induce catalepsy, does not affect physiological

parameters (heart rate, blood pressure, and body temperature), does not affect gastrointestinal transit, and does not alter psychomotor or psychological functions. No toxicity or side effects have been demonstrated in subjects taking up to 600 mg in a single dose for chronic use. Even higher doses of up to 1500 mg/day of CBD have been shown to be well-tolerated in humans.^{227,241-243}

Dosage

CBD from industrial hemp oil (high CBD, trace THC). Legal in US without need for a medical card; 5–15 mg bid to tid, with coconut oil (to improve absorption) and stevia (optional for improved taste), held sublingually for 2–3 minutes then swallowed. Doses may be increased weekly for improved response.

CBD:THC from medical cannabis. Ratios of CBD:THC vary according to the strains and dispensary. High CBD low THC is preferred (e.g., 20:1), or similar to the prescribed drug worldwide ratio of 1:1. Administration the same as previously but start with lower doses. 1–2 mg bid to tid to start and increase dose as tolerated. Check state regulations on the legality to prescribe for peripheral neuropathy or chronic pain conditions.

Precautions

CBD and medical cannabis products should be validated by third party laboratories and checked for microbial content, pesticides, herbicides, solvents, and percentage amounts of CBD and THC per unit batch or amount acquired. Avoid cannabinoid use in pregnancy and breast-feeding.

CBD may also potentiate many prescription pain medications, NSAIDs, anticonvulsants, and antidepressants and, therefore, reduction of those medications should be monitored as necessary. Acute glucocorticoid use may be potentiated by CBD, and chronic CBD use may downregulate the glucocorticoid response.²⁴⁴

Geranium Oil (*Pelargonium* spp.)

A patented formulation of geranium oil, Neuragen PN, has been clinically studied. It contains a proprietary blend of five essential oils and six homeopathic ingredients. A multicenter, double-blind, crossover trial and a randomized, double-blind, placebo-controlled clinical trial showed a significant reduction in neuropathic pain in 93% of patients within 30 minutes of the application of Neuragen PN. In addition to the immediate reduction of neuropathic pain, 70%–80% had lasting relief up to 8 hours.^{245,246} Geranium oil provides significant pain relief in as little as 5 minutes and lasts up to 8 hours. Therefore, geranium oil can be used as monotherapy or used in conjunction with other treatments for diabetic neuropathy for breakthrough pain or immediate pain relief.

Dosage

Neuragen PN is highly concentrated, and, therefore, one only needs to apply one to two drops to the affected area, rub in, and allow to absorb. It can be applied several times a day but no more than five times daily. For efficient application to wider areas, or for extremely sensitive skin, it is recommended to dilute four or five drops in 1 tablespoon of carrier oil, such as grapeseed oil or jojoba oil, before application. Neuragen PN is now also available in a gel for easy application. Pain relief may be immediate, but it is usually noticed within 30 minutes. If pain relief is not experienced with the first application, repeat the application over a period of 3 days.

Precautions

As with any essential oil, only a few drops are needed because it can irritate the skin. For patients with sensitive skin, it is best mixed with carrier oil first before direct application is attempted. Wash hands after use, and avoid contact with eyes and open sores. Discontinue if rash occurs.

Evening Primrose Oil

Evening primrose oil (EPO) is extracted from the seeds of *Oenothera biennis*. EPO is a rich source of omega-6 essential fatty acids, primarily gamma-linolenic acid (GLA) and linoleic acid, which are both essential components of myelin and the neuronal cell membrane.²⁴⁷ GLA has

demonstrated positive results in the treatment of experimental diabetes and may be more beneficial than docosahexaenoic acid (DHA) in preventing diabetic neuropathy.²⁴⁸⁻²⁵⁰ GLA is converted to prostaglandin E1 (PGE1) preferentially over PGE2. PGE1 has antiinflammatory, antiplatelet, and vasodilating properties. In patients with diabetes, however, levels of PGE1 are decreased, and levels of PGE2 and thromboxane are increased,²⁵¹ and therefore, inflammation, vasoconstriction, and platelet aggregation tend to be promoted.²⁵³ Supplementing the diet with GLA has been shown to augment the production of PGE1 (by bypassing the blocked enzymatic step delta-6-desaturase) that is seen in patients with hyperglycemia.²⁵⁴⁻²⁵⁶

Two of three randomized controlled trials showed positive effects of GLA in diabetic neuropathy.²⁴⁷ Two trials with GLA at 360 mg/day for 6 months and 480 mg/day for 1 year demonstrated statistically significant improvements in neuropathy scores, nerve conduction velocities, and action potentials. Therefore, EPO may be helpful for mild to moderate diabetic peripheral neuropathy.

Dosage

The dose is 360 mg/day of GLA from EPO (the most researched source of GLA, as opposed to borage oil or black currant oil), and it may be increased up to 480 mg/day. Obtain high-quality oil (preferably certified organic), packaged in light-resistant containers, refrigerated, and marked with a freshness date to avoid rancidity.

Precaution

EPO may increase the effectiveness of ceftazidime, chemotherapy agents, and cyclosporine, and may interact with phenothiazines and cause an increase in seizures. Patients taking antiplatelet agents or anticoagulants should use EPO cautiously or not at all. Theoretically, the use of nonsteroidal antiinflammatory drugs (NSAIDs) may counteract the effect of EPO.

Supplements

Many supplements have been shown to be helpful for the symptoms of diabetes (see [Chapter 33](#)) and, in particular, peripheral neuropathy. The

supplements with the best results for peripheral neuropathy are discussed here.

Acetyl-L-Carnitine

Acetyl-L-carnitine (ALC) is an acetylated form of L-carnitine, which is an amino acid that is responsible for the transport of fatty acids into a cell's mitochondria. ALC is far superior to normal L-carnitine in terms of bioavailability in that it is absorbed by the gastrointestinal tract, enters cells, and crosses the blood–brain barrier more readily than does unacetylated carnitine.

Peripheral neuropathy is a common side effect of chemotherapeutic drugs, which belong to the platinum, taxane, vinca alkaloid, and proteasome inhibitor families. Animal studies have shown the benefits of ALC as a specific protective agent when it is given concomitantly and after treatment for chemotherapy-induced neuropathy due to cisplatin, oxaliplatin, paclitaxel, and vincristine, without any interference with the antitumor activity of the drugs.²⁵⁷⁻²⁵⁹ ALC has been shown to reduce pain significantly in diabetic neuropathy.²⁶⁰⁻²⁶² Furthermore, studies in humans showed that ALC, given as a 1-g/day infusion over 1–2 hours for at least 10 days, improved chemotherapy-induced peripheral neuropathy in up to 73% of patients.²⁶³ Patients with chemotherapy-induced peripheral neuropathy who were treated with oral ALC (1 g three times a day) for 8 weeks showed sensory improvement (60%) and motor improvement (79%), and their total neuropathy scores, including neurophysiological measures, improved (92%), with symptomatic improvement persisting for a median of 13 months after ALC treatment.²⁶⁴ In addition to chemotherapy-induced peripheral neuropathy, multiple long-term (1-year) randomized, double-blind, placebo-controlled studies showed that ALC improves pain, nerve regeneration, and vibratory perception in patients with chronic diabetic neuropathy.^{265,266} ALC appeared to work more effectively in patients with type 2 diabetes, with a shorter duration of neuropathy than in patients with type 1 diabetes.²⁵²

Dosage

The recommended dose is 500 mg orally twice a day to 1000 mg orally three times a day. Better pain control is seen at the higher dose regimen.

Precautions

ALC may cause nausea, vomiting, diarrhea, headache, bladder irritation or infection, unusual body odor, stuffy nose, and rash. Other side effects associated with ALC include restlessness and difficulty sleeping.

Alpha-Lipoic Acid (ALA)

Alpha-lipoic acid (ALA), also known as thiotic acid, is approved for clinical use in the management of diabetic neuropathy in Germany, and has been extensively used there in medical practice since 1959.²⁶⁶ ALA is a universal antioxidant, exerting direct (scavenges free radicals) and indirect (participates in the process of recycling other natural antioxidants, thereby increasing glutathione, vitamins C and E, and coenzyme Q10) antioxidant activity.²⁶⁷⁻²⁷⁰ ALA chelates transition metal ions (e.g., iron and copper) and effectively mitigates toxicities associated with heavy metal poisoning.²⁷¹ Investigators have established that ALA protects against lipid peroxidation and increases the activity of antioxidant enzymes (e.g., catalase and superoxide dismutase) in peripheral nerves. By decreasing oxidative stress through the inhibition of hexosamine and AGE pathways, ALA normalizes impaired endoneural blood flow and impaired nerve conduction velocity.^{272,273}

Several studies have established the neurogenerative and neuroprotective effects of ALA. The efficacy and safety of ALA in peripheral and autonomic diabetic neuropathy have been demonstrated in many randomized, double-blind, placebo-controlled trials.²⁷⁴⁻²⁸⁸ A meta-analysis provided evidence that treatment with ALA significantly improves both positive neuropathic symptoms and neuropathic deficits to a clinically meaningful degree in diabetic patients with symptomatic polyneuropathy.²⁸⁹ Further studies have shown that the oral forms of ALA are effective for peripheral neuropathy.²⁹⁰ ALA has been shown to be effective for diabetic mononeuropathy of the cranial nerves with full recovery of all of the patients in the study.²⁹¹ The studies ranged from a minimum treatment of 3 weeks to 2 years, and, therefore, 3 weeks is likely to be the minimum treatment time. Although greater improvements were seen with higher doses, so were adverse effects such as gastrointestinal upset and headaches.²⁸⁹

Most studies on ALA used parenteral doses ranging from 600 to 1800 mg, which demonstrated more rapid response than oral doses at the

same dose range, and found a continuous daily improvement in symptom scores beginning on the eighth day of treatment.²⁸⁹ Unfortunately, the parenteral form of ALA is not currently available as a prescribed therapy in the United States, and only the oral form is available in various doses. In most studies, 600 mg seems to be the starting dose. To obtain similar results, patients should use high-quality products from manufacturers that source ALA from Europe (Germany or Italy).

Dosage

ALA is given orally at 600–1800 mg daily. Start with 600 mg daily, and increase up to 1800 mg daily in divided doses if needed.

Precautions

Although no evidence has indicated that ALA affects glycemic control, case studies have shown improved glucose handling in diabetic patients.²⁷¹ As a precaution, patients who are predisposed to hypoglycemia, including those receiving hypoglycemic agents, should have blood glucose levels monitored closely. In addition, because ALA acts as a chelator, monitor for possible mineral deficiencies. Gastrointestinal upset may occur at higher doses. Rarely, this supplement may cause rash.

B Vitamins

Benfotiamine: Vitamin B1

Benfotiamine, also known as S-benzoylthiamine-O-monophosphate, is a lipid-soluble derivative of vitamin B1 (thiamine) and is absorbed up to 3.6 times more than water-soluble forms. Vitamin B1 is associated with a 120-fold greater increase in the levels of metabolically active thiamine diphosphate. Its lipid solubility allows it to penetrate the nerves more readily. It has been found to provide a higher bioavailability of thiamine than its water-soluble counterparts.²⁹²⁻²⁹⁴ Benfotiamine reduces advanced glycation end-products (AGE) by 40%, which has been shown to prevent macro- and microvascular endothelial dysfunction in individuals with type 2 diabetes.²⁹⁵⁻³⁰⁰

Studies have shown that benfotiamine improves neuropathy scores significantly,^{301,302} increases nerve conduction velocity,³⁰³⁻³⁰⁵ and reduces HbA1c and pain.³⁰⁶ On the Russian market, it is one of the most studied drugs for neuropathic pain.³⁰⁶ In addition, it lowers inflammation and may be useful for ameliorating the analgesic effect of mu-opioid agonists on neuropathic pain.³⁰⁷⁻³⁰⁹ In a randomized, placebo-controlled, double-blind pilot study and phase III clinical study, investigators demonstrated a pronounced effect on the decrease in pain^{310,311} in conjunction with the previously described benefits. Benfotiamine may also be beneficial in preventing diabetic nephropathy³¹² and retinopathy.³¹³ Therapeutic benefits can be seen as early as 3 weeks, with the most significant improvements occurring in patients taking the highest-dose of benfotiamine, that is, 600 mg/day at 6 weeks.^{310,311,314}

Dosage

The recommended dose of benfotiamine is 150–300 mg twice daily specifically for diabetic peripheral neuropathy.

Methylcobalamin: Vitamin B12

Methylcobalamin is the active form of vitamin B12. In a small double-blind, placebo-controlled trial of type 1 and 2 diabetes with neuropathy, the patients given oral methylcobalamin at a dose of 500 mcg three times daily showed significant improvements in somatic and autonomic symptoms compared to placebo.³¹⁶ A review of several clinical trials on the use of methylcobalamin alone or in combination with other B vitamins found overall symptomatic relief of neuropathy symptoms that was more pronounced than electrophysiological findings.³¹⁷ In addition, supplementation of 1500 mcg/day methylcobalamin for 2 months resulted in improved vibratory perception thresholds and heart rate variability (a sign of improvement in autonomic neuropathy) in patients with diabetes.³¹⁸

Dosage

For the best bioavailability and absorption, the recommended dose is 500 mcg three times daily or 1500 mcg daily of methylcobalamin or 5-

adenosylcobalamin. Most generic vitamins contain cyanocobalamin, which may not be as effective or as beneficial.

B-Complex Multivitamin

Vitamins B1 (thiamine), B6 (pyridoxine), and B12 (cobalamin) play an important role in the pathogenesis of peripheral neuropathy in deficiency syndromes, such as those resulting from alcoholism or pernicious anemia, isoniazid-induced pyridoxine deficiency, and malabsorption syndromes. If peripheral neuropathy is caused by deficiency syndromes, use B-100 complex (a multivitamin that usually contains 25–100 mg of thiamine, riboflavin, niacin, pyridoxine, and pantothenic acid and may also include other vitamins such as folate) for ease of administration and intake of all B vitamins.

Dosage

B-complex multivitamin (B-100), one tablet once or twice daily, is taken for peripheral neuropathy caused by deficiency syndromes. The B vitamins methylcobalamin and 5-adenosylcobalamin (vitamin B12), and the 5-methyltetrahydrofolate (5-MTF) form of folate should be used in these formulations.

Precautions

Avoid excessive doses of vitamin B6 (pyridoxine). Doses higher than 250 mg/day can cause reversible nerve damage.

In prescribing B-complex vitamins, make sure that the patient is not already taking another vitamin supplement that may contain B vitamins. Vitamin B3 (niacin) in doses greater than 300 mg/day may cause headache, nausea, skin tingling, and flushing. Vitamin B6 in doses greater than 250 mg/day may cause reversible nerve damage.

Fish Oil: Omega-3 Fatty Acids

Similar to EPO (GLA), omega-3 fatty acids are also essential for healthy nerve cell membranes and blood flow.³¹⁹ Omega-3 fatty acids have been

found to have neuroprotective effects against experimental diabetic neuropathy, reduce neuropathic pain, proinflammatory cytokine production, and other metabolites and benefit macrovascular and microvascular functioning in diabetics.³²⁰⁻³²⁵ In a case series, omega-3 fatty acids were shown to decrease pain and improve function, and, in a randomized, double-blind, placebo-controlled trial, were found to be protective against paclitaxel-induced peripheral neuropathy.^{326,327} Furthermore, a clinical study of diabetic patients with neuropathy who consumed 1800 mg eicosapentaenoic acid (EPA) daily for 48 weeks reported significantly decreased cold and numb sensations and improved vibrational perception, in addition to improved vibratory threshold. Circulation, measured in the dorsalis pedis artery, and lipid profiles also significantly improved.³²⁸

Dosage

Doses are EPA, 1000–2000 mg/day, and DHA, 500–1000 mg/day. The natural triglyceride form provides superior absorption and bioavailability, up to 70% more than preparations with ethyl ester forms.³²⁹ For patients who are vegan or allergic to fish, a plant-based form of EPA and DHA called NutraVege is available. It contains Echium plantagineum oil (stearidonic acid, a precursor of EPA), and algal DHA and GLA. High-potency fish or plant oils should be used to obtain the clinical dose.

Precautions

Possible blood thinning effects may occur with higher doses. Patients taking anticoagulant medications should be closely monitored.

Pharmaceuticals

Capsaicin

Capsaicin, which is an extract of chili peppers, when applied topically, has been demonstrated to relieve neuropathic pain by affecting sensory fibers, especially C fibers,³³⁰ and by depleting endogenous neurotransmitter stores associated with pain transmission, such as substance P, vasoactive intestinal peptide, cholecystokinin, and somatostatin.³³¹ Capsaicin does not reverse, stabilize, or lessen

neuropathy but decreases the pain that occurs from it. It can result in a burning sensation with the first few weeks of use. Successive applications, however, result in a dose-dependent degeneration and desensitization of afferent fibers, blocking further action potential conduction.³³⁰ Patients should be advised to continue use, if the pain is tolerable, for at least 4–6 weeks before the full benefits are appreciated.

A Cochrane Database Systematic Review showed that capsaicin, either as repeated application of a low-dose (0.075%) cream or a single application of a high-dose (8%) patch, may provide a significant degree of pain relief to some patients with painful neuropathic conditions.³³² In addition, patients with postherpetic neuralgia and painful HIV-associated distal sensory polyneuropathy were studied in randomized, double-blind, multicenter trials using a high-concentration capsaicin dermal patch successfully for up to 1 year; this patch is now available by prescription.³³³⁻³³⁵

Dosage

Capsaicin cream is available over the counter (Capzacin HP, Zostrix HP). Various strengths range from 0.025% to 0.1%, although clinical studies use the 0.075% strength. The cream is applied to the affected area up to three or four times daily for at least 4–6 weeks. Clinical trials show that application must take place three or four times a day for improvement.³³² Using it daily, twice daily, or on an as-needed basis is likely to be ineffective.

The capsaicin 8% patch (Qutenza) is by prescription only and is applied in a physician's office. The painful area is pretreated with anesthetic, and the patch is applied for 1 hour and then removed. One patch provides relief for up to 3 months. Follow insert directions for specific application procedures.

Precautions

Application with gloves is recommended. Wash hands immediately after application, and avoid contact with the eyes or mucous membranes. Local skin irritation, which is often mild and transient but may lead to withdrawal, is common. Systemic adverse effects are rare.

Antidepressants

The Neuropathic Pain Special Interest Group of the International Association developed evidence-based guidelines for the pharmacological treatment of neuropathic pain using first-line treatment options, including tricyclic antidepressants (TCAs), dual reuptake inhibitors of serotonin and norepinephrine, and calcium channel $\alpha 2$ - δ ligands.³³⁶ The results of a systematic review defined clinical success as a 50% reduction in pain. Investigators found that TCAs were the most effective analgesics, followed by traditional anticonvulsants and the newer-generation anticonvulsants, respectively.³³⁷ However, the review concluded that the efficacy of most of these pharmacological treatments is limited because, for any particular drug, only 30% of treated patients experience analgesia.³³⁸ With these low analgesic response rates and the risk of side effects, the use of integrative therapies and dietary supplements is therefore recommended in a trial of benefit before treatment with pharmaceuticals.

Tricyclic Antidepressants

TCAs, such as amitriptyline (Elavil, Endep), nortriptyline (Aventyl, Pamelor), and desipramine (Norpramin), have been commonly used as the mainstay for the palliation of pain secondary to diabetic neuropathy.³³⁹ Many placebo-controlled, randomized controlled trials found TCAs to be efficacious for several different types of neuropathy.³⁴⁰ TCAs work by increasing the postsynaptic concentration of norepinephrine. Because the inhibitory pathways in the spinal cord use norepinephrine as a neurotransmitter, TCAs are believed to increase the inhibitory influence on nociceptive transmitting neurons.³⁴¹ Selective serotonin reuptake inhibitors (SSRIs), such as fluoxetine and paroxetine, have also been used; although they are better tolerated than TCAs, they have little or no efficacy in relieving pain.³⁴²⁻³⁴⁴

Dosage

To minimize side effects and encourage compliance, start therapy with amitriptyline or nortriptyline at a dose of 10 mg at bedtime. Titrate this dose upward to 25 mg at bedtime as side effects allow, in 10–25-mg increments. Even at lower doses, patients generally report rapid improvement in sleeping and begin to experience some pain relief in

10–14 days. If no pain relief is obtained with increased doses (usual range, 50–300 mg/day), the addition of gabapentin (Neurontin), alone or in combination with local anesthetic nerve blocks, is recommended.³⁴⁵ The slow onset of action of TCAs and their potential side effects often require a gradual dose buildup (6–8 weeks) before maximum efficacy and tolerance are achieved.

Precautions

Significant anticholinergic side effects, including dry mouth, constipation, sedation, and urinary retention, are common. TCAs are contraindicated in patients who have significant ischemic heart disease, and these drugs may also cause arrhythmias and orthostatic hypotension (thus should be avoided in older persons because of the risk of falling). Limit doses to less than 100 mg/day when possible. Screening electrocardiography for patients older than 40 years is recommended. These agents are not to be used with monoamine oxidase inhibitors (MAOIs).

Serotonin Norepinephrine Reuptake Inhibitors

- Venlafaxine (Effexor)
- Duloxetine (Cymbalta)

Although both drugs have been used traditionally as antidepressants, studies on venlafaxine and duloxetine have demonstrated beneficial treatment for reduction of painful diabetic neuropathy with better tolerability and fewer side effects than TCAs.³⁴⁶⁻³⁵⁰ Although these studies are positive and duloxetine has been granted US Food and Drug Administration (FDA) approval for the treatment of neuropathic pain, the effects have been found to be less than 12 weeks in duration, and therefore the long-term efficacy and safety are unknown.

Dosage

For venlafaxine ER, the dose is 150–225 mg daily; start with 150 mg daily, and increase to 225 mg daily if a greater analgesic effect is needed. The maximum dose of duloxetine is 60 mg daily; start with 30 mg daily and increase to 60 mg daily if a greater analgesic effect is needed. With both medications, higher doses increase the risk of side

effects.

Precautions

Nausea, dyspepsia, somnolence, and insomnia are possible. Venlafaxine may cause cardiac rhythm changes. Duloxetine may decrease sodium, uric acid, chloride, gamma-glutamyltransferase, and alanine aminotransferase. It may also increase bicarbonate and alkaline phosphatase levels.

Anticonvulsants

- Gabapentin: First-line choice
- Pregabalin (Lyrica): First-line choice

Gabapentin has been shown to be highly efficacious in the treatment of various painful neuropathic conditions, including postherpetic neuralgia and diabetic neuropathy.³⁵² Based on the reviewed randomized controlled trials, gabapentin shows good efficacy, a favorable side effect profile (especially when compared with phenytoin and carbamazepine), and fewer drug interactions; therefore, it may be a first-choice treatment in painful diabetic neuropathy, especially in older adults.^{353,354} The number needed to treat (NNT) was reported as 5.8.³⁵⁵ The precise mechanism of action of anticonvulsants to account for their analgesic effects is unknown. Anticonvulsants modulate both peripheral and central mechanisms through sodium channel antagonism, inhibition of excitatory transmission (e.g., N-methyl-d-aspartate receptor), or enhancement of gamma-aminobutyric acid-mediated inhibition.³⁵⁶

Pregabalin is a selective high-affinity ligand for the $\alpha 2\text{-}\delta$ subunit of the voltage-gated calcium channel,³⁵⁷ which plays a role in the pathological changes that are believed to be associated with neuropathic pain in humans.^{358,359} Double-blind, placebo-controlled trials have shown that pregabalin is effective in the treatment of diabetic peripheral neuropathy and postherpetic neuralgia, and that it produces significant improvement in various pain scores and reduced sleep interference.^{360,361} The FDA has approved pregabalin for the management of neuropathic pain associated with diabetic peripheral neuropathy and postherpetic neuralgia. Pregabalin is structurally and mechanistically related to gabapentin but differs from gabapentin in exhibiting linear pharmacokinetics with increasing doses and low intersubject variability. These properties may make pregabalin easier to prescribe and could impart a more effective dose range with potentially fewer side effects. Although pregabalin has

become a first-line agent in the treatment of diabetic peripheral neuropathy and postherpetic neuralgia, all of the studies were less than 13 weeks in duration, and, therefore, the long-term durability of the response and safety are unknown. The NNT was 6.3.³⁶² Physicians should also consider cost before prescribing this agent.

Gabapentin

Dosage

A single bedtime dose of 300 mg of gabapentin for 2 nights can be followed by 300 mg given twice daily for an additional 2 days. If the patient tolerates this twice-daily regimen, the dose can be increased to 300 mg three times a day. Additional titration upward can be carried out in 300-mg increments as side effects allow. Total daily doses greater than 3600 mg are not currently recommended.³⁴⁵ A possible combination with 10–25 mg of TCAs (see earlier) can be added for patients with sleep disturbance.

Precautions

The most serious concern with gabapentin is leukopenia. This drug can also cause somnolence, dizziness, ataxia, and fatigue. Taper dose over 7 days or longer to discontinue.

Pregabalin (Lyrica)

Dosage

Pregabalin is taken at 50–150 mg daily, divided into two or three doses. After an initial daily dose of 150 mg, it should be titrated with the patient's response and tolerability over 2 weeks to a maximum of 300 mg daily. Pregabalin dosage adjustment should be considered in cases of renal impairment.³⁶³

Precautions

The most common side effects are dizziness, somnolence, headache,

dry mouth, and peripheral edema.

Analgesics

Simple analgesics, such as acetaminophen, aspirin, naproxen, and ibuprofen, may be used in conjunction with anticonvulsants and antidepressants; however, the response is very poor. Caution must be taken because many NSAIDs received black box warnings and can cause fatal cardiac and gastrointestinal events. Do not exceed the recommended daily dose because of the risk of renal and hepatic toxicity, particularly in diabetic patients.

Narcotic analgesics are also suboptimal agents for pain control. Owing to their significant central nervous system and gastrointestinal side effects, coupled with the problems of tolerance, dependence, and addiction, these agents should rarely be used, if ever. If a narcotic analgesic is considered, the analgesic tramadol (Ultram), which binds weakly to opioid receptors, may provide some symptomatic relief.

Dosage

Tramadol, 50–100 mg, is taken every 6 hours as needed for pain; the maximum dose is 400 mg per day. Caution should be used with the combination of tramadol, antidepressants, and anticonvulsants, owing to increased seizure risk.

Biomechanical Modalities

Electrical Stimulation

Electrical stimulation modalities, such as transcutaneous electrical nerve stimulation (TENS)³⁶⁴ and application of spinal cord stimulators,³⁶⁵ have been used successfully to alleviate the pain and discomfort associated with peripheral neuropathy. TENS portable units that generate a biphasic, exponentially decaying wave form (pulse width 4 msec, 25–35 V, more than 2 Hz) should be used for 30 minutes daily for 4 weeks. A study showed that percutaneous electrical nerve stimulation (PENS), in addition to decreasing pain, improves the patient capacity for physical activity, sense of well-being, and quality of sleep, while reducing the need for oral nonopioid analgesic medication.³⁶⁶ PENS is similar to

electroacupuncture in that electrical stimulation is delivered via disposable acupuncture-type needles. It differs from electroacupuncture in that it is delivered along the peripheral nerves that innervate the region of neuropathic pain, rather than being delivered at acupuncture points or along meridians. Although the use of alternating low and high frequencies of 15 and 30 Hz at 30-minute intervals three times a week is recommended, the patient should be evaluated by a health care professional who is familiar with electrical stimulation techniques for adjustment of frequencies and time intervals as tolerated.

Neural Blockade

Local anesthetic peripheral and sympathetic blocks provide useful diagnostic information but tend to confer only temporary therapeutic benefits in patients with peripheral neuropathy.³⁶⁷

Surgery

Entrapment neuropathies, such as carpal tunnel syndrome, may be relieved by surgical decompression (see [Chapter 70](#)). In addition, compression or entrapment from cancers may be addressed by removal of the tumor directly.

Therapies to Consider

Agaricus brasiliensis

Agaricus brasiliensis (AbS) is native to Brazil and is widely grown in Japan because of its medicinal properties. AbS has traditionally been used for the prevention of a range of diseases, including cancer, hepatitis, atherosclerosis, hypercholesterolemia, dermatitis, and diabetes.³⁶⁸⁻³⁷⁰ Randomized, double-blind, placebo-controlled trials have shown that AbS improves insulin resistance in type 2 diabetes.³⁷¹ Furthermore, in animal studies, it has been shown to reduce inflammatory mechanisms and lower diabetic neuropathic pain.³⁷²

Tocotrienols

Tocotrienols, more specifically delta and gamma isomers that are derived from annatto and palm, are an important part of Vitamin E, which is now being extensively researched for its antihyperlipidemic, antidiabetic,

antiinflammatory, anticancer, and immune-supportive actions.³⁷³⁻³⁷⁶ In human and animal studies, tocotrienols have been shown to improve diabetes and to reduce neuropathic pain.³⁷⁷ Current clinical trials are underway to investigate neuroprotection by tocotrienols in type 1 and type 2 diabetes mellitus (VENUS). Note that tocotrienols are very temperature sensitive, therefore, these products should be kept refrigerated,³⁷⁸ and should not be taken with other forms of Vitamin E (e.g., alpha-tocopherols) for the best absorption.³⁷⁹⁻³⁸¹ Tocotrienols may be started at a dose of 125 mg bid or tid.

Prevention Prescription

- Eat a whole-foods, low-fat, high-fiber, plant-based diet.
- Avoid environmental toxins such as heavy metals, cigarette smoke, alcohol, pesticides, and herbicides.
- Prevent adult-onset diabetes by maintaining an ideal weight and staying physically fit and active.
- If possible, avoid specific toxins (see [Table 13.1](#)) and pharmaceutical agents that are known to cause neuropathy (see [Table 13.2](#)).
- Avoid doses of vitamin B6 (pyridoxine) greater than 250 mg/day.
- If taking the chemotherapeutic medications cisplatin, paclitaxel (Taxol), or vincristine, consider acetyl-L-carnitine, 1 g three times daily for 8 weeks.

Therapeutic Review

Lifestyle and Nutrition

- Daily exercise that consists of walking for at least 30 minutes per day three times per week should be implemented. If walking is not possible because of painful peripheral neuropathy, gentler forms of exercise, such as yoga or tai chi, three times a week for 30–90 minutes are therapeutic. A whole-foods, low-fat, high-fiber, plant-based diet with strict glycemic control should be strongly advised. Environmental and other toxins, such as heavy metals, cigarette smoke, alcohol, and pollution, should be avoided.

Mind-Body Therapy

Biofeedback

- Recommendation is for at least six 1-hr biofeedback sessions at approximately 1-week intervals. Thereafter, relaxation biofeedback techniques can be performed at home with the use of biofeedback home-use programs (e.g., emWave Pro, emWave 2, Innerbalance [HeartMath Institute]), audio CDs, or guided imagery exercises (for 10–20 minutes each day).

Bioenergetics

- Pulsed electromagnetic field (PEMF): BEMER vascular therapy mat for 10 minutes twice daily at level 3 (10.5 = microtesla) for 30 days.
- Acupuncture and neuroacupuncture points: upper one fifth sensory area (S 1/5) for the lower limbs, middle two fifths sensory area (S 2/5) for the upper limbs, and foot motor and sensory areas; ear points: ShenMen, sympathetic, foot; body points: GB-40, GB-34, SP-10, SP-6, ST-44, LR-3, and Bafeng (extra point). Electrical stimulation can be used for the ear and body points at a frequency of 100 Hz at a low intensity for 10–15 minutes for an enhanced response. Patients can receive 2 treatments per week for 10 weeks.
- Electroacupuncture: This treatment can be performed in two cycles of five sittings each (10 sessions) at 2-day intervals.

Botanicals

- *Curcumin longa*, *Boswellia serrata*, ginger, and black pepper (e.g., Bosmeric-SR, two caplets twice daily) or Curcumin C3 complex: 1000 mg three times daily.
- Cannabidiols (CBD) from industrial hemp oil: 5–50 mg tid, with coconut oil (to improve absorption) and stevia (optional for improved taste), held sublingually for 2–3 minutes then swallowed. Doses may be increased weekly for improved response.
- CBD:THC from medical cannabis. High CBD low THC is preferred (e.g., 20:1), or for more pain control, a ratio of 1:1, which is similar to the prescribed drug in other countries. Administration is the same as

previously, but start with lower doses. 1–2 mg bid to tid and dose up as tolerated. 

- Geranium oil (*Pelargonium* spp.): For topical pain relief, apply a few drops (i.e., Neuragen PN) to the affected area several times a day. 
- Evening primrose oil (EPO; *Oenothera biennis*): 360 mg orally daily of GLA from EPO. The dose may be increased up to 480 mg orally daily. 

Supplements

- Acetyl-L-carnitine (ALC): 500 mg orally twice daily to 1000 mg orally three times daily. ALC is used for both chemotherapy-induced and diabetic peripheral neuropathy. 
- Alpha-lipoic acid: 600–1800 mg orally daily; start with 600 mg orally daily and increase up to 1800 mg orally daily in divided doses if needed. 
- Benfotiamine: Lipid-soluble vitamin B1, 150–300 mg twice daily specifically for diabetic peripheral neuropathy. 
- Methylcobalamin or 5-adenosylcobalamin: Better-absorbed vitamin B12, 500 mcg three times daily or 1500 mcg daily. 
- B-complex multivitamin (B-100): One tablet once or twice daily for peripheral neuropathy caused by deficiency syndromes. 
- Fish oil (omega-3 fatty acids): Eicosapentaenoic acid (EPA), 1000–2000 mg/day, and docosahexaenoic acid (DHA), 500–1000 mg/day or a vegetarian plant-based option (i.e., NutraVege 2x). 

Pharmaceuticals

For topical relief:

- Capsaicin cream 0.075%: Apply to the affected area up to three or four times daily for at least 4–6 weeks. 
- Capsaicin patch (8%): One patch to area for 1 hour (after preanesthetic application) and then remove. It is applied in a doctor's office under supervision. 

For acute pain management, consider:

- Analgesics: Nonsteroidal antiinflammatory drugs (NSAIDs) as usually prescribed for pain, as well as narcotics. 

For chronic pain management:

Antidepressants

- Amitriptyline or nortriptyline: 10 mg orally at night; titrate the dose upward to 25 mg orally at night as side effects allow (usual range: 50–300 mg/day). 
- Gabapentin (first-line choice): 300 mg orally at night for 2 days, then 300 mg orally twice daily for 2 days; can be increased to 300 mg orally three times daily as tolerated, with increases in 300-mg increments as side effects allow; maximum daily dose, 3600 mg. 
- Pregabalin: 50 mg three times daily. After an initial daily dose of 150 mg, it should be titrated according to the patient's response and tolerability over 2 weeks to a maximum of 300 mg daily. 

Biomechanical Therapy

- Transcutaneous electrical nerve stimulation (TENS): Use of a TENS portable unit for 30 minutes daily for 4 weeks is recommended. 
- Percutaneous electrical nerve stimulation (PENS): This modality can be used three times a week; stimulation is delivered along the peripheral nerves that innervate the region of neuropathic pain. 
- Neural blockade: This provides only temporary therapeutic benefit. 
- Surgery: Surgical decompression may relieve symptoms in carpal tunnel syndrome; with neuronal entrapment from cancer, removal of the tumor itself may also be helpful.

CHAPTER 14

Multiple Sclerosis

Bradly Jacobs, MD, MPH, ABOIM, and Surya Pierce, MD

Pathophysiology

Multiple sclerosis (MS) is the most common cause of chronic neurological disability in young adults, with a prevalence that varies geographically from 1 to 2.5 per 1000.¹

Although its origin and exact mechanisms remain uncertain, MS is a complex disorder that is characterized by axonal injury, inflammation, and demyelination. The triggers for axonal loss are thought to be caused by inflammatory demyelination of the myelin sheath and ATP-related hypoxia of the neurons causing neurodegeneration. Progressive neurological disability is the result of this axonal damage and loss. Demyelination impairs the transmission of nerve impulses and results in fatigue, weakness, numbness, locomotor difficulty, pain, loss of vision, and other health problems. In general, MS is viewed as an autoimmune disorder that transpires when internal antibodies mistakenly direct their “attack” against the body’s own nerve cells.

Research suggests that MS is more correctly thought of as one end of a spectrum of central nervous system (CNS) disorders, and is the byproduct of a malfunctioning physiological immune response, the original purpose of which is protective. According to this view, all individuals are endowed with the potential ability to evoke an autoimmune response to CNS injuries (viral, bacterial, toxin, or direct injury). The inherent ability to control this response, so that its effect is beneficial, is limited, and correlates with an individual's inherent ability to resist autoimmune disease induction.²

Because of the wide variation in disease presentation and the development of treatment protocols, it is useful to categorize MS patients into the following four groups³:

1. Relapsing-remitting (RR) disease occurs at onset in 80% of cases, and is characterized by acute attacks followed by remissions with a steady baseline between attacks. Patients with a definite diagnosis of relapsing-remitting MS should be considered for disease-modifying therapy.
2. In 50% to 80% of patients with RR disease, progressive deterioration with less marked attacks occurs within 10 years of onset. The disease in these patients is called secondary progressive phase MS (SP-MS).
3. Primary progressive MS (PP-MS) occurs in 10% to 15% of patients and is characterized by progressive deterioration from the outset without superimposed relapses.
4. Approximately 6% of patients with PP-MS also experience relapses in parallel with their disease progression and are said to have progressive-relapsing MS (PR-MS).

Etiology

Research into the causes of MS has been rendered difficult by the marked variation in the disease expression. It is unclear whether MS is one disease with variable symptoms or whether the different subtypes represent unique causes.⁴ At present, four major theories for the cause of MS are recognized: immunological, environmental, infectious, and genetic.

Immunological Factors

The theory that MS is an organ-specific autoimmune disease, although unproven, is widely accepted. Antibodies against antigens that are located on the surface of the myelin sheath cause demyelination, either directly or by complement-mediated processes. Investigators have suggested that priming of myelin-reactive T cells occurs as part of the disease process in MS. Primed T cells that are reactive to myelin antigens may develop a phenotype that makes them more resistant to regulatory processes. The concept that autoantigens can drive B-cell clonal expansion and contribute to autoimmunity has been demonstrated in other autoimmune diseases. The role of B cells in the recovery from inflammatory demyelination has also been hypothesized.⁵

The hygiene theory claims that childhood exposure to infectious agents is beneficial to the maturing immune system through modulation of T-helper cells, that is, Th1 and Th2. Indeed, research has found that autoimmune conditions, including MS, are less prevalent in parts of the

world where infectious agents, such as helminths and toxoplasmosis, are endemic. Furthermore, case reports have documented a reduction in disease severity following travel to developing countries. Extrapolating from phase 1 trials on patients with inflammatory bowel disease, investigators conducted a phase 1 study enrolling five patients with MS and treating them with nonpathogenic helminths (*Trichuris suis* [pig whipworm]), given twice monthly for 3 months. The intervention was well tolerated with no adverse events, and patients experienced an average reduction of brain lesions from 6.6 to 2.0 on MRI, which then increased to 5.8 lesions 2 months after the intervention was discontinued.⁶ Another study using similar helminths showed that the treatment was well tolerated but that no benefit was seen.⁷ A 50-patient, phase 2, randomized study in Germany is now ongoing.^{8,9}

Environmental Factors

Several decades of research have documented that the incidence of MS increases with increasing distance from the Equator. Possible explanations for this finding include genetic predisposition in population groups, dietary factors, and levels of the active form of vitamin D. Evidence indicates that the timing of the exposure to an environmental agent plays a role, with exposure before puberty predisposing a person to the development of MS later in life.¹⁰ A dietary influence on MS was first reported by Swank et al. in 1952,¹¹ who noted that people living in colder climates tend to consume diets that are higher in fat compared to those living in more tropical regions, and that this dietary difference was linked to a higher incidence of MS in the colder regions.¹¹

The relationship between mercury from dental fillings and MS is very controversial.^{12,13} At present, there are insufficient data to render an opinion. However, exposure to cigarette smoke has been demonstrated to be a clear risk factor for developing MS, as well as increasing the severity of the illness.^{16,17} These findings suggest the possibility of environmental toxins or pollutants in the pathogenesis of MS.

Infectious Agents

At least 16 different infectious agents have been implicated as causes of MS; however, none has been definitely associated with the disease. At present, three agents are receiving the most attention: human herpesvirus-6, *Chlamydia pneumoniae*, and Epstein-Barr virus.

Genetic Factors

Although most cases of MS are sporadic, susceptibility to MS is substantially affected by genetic factors. For example, clear associations exist between certain subtypes of the major histocompatibility human leukocyte antigen (HLA)-DRB1 gene and susceptibility and the disease course in MS.¹⁸ However, the aggregate contribution of germline genetic variants to the disease expression of a given patient with MS may be modest. This concept is highlighted by the observation that the clinical expression of MS may be quite different between monozygotic twin siblings who both have the disease. It is therefore likely that several postgermline events influence the clinical expression of MS.¹⁹

Diagnosis

The hallmark for the clinical diagnosis of MS is neurological dysfunction that is disseminated in space and time. Objective evaluation includes magnetic resonance imaging (MRI), evaluation of cerebrospinal fluid, and evoked potential testing (measuring the electrical activity of the brain in response to stimulation of sensory nerve pathways). The pathological hallmark of MS is the presence of demyelinated plaques involving the periventricular white matter, optic nerves, brainstem, and cerebellum or spinal cord white matter ([Figs. 14.1](#) and [14.2](#)).

Integrative Therapy

Lifestyle

Smoking Cessation

As previously mentioned, tobacco smoke exposure is a risk factor for developing MS and is associated with a worse prognosis. Smokers with MS should be offered appropriate counseling and supportive measures to quit smoking.

In addition to being a major risk for other diseases, tobacco smoking is probably the most important disease-specific, modifiable risk factor for patients with multiple sclerosis who smoke.

Exercise

During the 1990s, people with MS were instructed to avoid strenuous physical activity due to fears that it may worsen their neurological status, such as occurs when MS patients get overheated. However, current research has demonstrated that physical activity is safe and well tolerated and has the same health benefits as in the general population. In addition, physical fitness and exercise have been associated with improved muscle strength, spasticity, cognition, reduced fatigue, and may even have neuroprotective properties.^{20-22,25,26}

Sunshine

There is an increased prevalence of MS in extreme latitudes. Furthermore, case-control studies have found that sunlight is associated with a reduced risk of MS diagnosis and mortality.^{27,29} Whether this association with sunlight is entirely attributable to vitamin D is unclear.

Mind-Body Therapy

Psychosocial Factors

Depression is common in MS, and death by suicide occurs seven times more frequently than in the general population. Combining counseling with body work therapies can be highly effective in countering depression in MS patients.

Psychological stress has been clearly identified as a trigger for relapses of MS and possibly contributes to disease progression.³⁰⁻³² Furthermore, coping styles may affect susceptibility to the harmful effects of stress in MS.³³ Given the relatively modifiable nature of life stress and coping, patients with MS should be encouraged to learn some form of stress reduction, stress management, or coping techniques (see [Chapter 94](#)).

Stress and coping strategies should be addressed in every patient with multiple sclerosis and may affect both the relapse frequency and disease progression.

FIG. 14.1 Multiple sclerosis. **A**, T2-weighted magnetic resonance imaging (MRI) of the brain showing multiple lesions located in the white matter characteristic of multiple sclerosis (*arrow*). **B**, T1-weighted MRI of the spine indicating a demyelinating plaque of multiple sclerosis in the mid-cervical region (*arrow*). (From Johnson MV. Demyelinating disorders of the CNS. In: Kliegman RM, Behrman RE, Jenson HB, eds. *Nelson Textbook of Pediatrics*. 18th ed. Philadelphia: Elsevier; 2007.)

Yoga

Yoga techniques have been shown to improve circulation, balance, the ability to relax, flexibility, and eyesight, and to reduce muscle tension—all features typically affected by MS.³⁴ A systematic review identified seven randomized clinical trials that evaluated the effect of yoga on MS and documented a clinical benefit on mood and fatigue.³⁶ In the absence of a specific yoga class for MS patients, an individualized yoga program that is developed closely with a qualified yoga teacher or therapist is likely to produce similar benefits.

Mindfulness Meditation

Mindfulness meditation involves paying attention in a systematic

manner with the intention of being awake and receptive to the present moment rather than focusing on the past or future. The Chinese characters depicting mindfulness meditation use the character for presence over the character for heart, implying that the intention is to bring presence of heart. The goal is to cultivate moment-to-moment awareness of personal thoughts, emotions, body, and surroundings. It has been successfully applied to a range of health issues that directly or indirectly relate to people living with MS (see [Chapter 100](#)). An 8-week mindfulness-based intervention demonstrated significant improvement in measures of nonphysical quality of life, depression, fatigue, and anxiety compared with usual care in patients with MS.³⁷ A 2014 systematic review identified three studies using mindfulness for MS and found benefits for quality of life, pain, fatigue, single leg standing balance, anxiety, and depression, with benefits persisting for 6 months after the intervention.³⁸

Nutrition

While there is a paucity of clinical data regarding the role of specific diets in the treatment of MS, it is likely that dietary factors influence the course of MS via modulation of inflammation.³⁹ The following are nutritional and dietary recommendations for patients with MS that generally target inflammation:

- In general, eating a diet relatively high in omega-3, polyunsaturated fatty acids is associated with positive health effects and may be recommended to most individuals. Primary sources of foods rich in omega-3 essential fatty acids include cold-water fish, nuts, seeds, and dark green leafy vegetables, which reduce inflammation by their effect on prostaglandins and leukotrienes (see [Chapter 88](#)).⁴⁰ Evidence is mixed on the benefit of omega-3 fatty acid supplementation for people with MS,⁴²⁻⁴⁴ possibly due to the variability in formulations and dosages (see [Supplements](#) section).
- Avoid trans fats. This is done by avoiding processed or packaged foods. The FDA has stated that trans fats are “not generally recognized as being safe.” There is clear evidence of excess risk for all-cause death and cardiovascular events with the consumption of trans fats. Beginning in 2018, the FDA will ban food manufacturers from producing foods with trans fats.

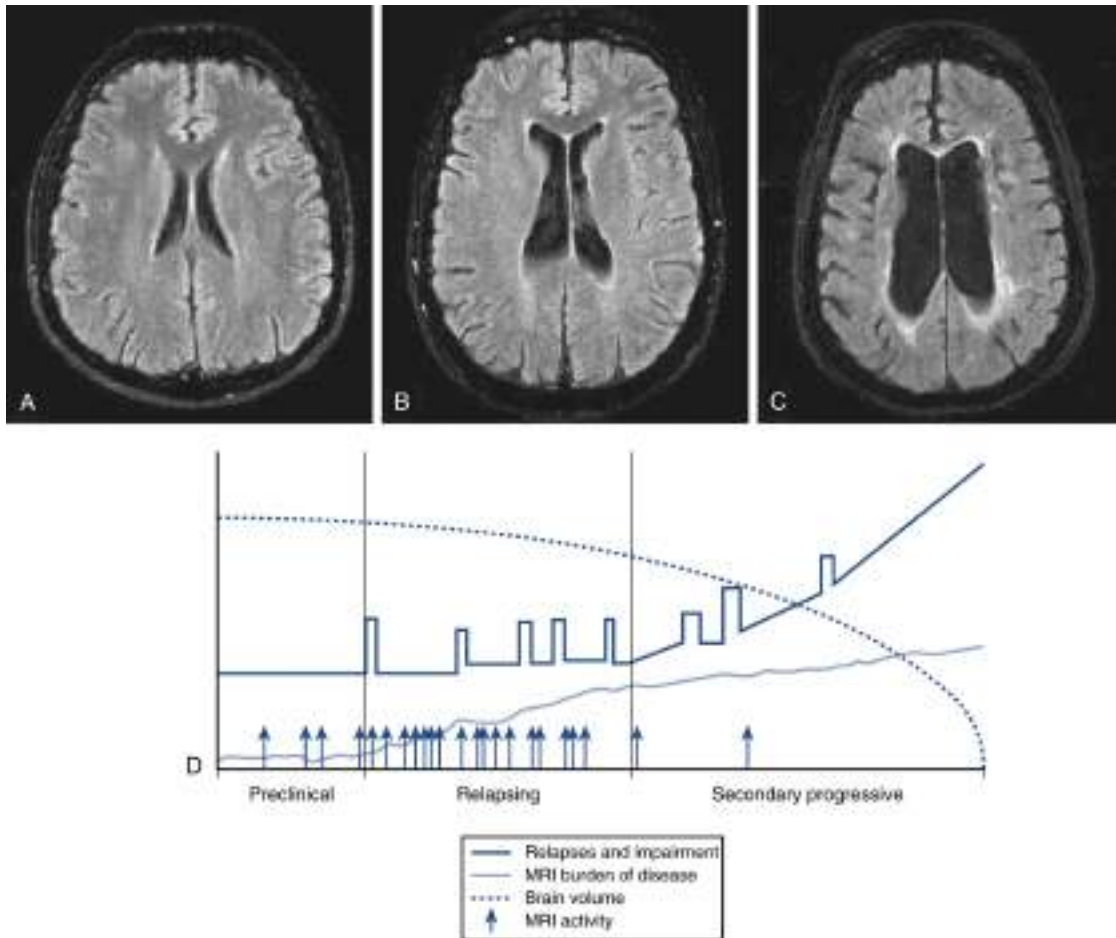

FIG. 14.2 Changes in magnetic resonance imaging (MRI) with disease duration. **A–C**, Comparison of three scans from patients with different disease durations, indicating the appearance of atrophy and ventricular dilation with time. **D**, As brain atrophy appears, a decline in the number of gadolinium-enhancing lesions is commonly seen. (From Lublin FD, Miller AE. Multiple sclerosis and other inflammatory demyelinating diseases of the central nervous system. In: Bradley WG, Daroff RB, Fenichel GM, Jankovic J, eds. *Neurology in Clinical Practice*. 5th ed. Munich: Butterworth-Heinemann; 2008.)

- Many practitioners recommend that patients with active symptoms should observe the effects of a structured *elimination diet*. This involves elimination of common or suspected food allergens or triggers for at least 2 to 4 weeks followed by a systematic rechallenge (see [Chapter 86](#)). Case reports have noted gluten sensitivity manifesting as optic neuritis,⁴⁵ and an increase frequency of gliadin and gluten IgA antibodies in MS.⁴⁶ Patients should keep a daily journal to monitor changes from baseline. Given that instituting an elimination diet can be challenging, some patients and practitioners opt for autoimmune

antibody testing while recognizing that these tests have variable sensitivity and specificity.

Energy Medicine

Magnet Therapy

Magnetic therapy is simply the therapeutic application of magnets and can be delivered in many forms. In a 12-week, randomized trial, subjects with MS laid down on a metal mat for 8 minutes twice daily. The device delivered low-frequency, pulsed electromagnetic field therapy. Another study had subjects with MS wear wristwatch-size, magnetic pulsing devices called Emermed for 10 to 24 hours daily for 2 months. Another device also delivered low-frequency magnetic stimulations at 37.5 mT and a sequence of pulses at 4 to 7 Hz three times weekly for 2 months. These studies demonstrated consistent benefits in reducing fatigue but no benefit for depression in subjects with MS.⁵³

Supplements

Vitamin D

Observational studies have shown that vitamin D levels positively correlate with a reduced risk of developing MS,⁵⁴ and that lower levels of vitamin D are associated with higher MS disease disability and activity⁵⁵ as well as relapse rates.⁵⁶ A 2015 study demonstrated that Europeans with genetically lowered vitamin D levels were twice as likely to develop MS.⁵⁷ A pilot randomized trial documented an inverse relationship between vitamin D levels and MS disease activity on MRI.⁵⁸ One study found that serum vitamin D3 levels greater than 100 nmol/L were associated with a 53% risk reduction of developing new lesions on MRI.⁵⁹ There are currently two ongoing clinical trials to evaluate the effect of supplemental vitamin D in patients with a clinically isolated episode of MS,^{60,61} and there are two clinical trials evaluating the effect of high-dose vitamin D3 (10,000 to 14,000 IU/daily) in patients with RR-MS who are also receiving interferon-beta.^{62,63} Among patients living with MS and who have normal renal function, dosages of 10,000 units daily have been used without evidence of toxicity.^{64,65}

Dosage

Titrate for a serum level greater than 80 ng/mL to achieve immunomodulatory effects. Titrate vitamin D3 up to 4000 to 10,000 IU units daily. Doses in the higher end of this range should be monitored with serum levels for vitamin D and calcium.

Precautions

Watch for the theoretical risk of hypercalcemia; however, recent dose-escalation safety studies have not validated this concern.

Thiol-based Antioxidants

Alpha-lipoic acid (ALA), N-acetylcysteine (NAC), and glutathione (GSH) are powerful antioxidants that scavenge free radicals such as reactive oxygen and reactive nitrogen species. Given our understanding of the role of oxidation in MS disease progression and severity, and the association of reduced glutathione levels in patients with MS, these compounds merit further investigation. Studies using the classic animal model for MS (*experimental autoimmune encephalomyelitis* [or *EAE*] mice) report a consistent reduction of disease severity and inflammation with ALA, and inhibition of acute EAE in mice through the scavenging of free radicals.⁶⁶ Human studies examining mediators of inflammation using ALA have documented mixed results.⁶⁷ There is limited data on humans using these compounds; however, multiple studies are now underway evaluating the effect of thiol-based antioxidants on MS disease progression in humans.

Dosage

- ALA: 600 mg twice daily.
- NAC: 600 mg three times daily.
- Glutathione: 600 to 800 mg intravenously diluted in 10 to 20 mL of sterile water and infused over 15 to 20 minutes two to three times weekly. (Glutathione is not absorbed orally.)

Precautions

- ALA: In general, quite well tolerated and safe. At higher doses can

infrequently cause nausea, vomiting, and skin irritation at the IV site when given intravenously.

- NAC: Infrequently causes nausea, vomiting, and diarrhea.
- GSH: Rapid infusion can provoke respiratory distress, coughing, rhinorrhea, and vertigo.

Magnesium

Magnesium is required for adequate levels of metabolized vitamin D products to be maintained in the circulation. At 800 mg/day, magnesium also has a mild effect on the muscle spasticity that is often associated with MS.

Dosage

600 to 1200 mg/day

Precautions

Individual tolerance for magnesium is variable. Advise patients to decrease the dose if diarrhea develops.

B-Complex Vitamins

B vitamins have been shown to aid cognitive function, act as antioxidants, and decrease the production of inflammatory cytokines.

Dosage

Varies by preparation.

Vitamin B₁₂

Deficiency of vitamin B₁₂ and errors in vitamin B₁₂ metabolism are known to cause demyelination of the CNS.⁶⁸ High doses of vitamin B₁₂ given intramuscularly have been shown to improve brainstem nerve function in chronic, progressive MS.⁶⁹ Teaching patients self-injection of vitamin B may be a cost-effective way of improving overall well-being.

Dosage

Oral doses are 1000 to 2000 mcg/day in the form of methylcobalamin. Intramuscular doses of hydroxycobalamin are 1000 mcg/day for 5 days, then twice weekly for 4 weeks, and then twice monthly.

Biotin

High-dose biotin (300 mg daily; 10,000% of the adequate daily intake) is thought to prevent both demyelination by triggering myelin synthesis and neurodegeneration by replenishing ATP in hypoxic neurons.⁷⁰

Biotin has traditionally been marketed for hair and nails. Biotin is a water-soluble B-vitamin called vitamin B7. One of its main functions is to facilitate fatty acid synthesis, and it avidly crosses the blood-brain barrier. Biotin is an essential coenzyme for five essential carboxylases, including acetyl-CoA-carboxylase (ACC). ACC is highly expressed in oligodendrocytes, which play a major role in myelin synthesis, and is the rate-limiting factor in the synthesis of malonyl-CoA, a critical building block for fatty acid synthesis. The current theory is that high dose biotin may markedly increase myelin repair through this mechanism.⁷⁰

A group of French investigators published a proof-of-concept case series of 23 adults with progressive MS receiving 100 to 300 mg of biotin daily for up to 36 months (mean 9.2 months). They reported that more than 90% of the subjects experienced improvements over baseline in disability and the progression of MS. Improvement occurred 2 to 8 months after treatment commenced.⁷¹ Results from a multicenter, randomized, blinded study were presented at the American Academy of Neurology in April 2015.⁷² Investigators reported a statistically significant difference between the proportions of subjects who experienced a reduction in disability in the active group (12.5%) compared to the placebo group (0%), as well as a significant difference in disease progression.⁷²

Dosage

300 mg daily.

Precautions

None documented; biotin is generally well tolerated.

Botanicals

Ashwagandha (*Withania somnifera*)

Ashwagandha is an Ayurvedic herb (see the discussion on [Ayurveda](#) later), also known as winter cherry, that is sometimes called Indian ginseng in reference to its rejuvenating and tonic effects on the nervous system. Ashwagandha's antiinflammatory, antioxidant, anxiolytic, and antidepressant activities all make this herb an important supplement for patients with MS.^{73,74}

Dosage

1 to 2 g of the whole herb in powdered form two or three times a day.

Precautions

Some Ayurvedic herbs have been found to have high levels of contaminants such as lead. By knowing the supplier's source of the herb, you can be sure your patient is not taking a contaminated product.

Curcumin (*Diferuloylmethane*)

One of the principal biologically active ingredients in turmeric (*Curcuma longa* plant; an Indian spice) is curcumin, a lipophilic compound that easily crosses membranes. Curcumin is a turmeric extract from the root of the *Curcuma longa* plant. Studies with EAE mice have consistently shown inhibition of oxidation and inflammation through upregulation of the nuclear translocation of nuclear factor-E2-related factor (Nrf2), and inhibition of nuclear-factor kappa-beta (NF-kB), respectively. Specific pathways affecting inflammation include decreased T-cell production of IFN-gamma and inhibition of Th1 and Th17 differentiation. A 2-year randomized, blinded, clinical trial examining the effect of curcumin as an adjuvant to IFN-B1a has completed recruitment and is now ongoing.⁷⁸ This compound has a proven safety record in humans, with dose escalation studies up to 8 g daily, and is well tolerated.⁷⁹ Whether the documented effectiveness in animal models will translate into humans has yet to be determined.

Dosage

500 mg to 3 g twice daily. For enhanced bioavailability, curcumin should be bound to a lipophilic compound or formulated with black pepper. Examples of formulations include standardization of 95% curcuminoids bound to black pepper extract (*Piper nigrum*, Bioperine[®]), or a preparation standardized to 70% to 80% curcumin, 15% to 25% desmethoxycurcumin, and 2.5% to 6.5% bisdemethoxycurcumin in a lipophilic emulsion.

Precautions

Higher doses may cause abdominal fullness or discomfort. It may increase blood levels of sulfasalazine by threefold.

Ginkgo biloba

Ginkgo has antioxidant effects and inhibits platelet-activating factor (PAF), which results in antiinflammatory properties and possible inhibition of glutamate excitotoxicity, thereby improving cognition. Three randomized trials found that ginkgo improved cognitive performance⁶⁷; however, the largest randomized study published to date (120 persons) found no benefits in cognitive performance.⁸⁰ In evaluating the herb's effect on fatigue, a 4-week, pilot, randomized study found benefits; however, no effect was found on attention/concentration nor visual-spatial memory.⁸¹

Dosage

The EGb-761 formulation should be used when possible, standardized to 24% flavone glycosides, 7% proanthocyanidins, and 6% terpene lactones at 120 mg twice daily.

Cannabinoids

Cannabinoids are psychoactive compounds with medicinal properties. Tetrahydrocannabinol (THC) and cannabidiol (CBD) are the most studied cannabinoids. CBD has substantially less psychoactive properties than THC. Synthetic cannabinoids (e.g., dronabinol) are closely related to

THC. Based on systematic reviews, the evidence published to date indicates that oral cannabis extract is clearly effective, and THC is most likely effective in reducing pain (excluding central neuropathic pain) and spasticity symptoms. They are probably not effective in improving tremor or signs of spasticity.⁸² There is insufficient evidence for effects on urge incontinence or bladder symptoms.⁸² Sativex oromucosal spray (unavailable in the US) is probably effective for spasticity symptoms, pain, and urinary frequency, and probably ineffective for signs of spasticity, incontinence episodes, and tremor.⁸² There is insufficient evidence for these outcomes with inhaled cannabis.⁸² Prior to recommending this therapy, physicians should counsel patients about the potential legal issues and unwanted side effects.

Dosage

The dose varies considerably depending on potency and patient tolerance. The dose of synthetic THC (e.g., dronabinol) varies from 2.5 to 10 mg daily. THC-CBD combination oral extracts, as capsules or mouth spray (e.g., Sativex which contains 2.7 mg THC and 2.5 mg CBD per spray), are used at doses varying from 2.5 to 120 mg daily.⁸²

Precautions

Generally well tolerated. Significant laboratory findings or serious adverse events have not been reported in clinical research. Mild to moderate side effects are common and include dizziness, drowsiness, and memory or concentration difficulties. Less frequently, research subjects reported nausea, constipation, dry mouth, or increased appetite.⁵³

Green Tea Polyphenol Epigallocatechin-Gallate

Epigallocatechin-gallate (EGCG) is an antioxidant that accumulates within the mitochondria of neurons and decreases apoptosis of neurons undergoing oxidative stress.⁸³ EGCG administered as 95% pure capsules 200 mg three times daily was administered to patients with MS over 12 weeks and was found to improve muscle metabolism during moderate exercise among men, possibly because of sex-specific effects on autonomic and endocrine control.⁸⁴ In 2015, investigators conducted both

a 10-person phase 1 case series study and a 13-person phase 2 randomized study using a Japanese product (polyphenon E) containing 50% EGCG at 400 mg twice daily. Results from the phase 1 study showed a 10% increase in N-acetyl aspartate levels (a marker of the number of neurons and their mitochondrial energy production), suggesting a neuroprotective benefit. One person experienced hepatotoxicity. The phase 2 study used a different product, and five of seven participants randomized to active treatment experienced hepatotoxicity, requiring discontinuation of the study. The same investigators will be conducting a phase 2 randomized trial with 48 participants using the 95% pure EGCG formulation.⁸⁵ There are several other studies listed on the clinicaltrials.gov website, and most of these focus on safety and neuroprotective effects.

Dosage

EGCG 95% pure 200-mg capsules three times daily.

Precautions

Until safety studies report otherwise, we do not recommend the use of high concentration EGCG compounds due to the documented hepatotoxicity risk.

Hormones

Estrogen and Oral Contraceptives

Estrogen has been found to have neuroprotective and immunomodulatory effects in women with active MS. Most patients with MS who become pregnant experience a significant decrease in symptoms, with mild exacerbation during the postpartum period.⁸⁶ Research has shown that estriol causes an immune shift from T-helper 1 to T-helper 2 cells. Studies have documented a reduction in symptoms and a decrease in gadolinium-enhancing lesions on MRI in women with MS who are treated with estriol or high dose ethinylestradiol.⁸⁷⁻⁹¹

Dosage

Ethinylestradiol 40 µg and desogestrel 125 µg as oral contraceptive therapy

Precautions

The concerns are the same as with all high-dose estrogen therapies.

Testosterone

Testosterone has also been found to have immunomodulatory and neuroprotective effects, as well as ameliorating MS symptoms, in men with active MS.^{86,92,94}

Dosage

Use micronized testosterone from compounding pharmacies. For men: 10 g of gel containing 100 mg testosterone

Precautions

Contraindications include polycythemia, benign prostatic hypertrophy (BPH), and prostate cancer. Serum testosterone levels should be monitored. Some patients experience skin dermatitis with topical application.

In a pilot, crossover study of 10 men with active MS who were receiving 10 g of gel containing 100 mg testosterone daily for 12 months, investigators reported improved cognitive function, slowing of brain atrophy on MRI, and no significant adverse events; however, no changes in new lesions were identified on MRI.⁹⁴

Pharmaceuticals

Corticosteroids

Evidence indicates that the administration of high-dose corticosteroids during MS relapses can improve the associated disabling symptoms, and oral and intravenous therapy have been found to have similar efficacy.⁹⁵⁻⁹⁷ Corticosteroids do not affect overall long-term functional recovery or outcomes.⁹⁵ Plasma exchange is indicated for patients with severe attacks that are refractory to high-dose corticosteroids.

Dosage

Methylprednisolone, 1 g/day intravenously (or an equivalent oral regimen). Prednisone, 1250 mg orally daily for 3 to 5 days. Low-dose oral dosage regimens vary. The most common regimen is prednisone 60 mg orally once a day for 5 days, then 40 mg orally for 5 days, followed by 20 mg for 5 days, 10 mg for 5 days, and finally 5 mg for 5 days.

Precautions

While generally well tolerated within the context of acute treatment, some people experience euphoria, psychosis, irritability, insomnia, depression, gastritis and ulceration, and osteoporosis from repeated use. High-dose corticosteroids may be associated with defects in long-term memory.⁹⁸⁻¹⁰⁰ High-dose corticosteroids given outside of a relapse in order to prevent disability progression may actually contribute to worsening of disability progression in some patients upon discontinuation of therapy.¹⁰¹

Disease-Modifying Treatments

Patients with a definite diagnosis of relapsing-remitting MS should consider disease-modifying therapies (listed in the following) recognizing that these therapies address the signs and symptoms of MS and are not curative. Their benefits include reduction in relapse rates and frequency of new brain lesions; however, the effect on progression to disability is uncertain. The choice of therapy should be based on patient preferences, values, and disease severity. When considering therapy, treating clinicians often recommend natalizumab for more rapidly progressive disease in patients who prefer a robust effect over safety. Interferon beta injectable formulations and glatiramer acetate are preferred for patients who value safety over effectiveness and ease of administration. Oral therapy with dimethyl fumarate should be considered for patients who value convenience and believe the robust effectiveness and safety findings from two large, multicenter, randomized, blinded trials, and one study (the CONFIRM study) suggesting noninferiority compared with glatiramer. Biotin is the newest compound under evaluation as a potential disease-modifying treatment

(see the Dietary Supplements section in this chapter). It is convenient, and initial findings suggest that it is very well tolerated and may be effective.

Fumaric Acid

Fumaric acid appears to have neuroprotective and immunomodulatory (not immunosuppressive) properties through nuclear factor (erythroid derived-2)-like2 (NRF2) activation. NRF2 concentrates in the cell cytoplasm causing immunoregulatory as well as cytoprotective effects via upregulation of antioxidant proteins.

In two large, phase 3, randomized clinical trials (CONFIRM [n = 1430] and DEFINE [n = 1200]), subjects with active MS were allocated dimethyl fumarate (BG-12) 240 mg two or three times daily, glatiramer acetate, or placebo for 48 weeks to 2 years, with primary endpoints being assessed at 2 years. Both studies showed reduction in relapse rates and in the development of new brain lesions identified on MRI. In the DEFINE trial, active treatment groups experienced a 50% reduction in the annualized relapse rate compared to placebo (0.17 and 0.19 vs. 0.36, respectively). Furthermore, 27% of the active treatment groups experienced a relapse compared to 46% of the placebo group, 36% had a relative risk reduction in disability progression compared to placebo, and there was a significant reduction in the average number of new or enlarging lesions on MRI in the active groups compared to placebo. The CONFIRM trial randomized people to BG-12 240 mg twice or three times daily, subcutaneous glatiramer acetate 20 mg daily, or placebo in a 1:1:1:1 ratio. At 2 years, the annualized relapse rate was significantly lower in the active treatment groups (0.22, 0.20, 0.29, respectively, compared to 0.40 in the placebo group), and the number of new or enlarging brain lesions on MRI were also significantly lower in the active treatment groups compared to placebo. No significant differences were identified between the two active classes of treatment. Adverse events were mild to moderate and included flushing and gastrointestinal events (diarrhea, nausea, or abdominal pain), which decreased over time.^{104,105}

Dosage

Dimethyl fumarate (*BG-12*, *Tecfidera*) 240 mg twice daily, then increase to 240 mg three times daily.

Precautions

Laboratory testing for lymphocytopenia should be done at baseline and every 4 to 6 months thereafter because cases of progressive multifocal leukoencephalopathy have been found to occur in patients with preexisting lymphocytopenia. Patients may experience flushing, diarrhea, nausea, or abdominal pain.

Interferon Beta

Interferon beta-1b was the first disease-modifying agent to be approved in the United States. The 5-year data suggest a 33% reduction in relapse frequency and new or enlarging brain lesions on MRI in patients treated with high-dose IFNB-1b (250 mcg) compared to placebo. Disease progression was slower with high-dose IFNB-1b compared to placebo (35% versus 46%, respectively).¹⁰⁶ In addition, all-cause mortality was lowered by 46% among those receiving 50 mcg or 250 mcg of IFNB-1b every other day compared to placebo (17.9, 18.0, and 30.6%, respectively).¹⁰⁷ Earlier commencement and duration of therapy have been shown to improve survival. While the published 5-year data is promising, the long-term benefit of life-long IFNB remains unclear because the published studies provided treatment for 2 years, at which time point there was unblinding and therefore substantial loss to follow up at 5 years. Of note, one third of patients developed neutralizing antibodies that reduced drug effectiveness.

Dosage

Interferon beta-1b (*Betaseron, Extavia*) 50 mcg or 250 mcg every other day by self-injection subcutaneously.

Interferon beta-1a (*Avonex, Rebif*) 22 mcg or 44 mcg three times weekly by self-injection subcutaneously.

Pegylated interferon beta-1a (*Plegridy*) 125 mcg once every 2 or 4 weeks subcutaneously or 30 mcg weekly by intramuscular injection.

Precautions

Injection site reaction, headache, fever, flu-like symptoms, pain, diarrhea, constipation, lymphocytopenia, elevation of liver enzymes, myalgias, depression, and anxiety may occur. Caution when using

concurrent potentially hepatotoxic medications.

Glatiramer Acetate

Glatiramer acetate (GA) is a synthetic copolymer of tyrosine, glutamate, alanine, and lysine that resembles the myelin sheath components and therefore induces GA-specific T-helper 2 cells, which secrete antiinflammatory cytokines in the CNS through cross-recognition with myelin autoantigens. Research suggests that GA promotes neurogenesis, is neuroprotective, and has antiinflammatory properties.

Dosage

Glatiramer (*Copaxone, Glatopa*) 20 mg subcutaneously daily or 40 mg three times weekly.

Precautions

Glatiramer is well tolerated by most patients. Local injection site reaction is the most prominent adverse reaction. Cases of hepatotoxicity have been reported.

Natalizumab

Natalizumab is a selective adhesion molecule inhibitor used for the treatment of relapsing forms of MS. It was withdrawn from the market shortly after U.S. Food and Drug Administration approval because of the development of progressive multifocal leukoencephalopathy. Consequently, this drug is available only through a restricted program under a risk evaluation and mitigation strategy (REMS) called the TOUCH prescribing program.

Therapies to Consider

Traditional Healing Systems

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) is a codified ancient healing system with a holistic approach that employs therapies such as acupuncture, herbs, and behavioral recommendations. In general, it views MS as

representing a heterogeneous group of causes and disease processes. From a TCM perspective, patients with MS often exhibit the signs of spleen deficiency with dampness blocking the channels, or liver or kidney deficiency. In the hands of an experienced practitioner familiar with MS, TCM can be a safe and effective modality. Additionally, separate aspects of TCM, such as acupuncture, are often used for MS-related symptoms. Use of acupuncture has been reported in up to 35% of MS patients.¹⁰⁸

Ayurveda

Ayurveda is among the oldest existing healing traditions. In explaining disease and healing processes, it relies on the interplay of the three *doshas*, or cardinal humors: *vata* (formed of ether and air), *pita* (formed of fire and water), and *kapha* (formed of earth and water). The Ayurvedic description of MS is analogous to that of biomedicine: an excess of *pita* (inflammation) burns up the *kapha* (myelin) and results in an excess of *vata*. For MS, the reduction of *pita* (inflammation) and the replenishing of the *kapha* (myelin) are often targeted with medicinal oils, diet, herbs, and lifestyle changes.

Prevention Prescription

- Eliminate tobacco
- Engage in stress reduction practice regularly, such as mindfulness or yoga
- Exercise regularly
- Ensure adequate sleep
- Get adequate sunlight
- Monitor vitamin D3 levels
- Eat an antiinflammatory diet (see [Chapter 88](#))
- Evaluate whether you might have food intolerances (e.g., dairy, wheat, corn, etc.) through conducting a 1-month elimination diet (see [Chapter 86](#))
- Consider high-dose biotin 300 mg daily

Therapeutic Review

Lifestyle

- Smoking cessation 
- Exercise
 - For muscle strength, spasticity, fatigue 
 - For cognition 
- Regular childhood sunshine exposure 

Mind-Body Therapies

- Yoga for mood and fatigue 
- Mindfulness meditation for QOL, pain, anxiety, depression, fatigue 

Magnetic Therapy

- Fatigue 
- Depression 

Nutrition

- Antiinflammatory diet 
- Elimination diet 

Supplements

- Omega-3 fatty acids (antiinflammatory) 
- 400 to 600 mg docosahexaenoic acid + 400 mg EPA
- Vitamin D (achieve levels just over 80 nmol/L) 
- Thiol-based antioxidants (NAC, ALA, GSH) 
 - N-acetylcysteine: 1000 mg twice daily
 - Alpha-lipoic acid: 600 to 1200 mg daily
 - Glutathione 600 to 800 mg IV two to three times weekly
- Biotin 300 mg daily 

Botanical

- Ashwagandha, 1 to 2 g of the whole herb in powdered form two or

three times a day 

Cannabinoids Spasticity Symptoms and Pain

- Oral cannabinoids extract 
- Synthetic THC (*dronabinol*) 2.5 to 10 mg daily 

Spasticity Symptoms, Urinary Frequency, and Pain

- Oromucosal spray (*Sativex*) 2.7 mg THC/2.5 mg CBD spray at a dose of 2.5 to 120 mg daily 
- Curcumin 500 mg to 3 g twice daily 
- Ginkgo biloba, standardized 24% flavone glycosides, 7% proanthocyanidins, and 6% terpene lactones, 120 mg twice daily
- Fatigue 
- Cognition (no effect) 
- EGCG 95% pure, 200-mg capsules three times daily 

Hormones

- Estriol oral 4 mg twice daily 
- Oral contraceptives in women: ethinylestradiol 40 mcg and desogestrel 125 mcg 
- Pregnancy 
- Testosterone in men: 10 g of gel containing 100 mg of testosterone 

Pharmaceuticals

Acute Relapse

- Corticosteroids oral or IV 

Disease-Modifying Therapy for Relapsing-Remitting MS

- Pig whipworm (*T. suis*) oral 
- Dimethyl fumaric acid (BG-12) oral 240 mg twice or three times daily

- Interferon beta-1b and -1a injection 
 - 1b 50 mcg or 250 mcg every other day by self-injection subcutaneously
 - 1a 22 mcg or 44 mcg three times weekly by self-injection subcutaneously
- Pegylated 1a 125 mcg once every 2 or 4 weeks subcutaneously or 30 mcg weekly by intramuscular injection
- Glatiramer acetate injection: 20 mcg daily subcutaneously 
- Natalizumab: 300 mg intravenously every 4 weeks 

Key Web Resources

Multiple Sclerosis Foundation. This not-for-profit organization seeks to provide "a comprehensive approach to helping people with MS maximize their health and well-being" through programming and education. The website provides a wide variety of information including disease basics, support group contacts, articles on complementary and alternative medicine therapies, online forums, and links for health professionals. In addition, they engage in regular fundraising events that help fund MS research.	http://www.msfa.org/Default.aspx
National Multiple Sclerosis Society. The Society's mission is to "mobilize people and resources to drive research for a cure and to address the challenges of everyone affected by MS." The website features updates on treatments and research, a comprehensive library, and advocacy and research-oriented resources.	http://www.nationalmssociety.org

Chapter 15

Parkinson's Disease

Adam D. Simmons, MD

Clinical Signs and Symptoms of Parkinson's Disease

Parkinson's disease is a progressive neurodegenerative disorder. Individuals with Parkinson's disease often exhibit a characteristic tremor, a shuffling gait, and masked facial expression. However, the effects of Parkinson's disease are much more widespread.

Preclinical

Parkinson's disease likely starts many years before it is first recognized by either physicians or patients, with subtle and nonspecific early symptoms. Typically, Parkinson's disease progresses slowly; however, the rate of progression is highly variable. In retrospect, many individuals can recall the development of early signs years before they first suspected they had Parkinson's disease. Commonly,

early symptoms include constipation in addition to a decreased sense of both smell and taste. Sleep difficulties, such as REM (rapid eye movement) behavior disorder and restless legs syndrome, may also predate motor symptoms by many years. Family members may have noted a decrease in the range of facial expressions, a softness and flatness in the voice, and a more passive personality. Some individuals diagnosed with Parkinson's disease are found to have suffered from late-onset depression for several years prior to diagnosis.

Early Symptoms

While the cardinal features of Parkinson's disease are described as resting tremor, rigidity, bradykinesia, akinesia, postural instability, flexed posture, and "freezing" episodes, these symptoms do not typically present all at once. The early motor signs of Parkinson's disease may be subtle and nonspecific, and are often recognized only in retrospect. A decrease in arm swing or stride length on one side while walking may lead to shoulder, upper back, low back, or hip pain. Decreased fine motor coordination may cause difficulty with buttons and clasps. Thus, getting dressed in the morning may become slower as Parkinson's disease

develops. Additional movements may slow and decrease in amplitude. For example, handwriting often becomes smaller and more difficult to read. When tremors first develop, they are often intermittent and most obvious during stressful situations.

As the disease progresses, physical signs become more obvious, and tremor is often more constant. However, tremor may be absent altogether in a proportion of patients, particularly those with a later age of onset. Parkinsonian tremor is typically present only at rest. A proportion of individuals learn to control tremors by keeping their hands active. As walking becomes more difficult, individuals with Parkinson's disease tend to become more sedentary. Difficulty with initiating movement, in combination with worsening balance, may make rising from soft chairs and car seats an arduous process. As the disease advances, akinesia (lack of movement) and bradykinesia (slowness of movement) continue to become more prominent, and posture may become more stooped. Individuals with Parkinson's disease may attribute these signs to weakness or stiffness of the limbs or body.

Nonmotor Symptoms

In addition to the more well-known motor symptoms, individuals with Parkinson's disease experience a wide range of nonmotor symptoms. Occasionally, these symptoms may be even more disabling than the motor symptoms. The nonmotor symptoms of Parkinson's disease are categorized broadly as psychiatric, autonomic, sleep-related, and sensory ([Table 15.1](#)).

Advanced Disease

Unfortunately, some symptoms of advanced Parkinson's disease are not responsive to any currently available medications or surgery. Motor freezing, or episodes when individuals feel that their feet are "glued to the floor," is typically difficult to treat with medications. However, specially modified canes and walkers, which use a laser to project a red line for patients to step over, have utility in breaking these episodes. Other strategies include walking to a rhythm, that is, a marching song. Safety modifications in the home, such as grab bars in the bathroom and kitchen, can help prevent falls and extend patient independence. As fine motor skills diminish, switching to garments without buttons and shoes with Velcro or elastic laces can help with getting dressed. Individuals

with low voice volume may benefit from the Lee Silverman Voice Therapy (LSVT) program.¹

Risk Factors

Epidemiological studies have identified factors that increase the risk of developing Parkinson's disease. By design, such studies are unable to identify definitive causes. While Parkinson's disease is generally more common in industrialized societies, it is observed at a greater frequency in rural areas.² Exposure to pesticides,³ heavy metals,⁴ some dairy products,⁵ and drinking well water have been shown to increase the risk of Parkinson's disease.⁶

TABLE 15.1

Nonmotor Symptoms in Parkinson's Disease

Psychiatric	Depression Anxiety Apathy Dementia Hallucinations Impulse control disorders
Autonomic	Constipation Orthostasis (lightheadedness on standing) Excessive sweating Urinary incontinence
Sleep Disorders	Insomnia REM behavior disorder Restless legs syndrome Excessive daytime sleepiness Fatigue
Sensory	Impaired sense of smell and taste Blurred vision Numbness and tingling Pain

Large doses of the pesticide rotenone has been shown to cause Parkinsonian syndrome in laboratory rats used experimentally as a model for studying Parkinson's disease.² Ironically, rotenone is currently allowed in organic farming practices, although typical exposure rates have not been shown to cause Parkinson's disease.

Trichloroethylene (TCE) is a degreaser used as a dry cleaning solvent to clean metal in factories and in

some household cleaning agents. A recent study of twins reported that occupational exposure to TCE increased the risk of Parkinson's disease by five-fold.⁸

Increasing exposure to cigarettes and coffee are correlated with a lower risk of developing Parkinson's disease.⁴ While smoking is not recommended as a preventive measure, both nicotine patches⁹ and caffeine¹⁰ are being investigated as possible therapies.

Pathophysiology

The underlying cause of Parkinson's disease remains elusive. The variety in the constellation of symptoms and rate of progression suggest Parkinson's disease is a collection of similar disorders rather than a single entity. A single etiology, therefore, is unlikely to be identified. The variety of epidemiological risk factors indicates multiple competing factors, including genetics, diet, and toxic exposures, among others that have yet to be identified, may contribute to the pathogenesis of Parkinson's disease. The balance of such factors likely determines individual risk of developing Parkinson's disease.

Lewy Bodies

The hallmark pathology of Parkinson's disease is the death of dopaminergic neurons in the brainstem and the presence of intraneuronal inclusions known as Lewy bodies. Lewy bodies contain multiple constituents. However, research has focused on aggregations of the protein alpha-synuclein bound to the intracellular chaperone protein ubiquitin¹¹ ([Fig. 15.1](#)).

FIG. 15.1 A combination of a pale body (arrow) and a small Lewy body (arrowhead) in melanized projection cells of the substantia nigra. (Reproduced from Braak H, Del Tredici K, Rüb U, et al. Staging of brain pathology related to sporadic Parkinson's disease. *Neurobiol Aging*. 2003;24:197–211.)

The Braak Hypothesis

A German pathologist, Hideo Braak, conducted an extensive and detailed study of the progression of Lewy body pathology in Parkinson's disease.^{12,13} His findings demonstrated the first signs of PD pathology appearing in the CNS are Lewy bodies in the olfactory bulb and the dorsal motor nucleus of the vagus nerve. From there, evidence of Lewy body formation and neuronal cell death spreads rostrally from the medulla. It is not until the substantia nigra is severely affected that patients develop the stereotypical motor symptoms of PD. This evolution and Braak's proposed staging system supports the concept of a preclinical stage of Parkinson's disease. Braak's study also indicates

Parkinson's disease is not simply a disease of dopamine deficiency, with other neurotransmitters also affected, including the serotonergic, histaminergic, and noradrenergic systems. These other neurotransmitters are thought to be involved in the etiology of many of the nonmotor symptoms of Parkinson's disease.

The Mitochondrial Hypothesis

A recurring theme in hypotheses of the etiology of Parkinson's disease is dysfunction of the mitochondria. Damage to mitochondrial complex I has been reported in individuals with Parkinson's disease.¹⁴ Impaired energy metabolism in the mitochondria of dopaminergic neurons may lead to production of reactive oxygen species,¹⁵ with the resulting oxidative damage to cell proteins, lipids, and DNA eventually leading to cell death.¹⁶

Alpha-Synuclein

Recent studies indicate a central role for the protein alpha-synuclein in the pathogenesis of Parkinson's disease. It has long been known that alpha-synuclein can be found bound to ubiquitin within Lewy bodies in areas of the brain affected by

Parkinson's disease.¹⁷ However, unbound alpha-synuclein may be more harmful to neurons.¹⁸ In conjunction with dopamine, alpha-synuclein enhances neuronal susceptibility to death from oxidative stress.¹⁹ Evidence is mounting that alpha-synuclein becomes capable of transmitting PD pathology when misfolded, much like the misfolded prion proteins responsible for the transmission of Creutzfeldt-Jacob ("mad cow") disease.²⁰⁻²²

Integrative Therapy

An integrative and multidisciplinary approach to treating Parkinson's disease should start with optimizing general health through exercise and diet. Some patients will choose to take supplements for their potential neuroprotective benefits, while others will prefer to wait for definitive studies. Pharmaceuticals will eventually be required to help control the motor symptoms of Parkinson's disease. A thorough discussion of the treatment of the nonmotor symptoms of Parkinson's disease can be very lengthy and beyond the scope of this chapter. Modalities from alternative medical systems will also be covered.

Nutrition

A large, prospective population-based study in Rotterdam, the Netherlands, found a higher dietary intake of omega-3 fatty acids was associated with a decreased risk of PD.²³ The effect was entirely due to the intake of plant-based α -linolenic acid rather than fish oils. Even without a preventive effect, fish oil may still have benefit for patients with Parkinson's disease. A separate double-blind, placebo-controlled study of patients with Parkinson's disease and major depression found improved mood symptoms in patients taking fish oil, with or without antidepressants.²⁴ Additionally, fish oil supplements were shown to reduce the risk of sudden cardiac death in otherwise healthy men in the Physician's Health Study.²⁵

Nutrition Suggestions for Patients With Parkinson's Disease

- Eat foods high in fiber to lessen constipation.
- Foods high in omega-3 fatty acids may be beneficial.
- Eat colorful fruits and vegetables for dietary sources of antioxidants.

Exercise

Aerobic Exercise

Aerobic exercise has a multitude of benefits for people with or without Parkinson's disease. A systematic review including multiple exercise modalities found significant benefit for people with Parkinson's disease.²⁶ Improvements were found in physical functioning, health-related quality of life, strength, balance, and gait speed. Additionally, a large cohort study demonstrated individuals with regular exercise had a better quality of life, better mobility, better physical function, less progression of disease, less caregiver burden, and less cognitive decline.²⁷ Data from animal studies have indicated aerobic exercise may be neuroprotective and slow the progression of Parkinson's disease.^{28,29}

Furthermore, exercise has utility in reducing depression and anxiety,³⁰ both common issues in Parkinson's disease. Forms of exercise that have been studied range widely from aerobic walking,³¹ tango dancing,³² and playing video games on a Nintendo Wii.³³ There is no clear evidence to suggest one form of exercise has greater benefit over another. Therefore, choosing an exercise program that is enjoyable enough to be continued is considered the best strategy.

Tai Chi

Tai chi is a martial art that started in ancient China as a means of self-defense. However, over time it became primarily used for health purposes. Tai chi emphasizes the cultivation of internal energy, qi, through the meditative properties of paying close attention to the details of movements. There are many different styles of tai chi, but all involve slow, relaxed, graceful movements, with each movement flowing into the next. The body is in constant motion and posture is important. Individuals practicing tai chi must concentrate, put aside all distracting thoughts, and breathe in a deep and relaxed but focused manner. In the Chinese community, people commonly practice tai chi in nearby parks, often in early morning before going to work.³⁴

The largest published study of tai chi in Parkinson's disease demonstrated a significantly reduced risk of falling.³⁵ Other studies evaluating objective improvements in laboratory measures of gait or balance have not shown measurable differences.³⁶ However, one of the same researchers did report improvements in some of the nonmotor symptoms of Parkinson's disease.³⁷ There is sufficient evidence to suggest tai chi is a safe and effective exercise for

reducing falls and improving general well-being in Parkinson's disease.

Benefits of Exercise in Parkinson Disease

Aerobic exercise has multiple benefits including:

- Increasing energy levels
- Decreasing depression and anxiety
- Potentially slowing disease progression
- Tai chi and yoga may help maintain and improve balance.

Supplements

N-Acetyl Cysteine

While there is evidence that glutathione can be transported actively across the blood–brain barrier, it is unable to cross passively or in large volumes.³⁸ Therefore, endogenous production is likely the primary source of brain glutathione stores. N-acetyl cysteine is a precursor to glutathione that is able to cross the blood–brain barrier.³⁹ It may, therefore, be a more effective way of increasing intraneuronal glutathione levels than intravenous infusions of glutathione. In animal studies, N-acetyl cysteine has been shown to increase glutathione levels in the

brain.⁴⁰ N-acetyl cysteine has also been shown to protect against cell death in animal models of Parkinson's disease.⁴¹ Although associated with the smell of rotten eggs, it is typically well-tolerated.⁴²

Dosage

1200 to 2400 mg per day

Precautions

Frequent side effects include nausea, vomiting, and diarrhea.⁴³

Glutathione

Glutathione is a potent, naturally occurring intracellular antioxidant. Glutathione levels are significantly reduced in the substantia nigra of patients with early Parkinson's disease.⁴⁴

Glutathione has been trialed as a twice daily intravenous infusion in a small open label study.⁴⁵ A more recent double-blinded study of intravenous infusions three times a week demonstrated a positive trend early but worsening of symptoms after treatment cessation.⁴⁶ A phase II clinical trial of an intranasal delivery system for glutathione, that bypasses the blood-brain barrier, is being conducted at Bastyr University.⁴⁷ However, there is

currently insufficient enough evidence to support the use of glutathione in the treatment of Parkinson's disease.

N-acetyl cysteine is a precursor of glutathione and can help replenish reduced glutathione levels as a result of reactive oxygen species that play a role in the pathogenesis of PD.

Co-Enzyme Q10

Coenzyme Q10 (CoQ10), or ubiquinone, is the electron receptor of mitochondrial complexes I and II. CoQ10 levels are significantly reduced in the mitochondria of individuals with early Parkinson's disease.⁴⁸ A randomized controlled trial in patients with Parkinson's disease reported a statistically significant slowing of the decline in a clinical rating scale (UPDRS) at the highest dose of 1200 mg of CoQ10 with 1200 IU of vitamin E.⁴⁹ However, a second and larger trial using 1200 mg and 2400 mg doses of CoQ10, in addition to 1200 IU of vitamin E, was halted due to a lack of beneficial effect. The authors concluded that CoQ10 was safe; however, there was a trend toward worse outcome in the treatment groups.⁵⁰

CDP-Choline

CDP-choline, or citicoline, is an intermediate in the synthesis of phospholipids, which are essential components in the assembly and repair of cell and mitochondrial membranes. Therefore, CDP-choline may have neuroprotective qualities as well as therapeutic effects in Parkinson's disease.^{51,52} Several studies have investigated using CDP-choline as a supplement to levodopa. CDP-choline reportedly allows reductions in levodopa doses by up to 50% without any reduction in symptom control.^{53,54} CDP-choline may enhance dopaminergic therapy in Parkinson's disease through multiple mechanisms, including decreased reuptake of dopamine leading to increased levels at the synaptic cleft. Additionally, CDP-choline activates tyrosine-hydroxylase and induces increased dopamine production.⁵⁵

Dosage

750 to 1500 mg orally per day

Precautions

CDP-choline use without lowering levodopa doses can lead to increased dyskinesias and other levodopa-induced side effects.

Vitamin D

Vitamin D is a secosteroid hormone that has modulating effects on immune and neural cells in addition to its classical actions on calcium and bone metabolism.⁵⁶ Vitamin D can be obtained from dietary sources as well as manufacture by the skin with exposure to sunlight. Vitamin D deficiency has been shown to be markedly more common in patients with Parkinson's disease.^{57,58} Additionally, vitamin D deficiency is associated with an increased risk of developing Parkinson's disease. Individuals with serum 25-hydroxyvitamin D concentrations greater than 20 ng/mL were reported to have a 65% lower risk of developing Parkinson's disease than those with levels below 10 ng/mL.⁵⁹ Vitamin D has been demonstrated to be neuroprotective in animal models of Parkinson's disease.^{60,61} Administration of 1,25-dihydroxyvitamin D₃ reportedly increases glial cell line-derived neurotrophic factor (GDNF) mRNA and protein levels in the striatum of rats.⁶² GDNF has shown promise as neuroprotective agent in animal models of Parkinson's disease.⁶³ A preliminary study demonstrated a trend toward improved balance with vitamin D supplementation;⁶⁴ however, further studies are required to determine the efficacy of vitamin D

supplementation in treating Parkinson's disease.

Vitamin E

Vitamin E (tocopherol) has been investigated by one of the longest studies of neuroprotection in Parkinson's disease. Ten-year follow-up data from the DATATOP study found no evidence that 2000 IU doses of vitamin E have efficacy in slowing the progression of Parkinson's disease.⁶⁵ Additionally, 14-year data from the Nurses Health Study found no association between reduced risk of developing Parkinson's disease and vitamin E supplementation. However, the consumption of nuts, which contain high levels of vitamin E, was found to be associated with a reduced risk of developing Parkinson's disease. Nut consumption may have served as a marker of a healthier diet.⁶⁶

Vitamin B₆ (pyridoxine)

Vitamin B₆ can increase peripheral conversion of levodopa to dopamine and should therefore be avoided in individuals taking carbidopa/levodopa. The decarboxylase inhibitor carbidopa can be used to prevent this effect, but may not be effective with high doses of vitamin B₆.⁶⁷

Creatine

Creatine monohydrate is a supplement often used to improve athletic performance, increase muscle mass, and serve as an intracellular energy source. In a small 12-month trial, creatine was found to marginally slow the progression of Parkinson's disease.⁶⁸ However, a much larger follow-up study (NET-PD) was halted at 5 years due to a lack of benefit. These findings do not support the use of creatine monohydrate in patients with Parkinson disease.⁶⁹

Botanicals

Green Tea (EGCG)

Epidemiological studies have indicated drinking three cups of tea per day may decrease the risk of developing Parkinson's disease by 28%. While other caffeinated beverages, such as coffee, also are linked with a reduced risk of Parkinson's disease,⁴ there is evidence that other constituents may account for at least some of the observed beneficial effects.⁷⁰ In addition to caffeine, green tea contains multiple polyphenols, catechins, and flavonols.⁷¹ The potent

antioxidant EGCG is the most studied component to date. Moreover, green tea may be beneficial in Parkinson's disease as an inhibitor of both apoptosis and of toxic alpha-synuclein fibrils in addition to its antioxidant effects.⁷²⁻⁷⁴

Dosage

3 cups per day

Precautions

Green tea can be a strong diuretic.

Curcumin

Curcumin is a phenolic compound with antiinflammatory properties that is found in the spice turmeric. Turmeric is commonly used in Indian and Asian foods, particularly curries. Curcumin has been used also for centuries in the Ayurvedic medical tradition in India. Curcumin has been shown to be a potent antioxidant that can attenuate loss of glutathione in cultured dopaminergic cells.⁷⁵ It has also been shown to reduce cell loss in an animal model of Parkinson's disease.⁷⁶ Additionally, curcumin reportedly protects against apoptosis in a cultured dopaminergic cell line,⁷⁷ with the aggregation of

alpha-synuclein and level of toxic misfolded variants reduced.⁷⁸

Dosage

Studies in people with Parkinson's disease have not yet to be reported. However, typical doses of curcumin for other conditions range from 400 to 600 mg curcumin in capsules three times a day, to 3 g turmeric root daily in divided doses.⁷⁹ As an alternative to taking curcumin capsules, patients may incorporate increased amounts of turmeric into their diet.

Precautions

Curcumin may cause mild stomach upset at high doses of several grams.

Mucuna Pruriens

Mucuna pruriens (velvet bean or cowhage) is a leguminous plant that has been used for centuries in Ayurvedic medicine for the treatment of Parkinson's disease. *Mucuna pruriens* contains levodopa as well as two components of the mitochondrial electron transport chain; coenzyme Q10 and nicotinic adenine dinucleotide (NADH).⁸⁰ In a single-dose, randomized controlled trial, a

mucuna seed powder formulation had comparable efficacy to levodopa in reducing Parkinsonian symptoms.⁸¹ This formulation had a quicker onset and caused less dyskinesias than levodopa. The results of an open-label study of another formulation, HP-200, in 60 patients over 12 weeks indicated *Mucuna pruriens* was well tolerated and helped alleviate Parkinsonian symptoms.⁸² Currently, neither formulation is commercially available.

Acupuncture

There have been few studies of the efficacy of acupuncture in patients with Parkinson's disease. Two meta-analyses of the current literature concluded that there is not sufficient evidence to support or refute the use of acupuncture in Parkinson's disease.^{83,84} Both reviews suggested that larger randomized controlled trials were warranted, particularly as some studies with design flaws reported promising results. For Parkinson's disease, acupuncture may be particularly useful in the treatment of some nonmotor symptoms or associated symptoms, such as back and joint pains. An open label study of acupuncture in 20 patients with Parkinson's disease reportedly statistically

significant improvements in sleep.⁸⁵ Additionally, 85% of patients reported subjective improvements in at least one individual symptom. A separate pilot study of acupuncture in Parkinson's disease demonstrated positive trends toward decreased nausea, improved sleep, greater ease of activities of daily living, and improved quality of life.⁸⁶

Pharmaceuticals

Levodopa

Levodopa remains the gold-standard therapeutic agent in Parkinson's disease. Levodopa is an amino acid that easily crosses the blood-brain barrier, where it is converted into dopamine to increase neuronal supply. Levodopa is combined with a decarboxylase inhibitor, carbidopa, in the US to prevent conversion in the peripheral bloodstream. Levodopa remains the most effective treatment for the majority of the motor symptoms of PD, with the possible exception of tremor. However, the administration of levodopa is often delayed in the mistaken belief that early treatment will shorten the number of years that it will remain effective.⁸⁷

Two new, long-acting, formulations of carbidopa/levodopa are now available. Rytary™ is

a capsule containing a combination of immediate-release and extended-release carbidopa/levodopa beads. Duopa™ is a gel formulation of carbidopa/levodopa that is continuously pumped through a PEG tube directly into the small intestine.

Dosage

Carbidopa/levodopa 25/100 mg three times a day (early disease). As the disease progresses, patients may take up to 2 g levodopa per day in divided doses as frequently as every 2 hours.

Precautions

Levodopa may cause lightheadedness, fatigue, nausea, confusion, hallucinations, dyskinesias, and lower extremity edema. However, levodopa tends to cause fewer side effects for the amount of benefit compared to other dopamine agonists.

Dopamine Agonists

Ropinirole, pramipexole, and the rotigotine patch are the primary dopamine agonists used in the US. All have very similar efficacy and are very effective at primarily treating the motor symptoms of Parkinson's disease. Dopamine agonists act as a replacement for decreased dopamine levels in the brain by directly stimulating dopamine receptors

and are often used in early Parkinson's disease to delay the introduction of levodopa and risk of developing dyskinesias.⁸⁸ Extended release formulations of both ropinirole and pramipexole are available.

Dosage

Ropinirole: start: 0.25 mg three times a day;
maximum of 24 mg per day

Pramipexole: start: 0.125 mg three times a day;
maximum of 4.5 mg per day

Rotigotine: start: 2 mg / 24 hr patch once a day;
maximum of 8 mg / 24 hr patch once a day

Precautions

Both dopamine agonists have a similar range of side effects. The most common are sleepiness, fatigue, nausea, and lower extremity swelling. Patients have fallen asleep while driving without first feeling sleepy.⁸⁹ There is also an increase in obsessive and compulsive behaviors that may rarely cause serious problems (i.e., gambling, sexual obsessions). Milder impulse control problems are common.⁹⁰

Rasagiline

Rasagiline is a highly-selective monoamine oxidase

type B (MAO-B) inhibitor that slows the endogenous breakdown of dopamine and its precursor, levodopa. Unlike rasagiline's older cousin, selegiline, no amphetamines are produced during the degradation of rasagiline. This difference is significant because amphetamines are considered to be neurotoxic. Rasagiline can be used as a stand-alone treatment in early Parkinson's disease, although its symptomatic effects are typically mild. In later disease, rasagiline can extend the length of action of levodopa and reduce "off" time. Recent studies have indicated that rasagiline may be neuroprotective via antiapoptotic effects. In a study using a delayed start design, rasagiline was found to slow the progression of the clinical symptoms of Parkinson's disease.^{91,92}

Dosage

Rasagiline 1 mg orally, once per day

Precautions

Rasagiline usually is very well tolerated with few side effects. Despite being an MAO inhibitor, there are no food restrictions and rasagiline can be used with many antidepressant medications. However, rasagiline should not be taken with tramadol or medications containing dextromethorphan. Rarely, rasagiline may cause a dangerous excess of

serotonin (serotonin syndrome), with symptoms including flushing, sweating, tremors, diarrhea, and elevated blood pressure.

COMT Inhibitors

Entacapone and tolcapone both inhibit the degradation of dopamine and levodopa by blocking the enzyme, catechol-O-methyl transferase (COMT). Entacapone is used more frequently as there have been rare cases of liver failure with tolcapone. Accordingly, hepatic enzymes must be monitored carefully during tolcapone treatment. Entacapone can increase the length of action of levodopa when taken concurrently. However, because entacapone has no effect on its own, it is also available as a combination pill with carbidopa/levodopa.

Dosage

Entacapone 200 mg taken with each dose of carbidopa/levodopa; maximum of 1600 mg per day (8 doses)

Precautions

Entacapone can potentiate the side effects of levodopa, including dyskinesia, lightheadedness, confusion, and hallucinations. Although not dangerous, patients will often be concerned if they

are unaware that entacapone may turn the urine a dark orange or yellow color.

Amantadine

Amantadine is an antiviral medication used to treat and prevent influenza infections. Amantadine was serendipitously found to reduce Parkinson's disease motor symptoms when it was given prophylactically in a nursing home. Amantadine can be used as a standalone treatment or in combination with rasagiline for the early symptoms of Parkinson's disease, including tremor.^{93,94}

Amantadine can also be used to reduce dyskinesias, fidgety movements that are a side-effect of levodopa, later in the course of the disease.

Dosage

100 mg twice a day to three times a day

Precautions

Amantadine may cause confusion and hallucinations, particularly in the elderly. Fatigue, lower extremity edema, lacy rash (levido reticularis), and lightheadedness are other common side effects.

Zonisamide

Zonisamide is an antiepileptic medication that has been found to have efficacy in treating Parkinson's disease. Zonisamide has specific efficacy for reducing tremor and is posited to work by several mechanisms. Zonisamide has been found to stimulate dopamine synthesis and may also directly inhibit the indirect pathway through delta opioid receptors.⁹⁵ Zonisamide has also been shown to reduce neuronal and astroglial cell loss in animal models of Parkinson's disease.^{96,97}

Dosage

25 mg to 100 mg per day as one dose or divided into two doses

Precautions

Kidney stones can occur in up to 1% to 2% of patients taking zonisamide,⁹⁸ and patients taking zonisamide should be advised to keep well-hydrated. Other side effects include weight loss, dry mouth, fatigue, and nausea.

Anticholinergic Medications

Anticholinergic medications are rarely used as a primary treatment for Parkinson's disease due to the high incidence of side effects, such as hallucinations, confusion, drowsiness, dry mouth,

urinary retention, and blurry vision. However, trihexyphenidyl can be very effective in treating tremor refractory to other medications.

Dosage

Trihexyphenidyl 6 mg to 15 mg per day in three divided doses

Surgery

Deep Brain Stimulation Surgery

Deep brain stimulation surgery for Parkinson's disease involves the placement of a permanent electrode into the basal ganglia for continuous, high-frequency electrical stimulation. Deep brain stimulation is considered in patients who remain responsive to levodopa, but its effects are not maintained. Surgical candidates may appear to cycle rapidly from feeling "frozen" to being wildly dyskinetic without spending much time in a comfortable state. Other patients may be considered for surgery if they are unable to tolerate sufficient doses of levodopa due to side effects. In a study of 255 patients that fit these criteria, deep brain stimulation surgery was shown to be more effective

than optimal medical management.⁹⁹ This study found patients who received deep brain stimulation were more likely to experience a clinically significant improvement in motor function (71% vs. 32%). On average, the deep brain stimulation group gained 4.6 hours of time with good motor function per day. However, serious adverse events were more common with deep brain stimulation. In a similar study, significant improvements in motor function were observed at four years after surgery.¹⁰⁰

Mind-Body Connection

Depression and anxiety are extremely common in Parkinson's disease, with approximately 20% to 40% of surveyed patients reporting these conditions.^{101,102} Depression in Parkinson's disease is frequently unrecognized, in part due to the significant overlap of outward manifestations.¹⁰³ In Parkinson's disease, depression may decrease quality of life more than motor symptoms.¹⁰⁴ Accordingly, it is important to screen for these disorders and initiate counseling if identified.

Increased stress levels have been found to exacerbate the symptoms of Parkinson's disease in a temporary fashion. While there is no significant

clinical evidence for or against their use, mindfulness-based stress reduction programs may be considered. A study of an 8-week mindfulness-based intervention reported an increase in grey matter density following the intervention.¹⁰⁵ Other mind-body exercises, such as yoga and Qi Gong, should be also be considered for stress reduction.

Prevention Prescription

For the treatment of Parkinson's disease, risk reduction rather than prevention is the goal.

- Engage in regular aerobic exercise.
- Drink 3 cups of tea per day, preferably green tea.
- Maintain a diet high in antioxidants and omega-3 fatty acids.
- Eat a handful (not a canful) of nuts daily (rich in vitamin E and in B vitamins).
- Reduce exposure to pesticides. Wash all fruits and vegetables carefully, including those that are grown organically.
- Reduce exposure to heavy metals. Test and filter well water as appropriate.
- Reduce exposure to industrial solvents and dry cleaning.

Therapeutic Review

The following is a summary of the therapeutic options for Parkinson’s disease. As Parkinson’s disease has a variety of manifestations and symptoms, the ladder approach to treatment may not always work but may be appropriate for mild motor symptoms. Because Parkinson’s disease is a chronic and progressive disease, the majority of patients will eventually need to be treated using strategies from multiple rungs of the ladder below.

Category	Item	Rating
Reverse Deteriorating Medications	If other medical conditions allow, stop all medications that may induce Parkinsonism such as neuroleptics, drugs, neuroleptics, and psychotropics. Anticholinergics, lithium, valproate, and amiodarone are more rarely implicated and typically more difficult to discontinue.	
	Reduce exposure to pesticides.	
	Have well water tested to reduce exposure to heavy metals.	
Mind-Body Therapy	Facilitate optimism. The placebo effect is very strong in Parkinson’s disease.	
Exercise	Encourage regular aerobic exercise.	
	Consider Tai Chi for stress management and improving balance.	
Nutrition	A high fiber diet may help with constipation.	
	Encourage foods rich in omega-3 fatty acids, such as salmon, walnuts, purple fruits, and flax seeds.	
	Use tannins in cooking.	
	Drink 3 cups of tea per day, preferably green tea.	
Neuroprotection	Ramipril 1 mg daily.	
	N-acetyl cysteine 600 mg twice daily.	
	Encourage regular aerobic exercise.	

Table Continued

Category	Items	Rating
Therapeutic Supplements	CDP-Choline 500 to 1250 mg daily. Reduce carbidopa/levodopa dose to 30%-50% if given together.	B ₂ 
Acupuncture	Acupuncture may help with the nonmotor and pain symptoms of Parkinson disease.	B ₁ 
Pharmaceuticals	The overall strategy is to initiate treatment with an MAO inhibitor and then trial either amantadine or a dopamine agonist in patients without cognitive impairment. Treatment should be initiated with carbidopa/levodopa in patients with prominent gait impairment, significant rigidity, or cognitive impairment.	
	Rasagiline: 1 mg daily.	A ₂ 
	Amantadine: 100 mg twice daily to three times daily.	B ₂ 
	Dopamine agonists	A ₂ 
	Rotigotine: start with 0.25 mg TID and titrate up to a maximum of 24 mg per day.	
	Pramipexole: start with 0.125 mg TID and titrate up to a maximum of 4.5 mg per day.	
	Rotigotine patch: start with 2 mg/24 hr and titrate up to a maximum of 8 mg/24 hr.	
	Carbidopa/levodopa IR: titrate up from carbidopa/levodopa 25/100 half tablet three times daily up to carbidopa/levodopa 25/250 QID as necessary.	A ₂ 
Table Continued		

Category	Items	Rating
	For tremor-predominant Parkinson's disease, start with:	
	Zonisamide: 25 mg to 100 mg daily.	B ₂
	Timoprostol-titrate up from 1 mg daily to twice daily then three times daily, to a maximum of 15 mg per day.	B ₂
	If carbidopa/levodopa wears off early consider:	
	Rasagiline: 1 mg daily (if not already being used).	A ₂
	Entacapone: 200 mg with each dose of carbidopa/levodopa up to 8 doses per day.	A ₂
	Rytary™ (carbidopa/levodopa) with dose conversion according to a chart found in the prescription insert.	A ₂
	If dyskinesias develop and are causing the patient problems, trial decreasing the dose of carbidopa/levodopa or division into smaller but more frequent doses. If this is not possible, consider adding:	
	Amantadine: 100 mg twice daily to three times daily.	B ₂
Surgery	Consider deep brain stimulation surgery targeting either the subthalamic nucleus or the globus pallidus internus for patients who respond to levodopa yet have severe motor fluctuations with rapid wearing off or dyskinesias.	A3
	Consider the Duopa™ pump for patients who respond to levodopa yet have severe motor fluctuations with rapid wearing off or dyskinesias but are not candidates for neurosurgery.	B3

CHAPTER 16

Otitis Media

David K. Becker, MD

Pathophysiology

Otitis media (OM) is a generic term for inflammation of the middle ear. Middle ear infections occur when fluid accumulates in the middle ear as a result of the body's inflammatory response to viral or bacterial infection. Occasionally, sterile fluid may accumulate due to dysfunction of the eustachian tube ([Fig. 16.1](#)), a finding more common in children as the eustachian tube occasionally fails to function sufficiently due to small size or abnormal shape. Otitis media is divided into 3 categories for clinical and research purposes: acute OM (AOM), OM with effusion (OME), and chronic OM with effusion (chronic serous OM or CSOM).¹ AOM is the most commonly diagnosed subtype and commonly occurs as part of, or a complication of, upper respiratory tract infection. The OME designation can be confusing as middle ear effusions occasionally present without signs of inflammation. Effusions may also occur as part of the healing process following AOM (which can last weeks to months) or as a complication of eustachian tube dysfunction. CSOM may be associated with auditory and speech impairments.² The tympanic membrane is a thin, sensitive layer of skin that, when inflamed or under pressure, can be a source of significant pain (see [Fig. 16.1](#)). Infectious causes of AOM include viral (influenza, adenovirus, others) and bacterial pathogens (nontypeable *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Moraxella catarrhalis*),^{3,4} with earache and fever common presenting symptoms. Factors that may predispose to an increased frequency of OM include atopy (allergic rhinitis and cow's milk allergy), exposure to prenatal and postnatal tobacco smoke,⁵ and exposure to air pollution.⁶

Integrative Therapy

An integrative approach to otitis media begins with primary prevention—reducing the risk factors that contribute to otitis. For management of acute or chronic OM, the goal is selecting a treatment approach that balances the relative risks and benefits of the range of options available that may help relieve symptoms and supporting the body's natural healing response. Finally, secondary prevention options should be considered for the reduction of recurrence and sequelae of repeat infections. Commonly used therapies for otitis include biologically based therapies (including pharmaceuticals), manual and body-based therapies, and homeopathy. It may be helpful to review with families the epidemiology and natural history of upper respiratory infections (URIs). The majority of young children have at least 6 URIs per year.⁷ URIs are common, frequently occur back to back, and can be frustrating for patients and families despite being a normal part of childhood experience. Because at least 80% of cases of AOM resolve without antibiotic treatment,⁸ the majority of patients can be observed without antibiotics, with treatment focused on symptom relief and supporting the body's healing response. Caution is warranted for careful observation for rare but significant complications of AOM, including mastoiditis, tympanic membrane perforation, and meningitis.

Nutrition

A number of nutritional interventions have been studied for recurrent acute otitis media (ROM). An interesting cross-sectional study found increased odds of pneumococcal carriage among children consuming a diet high in processed sweets, with a diet higher in fruits and berries found to be associated with a decreased risk of AOM (odds ratio, 1.36; 95% CI 1.03–1.9; P = 0.03).⁹ A small pilot study of 8 children administered 1 tsp of cod liver oil with vitamin A plus a selenium supplement found that study participants received antibiotics for 12% fewer days than controls.¹⁰

Biochemical

Pharmacies and natural health stores abound in remedies marketed for the treatment of symptoms associated with OM. Over-the-counter products containing pharmaceutical agents for management of cough

and congestion in young children have been strongly discouraged by the U.S. Food and Drug Administration due to concerns regarding potential harm and lack of efficacy.¹¹ Acetaminophen and ibuprofen can be effective in reducing fever and pain but can also have significant side effects. However, strong epidemiological evidence indicates acetaminophen may be associated with subsequent development of asthma if used with high frequency.¹² Judicious use is warranted.

Ibuprofen and/or acetaminophen can be used for pain relief in children with acute otitis media. But be careful with overprescribing acetaminophen as some data suggests excessive use may increase the risk of asthma.

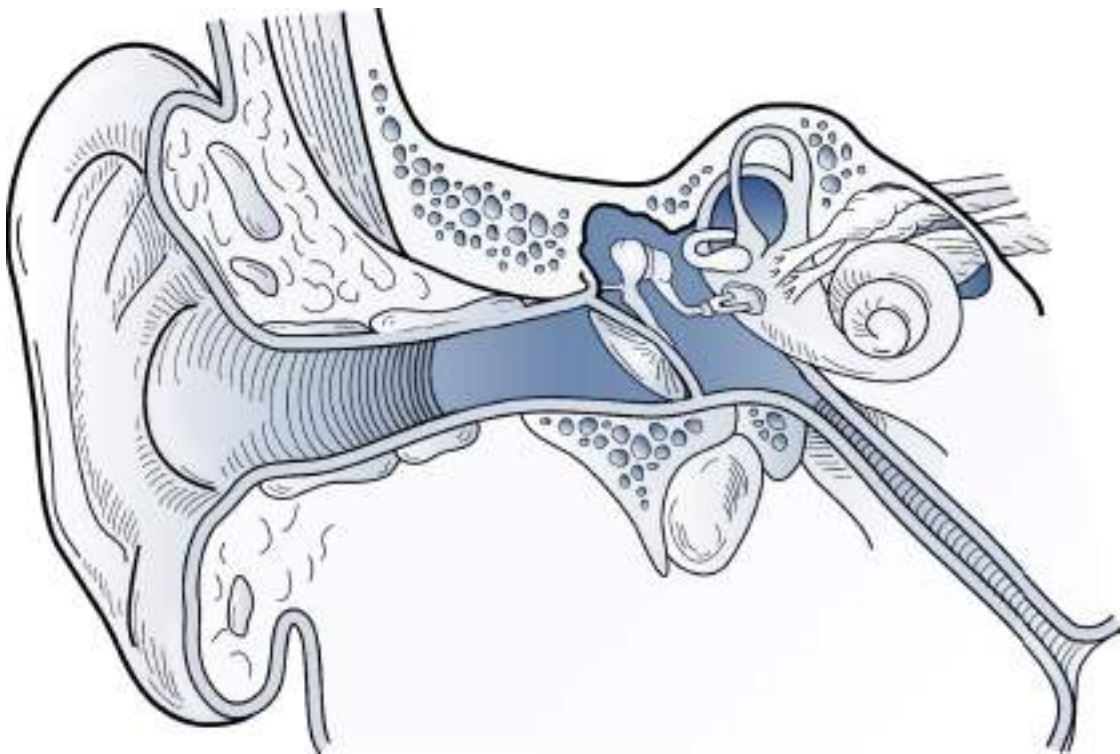

FIG. 16.1 Anatomy of the ear.

Botanicals

Combination Herbal Extract Ear Drops

Botanically based topical ear drops are available from a wide variety of manufacturers. Guidance on specific brands or herbal combinations is limited by a lack data and variability in the contents of products. A specific product combination used in previous studies included the following ingredients: garlic (*Allium sativum*), mullein flower (*Verbascum thapsus*), calendula flower, St. John's wort (*Hypericum perforatum*), lavender, and vitamin E in an olive oil base. In two separate trials of children aged 5–18 years, this combination was found to be effective as topical anesthetic drops in relieving pain.

Other botanical remedies for upper respiratory tract infections may have benefit in children with uncomplicated URI's and associated middle ear effusions⁷ (see [Chapter 18](#)).

Supplements

Xylitol

Several trials have evaluated the efficacy of xylitol in preventing AOM episodes. A Cochrane review found “fair evidence” that xylitol reduces AOM occurrences by up to 25% among children attending day care.¹³ However, a negative trial using a dose of 5 g three times a day suggests higher doses and frequency may be necessary.¹⁴

Dosage

The conclusions of a Cochrane review suggest 8–10 mg of xylitol in 5 divided doses daily may be necessary.

Precautions

Xylitol has few adverse effects but, when they do occur, they generally present as stomach upset and diarrhea. Xylitol is a polyol sugar that is avoided in the FODMaPs diet that has been reported to be beneficial for irritable bowel syndrome (see [Chapter 90](#)).

Vitamin D

Low vitamin D levels have been reported to be associated with poor health outcomes by numerous epidemiological studies. Two prospective

controlled trials of vitamin D supplementation in children with a history of ROM both reported a significantly reduced subsequent incidence of AOM among children with low initial levels of vitamin D.^{15,16} Of note, neither study attempted to achieve unusually high vitamin D levels. On average, vitamin D levels after the intervention were between 23 and 36.8 ng/mL.

Dosage

In those with ROM and low vitamin D levels, supplementation with vitamin D3 should be administered to raise serum levels to a level >25 ng/mL. Generally, 1000 IU of vitamin D are required to raise serum levels by 8–10 ng/mL.

Probiotics

Two comprehensive review studies and a recent randomized trial failed to provide evidence to support probiotics as an effective preventive strategy for AOM.¹⁷⁻¹⁹ The studies included in the reviews used different probiotic strains in varying quantities, which highlights the complexity of this research field. Another review suggests that probiotics may reduce the colonization of *Streptococcus pneumoniae*, but no direct reduction in AOM incidence has yet been shown.²⁰ Research in this area is growing but limited by the immense diversity of the microbiome. While there are not yet data that clearly support the use of probiotics for the treatment or prevention of OM, the safety profile and potential benefit mean a treatment trial in some circumstances is reasonable.

FIG. 16.2 A, Normal TM. B, TM with mild bulging. C, TM with moderate bulging. D, TM with severe bulging. (Courtesy of Alejandro Hoberman)

Pharmaceuticals

The widespread use of antibiotics for AOM has come under much-needed critical review over the past 5–10 years. While concerns regarding antibiotic resistance were of primary interest among conventional critiques, other concerns, including effects on the microbiome, have now gained recognition as well. Current guidelines from the American Academy of Pediatrics (AAP) emphasize the use of otoscopy to confirm the presence of acute erythema *and* purulent effusion causing *significant* bulging of the tympanic membrane as the most specific signs of a bacterial infection warranting antibiotic treatment to prevent significant

complications, particularly in younger children² ([Fig. 16.2](#)). Most cases of AOM do not have this combination of findings and can be observed and followed for resolution without the use of antibiotics as the initial treatment.

The most sensitive sign to support the use of antibiotics in acute otitis media is a bulging tympanic membrane with erythema and purulent effusion on otoscopy (see [Fig. 16.2](#)).

Should the use of antibiotics be indicated, first-line treatment should cover the most common bacterial pathogens, including *S. pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*.

Dosage

Amoxicillin at 80–90 mg/kg/day in divided doses twice daily is the first-line treatment for AOM.² Second-line options include amoxicillin-clavulanate and third-generation cephalosporins, including IM ceftriaxone in refractory cases.

Precautions

Overprescribing of antibiotics may result in growing resistance of microbial organisms. Diarrhea and GI intolerance are the most common side effects seen.

Biomechanical

Osteopathy

Two small studies have evaluated the efficacy of osteopathic manipulation in the management of ROM and/or CSOM.^{21,22} In Degenhardt and Kuchera's uncontrolled pilot study, eight children received weekly manipulative treatment for 3 weeks concurrent with traditional management. During a 1-year follow-up, only one child required surgical tube placement and 5 children had no recurrences.

A second, controlled study of 57 children aged 6 months to 6 years with at least 3 episodes of AOM in the prior 6 months evaluated the efficacy of a series of 9 osteopathic sessions over a 6-month period.

Children in the treatment group had significantly fewer surgical procedures and fewer episodes of AOM. No follow up beyond the 6-month trial period was conducted, and there was a dropout rate of 25%. No adverse reactions were reported.

Chiropractic

The literature on chiropractic intervention for OM is comprised primarily of case reports, case series, and commentaries. A comprehensive review by Pohlman and Holton-Brown of both the osteopathic and chiropractic literature was published in 2012.²³ Of the 49 publications reviewed, only 3 were clinical trials and only one of those was a chiropractic intervention. This study randomized 20 patients aged 6 months to 6 years into treatment and sham spinal manipulation arms. However, data from this study could not be analyzed as the validity of the otoscopy and tympanometry was poor. Pohlman and Holton-Brown, citing the limited quality of data in addition to the absence of serious adverse reactions, concluded that there was inadequate evidence to support or refute the use of spinal manipulation in children with ROM or CSOM.

Surgery

Updated AAP guidelines for the management of OM note the controversial nature of surgical intervention for ROM or CSOM.² There is a lack of consensus among otolaryngologists regarding recommendations for surgery, with roughly a third each saying they would “never,” “sometimes,” or “often or always” place tympanostomy tubes for a hypothetical case of a 2-year-old with recurrent AOM. Tympanostomy tube insertion has been demonstrated to reduce subsequent bouts of AOM and improve disease-specific quality of life measures (including hearing loss and speech impairment). Careful weighing of the risks and benefits is warranted. The AAP concluded that “clinicians may offer tympanostomy tubes for ROM” (defined as 3 episodes in 6 months or 4 episodes in 1 year).

Therapies to Consider

Homeopathy

A handful of small studies have suggested the benefit of homeopathy in the treatment of AOM (PIR).⁸ While quality studies are lacking, the safety profile of homeopathic remedies is excellent provided the products used

are truly homeopathic and do not contain physiologically active quantities of natural health products. Hopefully, controlled trials comparing homeopathic remedies with other treatment modalities will help clarify relative benefit (see [Chapter 115](#)).

Prevention Prescription

Primary Prevention Prescription

- Encourage and facilitate exclusive breast-feeding for at least 4–6 months.
- Educate families about, and advocate for, limiting exposure to air pollution and tobacco smoke.
- Avoid unnecessary antibiotic exposure.
- Guide families on how to make nutritious food choices, including creative ways to get adequate whole grains, fruits, vegetables, healthy proteins, and oily fish.
- Vaccination for *Pneumococcal* and *Haemophilus influenzae* infections may be efficacious in the prevention of some AOM episodes.

Secondary Prevention Prescription

- Consider one or more of the following for prevention of recurrent AOM and OME:
 - Primary prevention measures
 - Vitamin C: 100–500 mg daily
 - Vitamin D: 1000 IU daily
 - Probiotics: at least 10 billion organisms daily of *Lactobacillus* and *Bifidobacteria*
 - Omega-3 fatty acids: at least 1 g of DHA and EPA combined, daily
 - Xylitol: at least 5 g, five times daily

Therapeutic Review

Environmental

- Address potential allergens and triggers of upper respiratory inflammation (tobacco smoke, cow's milk protein). 

Botanicals

- Herbal extract ear drops: use 2–3 drops in infected ear every 4 hours as needed for pain. 

Manipulative and Body-based Methods

- Consider osteopathic or chiropractic treatments for patients who are being considered for surgical intervention. 

Pharmaceuticals

- Use antibiotics judiciously in younger patients and those with marked signs of inflammation and increased middle ear pressure. Amoxicillin at 80–90 mg/kg/day in divided doses twice daily is the first-line choice 
- Acetaminophen or ibuprofen for pain relief. 

Surgery

- Myringotomy tubes may be considered in cases with hearing loss and/or speech delay.

Chapter 17

Chronic Sinusitis

Robert S. Ivker, DO

Pathophysiology

Prevalence

Since 1981, chronic sinusitis has been ranked among the most common chronic diseases in the United States. It is currently the most common respiratory condition in the world. According to the National Center for Health Statistics (a division of the Centers for Disease Control and Prevention [CDC]), approximately 40 million Americans of all age groups suffer from this ailment.¹ Chronic sinusitis affects nearly 15% of the population, corresponding to one out of every seven individuals. Furthermore, 22% of all women between the ages of 45 and 64 years are reported to have chronic sinusitis (compared to 15% of men in this age group), an incidence approximately equal to that of hypertension. Sinusitis is second only to arthritis among the most common chronic diseases affecting

women in this age group. In men in this age group, sinusitis ranks fourth behind hypertension, hearing impairment, and arthritis. It was the primary reason for nearly 12 million physician office visits in 1995,^{2,3} and over 200,000 sinus surgical procedures were performed in 1994⁴ (the current number is more than 300,000). Medical costs for diagnosing and treating this condition are estimated to be greater than \$10 billion annually.

When sinusitis is considered together with allergic rhinitis (the fourth most common chronic condition), asthma, and chronic bronchitis (the eighth and ninth most common conditions, respectively), respiratory disease resulting from these ailments affects more than 90 million people—nearly one out of every three Americans—and thus constitutes our first environmental epidemic. In the 1960s, none of these four respiratory conditions were among the top 10 chronic health problems.

Etiology

The modern-day plague of air pollution is insidiously destroying the respiratory tract of those breathing polluted air. According to the Environmental Protection Agency (EPA), 60% of Americans currently live in areas where the air

quality makes breathing a risk to their health. A 1993 study performed by the EPA and Boston's Harvard School of Public Health reported that 50,000 to 60,000 deaths a year are caused by particulate air pollution.⁵ A subsequent study in 1995 bolstered the earlier findings while concluding that people who live in highly polluted cities die earlier (approximately 10 years sooner, a 15% decrease in life expectancy) than if they had been breathing healthier air. In addition to particulates, other components of toxic air include carbon monoxide, ozone, sulfur dioxide, nitrogen dioxide, hydrocarbons, and lead.

The nose and sinuses are lined by the respiratory epithelium. By virtue of the histological and physiological characteristics of its outermost lining, the ciliated mucous membrane or mucosa—serve as the body's air filter, humidifier, and temperature regulator as well as protector of the lungs. This continuous mucous membrane that extends from just inside the nostrils to the alveolar sacs in the lungs is a connected porous protective shield for the body's air portal. The respiratory epithelial mucosa serves as a vital component of the immune system and acts as the first line of defense against bacteria, viruses, pollen, animal dander, cigarette smoke, dust, chemicals, automobile exhaust, and other

potentially harmful air pollutants. The majority of its function of filtration, humidification, and temperature regulation occurs in the nose and in the four pairs of paranasal sinuses (maxillary, ethmoid, frontal, and sphenoid) comprising the entrance and vestibule of the respiratory tract.

Although the human body is a self-healing organism, the self-rejuvenating process typically requires a period of rest and recovery. The primary challenge preventing healing of the respiratory mucosa is continuous respiration of approximately 20,000 breaths per day. When the air that we breathe is polluted and dry, as indoor air tends to be, especially during the winter months, the mucous membrane can easily become mildly inflamed from the chronic irritation in addition to one or more of the etiological factors listed later. Without the opportunity for rest and recovery, chronic irritation often leads to chronic inflammation, the underlying pathophysiological process of chronic sinusitis. Chronically inflamed mucosa is weak and therefore more vulnerable to cold viruses, the most common trigger for sinus infections. The mucosa may also become hyperreactive and more sensitive to a wide variety of allergens, foods, and chemicals. Nothing is more important to optimal physical well-being than the quality of the air breathed and the

ability to breathe it. Pollutant-laden air often has far less than the optimal 20% oxygen or negative ion content (3000 to 6000 ions / cm³), thus adding to its effect as a chronic irritant in causing inflamed and hypersensitive mucous membranes. Chronically inflamed mucosa often results in increased mucus secretion (rhinorrhea and postnasal), head and nasal congestion with some degree of obstruction of the ostia, headaches, and nasal allergy.

Symptoms and Diagnosis

Chronic sinusitis is defined as persistent or recurrent episodes of infection or inflammation of one or more sinus cavities that produce the majority or all of the following symptoms and signs: headache, facial pain, head congestion, purulent postnasal drainage or rhinorrhea, and fatigue.⁶ Purulent mucus does not always indicate infection; however, it does always indicate some degree of inflammation. Although most otolaryngologists rely on computed tomography scanning for the definitive diagnosis of sinusitis, a good history and physical examination to detect the presence of most or all of the defining signs and symptoms of chronic sinusitis can provide a reliable diagnosis of acute

sinusitis in primary care settings. Patients who are most debilitated by chronic sinusitis typically have some degree of fungal sinusitis. Unfortunately, even in 2015, no consistently reliable laboratory tests are available for the definitive diagnosis of chronic sinusitis. As *Candida* is a normal inhabitant of the body, the identification of *Candida* overgrowth can be challenging with laboratory testing alone. Accordingly, clinicians should consider the use of patient history, Dr. William Crook's *Candida* Questionnaire and Scoresheet (see [Fig. 17.1](#)), and the therapeutic response to antifungal treatment to confirm the diagnosis of fungal sinusitis.

Risk Factors for Acute and Chronic Sinusitis

- Infections: the common cold causes inflammation and ciliostasis.⁷ Candidiasis, yeast overgrowth, or fungal sinusitis may cause severe respiratory and systemic inflammation.
- Environment (both indoor and outdoor air pollution and pollen)
- Lifestyle (diet, cigarettes, and other sources of smoke)
- Allergies: Half of chronic sinusitis sufferers have allergies to pollen or food.
- Food sensitivities

- Emotional stress, particularly repressed anger and grief (unshed tears)
- Dry air: Air with less than 30% relative humidity occurs in an arid or semiarid climates or as the result of forced-air heating systems, air-conditioning (particularly in cars), oxygen therapy, or wind.
- Cold air: the ideal temperature is greater than 65°F.
- Occupational hazards: those at highest risk include automobile mechanics, construction workers (especially carpenters), painters, beauticians, firemen, airport, and airline personnel.
- Gastroesophageal reflux disease
- Dental infection: infection of the upper teeth may spread to the maxillary sinuses.
- Malformations (polyps, cysts, deviated septum)

Fungal Sinusitis

Since the early 1990s, I have treated the patients who have presented with the most severe and challenging cases of chronic sinusitis using an antifungal regimen. A landmark Mayo Clinic (Rochester, MN) study,⁸ published in September 1999, reported an immune system response to fungus, rather than to bacterial infection, as the

cause of the majority of cases of chronic sinusitis. The investigators reached this conclusion after studying 210 patients with chronic sinusitis and identifying 40 different species of fungus, including *Candida*, in the mucus of 96% of participants. Similar organisms were identified in a control group of normal healthy volunteers. The investigators concluded that the immune response to these fungi in patients with chronic sinusitis is markedly different from that of healthy people and that this unusual immune reaction is responsible for the chronic inflammation, pain, and swelling of the mucous membranes associated with sinusitis. These investigators termed the condition “allergic fungal sinusitis.” However, the investigators failed to speculate on the possible impact of previous multiple courses of broad-spectrum antibiotics on the immune response to fungal organisms in these patients. The resultant profound disruption of the normal bacterial flora of the mucosa likely contributed to the immune response observed. However, this issue was not addressed, and this study concluded simply by stating, “we must begin looking at chronic sinusitis as more than simply a bacteriological and/or anatomical problem, but as a dysfunction of the immune system mediated by a fungus.”

Between October, 1999, and February, 2000, my colleagues and I⁹ conducted a study with 10 patients of an allergist-immunologist, who were symptomatic despite aggressive conventional treatment for chronic sinusitis (four of the patients also had asthma). The study consisted of five group sessions with follow-up evaluations at 1-year and again at 7.5 years. Dr. William Crook's Candida Questionnaire and Scoresheet ([Fig. 17.1](#)) was used as part of baseline measurements, and all 10 patients scored in the "probably yeast-connected" category or higher. All patients were treated with the Sinus Survival Program (currently called the Respiratory Healing Program, shown in the following) in addition to fluconazole. Statistically significant improvement was observed 1 month following the introduction of fluconazole and again at the end of the 5-month study. Although asthma outcomes were not measured, three of the four asthmatic patients reported marked improvements in asthma symptoms, and they were able to reduce treatment dosage or stop inhaler use. At both the 1-year and 7.5-year follow-up assessments, improvements in sinusitis symptoms and quality of life were either maintained or enhanced in all participants. This is the only published long-term study of the treatment for fungal sinusitis.

Note

An allergic inflammatory response to fungal organisms is an important etiological factor in chronic sinusitis.

Integrative Therapy

The Respiratory Healing Program

Although antibiotics have been the mainstay of conventional medical treatment for chronic sinusitis, often followed by sinus surgery if the problem has not resolved, these therapeutic modalities increasingly offer only temporary relief and fail to resolve or cure chronic sinusitis. In a study of 161 children with acute sinusitis, researchers concluded that “antimicrobial treatment offered no benefit in overall symptom resolution, duration of symptoms, recovery to usual functional status, days missed from school or child care, or relapse and recurrence of sinus symptoms.”¹⁰ For the growing number of patients who have failed to respond to repeated courses of broad-spectrum antibiotics and surgery, postoperative patients, and the growing numbers of individuals who elect not to have (or are not candidates for) surgery or to take

antibiotics, the Respiratory Healing Program has consistently produced successful outcomes.

Candida Questionnaire and Score Sheet

This questionnaire is designed for adults, and the scoring system isn't appropriate for children. It lists factors in your medical history that promote the growth of *Candida albicans* (Section A), and symptoms commonly found in individuals with yeast-connected illness (sections B and C).

For each "Yes" answer in Section A, circle the point score in the box at the end of the section. Then move on to sections B and C and score as directed. Filling out and scoring the questionnaire should help you and your doctor evaluate the possible role of candida in contributing to your health problems. Yet, it will not provide an automatic "Yes" or "No" answer.

SECTION A: HISTORY POINT SCORE:

- (1) Have you taken tetracyclines (Sumycin, Panmycin, Vibramycin, Minocin, etc.) or other antibiotics for acne for one month or longer? 25
- (2) Have you, at any time in your life, taken other "broad spectrum" antibiotics* for respiratory, urinary, or other infections for 2 months or longer or in shorter courses 4 or more times in a 1-year period? 20
- (3) Have you taken a broad spectrum antibiotic* — even in a single course? 6
- (4) Have you, at any time in your life, been bothered by persistent prostatitis, vaginitis, or other problems affecting your reproductive organs? 25
- (5) Have you been pregnant:
2 or more times? 5
1 time? 3
- (6) Have you taken birth control pills:
For more than 2 years? 15
For 6 months to 2 years? 8
- (7) Have you taken prednisone, Decadron, or other cortisone-type drugs by injection or inhalation:
For more than 2 weeks? 15
For 2 weeks or less? 6
- (8) Does exposure to perfumes, insecticides, fabric shop odors, and other chemicals provoke:
Moderate to severe symptoms? 20
Mild symptoms? 5
- (9) Are your symptoms worse on damp, muggy days or in moldy places? 20
- (10) Have you had athlete's foot, ringworm, jock itch, or other chronic fungus infections of the skin or nails? Have such infections been:
Severe or persistent? 20
Mild to moderate? 10
- (11) Do you crave sugar? 10
- (12) Do you crave breads? 10
- (13) Do you crave alcoholic beverages? 10
- (14) Does tobacco smoke really bother you? 10

TOTAL SCORE, SECTION A:

* Including ampicillin, amoxicillin, Augmentin, Keflex, Ceclor, Bactrim, Septra, Levaquin, Zithromax, and many others. Such antibiotics kill off "good germs" while they are killing off those which cause infection.

SECTION B: MAJOR SYMPTOMS

For each of your symptoms, enter the appropriate figure in the point score column:

Not at all 0 points

Occasional or mild 3 points

Frequent and/or moderately severe 6 points

Severe and/or disabling 9 points

Add total score and record it in the box at the end of this section.

POINT SCORE:

- (1) Fatigue or lethargy
- (2) Feeling of being "drained"
- (3) Poor memory or concentration
- (4) Feeling "spacey" or "unreal"
- (5) Depression
- (6) Numbness, burning, or tingling
- (7) Muscle aches
- (8) Muscle weakness or paralysis
- (9) Pain and/or swelling in joints
- (10) Abdominal pain
- (11) Constipation
- (12) Diarrhea
- (13) Bloating
- (14) Troublesome vaginal discharge
- (15) Persistent vaginal burning or itching
- (16) Prostatitis
- (17) Impotence

- (18) Loss of sexual desire
- (19) Endometriosis or infertility
- (20) Cramps and/or other menstrual irregularities
- (21) Premenstrual tension
- (22) Spots in front of the eyes
- (23) Erratic vision

TOTAL SCORE, SECTION B:

SECTION C: OTHER SYMPTOMS

For each of your symptoms, enter the appropriate figure in the point score column:

Not at all 0 points

Occasional or mild 1 point

Frequent and/or moderately severe 2 points

Severe and/or disabling 3 points

Add total score and record it in the box at the end of this section.

POINT SCORE:

- (1) Drowsiness
- (2) Irritability or jitteriness
- (3) Incoordination
- (4) Inability to concentrate
- (5) Frequent mood swings
- (6) Headache
- (7) Dizziness/loss of balance
- (8) Pressure above ears, feeling of head swelling, and tingling
- (9) Itching
- (10) Other rashes
- (11) Heartburn
- (12) Indigestion
- (13) Belching and intestinal gas
- (14) Mucus in stools
- (15) Hemorrhoids
- (16) Dry mouth
- (17) Rash or blisters in mouth
- (18) Bad breath
- (19) Joint swelling or arthritis
- (20) Nasal congestion or discharge
- (21) Postnasal drip
- (22) Nasal itching
- (23) Sore or dry throat
- (24) Cough
- (25) Pain or tightness in chest
- (26) Wheezing or shortness of breath
- (27) Urinary urgency or frequency
- (28) Burning on urination
- (29) Failing vision
- (30) Burning or tearing of eyes
- (31) Recurrent infections or fluid in ears
- (32) Ear pain or deafness

TOTAL SCORE, SECTION C:

TOTAL SCORE, SECTION A:

TOTAL SCORE, SECTION B:

GRAND SCORE:

The Grand Total Score will help you and your doctor decide if your health problems are yeast-connected. Scores in women will run higher as 7 items in the questionnaire apply exclusively to women, whereas only 2 apply exclusively to men.

IF YOUR SCORE IS: SYMPTOMS ARE:

- 180 (women) almost certainly yeast-connected
- 140 (men)
- 120 (women) probably yeast-connected
- 80 (men)
- 60 (women) possibly yeast-connected
- 40 (men)
- Less than
- 60 (women) probably not yeast-connected
- 40 (men)

FIG. 17.1 Candida Questionnaire and Score Sheet

(From Crook WG. The yeast connection: a medical breakthrough. 3rd ed. Jackson, TN: Professional Books; 1986.)

The goal of this integrative holistic treatment program for chronic sinusitis is to address the primary cause (inflammation) by healing the chronically inflamed mucous membrane. Although this is a relatively complex problem with multiple risk factors contributing to chronic inflammation, what makes this approach so effective is that each of these factors is either mitigated or eliminated.

Components of the Respiratory Healing Program for Chronic Sinusitis

- Treating and preventing sinus infections and colds
- Practicing nasal hygiene—spraying, steaming, and irrigating
- Eating a healthy, antiinflammatory, and hypoallergenic diet in combination with

antiinflammatory and antioxidant vitamins and supplements

- Improving indoor air quality
- Treating yeast overgrowth or fungal sinusitis
- Detoxification
- Treating allergies
- Strengthening and restoring balance to the immune system
- Healing the issues in your tissues: mental, emotional, spiritual, and social health factors

If the patient closely adheres to the first seven components listed here, he or she will usually experience significant improvement within 1 to 2 months, regardless of the duration of chronic sinusitis. Depending on the patient—the severity of the condition, the level of commitment, and my sense of the patient’s capability—I typically introduce the first five components at the first session, followed a month later by detoxification and recommendations for strengthening immunity and mitigating allergies. The third and fourth sessions, 2 and 3 months into the program, are focused on mental and emotional health and on spiritual and social health, respectively.

The keys to curing chronic and fungal sinusitis are becoming a highly skilled practitioner in the art of preventive medicine (specifically preventing sinus

infections) and making a commitment to healing one's life. My more than three decades of experience in treating extremely challenging cases of chronic sinusitis have made it apparent that mental, emotional, social, and spiritual factors have a profound impact on the degree of inflammation and immune dysfunction. Specifically, repressed anger may be the single most significant cause, with unshed tears (grief resulting from the perceived loss of love) (see [Chapters 99](#) and [102](#)). To have the greatest therapeutic benefit, the following recommendations should be practiced on a daily basis and incorporated into one's lifestyle. From the foregoing published study and statistics I have derived from patient questionnaires since 1990, more than 90% of patients who make at least a 3-month commitment (and three to four office visits) to the Respiratory Healing Program experience significant improvements in their symptoms of chronic sinusitis, with the majority of patients ultimately cured.

Integrative Therapy: Treating and Preventing Sinus Infections and Colds*

Natural Antibiotics

Garlic

Allimed[®] or Allimax[®] (both 100% pure allicin, the active ingredient in garlic) is my first choice treatment for sinus infections because studies have shown it to be highly effective as an antibacterial,^{11,12} antiviral (kills cold viruses),¹³ and antifungal.¹⁴ In my practice, it has been consistently effective in treating and preventing sinus infections and colds. However, garlic needs to be taken in therapeutic doses. Allimed (450 mg/capsule) and Allimax (180 mg/capsule) are both available in a liquid form for children.

Dosage

For treating a sinus infection: Allimed, two capsules three times daily for 10 days; or Allimax, five capsules three times daily for 10 days.

For treating colds and preventing sinus infections: at the first sign of a cold, Allimed, two capsules (or Allimax, five capsules) three times daily for 2 to 3 days; then one capsule (or Allimax, two capsules) twice daily for 2 to 3 days if symptoms have subsided.

EchinOsha and Elderberry

The commercial formulation EchinOsha with elderberry contains two antiviral herbs, Echinacea¹⁵ and elderberry¹⁶ (also effective with the influenza virus), in addition to osha root, which helps to strengthen the immune system. This preparation is contraindicated during pregnancy and in patients with autoimmune disease.

Dosage

EchinOsha, for treating colds and flu: 1 to 2 teaspoons every 2 to 4 hours for as long as symptoms are present; or Echinacea extract, 2 drops four to five times a day.

Yin Chiao

This antiviral Chinese herb is available in health food stores.

Dosage

For treating colds: three to five tablets or capsules (300 to 500 mg each) four or five times a day in the first 48 hours.

TABLE 17.1

Physical and Environmental Health Components of the Sinus Survival Program

Measure	Preventive Maintenance	Treatment
Sleep	7–9 hr; no alarm clock	8–10+ hr / day
Negative ions or air cleaner	Continuous operation; use ions, particularly with air conditioning	Continuous operation
Room humidifier, warm mist	Use during dry conditions, particular during winter when central heat is on and in summer if air conditioner is on	Continuous operation
Saline nasal spray	Use daily, particularly if exposed to dirty or dry air	Use daily every 2–3 hr
Steam inhaler	Use as needed if exposed to dirty or	Use two to four times / day; add

	dry air	eucalyptus oil
Nasal irrigation	Use as needed if exposed to dirty or dry air	Use daily, two to four times / day, after steam
Water, filtered	Drink 1 / 2 oz / lb body weight; with exercise, drink 2 / 3 oz / lb	1 / 2–1 / 3 oz / lb of body weight
Diet	Emphasize fresh fruit and vegetables, whole grains, fiber; limit sugar, dairy, caffeine, and alcohol	No sugar, dairy, alcohol
Exercise, preferably aerobic	Minimum of 20–30 min three to five times / wk; avoid outdoors with high pollution or pollen levels and extremely cold temperatures	No aerobic exercise; moderate walking allowed; avoid outdoors with high pollution or pollen levels and cold temperatures

Modified from Ivker RS. Sinus survival: the holistic medical treatment for sinusitis, allergies, and cold. 4th ed. New York: Tarcher / Putnam; 2000.

Grapefruit Seed Extract

In capsule or liquid form, grapefruit seed extract, which is antifungal and antiviral, is available in health food stores.

Dosage

250 mg three times daily or 10 drops in water three times daily (the liquid form has an unpleasant taste).

Nasal Sprays

Sinus Survival Spray

This saline nasal spray that contains purified water with Himalayan salt, aloe vera, berberis aquifolium, and potassium sorbate. The combination of aloe and Himalayan salt has an antiinflammatory effect, and the berberis is antiviral ([Table 17.1](#)).

Dosage

Every 1 to 2 hours with infection; apply a dab of peppermint oil to the outside of the nostrils following each application. Use for both treatment and prevention on a daily basis.

Nasal Rescue (Ionic Silver Spray)

This is highly effective in killing bacteria, viruses, or fungi. It contains ionic silver.

Dosage

Every 15 to 20 minutes for maximum effectiveness; apply a dab of peppermint oil to the outside of the nostrils following each application. Use only for treating infection.

Nasal Hygiene (see [Table 17.1](#))

Steam Inhaler

This acts as a decongestant^{17,18} and mucolytic. Highly medicinal eucalyptus oil, peppermint oil, and tea tree oil should be added to the steam. Use three to four times a day for at least 15 to 20 minutes if treating an infection, and once or twice daily preventively for treating chronic inflammation.

Irrigation

Perform three to four times a day for treating a sinus infection, immediately following the use of the

steam inhaler.^{19,20} A pulsatile irrigator is the most effective irrigating device and the only device shown to remove the biofilms. Irrigation is one of the best methods for quickly eliminating (and preventing, once or twice daily) sinus infections, in addition to treating chronic and fungal sinusitis (see [Chapter 113](#)).

Antiinflammatory and Antioxidant Vitamins and Supplements

Vitamin C

A regimen of 3000 to 5000 mg three times a day with meals is followed, for its antiinflammatory and antioxidant effects. Use this high dosage until symptoms subside, and then reduce to 2000 mg three times a day. Vitamin C is most effective if taken in the form of Ester C or a mineral ascorbate (for better absorption and gastrointestinal tolerance), rather than ascorbic acid. Dosage should be reduced if diarrhea occurs.²¹⁻²⁶

Vitamin D-3

I recommend 50,000 units daily for 3 days and then

reduce to 10,000 daily for the remainder of the treatment. Vitamin D-3 is a potent immune strengthener. Studies have demonstrated that most illnesses are accompanied by a deficiency in vitamin D. [27-31](#)

Grape Seed Extract

Patients should take 300 mg in the morning on an empty stomach. Grape seed is a powerful antioxidant, antiinflammatory, and antihistamine. [32-34](#)

Fish Oil

Eicosapentaenoic acid (EPA) 1000 to 3000 mg / docosahexaenoic acid (DHA) 500 to 900 mg per day. Fish oil contains a combination of omega-3 and omega-6 fatty acids and is an excellent natural antiinflammatory. [35-37](#)

Sleep

Sleep of 9 to 10 hours or more has been shown to have benefit in treating sinus infections, with 7 to 9 hours beneficial for prevention. Adequate sleep is perhaps the most effective, convenient, and least

expensive way to strengthen the immune system.

Diet

Patients should predominantly eat organic vegetables and fruits as well as nongluten grains (brown rice, quinoa, millet, buckwheat, and amaranth), fiber, and protein; they should avoid sugar, dairy, wheat, other carbohydrates (especially gluten grains), caffeine, and alcohol. Sugar weakens immunity, and wheat, dairy, and gluten grains are the most common causes of food allergy (often a trigger of sinus infections).

Patients should also drink at least $\frac{1}{2}$ oz of filtered water per lb of body weight (e.g., 160 lbs = 80 oz/day). For colds, patients should drink lots of warm or hot liquids; ginger root or peppermint tea is recommended, possibly including ginger, honey, lemon, cayenne, cinnamon, and a teaspoon of brandy (see [Chapter 18](#)).

Emotional Factors

Treat the emotional cause. Sinus infections may be influenced by repressed anger or unshed tears. I recommend the safe release of anger, as well as reflecting on feelings of grief or some sense of loss.

The feeling of grief or loss is typically not as obvious as anger, but it's probably there, just a bit deeper. Journaling is another excellent method for releasing either or both of these painful emotions (see [Chapter 98](#)).

Improving Indoor Air Quality (see [Table 17.1](#))

Ideal air quality is rated according to clarity (freedom from pollutants), humidity (between 35% and 55%), temperature (between 65° and 85°F), oxygen content (21% of total volume and 100% saturation), and negative ion content (3000 to 6000 .001 micron ions per cm³). Air that is clean, moist, warm, oxygen-rich, and high in negative ions is healing to the mucous membrane (see [Table 17.1](#)). To create optimal indoor air, I recommend the following:

- A negative ion generator³⁸⁻⁴⁰: used as an air cleaner and placed in rooms in which patients spend the bulk of their time, particularly the bedroom and office
- Furnace filter: an electrostatic or pleated filter (e.g., Filtrete by 3M)
- Air duct and furnace cleaning
- Carpet cleaning
- Use of a humidifier: a warm-mist room unit,

particularly during the winter months

- Plants, particularly those able to remove formaldehyde (boston fern, chrysanthemums, striped Dracaena, dwarf date palm) or carbon monoxide (spider plant)

Treating Yeast Overgrowth and Fungal Sinusitis

The majority of severe and unresponsive (to conventional treatment) cases of chronic sinusitis require anti-Candida antifungal treatment.

Although very similar in its holistic scope, the comprehensive treatment program for fungal sinusitis or yeast overgrowth and candidiasis is more challenging than the regimen for simple chronic sinusitis (i.e., without a significant degree of candida overgrowth), chiefly because of the restrictive Candida-control diet. The treatment program depends upon how sick the patient is, which can be reliably determined through medical history and Dr. Crook's Candida Questionnaire & Scoresheet (see [Fig. 17.1](#)). If yeast symptoms are confined to the gastrointestinal tract or vagina, the program is shorter and simpler than if yeast toxins have spread throughout the body and are causing recurrent sinus infections in addition to inflammation in other parts of the body (e.g.,

myalgia, arthralgia, mental “fog,” or severe fatigue). In the case of systemic inflammation, which is most often the situation in patients with severe chronic sinusitis, curing the condition can take from 6 months to 1 year.

The treatment program for fungal sinusitis consists of four components. I recommend integrating all four of the following components simultaneously for the best possible outcomes:

1. Reduce the overgrowth of Candida.
2. Eliminate the fuel for the growth of Candida organisms through diet. Starve them!
3. Restore normal bacterial flora in the bowel.
4. Strengthen the immune system.

Reducing the Yeast Overgrowth

Until recently, I relied heavily on the prescription antifungal Diflucan (Fluconazole) to kill Candida. The dosage I prescribe is 200 mg daily for 6 weeks, followed by 200 mg every other day for 3 weeks. Although Diflucan is effective, it often results in a die-off, or Herxheimer’s reaction, which usually occurs during the first two weeks of treatment and typically lasts for 2 days to 1 week. Diflucan is so effective in killing yeast that dying organisms

release a “flood” of toxins into the bloodstream that can cause fatigue, headaches, congestion, increased mucus drainage, nausea, loose stools, flulike aches and pains, and any other symptom (usually resulting from inflammation) that yeast toxins are known to produce. Distilled water (both drunk and used as an enema), vitamin C, and ibuprofen all have benefit in reducing die-off symptoms.

Although for a short time patients may possibly feel worse after starting treatment with Diflucan, they may also choose to look at the “regression” resulting from die-off as a confirmation of the diagnosis of Candida overgrowth, as well as a hopeful sign that they are eliminating yeast and will be feeling much better very soon. Following die-off, the majority of patients experience a level of health significantly greater than they had before the Candida overgrowth.

Prescription drugs, however, rarely provide the entire solution. In addition to antifungal supplements and probiotics, patients must also be prepared to adhere strictly to dietary recommendations.

In 2004, I demonstrated antifungal supplements, Allimax and Allimed, to be nearly as effective as fluconazole, although not as fast acting. Antifungal supplements have no harmful side-effects

(antifungal drugs have a minimal risk of liver toxicity), and the die-off reaction is usually less severe. Allimed contains the same 100% pure allicin, called allipure, as Allimax; however, each capsule of Allimed is 450 mg rather than the 180 mg capsules of Allimax. Allimed is available only through practitioners and is expensive. Allimed can be used as first-line treatment for mild to moderate candidiasis, or in conjunction with fluconazole in severe cases. Antifungal supplements also work well in treating sinus infections, as noted earlier, because they are highly effective antibacterial agents.

Other antifungal supplements with utility in treating chronic sinusitis include the following:

- Candex or Candisol. This supplement contains an enzyme that destroys the cell wall of candida organisms and reduces die-off symptoms. It is particularly helpful in patients who have both sinusitis and asthma. Not infrequently, die-off symptoms worsen asthma and make breathing more difficult. Candex and Candisol are well tolerated and consistent components of the Candida treatment program. Candex is readily available in most health food stores. Candisol, which has a higher strength of the active ingredient, is available only through practitioners.

- Flora Balance or Latero Flora. This unique strain of bacteria, *Bacillus laterosporus* B.O.D., is available in some health food stores as Flora Balance or through physicians as Latero-Flora. It has been tested extensively and found to be highly effective for gastrointestinal dysfunction, food sensitivities, and candidiasis.

- Grapefruit seed extract. Can be taken in liquid or capsule form, this supplement is also available in most health food stores.

I take an aggressive approach to treating fungal sinusitis and usually use several of the products described previously in combination (but not all of them together), along with either fluconazole or Allimed.

Numerous products available in health food stores can help to eliminate Candida. The majority of products contain caprylic acid, garlic, pau d'arco, plant tannins, grapefruit seed extract, oregano oil, and other herbs that act directly on Candida or indirectly by strengthening the immune system, although the majority of these products do not work as quickly as the regimen recommended previously. Patients may find it helpful to rotate antifungal supplements and not continue the use of the same product for longer than approximately 2 months.

Eliminating the Fuel for Candida Through Diet

In addition to strengthening the immune system, diet is the foundation of any antifungal treatment program. As each individual has a unique body chemistry, no two Candida-control diets will be exactly the same. Moreover, every physician who treats candidiasis and fungal sinusitis has somewhat different dietary recommendations. However, the majority of individuals with yeast overgrowth are far more susceptible to food allergies, and the following basic principles apply to almost any patient who opts for a Candida-control, hypoallergenic, and antiinflammatory diet:

1. A diet consisting primarily of protein and fresh organic vegetables, with a limited amount of complex carbohydrates and fat-containing foods, and a small amount of fresh fruit.
2. Sugar and concentrated sweets are always avoided.
3. The minimum time frame for maintaining the diet is 3 to 6 months, although the diet can be less restrictive the longer it is followed.
4. The best practice is to rotate acceptable foods and not eat a particular food more than once every 3 or 4 days. This is especially true for grains.
5. Changing one's diet can be a challenge. The more

involved the patient is in the process, including planning, shopping, and cooking, the easier and more rewarding it will be.

Note: For the first 21 days, avoid starch and high sugar foods, including fruit. Also avoid yeast and mold foods (see later).

Foods to Include at the Onset of the Diet

Vegetables

Vegetables should be eaten freely and comprise 50% to 60% of total diet. Vegetables may be eaten raw or lightly steamed and should be organic and clean (washed well). Vegetables with high water content and low starch are preferable. The following are recommended:

- Green leafy: all lettuce, spinach, parsley, cabbage, kale, collard greens, watercress, beet greens, mustard greens, bok choy, and sprouts
- Other low-starch vegetables: celery, zucchini, summer squash, crookneck squash, green beans, broccoli, cauliflower, brussels sprouts, radish, bell pepper (green, red, yellow), asparagus, cucumber, tomato, onion, leek, garlic, and kohlrabi
- Moderately low starch: carrot, beet, rutabaga, turnip, parsnip, eggplant, artichoke, avocado, water

chestnuts, peas (green, snow peas), and okra

Protein

Protein should be eaten predominantly at breakfast and lunch with no less than 60 g per day including antibiotic- and hormone-free meats; fresh or deep-water ocean fish; raw organic seeds and nuts; and acceptable proteins such as fish, canned fish (salmon and tuna—no more than two times per week), turkey, ground turkey, chicken, lamb, wild game, Cornish hens, eggs (limit two to four per week), and seeds and nuts (almonds, cashews, pecans, filberts, pine nuts, Brazil nuts, walnuts, pistachios, sunflower seeds, raw or dry roasted sesame seeds, pumpkin seeds).

Complex Carbohydrates

Complex carbohydrates include starchy vegetables, legumes (introduced after the first 21 days), and whole grains. These should only be consumed in sufficient quantities to maintain energy (ideally, one serving a day or less), with restriction varied according to food allergies, which can be determined with food rotation. Following are the recommended sources:

- Starchy vegetables: new and red potatoes, sweet

potatoes, yams, winter squash (acorn, butternut), pumpkin

- Legumes: lentils, split peas, black-eyed peas, beans (kidney, garbanzo, black, navy, pinto, lima, adzuki)

- Nongluten grains: brown rice, millet, quinoa, buckwheat, and amaranth, sprouted or cooked, organic and clean; available in bulk at health food stores; grains rotated every four days; tasty as breakfast cereals, in salads and soups, and in casseroles and stir-fry; stored away from light and heat in airtight containers; other whole grains (with gluten) that should be eaten in only limited amounts: barley, spelt, wild rice, corn, oats, cornmeal, bulgur, couscous

Flaxseed Oil

Flaxseed oil should be taken as 1 to 2 tablespoons daily on grains or vegetables or as a salad dressing, not heated or used for cooking. Flaxseed oil should be kept refrigerated and away from light. Other acceptable oils (cold-pressed) include extra virgin olive oil, canola, walnut, and macadamia nut used within 6 weeks of opening.

Foods to Include After 21 Days

Fruits

Fruits are introduced into the diet slowly as one serving per day until patients are sure they do not make symptoms worse. One starts with melons, berries (blueberries, raspberries, huckleberries, blackberries), lemon, and grapefruit (only after first 21 days of the diet) and then chooses from among most other fresh fruits, all of which are generally sweeter than the first group. These include apple, pear, peach, orange, nectarine, apricot, cherry, and pineapple. Fruit juices should be very diluted to at least 1:1 with water. Freshly squeezed fruit juice is considered best. Full-strength juices, canned fruit juices, and all dried fruits are avoided.

Yeast and Mold-Containing Foods

Yeast and mold-containing foods are allowable only if the patient is not allergic. However, these should be introduced very gradually (no more than one particular food every 3 to 4 days) and not until at least 3 weeks into the diet. Yeast and mold-containing foods include the following: fermented dairy products such as yogurt, kefir, buttermilk, low-fat cottage cheese, and sour cream; fermented foods such as tofu, tempeh, miso, and soy sauce; and raw almond butter, and raw sesame tahini.

Foods to Avoid

- Refined sugar and sugar-containing foods: cakes, cookies, candy, doughnuts, pastries, ice cream, pudding, soft drinks, pies, etc.; anything containing sucrose (table sugar), fructose, maltose, lactose, glucose, dextrose, corn sweetener, corn syrup, sorbitol, and mannitol; honey; molasses; maple syrup; date sugar; barley malt; rice syrup; NutraSweet; and saccharine; table salt (often contains sugar; sea salt preferred).
- To diminish sugar cravings: chromium picolinate, 200 mcg twice daily; biotin, 500 to 1000 mcg twice daily; and a yeast-free B-complex, 50 mg twice daily, only if the patient is not already taking a comprehensive multivitamin; craving also eliminated by 4 days without any sugar
- Milk and dairy products: all cheeses (unsweetened soy milk and butter allowed, but not in excess)
- Bread and other yeast-raised baked items, including cakes, cookies, and crackers; whole grain cereals; pastas; tortillas; waffles; and muffins
- Beef and pork
- Mushrooms: all types
- Rye and wheat (avoided for first 3 weeks)
- Grapes, plums, bananas, dried fruit, canned fruit,

and canned vegetables

- Alcoholic beverages
- Caffeine: both tea and coffee (herbal tea and green tea allowed)
- White or refined flour products, packaged or processed and refined foods
- Fried foods, fast foods, sausage, and hot dogs
- Vinegar, mustard, ketchup, sauerkraut, olives, and pickles (raw apple cider vinegar allowed)
- Margarine, preservatives (e.g., in frozen vegetables)
- Refined and hydrogenated oils
- Leftovers (can be frozen for later)
- Rice milk (high carbohydrate content)

This diet is meant to be a guide. Responses to this diet will vary greatly depending upon the severity of candidiasis, food allergies, and type of medication (if any) the patient is taking to eliminate Candida. The majority of individuals who closely adhere to this diet will experience a significant improvement within 1 month. If the diet is followed for 3 to 4 weeks, in addition to taking medication or antifungal supplements, and the patient reports no improvement, the diet should be changed back to a basic vegetable (low-starch) and protein diet, and food allergy or leaky gut syndrome should be highly suspected. The offending food is often one

eaten every day and for which the patient has developed a craving. If new foods are reintroduced very gradually, such as every 3 to 4 days, then the offending food should be easily detected from symptoms that arise after eating it.

Initially many patients complain, “there’s nothing to eat on this diet.” Losing 8 to 10 pounds of body weight during the first month is not unusual. Many different nutritious and tasty choices are available, however, and weight loss will stabilize unless patients are significantly overweight. A key factor in successfully maintaining the diet lies in finding desirable recipes. Candida-control diet cookbooks are relatively easy to locate in most health food stores.

This Candida-control, hypoallergenic, and antiinflammatory diet is essentially the same diet I recommend to all my patients with chronic sinusitis, although it need not be quite as restrictive if fungal sinusitis is not a significant factor.

My basic dietary recommendations are to avoid milk and dairy products, sugar, wheat, caffeine, and alcohol,⁴¹⁻⁴⁶ as well as to increase intake of fresh organic vegetables and fruits, whole grains, fiber, and protein.

Restoring Normal Bowel Bacterial Flora

The best way to restore normal bacterial flora in the bowel is through the administration of probiotics, specifically those containing *Lactobacillus acidophilus* and *Bifidobacterium bifidum*. The probiotic should contain a minimum of two billion CFUs (colony forming units); however, I've recently been recommending preparations with 20 billion CFUs. Patients should start taking a probiotic supplement at the very beginning of the treatment program for fungal sinusitis. Intestinal bacteria can be restored through a multitude of *Lactobacillus acidophilus* and *Bifidobacterium bifidum* products available in health food stores.

Many yogurt products do not contain a high amount of viable organisms by the time they reach the consumer. This is especially true of highly processed yogurt products and those with many additional ingredients. Individuals who are sensitive to dairy products, as well as those with chronic respiratory disease, should not use yogurt as a consistent source of beneficial bacteria because milk protein may contribute to inflammation of the mucous membrane. Brands of yogurt that have added sweeteners should be avoided.

Strengthening the Immune System

Immune strengthening is a vital aspect of treating Candida overgrowth and fungal sinusitis. The three steps described previously can all contribute in varying degrees to a stronger immune system. Both regular aerobic exercise⁴⁷ and, especially, adequate sleep, in addition to the recommendations for strengthening mental, emotional, social, and spiritual health (see later), can have a profound impact on creating a strong immune system. The combined effect of these aspects of the Respiratory Healing Program can potentially have a far greater effect on immune function than can any single supplement or food.

Improvements in chronic sinusitis may become evident within 2 to 3 weeks of beginning the Candida treatment program; however, a period of 3 months to 1 year in the most severe cases is usually required to complete the healing process.

Practitioners should strongly recommend that patients maintain a healthy diet without reverting back to excess sugar and alcohol or an excess of any food.

Detoxification

In conjunction with treating Candida overgrowth (particularly because these organisms release massive amounts of toxins as they die), a detoxification process should be initiated (see [Chapter 106](#)). Options for detoxification include the following:

Water

Patients are advised to drink copious amounts of water (filtered or distilled), at least half an ounce per pound of body weight.

UltraInflamX-360

The core medical food drink UltraInflamX-360 (Metagenics, San Clemente, California) reduces inflammation and promotes accelerated detoxification. This highly researched nutraceutical contains patented, proprietary ingredients.

Published research is available in the literature, [48-50](#) in addition to clinical trials from the Functional Medicine Research Center in Gig Harbor, Washington. I recommend a 3-month course of UltraInflamX-360 with the following regimen:

- First week: one scoop twice daily

- Second and third weeks: two scoops twice daily
- Following the third week, for 3 days only: no food eaten, and two scoops taken four to five times per day
- Fourth, fifth, and sixth weeks: two scoops twice daily
- Seventh, eighth, and ninth weeks: two scoops once daily
- Tenth, eleventh, and twelfth weeks: one scoop daily

Natural Cellular Defense

Natural Cellular Defense (NCD, Waiora, Boca Raton, Florida) is a detoxifier, alkalizer, and immune strengthener composed of a mineral (clinoptilolite zeolite) micronized and purified by a patented process and suspended in sterile water. NCD is approved by the U.S. Food and Drug Administration and generally recognized as safe (GRAS). NCD removes heavy metals, dioxins, and petrochemical and other environmental toxins. As an alkalizer (raises digestive pH), NCD assists immune function by eliminating many bacteria and viruses in the GI tract, as well as Candida, which thrives in a more acidic environment.

Colon Hydrotherapy

I recommend colonic treatments as a rapid method of removing excess Candida from the bowel and mitigating die-off effects. Much more effective than an enema, colon hydrotherapy is best performed on a weekly basis (twice during the first week) for 6 weeks in conjunction with taking an antifungal drug. Hydrotherapy can help cleanse the bowel of Candida, toxins, and dead yeast organisms while assisting the inflamed lining of the bowel to begin the healing process. Colonic treatments can also significantly enhance the detoxification process by stimulating the liver to release toxins (the liver is the primary detoxification organ in the body), while also helping to flush the small bowel with water absorbed by the body through the colon. These treatments need to be performed by trained colon hydrotherapists, who are usually found in most cities by calling the office of a naturopath or chiropractor.

Far-Infrared Sauna

Although I have had no experience either personally or with patients who have used a far

infrared (FIR) sauna, numerous reports and references⁵¹⁻⁵³ regarding the efficacy of far infrared (FIR) sauna for detoxification have been published. Several FIR sauna devices are portable, convenient, and economical and can be used in the privacy of the patient's home.

The primary advantage of the FIR sauna is that a conventional sauna heats the air in the chamber to a very high temperature, which in turn heats the body. The FIR sauna works differently. Neither oxygen nor nitrogen molecules in the air can block the FIR wave, thus allowing the FIR wave to penetrate the body to a depth of approximately 2 inches without injuring the skin with hot air.

Mind-Body Therapy

Mental and Emotional Health Recommendations

Most sufferers of chronic sinusitis have repeatedly heard the message, "You're going to have to live with it" from their physicians, or have come to this conclusion themselves. This belief often adds to already existing feelings of anger, sadness, fear, and possibly hopelessness. Essential mental and emotional components of the Respiratory Healing Program include the following: modifying beliefs

and attitudes through affirmations and visualizations; creating a goal list and an ideal life vision (developing clarity about personal and professional objectives); learning to express painful emotions, especially through the safe release of anger, journaling, and finding more humor, optimism, and play in life.

Physical problems with the nose and sinuses bioenergetically correspond to mental and emotional issues associated with self-evaluation, truth, intellectual abilities, openness to the ideas of others, the ability to learn from experience, emotional intelligence (the ability to identify, experience, and express feelings), and feelings of adequacy. These issues are all associated with the sixth (“third eye”) chakra in Ayurvedic medicine. I have found most patients with chronic sinusitis to be high achievers, perfectionists who set very high standards of performance for themselves and tend to be unforgiving of themselves and others for making mistakes. The repressed anger felt by most sinus sufferers is often self-directed. Assisting the patient to achieve a heightened sense of awareness of the possible contributing factors can help to begin the process of healing.

Mental and Emotional Health Practices

- Affirmations
- Visualizations⁵⁴
- Goal or ideal vision list

These first three should be practiced daily for 10 to 20 minutes. Affirmations are most effective when written, recited, and visualized.

- Anger release (safely): punching (a punching bag, sofa, or pillow), screaming, stamping; while simultaneously exhaling the “shhhh” sound; highly therapeutic for chronic sinusitis

- Journaling⁵⁵
- Optimism
- Humor
- Biofeedback
- Psychotherapy: cognitive therapy and family therapy
- Play
- Energy medicine modalities: healing touch, Reiki, qi gong, or craniosacral therapy

Spirituality

Spiritual and Social Health Recommendations

Integrative holistic medicine is based on the belief that unconditional love is life’s most powerful healer. Its corollary, the perceived loss of love is our

greatest health risk, is also the spiritual cause of chronic sinusitis and all disease. Healing the spirit is by far the most powerfully therapeutic component of the Respiratory Healing Program. Spiritual health is simply learning to love one's self in body, mind, and spirit. The first step in the Respiratory Healing Program is to love and nurture the sinuses (i.e., to heal the chronically inflamed mucous membrane). To heal the self spiritually involves connecting to a higher power (God, Spirit, or whatever term one is comfortable with) in a personal way and becoming attuned to this energy. By engaging in this spiritual healing process, individuals experience a profound reduction in feelings of fear and a greater capacity for unconditional love of self and of others. They are also better able to identify special talents and gifts. This awareness helps them to fulfill their life's purpose while fully experiencing the power of the present moment. The spiritual practices I recommend most are prayer, meditation,⁵⁶ gratitude, and spending time in nature.

Relationships with others are the crucible that most strongly determines the spiritual health of each person. Optimal social health consists of a strong positive connection to others in community and family and intimacy with one or more people. It is

often much easier to feel a connection with Spirit during moments of solitude than it is to express that connection through interactions with others. At the same time, relationships offer the greatest opportunities for spiritual growth and for learning how to receive and impart unconditional love. True spiritual health is a balance between the autonomy of the self and intimacy with others.

On the basis of a growing number of relationship studies, researchers have concluded that social isolation is statistically just as dangerous as smoking, high blood pressure, high cholesterol, obesity, or lack of exercise. A separate study has shown that marital conflict can weaken immunity.⁵⁷

The primary opportunities available to each person for improving social health include forgiveness, friendships, selfless acts and altruism, support groups,⁵⁸ and especially marriage, committed relationships, and parenting. Practicing forgiveness is particularly challenging for, and most helpful to, the typical patient with chronic sinusitis. Much of patient anger, which often precipitates a sinus infection, is ultimately self-directed for making perceived mistakes. In learning to forgive themselves, such patients are able to expand their capacity to forgive others and thereby heighten intimacy in their relationships (see [Chapter 99](#)).

Preventive Prescription

1. Become more aware of the quality and quantity of the air you are breathing, water you are drinking, the food you are eating, exercise and sleep you are getting, and, most importantly, the stress you are experiencing. Close below the surface of stress lies anger, with yourself or others; and deep within your heart you will find shame, fear, and grief for your perceived loss of love from early childhood.
2. Pay more attention to how each of the foregoing factors affects the condition of your sinuses.
3. Once you have learned what factors contribute most to the way your sinuses feel, then determine which of the recommendations in the earlier integrative therapy section are consistently effective in improving the way you feel. The daily practices that are most helpful to nearly every sinus sufferer are adequate sleep and water intake, elimination of dairy products and a significant reduction in sugar intake, use of a saline / aloe nasal spray, inhaling medicinal eucalyptus oil, nasal irrigation (any method), journaling, anger processing, and a spiritual or meditative practice.
4. Repeat to yourself several times a day:
 - I'm always doing the best I can. There are no mistakes, only lessons.

- I am totally accepting of myself exactly as I am.
- I am here now in this present moment.
- I am here to love and be loved.

5. Remember that you are a unique individual with a different set of needs, desires, beliefs, and gifts than anyone else. As you heighten your level of self-awareness, your intentions will be clear and you will be much better able to care for yourself, heal your life, and potentially cure your chronic sinusitis.

Therapeutic Review

Lifestyle

- Sleep: Adequate good quality sleep can help improve immune function. 
- Use a negative ion generator as an air cleaner in the bedroom and office. 
- Saline nasal spray: Use daily every 2 to 3 hours. Saline sprays containing aloe vera are most helpful. 
- Steam inhaler: Use this device for 15 to 20 minutes two or three times daily. 
- Medicinal eucalyptus oil: This can be added to the steam for optimal benefit or inhaled from a tissue several times a day. 

- Nasal irrigation: Use one of several methods for nasal irrigation, although a pulsatile irrigator is most effective. Perform two to three times daily. This modality is best performed following steam inhalation therapy. 

- Exercise: Engage in regular aerobic exercise three to five times per week for at least 30 minutes. 

Nutrition

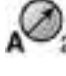

- Avoid milk and dairy products, sugar, wheat, caffeine, and alcohol. 

- Increase intake of fresh organic vegetables and fruits, whole grains, fiber, and protein. 

- Increase water intake (filtered or distilled) to at least ½ oz/lb of body weight. 

- If candidiasis is suspected (e.g., history of multiple antibiotics), strict adherence to a Candida-control diet is recommended. This diet avoids yeast-containing foods, such as breads, and foods that promote yeast growth such as refined sugars, processed foods, cheeses, peanuts, vinegar, and alcoholic beverages. 

Supplements

- Vitamin C: 1000 to 2000 mg three times daily 

- Vitamin D-3: 5000 to 10,000 I.U. daily 

- Grape seed extract: 100 to 300 mg daily in the

morning on an empty stomach 

- Selenium: 100 to 200 g daily 
- Essential fatty acids: 2 tablespoons/ day of flaxseed oil and 1 to 4 g docosahexaenoic acid/ eicosapentaenoic acid daily. 

Botanicals

- Garlic as 100% pure allicin (Allimed or Allimax): 450 mg daily preventively or 900 mg three times per day for treating a sinus infection or fungal sinusitis 

- Echinacea: 2 dropperfuls four to five times per day for treating a sinus infection 

- Grapefruit seed extract: 250 mg twice daily for treating a sinus infection or fungal sinusitis 

Pharmaceuticals, Surgery, and Candida or Fungal Sinusitis Treatment

- Fluconazole or other antifungal drugs, if the history and symptoms indicate candida or yeast overgrowth and fungal sinusitis 

- Candida-control diet 

- Antifungal supplements 

- Probiotics containing Lactobacillus acidophilus and Bifidobacterium bifidus 

- Surgery (polypectomy), usually indicated for

nasal polyps (A, 3)

Mind-Body Therapy

- Affirmations, visualizations, goals, or ideal life vision list, practiced daily for 10 to 20 minutes 
- Anger release (safely) 
- Journaling 
- Biofeedback 
- Psychotherapy 
- Energy medicine modalities: healing touch, reiki,

Qi gong, or craniosacral therapy 

Spirituality

- Prayer, meditation 
- Gratitude, intuition, spiritual practices: observing a weekly Sabbath; fasting; practices around earth, air, fire, water 
- Forgiveness, communication exercises: shared vision, attentive listening 
- Support groups 

The three primary components of the Respiratory Healing Program for treating, preventing, and curing chronic sinusitis are as follows: reduce or eliminate inflammation of the mucous membrane, stop infection, and strengthen immunity.

CHAPTER 18

Viral Upper Respiratory Infection

Bruce Barrett, MD, PhD

Humanity's most frequent illness, the common cold, is caused by acute viral infection of the upper respiratory tract.¹⁻⁴ Acute respiratory infections (ARIs) are often classified as being caused either by influenza, the most serious of the common viruses, or other viruses (noninfluenza ARI). In the United States, noninfluenza ARI accounts for more than 20 million clinic visits and 40 million lost days of school and work, with total costs estimated at \$40 billion, making noninfluenza ARI the seventh most expensive illness.⁵⁻⁷ Influenza causes an annual mid-winter epidemic that varies year to year, but can be a major cause of hospitalization and death.⁸⁻¹⁰

Although colds are often considered a nuisance rather than a major public health threat, even rhinovirus, the least pathogenic of the common cold viruses, may cause death among elderly and immunocompromised individuals.¹¹⁻¹³

On average, children experience four to six symptomatic colds per year, in addition to several asymptomatic infections. For adults, the average is two to three symptomatic colds per year and perhaps one or two asymptomatic infections.¹⁴⁻¹⁶ Some individuals are particularly prone to colds, whereas others get them infrequently.¹⁷ Numerous factors appear to be involved, but overall, susceptibility remains poorly understood.

Although there still is no good proven cure for the common cold, a number of treatments have been reported to have symptom-reducing benefit in one or more randomized controlled trials (RCTs).¹⁸⁻²⁴ In terms of prevention, behavioral strategies such as hand washing, regular exercise, and smoking avoidance are widely accepted to be at least somewhat effective.²⁵⁻³¹ Immunization is considered impractical, as there are hundreds of strains of viruses. Our own research indicates training in

mindfulness-based stress reduction may serve to reduce incidence, duration and impact of viral ARI.³²⁻³⁶

Pathophysiology

As an *illness*, the common cold is characterized by nasal congestion and drainage, sneezing, sore or scratchy throat, cough, and general malaise.³⁷⁻³⁹ Cough may or may not be present and tends to occur later in the disease, occasionally lasting for weeks after other symptoms have resolved. The severity of symptoms varies markedly, from barely noticeable to truly debilitating.⁴⁰ While true fever is atypical for most viruses, feelings of feverishness and chilliness are common.⁴¹

There is no proven cure for the common cold. Even the most positive previous trials have reported only modest symptomatic benefit, with little or no duration of benefit.

As an infectious *disease*, viral ARI is characterized by the replication of viruses in the nasopharyngeal epithelium,⁴² leading to a cascade of local and systemic immune responses.⁴³⁻⁴⁵ Viral replication triggers cytokine-mediated local inflammatory reactions, in addition to the recruitment of white blood cells. Parasympathetic neural pathways activate and coordinate local responses. Blood vessels dilate and capillaries leak, causing edematous tissue and transudates in the nasal passages.⁴⁶ Mucous glands are activated, resulting in mild to copious exudative discharge. Inflammatory changes in the respiratory epithelium may persist for days or weeks after viral shedding dies down. Activation of inflammatory mechanisms leading to bronchial constriction makes viral ARI the most frequent cause of asthma exacerbation.⁴⁷

Rhinovirus is the single most common etiological agent, but accounts for less than half of all ARIs.⁴⁸⁻⁵⁰ Other causative viruses include adenovirus, coronavirus, enterovirus, influenza virus, parainfluenza, and respiratory syncytial virus (RSV).^{4,51} Metapneumovirus^{52,53} and bocavirus⁵⁴⁻⁵⁶ are now known to cause ARI illness in both children and adults. There are likely additional viruses that are as yet undiscovered; even the best research laboratories fail to identify an etiological agent in up to one quarter of individuals with obvious colds. A small number of bacteria, such as streptococcus and *Haemophilus influenzae*, may cause common cold syndrome.

Respiratory viruses follow seasonal patterns. Influenza and RSV infections only occur during the winter months, with rhinovirus colds typically observed in the fall and spring. Adenovirus infection appears year-round. Parainfluenza mini-epidemics are episodic, while sporadic outbreaks of atypical agents, such as *Bordetella pertussis*, further complicate the epidemiology of ARI.

The spectrum of illness varies greatly within and among agents. In general, influenza causes the most severe illness and is therefore often classified separately from other viral ARIs. Nevertheless, the majority of illness episodes caused by influenza are indistinguishable from those caused by other viruses, with a significant number of influenza infections reported to be asymptomatic.⁵⁷⁻⁶² Less than a quarter present with the classic “influenza-like illness” symptoms of rapid onset, fever, cough, headache, and myalgia. Despite a coordinated system to provide influenza vaccine (flu shots) each fall, influenza is implicated in as many as 20,000 deaths each year.^{8,9,63}

Psychosocial Influences

Common colds are influenced by a variety of biological, psychological, and social factors. Numerous cross-sectional and prospective epidemiological studies have provided relatively consistent findings.¹⁴⁻¹⁶ Colds occur most frequently among infants and children, and among adults in contact with them. Children who are in preschool daycare have more colds than those who are not, but have fewer colds during subsequent school years.^{64,65} While moderate regular exercise protects against infection, excess activity, such as running a marathon, increases risk temporarily.^{31,66-68} Poor mental health has been shown to be associated with increased risk.^{69,70} Stress, both acute and chronic, is known to increase ARI risk.⁷¹⁻⁷³ Sheldon Cohen first demonstrated this by showing that perceived stress predicted not only whether volunteers would become sick when exposed to rhinovirus, but whether and to what extent they would shed virus.⁷⁴⁻⁷⁶ Childhood socioeconomic status,⁷⁷ number and quality of social relationships,⁷⁸ and negative emotion^{79,80} have also been shown to predict viral shedding, as well as severity and duration of cold symptoms. Subsequent studies have corroborated these findings.^{62,71,81-84} Building on this background, my research team conducted a randomized trial finding that training people in mindfulness-based stress reduction can lead to substantive reductions in ARI illness episodes.³²⁻³⁶ An earlier study by Dr. Rakel and I on placebo

effects and the influence of doctor–patient interaction indicated that empathetic patient-oriented clinicians may be able to positively influence common cold outcomes.⁸⁵

The common cold is an excellent example of how the mind and body interact. Stress can increase susceptibility while social support can reduce incidence. Perceived empathy of caregivers may also reduce illness severity and duration.

Integrative Therapies

There are hundreds of reported treatments for the common cold.^{18-23,27,86} Globally, botanical remedies have been the mainstay of treatment. Descriptions of herbal therapies for common cold fill countless pages of notes and treatises by physicians, anthropologists, and ethnobotanists.⁸⁷⁻⁹⁰ However, relatively few of these traditional remedies have been adequately tested for pharmaceutical properties and clinical effectiveness. The present section will review several botanicals that are widely used or have been evaluated by randomized controlled trials (RCT). The next section will cover the use of nonbotanical complementary treatments, such as vitamin C and zinc. Finally, this chapter will briefly describe conventional therapies, such as antihistamines, decongestants, and cough medications.

Botanicals

***Andrographis* (*Andrographis paniculata* or *Justicia paniculata*)**

Andrographis is indigenous to Asia, with traditional use most prominent in India. Of the 28 *Andrographis* species, *A. paniculata* is most commonly used for the treatment of ARI. According to Ayurvedic tradition, *Andrographis* is attributed to many important medicinal properties and is used for the treatment of constipation, digestion, fever, pain, sore throat, snake bite, and to clean the blood. In the West, *andrographis* is most commonly used as a common cold treatment or preventative.

Various laboratories have reported antimicrobial,⁹¹ antihyperglycemic,^{92,93} antiinflammatory,⁹⁴ immunomodulatory,^{95,96} and psychopharmacological⁹⁷ effects attributable to andrographolide, flavonoids,⁹⁸ and other phytochemical constituents. There have now been at least eight RCTs published including more than 1000 subjects that have evaluated various *andrographis* derivatives in the treatment of ARI, including pharyngitis.⁹⁹⁻¹⁰⁶ Systematic reviews by Coon and Ernst¹⁰⁷ and Poolsup et al.¹⁰⁸ conclude the following:

“Collectively, the data suggest that A. paniculata is superior to placebo in alleviating the subjective symptoms of uncomplicated upper respiratory

tract infection. There is also preliminary evidence of a preventative effect. A. paniculata may be a safe and efficacious treatment for the relief of symptoms of uncomplicated upper respiratory tract infection; more research is warranted."¹⁰⁷

*"Current evidence suggests that A. paniculata extract alone or in combination with A. senticosus extract may be more effective than placebo and may be an appropriate alternative treatment of uncomplicated acute upper respiratory tract infection."*¹⁰⁸

The most recent trial, not included in the reviews referred to previously, also reported positive results.¹⁰⁹ Based on published evidence, and with no evidence of serious safety concerns, it seems reasonable for adults to seek relief from ARI symptoms with andrographis-based cold remedies. There is insufficient evidence to favor specific products, dosing regimen, or particular standardization procedures for phytochemical content. For pregnant women and children, it seems prudent to recommend against the use of andrographis because there is little data from studies in these populations to exclude risk of harm.

Dosage and standardization

The majority of clinical trials used products standardized to 4 or 5 mg andrographolide per tablet. A reasonable dose regimen would be two to four of these tablets, three times daily, for the first few days of a cold.

Precautions

There are no known side effects of andrographolide; however, as with all medicinal treatments, caution and careful use are recommended.

Astragalus (Astragalus membranaceus; Astragalus mongholicus)

Astragalus is an important medicinal plant in traditional Chinese medicine.¹¹⁰ While there are dozens, if not hundreds, of reported uses, astragalus extracts are commonly used for both the treatment and

prevention of the common cold.¹¹¹ While antiviral activity has been reported, immunomodulation is the purported mechanism of action. Indeed, several studies have reported the effects of astragalus on the immune system, from enhanced immunoglobulin production to restoration of lost T-cell activity.¹¹²⁻¹¹⁶ Astragalus root contains astragaloside, flavonoids, and saponins, which are variously thought to be involved in various hypothesized mechanisms of action. Unfortunately, due to a lack of human ARI trials, no clear recommendations can be made for or against the use of astragalus for the treatment or prevention of common cold, and no specific doses or precautions have been reported.

Carrageenan

Carrageenans are linear sulfated polysaccharides deriving from Irish moss (*Chondrus crispus*) and other seaweed and algae. Carrageenans are widely used in the food and cosmetics industry for the thickening, stabilizing, and gelling of a wide variety of products, including toothpaste. During the past decade, a carrageenan-based nasal spray has been tested as common cold treatment, with positive results reported.¹¹⁷ Eccles et al. reported reductions in inflammatory cytokines levels and symptoms in a randomized trial among N = 35 young adults.¹¹⁸ Fazekas et al. reported an RCT among N = 153 children, which found reductions in viral load and time to viral clearance, but no symptomatic benefit.¹¹⁹ Ludwig et al. reported an RCT among N = 211 adults, where “alleviation of symptoms was 2.1 days faster in the carrageenan group in comparison to placebo (p = 0.037).” It appears that all of these studies were sponsored by the same company, Marino Med, and that their product is available in Europe but not the United States. While these results are certainly intriguing and carrageenan nasal spray is likely safe, further research is required before specific recommendations can be made regarding its use for the treatment of URI.

Dosage

The formulation used in the trial above was Iota-Carrageenan (0.12%) in a saline solution, one spray in each nostril, three times daily for 4 days.

Chamomile (Matricaria chamomilla; Matricaria recutita, German chamomile; Chamaemelum nobile, Roman chamomile)

Chamomile has been used widely as a botanical remedy for centuries for a variety of purposes, including dysmenorrhea, gingivitis, hemorrhoids, infantile colic, indigestion, insomnia, nausea, vaginitis, and topically, for a variety of skin conditions.¹²⁰ In the United States, chamomile is most often used as a calmate or sedative, and for the treatment of irritable bowel syndrome. However, chamomile is also used for acute respiratory infection and hence merits inclusion in the present review. As a common cold remedy, chamomile can be taken as an infusion (chamomile tea) or as an inhalation by boiling the flowering tops. A study evaluating inhaled vapors from boiling chamomile reported benefit but was of insufficient quality to reach firm conclusions.¹²¹

Dosage

Although there is limited evidence, a cup or two of chamomile tea as supportive treatment for the common cold is safe and may be beneficial.

Precautions

While there are no known dose-dependent adverse reactions, allergic sensitivity, including several cases of anaphylaxis, has been reported.¹²²

Echinacea (Echinacea angustifolia; Echinacea purpurea; Echinacea pallidae)

All dozen species from the genus *Echinacea* are indigenous to North America. Native communities discovered many medicinal uses, later transferring their knowledge to European settlers.¹²³ In the 1920s, *Echinacea* was introduced into Germany, where it has been popular ever since. Today, echinacea extracts are widely used in America, Europe, and elsewhere, particularly for the prevention and treatment of the common cold.¹²⁴ A considerable body of evidence exists regarding the uses of echinacea, including 24 randomized trials including more than 3000 participants,¹²⁵ and dozens of in vitro and animal studies.¹²⁶⁻¹²⁸ While there is consensus that various echinacea extracts display immunologic

activities, such as promoting macrophage activation and inducing cytokine expression,¹²⁹⁻¹³⁷ there is considerable disagreement concerning which of the many echinacea-derived phytochemicals are involved. Various alkylamides, glycoproteins, polysaccharides, and caffeic, cichoric, and caftaric acids have all been implicated. Differing extracts from all three species and from various plant parts have shown immunoactivity in laboratory models. To my knowledge, no credible head-to-head, dose-finding, or viral load outcome studies have been reported, with very little pharmacokinetic information available.^{138,139} A comprehensive safety review notes a number of reported allergic reactions but suggests no dose-dependent adverse effects or major drug interaction concerns.¹⁴⁰

Randomized clinical trials testing echinacea extracts for the prevention and treatment of common cold were first conducted in Europe, with several early trials reporting positive result.¹⁴¹⁻¹⁴⁸ More recent trials in the US and elsewhere have reported mixed results, with higher quality trials finding no benefit.¹⁴⁹⁻¹⁵³ I directed two of those trials. The first was flatly negative¹⁵⁴; however, the second observed some positive trends.¹⁵⁵ Preventive trials have all trended in beneficial directions, but none have individually demonstrated clearly positive results.¹⁵⁶ Systematic reviews of the two dozen reported trials vary in their interpretation of the evidence.¹⁵⁷⁻¹⁶³ Our recent Cochrane review¹²⁵ and JAMA publication¹⁵⁶ found no clear benefit among treatment trials but noted that prevention trials consistently favored some benefit. Not included in those reviews, a recent head-to-head trial of an echinacea tea against the antiinfluenza drug oseltamivir in influenza-like illness found the echinacea preparation to be equally effective.¹⁶⁴ A recent review argued that positive trials may be due to inadvertent unblinding, with either placebo effect or participant reporting bias contributing to false positive results.¹⁶⁵ It is also possible that negative studies have gone unreported, thereby yielding publication bias.

Given that echinacea extracts appear safe and that the vast majority of published trials have reported positive trends, it seems reasonable to cautiously support the use of echinacea in adults, particularly those with favorable personal experience and positive expectations.¹⁶⁶

Dosage and standardization

Positive trials have used differing formulations, with preparations

made from the leaf and flower of *Echinacea purpurea* most widely used. However, preliminary evidence suggests that alkylamides from the roots of *E. purpurea* and *E. angustifolia* may have the greatest bioavailability and immunoactivity.^{139,167,168} While there is a lack of consensus regarding standardization criteria, the majority of experts agree that echinacea extracts should be used as early as possible in the course of a cold, with multiple doses per day for the first few days of symptoms. Beyond that, no specific doses or precautions have been identified.

Precautions

My own opinion is that use in children should be discouraged, as the best pediatric RCT found no positive effects but did report a slight increase in the incidence of skin rash among patients randomized to echinacea.¹⁶⁹ While there is a modest case control study finding no adverse effects in pregnancy,¹⁷⁰ I caution against its use as the risks are theoretically substantive.

There is greater evidence regarding echinacea, zinc, and vitamin C than any single conventional therapy. Unfortunately, there is a negative trial for every positive one.

Elderberry (*Sambucus nigra*)

Preliminary research indicates elderberry extracts may have antiinflammatory and antiviral antiinfluenza properties.¹⁷¹⁻¹⁷³ A Norwegian RCT among N = 60 volunteers reported potential symptom reduction benefit in influenza-like illness.¹⁷⁴ To my knowledge, those findings have not been replicated. With only one small limited trial and no good safety data, the use of elderberry for the treatment of URI is intriguing but unlikely to become widely adopted.

Garlic (*Allium sativum*)

Garlic is widely used as a food and flavoring. Medicinally, there are hundreds of reported uses of garlic. The most prominent of these is moderation of cholesterol and other lipids, for which modest beneficial activity has been reasonably established.¹⁷⁵⁻¹⁷⁸ While in vitro studies have

reported antibacterial and antiviral effects, only one relevant human trial of the efficacy of garlic in treating the common cold has been reported.¹⁷⁹ Josling reported a RCT in which 146 participants were randomized to daily garlic or placebo capsules for 12 weeks.¹⁸⁰ Dramatic between-group differences were observed, with 65 colds in the placebo group and 24 in the garlic group ($p < 0.001$), with an average cold duration of 5.0 days among those taking placebo versus 1.5 days among those taking garlic ($p < 0.05$). While the study was reportedly double-blind, proof of blinding was not provided. The active treatment was “an allicin-containing garlic supplement” dosed at “one capsule daily.” No further information on extraction methods, phytochemical composition, or amount of garlic was provided. Nevertheless, it may be reasonable to tentatively support the use of garlic as the risk of side effects is low, cardiovascular benefits are likely, and garlic is tasty.

Dosage

My personal recommendation is to use fresh garlic in cooking as much and often as palatable while being conscious of the cardiovascular and cold-prevention benefits of garlic.

Ginger (*Zingiber officinale*)

Ginger root is also very widely used as a food flavoring as well as for its medicinal properties. There is reasonable evidence supporting its effectiveness as an antinausea agent¹⁸¹⁻¹⁸³ and in the treatment of vertigo,¹⁸⁴ dysmenorrhea,¹⁸⁵⁻¹⁸⁷ and knee osteoarthritis.¹⁸⁸ In the ARI setting, one small trial of a ginger and goldenrod combination reported small benefits.¹⁸⁹

To my knowledge, no other trials of ginger root in the treatment of URI have been completed. Nevertheless, as ginger is widely used as a treatment for colds and flu, and as I personally happen to use ginger as a common cold remedy, it is included in this review.

Dosage

Buy a nice ginger root at the local grocery store, shave off the peel and slice the root thinly using a sharp knife, being careful not to cut one's

fingers. Drop the sliced ginger into boiling water and steep for 5 minutes, then add honey and lemon to taste. Sip slowly, and *feel* the ginger work! (Dr. Barrett's personal recipe)

Ginseng (*Panax ginseng*, *Panax quinquefolium*)

Asian (*P. ginseng*) and American (*P. quinquefolium*) ginseng are used for a wide variety of purposes. The genus name *Panax*, chosen by Linnaeus, in fact derives from the same root word as Panacea, the Greek goddess of healing. The most widespread medical theory supporting the use of ginseng derives from traditional Chinese medicine.¹⁹⁰ Ginseng is thought to have "adaptogenic" attributes, which bring balance, homeostasis, and healing.¹⁹¹⁻¹⁹³ Some evidence of the effectiveness of a *P. ginseng* extract in preventing common cold comes from an Italian trial among N = 227 individuals followed for 12 weeks.¹⁹⁴ A Korean preventive trial evaluating *P. ginseng* among N = 100 individuals reported 12 cases of ARI (25%) in the ginseng group, compared to 22 (45%) in the placebo group.¹⁹⁵ A series of Canadian studies of a polysaccharide-rich *P. quinquefolium* extract reported immunomodulatory changes.¹⁹⁶⁻¹⁹⁸ An RCT among N = 198 elderly nursing home residents reported reductions in both cold and flu episodes.¹⁹⁹ A second preventive trial using the same formulation among N = 323 subjects reported a statistically significant 13% difference in incidence in cold and flu episodes during 4 months of observation.^{200,201} The proprietary formula used in this series of research has been approved for use in Canada. In the U.S., it would seem reasonable for preventive-minded people to use small doses of ginseng extracts (either *P. ginseng* or *P. quinquefolium*) regularly during the cold and flu season; however, as evidence is modest and safety not established, the use of ginseng in pregnancy and among children is not advised. Evidence is insufficient to recommend specific dosing or side effects.

Dosage

For prevention during times of high risk, take 100 mg daily. For acute infection, consider 100 mg twice daily for 9 days.

Precautions

Ginseng is generally well tolerated but may cause insomnia,

tachycardia, and elevated blood pressure.

Goldenseal (*Hydrastis canadensis*)

Goldenseal is among the top selling botanicals in the United States. In addition to cold remedies, *Hydrastis* extracts are found in treatments for allergy and in digestive aids, feminine cleansing products, mouthwashes, shampoos, skin lotions, and laxatives.¹²⁰ Goldenseal is combined with echinacea in many cold therapies. However, there are currently no RCTs evaluating the efficacy of goldenseal, either alone or in combination with echinacea. The phytochemical constituent berberine is pharmacologically active, and in overdose can cause significant toxicity, including cardiac arrhythmia and death.²⁰² Goldenseal is contraindicated in pregnancy and lactation. Berberine-rich extracts are included in many traditional Chinese medicines. The demand for goldenseal has led to overharvesting and to the substitution of other plants containing berberine or similar compounds. Given these considerations, I do not recommend goldenseal for the prevention or treatment of the common cold.

Lemon (*Citrus limon*)

Originally from India, the lemon tree is now cultivated throughout the world and used as a food, flavoring, and botanical remedy. Medicinal uses include the prevention and treatment of scurvy. Lemon is also used for malaria, rheumatic arthritis, and fever, in addition to numerous other indications. Lemon juice and lemon-flavored teas are used for the prevention and treatment of colds, coughs, and flu. While rigorous evidence of the effectiveness of lemon is lacking, lemon is generally recognized as safe and to have important nutritional value as a source of vitamin C (ascorbic acid), thereby making lemon a good choice for those who derive symptomatic comfort.

Peppermint (*Mentha piperita*)

Peppermint and other members of the mint family are widely used for a variety of medicinal purposes, including coughs and colds, as well as for a variety of gastrointestinal purposes. When treating colds, mint teas and infusions are taken internally, while mint oils are applied topically. Peppermint oil is composed primarily of menthol, menthone, and menthyl acetate. Menthol especially has been extracted and included in various topical cold remedies classified as “menthol rubs.” While neither

mint teas nor menthol rubs have been subjected to rigorous randomized controlled trials evaluating their efficacy in treating the common cold, both applications seem reasonable from a cost, risk, and potential benefit perspective, at least in adults. More concentrated preparations, such as peppermint oil, should not be applied to the mucosa of infants or young children, as direct inflammatory toxicity can result. Bronchospasm, tongue swelling, and even respiratory arrest have been rarely reported.^{202,203}

Umckaloabo (*Pelargonium sidoides*)

Various preparations of this South African plant have been used for centuries following ethnobotanical tradition.²⁰⁴⁻²⁰⁷ Antiviral effects, including antiinfluenza activity, have been reported.^{208,209} Three RCTs in adults (N = 746) and three RCTs in children (N = 819) have yielded somewhat inconsistent yet generally positive findings.²¹⁰⁻²¹² A 2013 Cochrane review concluded that “*P. sidoides* may be effective in alleviating symptoms of acute rhinosinusitis and the common cold in adults, but doubt exists. It may be effective in relieving symptoms in acute bronchitis in adults and children, and sinusitis in adults.”²¹³ Scientific interest in *Pelargonium* is relatively recent, and conclusions to date are tentative. However, umckaloabo seems a reasonable choice for adults looking for a natural treatment for cough, cold, or bronchitis. No specific formulation or dose regimen can be recommended.

Dosage

The formulation used in the above research was Eps 7630, which is an 11% aqueous ethanolic extract available in Europe. In America, the most commonly available form is a 1X homeopathic dose through a variety of brand names. The effectiveness of homeopathic doses is unknown.

Precautions

While no dose-dependent adverse effects are known, gastrointestinal disturbance and hepatotoxicity have been reported,²¹⁴ and the results of a previous study indicated that allergic reactions may be a relatively frequent problem.²¹⁵

There are several trials supporting the use of Andrographis, pelargonium (umckaloabo), and intranasal carrageenan gel. These are ones to watch!

Vitamins, Minerals, and Home Remedies

Chicken Soup

Hot chicken soup is the epitome of traditional cold remedies, and its use is supported by many personal testimonies. Chicken soup as a cold remedy is somewhat supported by at least two human studies, one reporting inhibited neutrophil chemotaxis²¹⁶ and the other indicating increased nasal mucus velocity and decreased nasal airflow resistance.²¹⁷ No RCTs using patient-oriented outcomes have been reported. Personally, I would be much more enthusiastic if the chicken industry adopted more responsible sanitary, environmental, and animal welfare policies. In the meantime, the use of soup made from free-range chickens and substantial quantities of wholesome organic vegetables can be cautiously supported, although I personally prefer soup with vegetables only.

Honey

Honey is widely used as a food and flavoring, and has been advocated as a treatment for cough and other ARI symptoms, particularly for children. A 2012 Cochrane review found two trials including 265 children.²¹⁸⁻²²⁰ While the quality of the trials was considered mediocre, the authors concluded that “honey may be better than ‘no treatment’ and diphenhydramine in the symptomatic relief of cough but not better than dextromethorphan.”²¹⁸ These may not be fair comparators, as diphenhydramine is not known to have antitussive properties and dextromethorphan and other OTC drugs are not recommended for children.²³ Nevertheless, honey may be a reasonable choice for cough in children aged 2 to 10 years as it is safe and tastes good. Honey does contain large amount of glucose and fructose, so tooth-brushing afterwards is recommended. Honey is not recommended for infants due to the risk of *Clostridium botulinum* infection.

Dosage

Consider adding a teaspoon of honey to ginger, chamomile, or peppermint tea.

Consider adding a teaspoon of honey for cough and a squeeze of lemon to a tea made with one or more of the botanicals discussed as having positive evidence against viral URI.

Dry Saunas and Hot Baths

In 1990, Ernst et al. reported a nonrandomized 6-month prevention trial in which, “25 volunteers were submitted to sauna bathing, with 25 controls abstaining from this or comparable procedures. In both groups the frequency, duration and severity of common colds were recorded for 6 months. There were significantly fewer episodes of common cold in the sauna group. This was found particularly during the last 3 months of the study period when the incidence was roughly halved compared to controls. It is concluded that regular sauna bathing probably reduces the incidence of common colds, but further studies are needed to prove this.”²²¹ The research community apparently did not heed Dr. Ernst’s sage advice as, to my knowledge, there have been no subsequent trials testing the therapeutic properties of hot water bathing in the prevention or treatment of common cold. However, in 2010, Pach et al. reported a trial evaluating hot dry sauna as a treatment for the common cold, in which N = 157 individuals were randomized to wearing a winter coat in a hot dry sauna or wearing a coat in the sauna at room temperature.²²² Trends towards symptomatic benefit and reduced medication use were noted at various time points during the 7 days of treatment; however, the overall conclusion was that “inhaling hot air while in a sauna has no significant impact on overall symptom severity of the common cold.”²²² Despite the limited research on hot baths and the disappointing results of the previous dry sauna trial, these are modalities that I would personally recommend, should the opportunity exist, as long as one is reasonably healthy and the facilities are clean. However, I do not recommend wearing a winter coat in the sauna as I do not consider this proper attire. An optional bathing suit may perhaps be more appropriate, and certainly easier for laundering. There is no data regarding the optimal frequency, duration, or temperature of saunas and baths for the prevention or treatment of URI.

Precautions

Although saunas and hot baths are generally safe and potentially therapeutic, adequate hydration and care when standing up are important because heat-induced peripheral vasodilation can lead to orthostatic hypotension, dizziness, and increased fall risk.

Inhaled Hot Moist Air

One widespread traditional cold remedy involves the inhalation of hot moist air, often with a botanical or other additive. As noted above, benefits of inhalation of vapors from chamomile tea were reported by a previous clinical trial.¹²¹ The most recent Cochrane review evaluated six heterogeneous RCTs with a total of 394 trial participants reporting mixed results.²²³ While it seems reasonable to recommend humidification when the air is dry, and perhaps advocate the inhalation of hot moist air for those that find it comforting, it should be noted that water boils at around 100 °C, and inhalation of vapors near this temperature may cause significant thermal damage. Be careful!

Hot Toddy

I have been impressed by the number of people, including several physicians, who have come up after a lecture to tell me that their favorite cold remedy was some form of a hot alcoholic beverage, such as a “hot toddy” or hot buttered rum. While to my knowledge no trials have tested any of these remedies, testimonies of symptomatic benefit should not be totally disregarded. At a societal level, there is a well-known inverse relationship between moderate regular consumption of alcoholic beverages and the number and severity of colds.²⁸ Those who consume one or two drinks daily have fewer and less severe colds than both those who drink heavily and fewer colds than those who do not drink alcohol at all. One study found this relationship to be most pronounced for red wine.²²⁴ Personally, I like to add a bit of rum to a cup of hot orange juice as a nighttime cold remedy. However, this would be contraindicated among those with alcohol use disorders, in children, pregnant women, and individuals who need to use a motor vehicle or who operate hazardous machinery.

Nasal Saline

What could be more healthful and therapeutic than a mild saltwater rinse of the nasal cavities? While saline nasal lavage is a longstanding tradition in many cultures, it is only recently that Western biomedicine has begun to integrate this practice. Currently, there are a number of positive trials among individuals with allergic rhinitis and chronic sinus symptoms, including one at the University of Wisconsin Department of Family Medicine.²²⁵

A 2015 Cochrane review evaluated the results of five RCTs, two in adults (N = 205) and three in children (N = 544), all comparing nasal saline to routine care of common cold.²²⁶ These authors concluded, “nasal saline irrigation possibly has benefits for relieving the symptoms of acute URIs. However, the included trials were generally too small and had a high risk of bias, reducing confidence in the evidence supporting this.” In the largest adult trial, Adam et al. randomized 140 individuals to one of three groups: hypertonic saline, normal tonic saline, or no treatment (two squirts per nostril, three times per day.) No significant differences were observed between groups in terms of duration or severity of symptoms.²²⁷ On the other hand, the largest pediatric trial published to date reported significant improvements in breathing and reductions in nasal secretions.²²⁶ In addition to trials designed to test nasal saline, there is some evidence from trials using saline as a placebo. For example, Diamond et al. reported a trial in which 955 participants were randomized to one of three doses of nasal ipratropium, to the “placebo” saline vehicle, or to no treatment at all.²²⁸ The nasal saline vehicle yielded greater benefit compared to no treatment than did any of the ipratropium doses when compared with each other or with saline.

Overall, nasal saline is a remedy with potential benefit and virtually no cost or significant risks. I suggest twice daily treatment for the first few days of a cold (see [Chapter 113](#)).

Probiotics

Probiotics are live bacteria that are thought to support healthy gastrointestinal function. Several trials have demonstrated benefit for antibiotic-associated diarrhea²²⁹ and have indicated benefit for irritable bowel syndrome and other conditions.²³⁰⁻²³⁴ Interestingly, there is now reasonably strong preliminary evidence that probiotics may also prevent or ameliorate ARI illness. This evidence includes more than a dozen trials testing the efficacy of probiotics in preventing cold and flu illness episodes.²³⁵⁻²⁴³ One RCT was conducted among elderly individuals,²⁴⁰ and

two involved children.^{239,242} One of these was aimed at preventing diarrheal illness but instead provided evidence of cold and flu prevention.²⁴² Two recent meta-analyses reviewed more than a dozen RCTs including more than 3000 participants and noted “significantly fewer numbers of days of illness per person”²⁴⁴ among those receiving probiotics versus placebo, concluding that “the results implied that probiotics had a modest effect in common cold reduction.”²⁴⁵ Various formulations are available without prescription and, to my knowledge, there are no significance concerns regarding adverse effects. Until further evidence becomes available, we can be cautiously optimistic and perhaps even advocate probiotics for preventing or treating common cold; however, no specific products or dose regimens can be singled out as particularly effective (see [Chapter 105](#)).

Vitamin C (Ascorbic acid)

The use of vitamin C for the prevention and treatment of the common cold became widespread after double Nobel laureate Linus Pauling promoted his belief in this therapy in the 1950s and 1960s.²⁴⁶ By the early 1970s, three major trials conducted in Toronto by T.W. Anderson indicated preventive effectiveness.²⁴⁷⁻²⁴⁹ Over the next few decades, more than 30 trials including more than 12,000 participants have been reported.^{250,251} Interestingly, approximately half of these trials reported positive results, far more than would be expected by chance; however, this was not enough to convince more skeptical scientists. While there is no clear consensus regarding the reasons why some trials found benefit and others did not, it seems reasonable to tentatively conclude some preventive effectiveness, as concluded by a recent Cochrane systematic review:

“Regular supplementation trials have shown that vitamin C reduces the duration of colds, but this was not replicated in the few therapeutic trials that have been carried out. Nevertheless, given the consistent effect of vitamin C on the duration and severity of colds in the regular supplementation studies, and the low cost and safety, it may be worthwhile for common cold patients to test on an individual basis whether therapeutic vitamin C is beneficial for them.”²⁵⁰

The evidence supports modest preventive effectiveness for doses of

200 mg to 500 mg daily. Benefits of larger doses for prevention, or as treatment for new onset colds, is supported by some trials and systematic reviews,²⁵² while other trials have reported contradictory results.²⁵³ Given the generally accepted safety of ascorbic acid at doses up to a few grams per day over short periods, it seems reasonable to cautiously support its use in treating URI, particularly among individuals those positive experiences and expectations (very high doses, such as the 18 grams per day that Linus Pauling was reportedly taking up to his death at age 93 in 1994, have not been tested in trials and cannot be supported). Regular intake of vitamin C rich foods, however, can be enthusiastically supported because greater intake of fresh fruits and vegetables has been associated with many health benefits in dozens of large observational studies and has no known risks.

Vitamin D

In combination with calcium, vitamin D is widely recommended as a preventive or treatment for osteopenia and osteoporosis. Interest in vitamin D for a wide variety of other health concerns has blossomed over the past decade. Vitamin D for common cold prevention and treatment has been advocated, bolstered by the fact that vitamin D levels are low and ARI incidence is high during winter months.²⁵⁴ Unfortunately, enthusiasm has not been matched by evidence. To my knowledge, there is only one good quality RCT evaluating vitamin D for preventing colds.²⁵⁵ Although the results trended towards slight benefit, the general interpretation was negative.²⁵⁶

Zinc

In some ways, the story of zinc for the treatment of colds is similar to that of vitamin C. Reportedly, the physician George Eby noticed rapid recovery from an ARI in a child hospitalized and given zinc for unrelated reasons. This observation was followed by an RCT that reported positive results in 1984 (but had methodologic flaws).²⁵⁷ Since then, a dozen trials with more than 1300 participants have been conducted using various zinc preparations.²⁵⁸⁻²⁶³ Trials testing zinc acetate in doses of 75 mg or more have tended to report the most positive results.²⁶⁴ The most recent Cochrane review was generally positive,²⁵⁹ and many authorities now recommend zinc as a treatment for common cold.²⁶⁵ However, there are concerns regarding adverse effects, such as unpleasant taste and/or nausea. While zinc is an essential mineral, with many known protective

effects when ingested in foods in appropriate doses,^{266,267} use of relatively high doses during acute illness may confer minimal risks. Advocates recommend frequent dosing (every 2 to 3 hours) for the first 2 or 3 days of a cold, a dosing regimen that some patients may not find convenient. Nasal irritation is common, and loss of sense of smell has been reported.²⁶⁸ My personal recommendation is to tentatively support the use of oral or nasal zinc preparations among those who have experienced benefit and/or express positive feelings about the treatment but to not recommend use among children or pregnant women.

Dosage

Zinc gluconate, one table or lozenge containing 9–24 mg of elemental zinc, up to every 2 or 3 hours while awake, for the first few days of ARI illness.

Precautions

Zinc can inhibit the absorption of other minerals (copper) if used for extended periods of time. Nasal formulations have been associated with the loss of smell.

Among 13 trials of zinc including 1400 participants, approximately half reported positive and half reported negative results.

Mind Body

Placebo, Meaning, and Mind-Body Effects

During the past two decades I have read reports of hundreds of trials and dozens of systematic reviews and become increasingly convinced of the importance of mind-body effects, otherwise described as placebo or meaning effects.²⁶⁹⁻²⁷³ Positive thinking, suggestion, expectancy, and belief in the therapeutic value of a given remedy can be a powerful healing force. While regular exercise, balanced nutrition, and tobacco cessation are clearly associated with fewer and less severe illness episodes, so too are positive mental health attributes such as favorable psychological profile and healthful social relationships. Psychological predispositions, especially sociability and a positive emotional style, are

predictive of both symptomatic and physiological outcomes. For the integrative clinician, this means that understanding an individual's belief system may be a crucial part of the therapeutic encounter. If a patient already believes in a safe therapy, reinforcing that belief may enhance the therapeutic response. If patients are wary of a mentioned remedy, clinicians should not press the issue. Remember that reassurance, empathy, empowerment, and positive prognosis can all be usefully employed in the clinical encounter.

Pharmaceuticals and Conventional Cold Products

Antihistamines

Drugs blocking the effects of histamine have been sold as cold remedies for more than a century but, interestingly, have been subjected to less in terms of rigorous RCT research than alternatives such as vitamin C, zinc, and echinacea. Nevertheless, there is reasonable evidence of the modest benefit of first generation antihistamines, such as diphenhydramine, clemastine fumarate, and chlorpheniramine, in reducing nasal drainage.²⁷⁴⁻²⁷⁷ However, effects appear to be more attributable to anticholinergic mechanisms than antihistamine effects, and second generation "nonsedating" antihistamines do not seem to provide benefit.²⁷⁸ For adults who do not mind the potential sedating or membrane-drying effects, or those with allergic responses, a first generation antihistamine may be a reasonable choice. For children, where there is no positive evidence whatsoever, antihistamines should be reserved for allergic rather than infectious rhinitis.

Decongestants

The oral decongestant, pseudoephedrine, has been tested in several clinical trials and appears to have minor benefit in reducing nasal congestion and drainage.²⁷⁹⁻²⁸² Side effects, including anxiety, dizziness, insomnia, and palpitations, are fairly common. More worrisome is the potential risk of elevated blood pressure and cardiac arrhythmia. Phenylpropanolamine, for decades a popular over-the-counter decongestant, was taken off the market after studies indicated an association with increased mortality, particularly among elderly individuals.²⁸³

The topical intranasal decongestant, oxymetazoline, has been shown to

decrease nasal airway resistance as well as mucus production and drainage.²⁸⁴⁻²⁸⁷ Intranasal phenylephrine has been less extensively studied but likely has similar effects. Unfortunately, these proven benefits come at the risk of nasal membrane dryness and discomfort. Oxymetazoline should be used for no more than 4 days as rebound nasal congestion can occur.

Cough Suppressants

Dextromethorphan, the active ingredient in cough remedies designated with “DM,” is widely used as an over-the-counter cough suppressant. Codeine, and to a lesser extent hydrocodone, are prescribed for cough and are thought to work through similar opioid-mediated mechanisms. As such, these medications have side effects including sedation, constipation, and, potentially, respiratory suppression. While most patients and clinicians agree that these remedies work, there is considerable debate over effect size and mechanism of action due to a lack of appropriate evidence.²⁸⁸⁻²⁹⁰ The best systematic review of cough remedies for children and adults concluded: “there is no good evidence for or against the effectiveness of OTC medicines in acute cough.”²⁹¹ Benzonatate (Tessalon perles) is licensed as a prescription antitussive but appears to have been given this indication despite a lack of good evidence.

Analgesics/Antipyretics

There is no doubt that acetaminophen and nonsteroidal antiinflammatories (NSAIDs), such as aspirin, ibuprofen, and naproxen, are effective in treating pain and fever that may accompany the common cold. However, some reports suggest that viral shedding may be prolonged by analgesics.^{292,293} While limited use for pain reduction is eminently reasonable, the widespread use of NSAIDs for general common cold symptoms is not justified, as evidence-of-benefit is marginal, and many thousands of individuals die each year from NSAID-attributable gastrointestinal hemorrhage and congestive heart failure.²⁹⁴⁻²⁹⁶

Anticholinergics

Ipratropium nasal spray has been evaluated by several good quality RCTs regarding its efficacy in the amelioration of the symptoms of infectious and allergic rhinitis.^{297,298} These trials, including a dose-

response trial among 955 individuals with community-acquired common cold,²²⁸ reported definite benefit in terms of reduced nasal congestion and drainage. Common side effects include headache, uncomfortable nasal dryness, and nosebleed.

Combination Formulas

The multibillion-dollar market in cold remedies is dominated by numerous products containing combination formulas. Loopholes in FDA regulations have allowed pharmaceutical companies to mix various decongestants, antihistamines, analgesics, and antitussives, and then market these products under a variety of brand names and questionable claims. While there is some evidence of the effectiveness of these products from several RCTs,^{274,299} very few if any of currently marketed products have been tested in large, well-controlled RCTs. Personally, I recommend against using any combination cold formula, with a possible exception for those who are convinced that a specific formula works for them. Perhaps most importantly, clinicians as well as parents should be made aware that no cold formula has ever been proven to work in children. In my opinion, acetaminophen (paracetamol) is the only currently justifiable treatment of pain in children.

Antivirals

Dozens of phase I and II trials using experimental rhinovirus infection models have reported benefit for several different antiviral drugs.³⁰⁰⁻³⁰⁴ None, however, have demonstrated safety or efficacy in the treatment of community-acquired colds and therefore none can currently be recommended. Nevertheless, this remains an active area of research; safe and effective antiviral cold treatments may become available in the future.

Conventional treatments, such as antihistamines, decongestants, and cough remedies, may help slightly with some symptoms but do tend to have side effects.

Prevention Prescription

- Do not smoke

- Exercise regularly
- Wash hands frequently
- Eat a balanced nutritious diet, including foods containing vitamin C and zinc
- Maintain supportive social relationships
- Reduce exposure to people with colds
- Reduce stressors and/or negative responses to stress
- Antibiotics should not be used for the treatment of cold symptoms in children or adults.
- There is some evidence for the effectiveness of andrographis (400 mg twice daily), vitamin C (200–500 mg daily), ginseng (100 mg daily), and probiotics in the prevention of colds. As the evidence is weak, consider these treatments only during high-risk times.

Therapeutic Review

Below is a summary of therapeutic options for common cold. None are proven beyond reasonable doubt to be safe and effective. Nevertheless, these are all reasonable options given best current evidence of benefit and harm.

Treatment of Common Cold

Botanicals

- Andrographis. Consistent preliminary evidence of benefit, no major concerns of harm. No good reason to pick one formulation or dose regimen over another. A common dose is 400 mg of dried herb, or extract containing 5 to 20 mg of andrographolide, up to three times daily for the first few days of illness. 
- Echinacea. Contradictory evidence, with several positive trials. Evidence on prevention is more consistent than that for treatment. No serious concerns of harm but should be avoided in pregnancy. Use three or four times daily for the first few days of a cold. No strong reason to pick one formulation over another 
- Pelargonium/Umckaloabo. Contradictory evidence, with a few positive trials. No serious concerns of harm. Use three or four times

daily for the first few days of a cold. No strong reason to pick one product over another 

Supplements

- Vitamin C. Contradictory evidence, with several positive trials. Water-soluble vitamin. Necessary nutrient. Very safe in reasonable doses. 
- Zinc. Contradictory RCT evidence, with several positive trials, particularly with higher doses of zinc acetate. Use lozenges frequently for the first couple days of a cold. Side effects may include bad taste or nausea. 
- Astragalus, chamomile, garlic, ginger, ginseng, lemon, peppermint, hot baths, hot moist air, nasal saline, and chicken soup are all unproven but safe supportive therapies. 

Pharmaceuticals

- First generation (sedating) antihistamines may decrease nasal congestion but may cause drowsiness. 
- Intranasal decongestants appear to be effective in decreasing nasal congestion and drainage but quite often cause nasal dryness or irritation, and, rarely, insomnia, palpitations, or elevated blood pressure. 
- Oral decongestants may be effective in decreasing nasal congestion but may cause insomnia, palpitations, or elevated blood pressure. 
- Intranasal ipratropium appears to be effective in decreasing nasal congestion and drainage but may cause headache, nasal irritation, or nosebleed. 
- Antivirals for true influenza of no more than 36 hours duration may reduce symptom severity, duration, and infectivity 

There is no good evidence of the effectiveness of any treatment, conventional or integrative, in children. While children can suffer side effects, they are less likely than adults to benefit from the placebo

effect. Dr. Barrett says, “Don’t drug the kids!”

CHAPTER 19

HIV Disease and AIDS

Stephen Dahmer, MD, and Benjamin Kligler, MD

Pathophysiology

The human immunodeficiency virus (HIV) is a highly contagious lentivirus (family Retroviridae) that causes the potentially life-threatening condition acquired immunodeficiency syndrome (AIDS). Since 1981, when the first case of AIDS was reported in the United States, the disease has become a global pandemic, resulting in an estimated 65 million infections and 25 million deaths worldwide. Currently, approximately 0.8% of the world is considered to have people living with HIV / AIDS (PLWHA).¹

Many PLWHA are unaware that they are infected with the virus, and an estimated 10%–60% of individuals with early HIV infection will not experience symptoms. In April 2013, the USPSTF recommended that clinicians screen all adolescents and adults aged 15–65 years for HIV infection. Younger adolescents and older adults who are at increased risk should also be screened. They also recommend screening all pregnant women, including those who present in labor with unknown HIV status.²

In practice, the possibility of acute HIV infection should be considered in patients who present with any ill-defined febrile illness. Suspicion should be heightened for those presenting with HIV-consistent symptoms, including diarrhea, rash, lymphadenopathy, aseptic meningitis, and mucocutaneous ulcers. In the United States, the recommended algorithm for screening involves an initial fourth generation combined antigen / antibody immunoassay with confirmatory immunoassay of a second type followed by HIV viral testing if there is a discrepancy.³ Since 1997, home testing kits have been available for patients to test themselves, and a new smartphone testing device could also soon be available.⁴

Two types of HIV have been characterized: HIV-1 and HIV-2. HIV-1 was discovered first; it is more contagious and virulent and, therefore, the cause of the majority of HIV infections globally. HIV-2 has poor capacity for transmission and is largely confined to West Africa.

Since 1996, AIDS has been transformed into a serious but manageable chronic illness by the widespread use of antiretroviral medications (highly active antiretroviral therapy [ART or HAART]). Many of the current challenges in the management of HIV-positive patients pertain to minimizing the possibility of developing viral resistance while maximizing quality of life by preventing or controlling the adverse effects associated with the use of antiretrovirals. A newer challenge is the prevention and treatment of chronic disease as life expectancy increases. For all patients with early HIV infection, genotypic drug resistance testing as well as hepatitis B and C serologies should be performed because they can influence treatment choice.⁵

Integrative Therapy

PLWHA have a strong history of being active regarding their health care. Since early in the epidemic, they have advocated for effective, available treatments. AIDS activists have long promoted the idea that individuals living with HIV should not only have access to all potentially effective therapies but also the right to make informed choices about which treatments to use, including complementary therapies (as recently popularized in mainstream culture by the movie *Dallas Buyers Club*).

People with HIV disease typically use integrative approaches for several reasons. First is to promote healthier functioning of the immune system. Second is for a claimed antiviral effect of the therapy. Third is to treat an HIV-associated symptom or condition. Fourth is to mitigate one or more side effects of antiretroviral medications, as in the use of glutamine supplements for protease inhibitor (PI)-associated diarrhea. Finally, many use integrative therapies simply to improve their quality of life or gain a sense of empowerment by being involved in their own care.

Lifetime use of complementary and alternative medicine (CAM) by PLWHA ranges from 30% to 90%, with national studies suggesting CAM use around 55% and practitioner-based CAM about 15%. Vitamins, herbs, and supplements are the most common, followed by prayer, meditation, and spiritual approaches. CAM use is predicted by the

length of time since HIV diagnosis as well as a greater number of medications/symptoms. CAM is often used to address limitations or problems with antiretroviral therapy.⁶ Although the advent of effective pharmaceutical treatment for HIV has led to a decrease in the use of CAM, rates of use nevertheless remain high. In a cohort of HIV-positive adults (N = 642) followed semiannually in the Nutrition for Healthy Living (NFHL) study between 1995 and 1999, HAART use increased from 0% to 70%, but ingested CAM use decreased only from 71% to 52%.⁷ The investigators concluded that most people with HIV at this point apparently feel that “CAM therapies complement, rather than replace ART [and that] physicians should routinely ask about ingested CAM therapy use in HIV-positive patients.”⁷

In a recent survey of 1000 randomly selected infectious disease (ID) practitioners, 75% felt that CAM and integrative medicine modalities are useful.⁸ Despite acceptance and persistent use of CAM, assessment of these popular CAM therapies among HIV-positive populations continues to be problematic. Approximately 20% of the existing studies have assessed the reliability and 3% assessed the validity of the CAM instruments employed, making evidence-based recommendations very problematic.⁹

Pharmaceuticals

Antiretroviral Therapy

Over the past two decades, ART has radically altered the natural history of HIV infection, and advances continue to evolve.¹⁰ Opportunistic diseases have become less common, and mortality has declined to the point that HIV-infected individuals now have a near-normal life expectancy ([Table 19.1](#)).¹¹ More than 50% of deaths in PLWHA receiving ART are now related to conditions other than AIDS.¹² It is recommended that all HIV-positive individuals start ART regardless of CD4 count to both reduce the risk of disease progression and prevent transmission.¹³ Those starting ART should be willing and able to commit to treatment and understand the benefits and risks of therapy and the importance of adherence. The recommendation for those with CD4 count > 500 cells/mm³ is based on expert opinion with the stated caveat that patients may choose to postpone therapy, and providers, on a case-by-case basis, may elect to defer therapy on the basis of clinical and/or psychosocial factors.

In 1987, a drug called AZT became the first-approved treatment for HIV disease. Since then, approximately 30 drugs have been approved, with more under development. These medications fall into several classes. The first category is the antiretrovirals, used for their specific activity against HIV. These agents are currently divided into six groups: (1) the nucleoside reverse transcriptase inhibitors (NRTIs), which include zidovudine (Retrovir), emtricitabine (Emtriva), abacavir (Ziagen), didanosine (Videx), stavudine (Zerit), and lamivudine (EpiVir); (2) the PIs, which include indinavir (Crixivan), nelfinavir (Viracept), amprenavir (Agenerase), and numerous others; (3) the nonnucleoside reverse transcriptase inhibitors (NNRTIs), which include rilpivirine (Edurant), efavirenz (Sustiva), and nevirapine (Viramune). Newer classes include (4) entry inhibitors (including fusion inhibitors), such as enfuvirtide (Fuzeon) and maraviroc (Selzentry); (5) integrase inhibitors, such as raltegravir (Isentress) and dolutegravir (Tivicay); and (6) multiple-class combination drugs, such as efavirenz + tenofovir + emtricitabine (Atripla), which are technically not a separate class of HIV medications but combinations of the previously mentioned classes into one single pill with specific fixed doses of these medicines. Currently, the most common approach is to use these agents in combinations of at least two drugs (4/5th of the preferred initial regimens for ART-naive patients are integrase based) to reduce the possibility of viral resistance.

Consensus has shifted multiple times in deciding the optimal time to start ART therapy, with the most recent recommendations leaning strongly toward early ART for all PLWHA. Released at the time of publication were results from the Strategic Timing of Antiretroviral Treatment (START) study, the first large-scale randomized clinical trial to establish that earlier antiretroviral treatment benefits all HIV-infected individuals; 4685 patients with HIV from 35 different countries were followed for an average of 3 years, and serious AIDS events as well as serious non-AIDS events and death were recorded. As of March 2015, a total of 41 (0.6 per 100 patient years) of those events were found in the early treatment group and 86 (1.25 per 100 patient years) in the delayed group (Hazard ratio Arm A/B [95% confidence interval; CI]= 0.47 [0.32–0.68]).¹⁴

The second category of pharmaceuticals, used less widely since the advent of effective antiretroviral medications, comprises the prophylactic agents used for prevention of specific HIV-related opportunistic infections. These drugs include trimethoprim-sulfamethoxazole (Septra, Bactrim) for prophylaxis of *Pneumocystis carinii* pneumonia and

toxoplasmosis and azithromycin and rifabutin for prophylaxis of *Mycobacterium avium* infection.

TABLE 19.1
When to Start Antiretroviral Therapy

Measure	Recommendation
Specific Conditions	
Symptomatic HIV disease	Antiretroviral therapy recommended regardless of CD4 cell count
Pregnancy	
High HIV-1 RNA level (> 100,000 copies/mL)	
Rapid CD4 count decline (> 100 cells/mm ³ per year)	
Active hepatitis B or C* virus coinfection	
Active or high risk for cardiovascular disease	
HIV-associated nephropathy	
Symptomatic primary HIV infection	
Age > 60 years	
Risk for secondary HIV transmission is high	
CD4 cell count ≤ 500 cells/mm ³	Antiretroviral therapy recommended
CD4 cell count > 500 cells/mm ³	Antiretroviral therapy should be considered †

* Active co-infection with HCV or HBV requires treatment with specific antiretroviral regimens.

† New recommendations for HIV patient care include offering ART to all patients regardless of CD4 cell count, changes in therapeutic options, and modifications in the timing and choice of ART in the setting of opportunistic illnesses such as cryptococcal disease and tuberculosis.

From Thompson MA. Antiretroviral treatment of adult HIV infection: 2010 recommendations of the International AIDS Society-USA panel. *JAMA* 2010;304:321–333.

People living with HIV / AIDS must be more than 95% adherent to their treatment plans in order for them to remain effective. This means that missing more than one dose per month may reduce effectiveness of therapy.

Pre- and Postexposure Prophylaxis

Currently, no vaccine or cure for HIV is publicly available. Interesting areas of research include CpG 7909 and stem cell transplant (“Berlin patient”). Unfortunately, all stem cell transplant HIV recipients to-date

have relapsed. The universally recommended method for the prevention of HIV is to avoid blood-to-blood contact and to practice safe sex. On July 16, 2012, the U.S. Food and Drug Administration (FDA) approved Truvada (emtricitabine/tenofovir disoproxil fumarate) as the first drug to reduce the risk of HIV infection in uninfected individuals who are at high risk and/or engage in sexual activity with HIV-infected partners. Truvada is taken daily as preexposure prophylaxis (PrEP) in combination with safer sex practices to reduce the risk of sexually-acquired HIV infection. When taken consistently, PrEP has been shown to reduce the risk of HIV infection by up to 92%.¹⁵ Postexposure prophylaxis (PEP) can be prescribed for people who have recently been exposed to HIV; it involves starting ART no more than 72 hours (3 days) after exposure. Two to three drugs are usually prescribed (preferred regimen is Raltegravir [Isentress] 400 mg po twice daily PLUS Tenofovir/Emtricitabine 300/200 mg [Truvada] po once daily), and they must be taken for 28 days. PEP is not always effective; it does not guarantee that someone exposed to HIV will not become infected.¹⁶

A trial using a three-drug combination pill of the brand name Complera that includes emtricitabine 200 mg, rilpivirine 25 mg, and tenofovir disoproxil fumarate 300 mg once daily with food for 28 days in 100 HIV-infected men resulted in no acquisition of HIV at 12 weeks.¹⁷

Lipodystrophy

In a separate category, on November 10, 2010, the FDA approved Egrifta (tesamorelin) to treat HIV patients with lipodystrophy (associated with many ART medications), a condition in which excess fat develops in different areas of the body, most notably around the liver, stomach, and other abdominal organs. Although it may decrease visceral abdominal fat in PLWHA, it has not been shown to provide any clinical benefit (e.g., decrease in cardiovascular risk or improved quality of life); it is nonformulary, and the estimated 30-day price is \$2042.¹⁸ Long-term safety is yet another concern, and a 10-year observational study is currently underway.¹⁹

Smoking

According to Centers for Disease Control and Prevention (CDC) estimates in 2009, 42% of HIV-infected Americans in care smoked cigarettes (one of the highest rates of smoking for any subgroup).²⁰ Smoking poses a special hazard to PLWHA beyond its already well-established negative effects on the health.²¹ Evolving science supports the idea that HIV infection is associated with a chronic state of persistent inflammation (regardless of CD4/viral load) and that this inflammation increases the risk for illnesses for which smoking is already a well-established cause. Additionally, smoking inhibits effective CD4+ T lymphocyte function and thereby increases the risk for certain infections (e.g., pulmonary).²² Quit rates are 37% lower for HIV-infected smokers than for subjects in the general population.²⁰

Nutrition

Early research in the 1980s showed that decreases in body weight, body mass index, and body fat percentage may be the first signs of declining nutritional status resulting from HIV disease and may begin even during the early asymptomatic phase of HIV infection. PLWHA experience HIV-associated wasting and lose body mass despite nutritional intake that should be adequate for their height and weight. In a study of nutritional status in 108 HIV-positive patients, both with and without AIDS, body weight, serum cholesterol level, and CD4+ level progressively decreased over a 6-month period and HIV-associated wasting persisted.²³ This study also found a significant relationship between low serum cholesterol—a marker for poor nutrition—and adverse patient outcome.

Nutrition counseling and intervention in the early stages of HIV disease constitute important components of a prevention-oriented treatment plan because these measures may help forestall adverse nutritional changes in HIV-positive patients. Although definitive data supporting specific nutritional recommendations are scarce, reasonable suggestions include the following: a diet high in omega-3 essential fatty acids such as flaxseed and fish oils; small, frequent meals to ensure adequate intake of calories and to reduce the likelihood of malabsorption; avoidance of simple sugars, which may inhibit immune function on a short-term basis as shown by some studies; and avoidance of large amounts of alcohol and caffeine. In 227 HIV-infected patients, adherence to a Mediterranean dietary pattern was favorably related to cardiovascular risk factors in patients with fat redistribution²⁴ (see [Chapter 88](#)).

Another purpose for which nutritional interventions are widely used is to address the problems with malabsorption experienced by many HIV-positive patients. Common recommendations include the use of *Lactobacillus*, *Bifidobacterium*, and other “friendly bacteria” to maintain proper balance of intestinal flora (see [Chapter 105](#)) and the use of whole food-based nutrition to prevent the development of subclinical vitamin deficiencies or promote higher intake of the supplements discussed in the following sections. Although these recommendations have not yet been shown to affect the course of HIV disease progression, all are safe and reasonable to include in an integrative treatment plan.

Supplements

Multivitamins

Many clinicians have routinely recommended multivitamin supplementation for HIV-positive patients. A double-blind, placebo-controlled study of multivitamin (vitamins B, C, and E) supplementation in 1078 HIV-positive pregnant women in Tanzania demonstrated that over a 6-year follow-up period, women taking multivitamins had significantly less progression to World Health Organization (WHO) stage 4 disease or died compared with women given placebo (relative risk = 0.71).²⁵ Subjects in the multivitamin group also had significantly higher CD4+ and CD8+ cell counts and significantly lower viral loads. Adding vitamin A to this multivitamin regimen did not improve the outcome and, in fact, reduced the benefit of multivitamin therapy on some of the outcome measures.

Vitamin A

Vitamin A supplementation has been extensively studied for ameliorating infection with HIV in adults and for possibly reducing the likelihood of vertical HIV transmission. An association between lower vitamin A levels, lower CD4+ counts, and higher risk of progression to AIDS was reported.²⁶ A study in African women demonstrated a connection between vitamin A deficiency and increased maternal-to-fetal transmission of HIV.²⁷ However, other prospective trials, including one with 341 HIV-positive patients followed over 9 years, demonstrated no significant difference in the risk of AIDS progression with vitamin A levels.²⁸ Trials of high-dose vitamin A supplementation also failed to show an effect on CD4+ or CD8+ counts, viral loads, lymphocyte

responsiveness to mitogens, or progression of disease.²⁹ The association between vitamin A deficiency and increased vertical transmission of HIV initially reported in Kenya was not borne out in subsequent U.S. studies. The Women and Infants Transmission Study (WITS), a large prospective ongoing cohort study, found that vitamin A level does not correlate with increased risk of HIV vertical transmission in North America.³⁰ The investigators suggested that vitamin A supplementation in addition to prenatal vitamins is not necessary.

Dosage

15,000 IU of **mixed carotenoids**

Precautions

Chronic intake of preformed vitamin A can be toxic, leading to hair loss, confusion, liver damage, and bone loss.

Vitamin B₁₂

Supplementation with a B-complex vitamin may be beneficial in HIV-infected patients. Lack of vitamin B₁₂ has been associated with peripheral neuropathy and myelopathy; a 9-year prospective cohort study in 310 patients found vitamin B₁₂ levels to be an early and independent marker of HIV disease progression, and time to development of AIDS was found to be 4 years less on an average in subjects observed to have lower vitamin B₁₂ levels.³¹ Despite equivocal results of intervention trials using B₁₂ supplementation, supplementation continues to be widely used in HIV disease.

Dosage

100–1000 mcg daily

Precautions

No significant adverse effects of B₁₂ supplementation have been reported.

Antioxidants: Vitamins C and E, Selenium, and α -Lipoic Acid

Vitamins C and E both have been explored for a role in the treatment of HIV disease owing to their antioxidant properties. Other substances including selenium and α -lipoic acid are commonly used for the same purpose. In addition, vitamin C has been shown in vitro to inhibit viral replication at high doses.³² On the basis of this finding, intravenous vitamin C has been widely used to achieve the high serum levels necessary for antiviral activity. No evidence supports this aggressive approach, although anecdotally it has not been proved to be as dangerous as was initially feared. α -lipoic acid has theoretical, yet clinically unsubstantiated, use in HIV for HIV-related dementia, hepatoprotection, peripheral neuropathy, and lipodystrophy.

The role of antioxidant supplements in general in HIV disease requires further study. A 2009 review of 19 studies showed that evidence to support standard selenium supplementation in patients with HIV is both limited and insufficient, yet although the available evidence for selenium supplementation is weak, its low toxicity and side-effect profile seem to pose minimal risks, especially at low doses.³³ Vitamins E and C at more standard doses are safe and may decrease lipid peroxidation and enhance the immune system; however, conclusive evidence on the effects of these vitamins in HIV disease is still lacking. Higher doses of vitamin E should be avoided as elevated serum levels could potentially increase the risk of cardiovascular disease in PLWHA.³⁴

Dosage

Vitamin E 400 units daily; vitamin C 500–2000 mg one to three times daily; selenium 55–70 mcg daily; α -lipoic acid 20–50 mg daily

Precautions

Concomitant administration of high doses of vitamin C can reduce steady-state indinavir plasma concentrations.³⁵

Vitamin D

While best known for its effects on bone health, vitamin D deficiency has also been associated with muscle weakness, more than a dozen types of internal cancers, multiple sclerosis, and type 1 diabetes mellitus. Most

recently, there has been peaked interest in its immunomodulatory actions, especially related to PLWHA.^{36,37} Observational studies conducted in PLWHA who are not taking ART have reported associations between vitamin D deficiency and susceptibility to tuberculosis, upper respiratory tract infection, and oral candidiasis, raising the possibility that supplementation might reduce susceptibility.³⁸ Although its clinical effects are still under investigation, the high potential for benefit of vitamin D coupled with its excellent safety profile and the high prevalence of deficiency in the U.S. population suggest that we should encourage supplementation in PLWHA regardless of ART.

Dosage

Because the IOM has doubled the safe upper limit from 2000–4000 IU of vitamin D per day, in our practice we have moved toward recommending 1000–2000 IU of D₃ daily in summer and 2000–4000 IU of D₃ daily in winter.

Precautions

Vitamin D toxicity can cause hypercalcemia and anemia. Symptoms include fatigue, gastrointestinal (GI) intolerance, bone pain, and a metallic taste.

N-Acetylcysteine

Because of the strong evidence that depletion of glutathione levels correlates with progression of HIV infection, much interest has been focused on the use of the nutritional supplement N-acetylcysteine (NAC) as a means to replete intracellular glutathione levels.³⁹ Despite its early promise, however, NAC has not been proven beneficial in the treatment of HIV disease. One randomized controlled trial failed to show any influence of NAC on T-cell counts or disease progression.⁴⁰ Despite the lack of evidence supporting its use, this supplement is commonly used.

Dosage

The dose of NAC is 600–1200 mg daily.

Precautions

Can cause GI adverse effects including nausea, abdominal pain, and irregular bowel movements.

I-Carnitine

I-Carnitine (ALCAR) may be helpful in mitigating some of the adverse effects of antiretroviral medications, including peripheral neuropathy and dyslipidemia. Acetylcarnitine acts to facilitate transport of essential fatty acids across cell membranes and thus may have a role in normalizing intracellular lipid metabolism and regulating peripheral nerve function and regeneration. Decreased levels of carnitine have been found in HIV-positive people; in addition, patients with AIDS experiencing neuropathy with zidovudine or didanosine therapy had significantly lower levels of acetylcarnitine than those with AIDS but without neuropathy.⁴¹ One open trial of oral acetyl-l-carnitine supplementation (1500 mg twice daily) for up to 33 months in 21 HIV-positive patients with established antiretroviral-induced neuropathy found an improvement in neuropathic grade in 76% of patients.⁴² HIV RNA load and CD4+ and CD8+ cell counts were not altered. An increased proliferation of peripheral blood mononuclear cells in vitro was noted after oral supplementation with l-carnitine; a significant decrease in triglyceride levels was also noted.⁴³

Dosage

Give 2000–3000 mg of l-carnitine orally daily for HIV-positive patients with peripheral neuropathy or high triglyceride levels.

Precautions

Can cause GI distress and body odor. Urine, breath, and sweat can have a fishy odor; further study of this supplement is needed to substantiate the possible benefits.

I-Glutamine

I-Glutamine supplementation has been shown in animal models to speed proliferation of colonocytes. Glutamine deficiency is also hypothesized to play a role in the process of HIV-associated wasting.⁴⁴ Many patients

taking PIs experience chronic diarrhea as a medication side effect. A randomized trial involving 35 HIV-positive men with PI-induced diarrhea found that when added to a regimen of fiber and probiotic supplementation, l-glutamine (30 g/day) significantly decreased the frequency of diarrhea and the need for antidiarrheal medications.⁴⁵ Anecdotally, many patients find glutamine to be helpful in mitigating this side effect even at lower and more easily administered doses.

Dosage

Give 2000 mg daily of l-glutamine in two or three divided doses, with the dose titrated upward as needed to 40 g daily.⁴⁶

Precautions

Patients with cirrhosis and seizure disorder should avoid glutamine as it can potentially worsen these conditions.

Calcium Carbonate

Several studies to date have shown that calcium carbonate supplementation can help reduce the frequency of PI-associated diarrhea.^{47,48} The dose typically used is 500 mg twice daily, although some clinicians report that a higher dose may be more effective. This treatment has no reported interactions or adverse effects.

Dosage

Usual dose of calcium carbonate is 500 mg twice daily.

Precautions

As we further elucidate the effect of calcium supplementation on cardiovascular risk, the decision to supplement should be made based on risks and benefits stratified to individual patients.⁴⁹

Omega-3 Polyunsaturated Fatty Acids

Patients under ART have a unique dyslipidemia (elevated triglycerides and nonhigh-density lipoprotein-cholesterol [non-HDL-C] and low HDL-

C) with insulin resistance (characterized by hypoadiponectinemia). Dyslipidemia along with other possible factors (inflammation related to the viral infection itself) are reported to increase risk of cardiovascular disease in PLWHA. One study randomized 51 patients in a placebo-controlled, double-blind trial to receive either two capsules of Lovaza fish oil twice daily or two capsules of placebo. After 12 weeks, the omega-3 group noted slightly decreased plasma triglycerides and induced antiinflammatory effects by increasing the formation of antiinflammatory leukotriene B5.⁵⁰ Fifty-four subjects with HIV and elevated serum triglycerides (higher than 150 mg/dL) were randomly assigned to a control group or an intervention group and given supplemental omega-3 fatty acids for 13 weeks. The investigators documented dramatically reduced serum triglycerides, decreased arachidonic acid in the phospholipid fraction, and reduced de novo lipogenesis associated with the metabolic syndrome in the intervention group.⁵¹

Dosage

Dose is 4 g/day of docosahexaenoic acid and eicosapentaenoic acid, the main essential fatty acids found in fish oil.

Precautions

High doses (more than 6 g) can increase free radical production and can have an antiplatelet effect.

Zinc

Adequate zinc is necessary for immune function, and zinc deficiency is estimated to occur in more than 50% of HIV-infected adults. A prospective, randomized controlled clinical trial involving 231 HIV-infected adults with low plasma zinc levels revealed that zinc supplementation for 18 months reduced the likelihood of immunological failure by four-fold while controlling for age, sex, food insecurity, baseline CD4+ cell count, viral load, and ART (relative rate, 0.24; 95% CI, 0.10–0.56).⁵²

Dosage

Doses generally suggested are 50–75 mg per day for men and 40–60 mg per day for women on zinc picolinate.

Precautions

High doses can inhibit the absorption of other minerals, most significantly copper. Zinc should be taken with meals to avoid nausea and vomiting.

Chromium

Chromium is an essential micronutrient, and its deficiency has been reported to cause insulin resistance, hyperglycemia, and hyperlipidemia. A randomized, double-blind, placebo-controlled trial enrolled 52 HIV-positive subjects with elevated glucose, lipids, or evidence of body fat redistribution who also had insulin resistance. Chromium was tolerated without side effects and resulted in a significant decrease in the following: Homeostatic Model Assessment-Insulin Resistance (HOMA-IR, an insulin resistance indicator) (median [interquartile range; IQR]; pre, 4.09 [3.02–8.79]; post, 3.66 [2.40–5.46]; $p = .004$); insulin (pre, 102 [85–226]; post, 99 [59–131] pmol/L; $p = .003$); triglycerides, total body fat mass (mean \pm standard error of mean [SEM]; pre, 17.3 \pm 1.7; post, 16.3 \pm 1.7 kg; $p = .002$), and trunk fat mass (pre, 23.8 \pm 1.9; post, 22.7 \pm 2.0%; $p = .008$).⁵³

Dosage

The dose is 400 mcg/day chromium-nicotinate.

Precautions

There are at least three reports of kidney damage in patients who took chromium picolinate.

K-PAX Immune Support Formula

In 2006, a double-blind, placebo-controlled, randomized clinical trial of 40 HIV-infected patients showed that a broad-spectrum micronutrient supplement could produce a statistically significant 24% increase in the mean CD4+ cell count of individuals taking stable HAART ($p = .01$).⁵⁴ The micronutrient supplement tested (K-PAX Immune Support Formula,

Mill Valley, California) included 33 ingredients and was consumed twice daily with food. The supplement is currently paid for by the New York AIDS Drug Assistance Program. For ingredients of the immune support formula used in the research, see [Table 19.2](#).

Dosage

Four capsules twice per day (for less than 120 lbs) or eight capsules twice per day (for more than 120 lbs)

Precautions

No significant adverse effects or interactions with K-Pax have been demonstrated to date.

TABLE 19.2

Immune Support Formula for HIV Infection Found in K-PAX Formulation

Micronutrient	Total Daily Dosage	Micronutrient	Total Daily Dosage
N-Acetylcysteine (NAC)	1200 mg	Calcium	800 mg
Acetyl l-carnitine	1000 mg	Magnesium	400 mg
α -Lipoic acid	400 mg	Selenium	200 mcg
β -Carotene	20,000 units	Iodine	150 mcg
Vitamin A	8000 units	Zinc	30 mg
Vitamin C	1800 mg	Copper	2.0 mg
Vitamin B ₁	60 mg	Boron	2.0 mg
Vitamin B ₂	60 mg	Potassium	99 mg
Pantothenic acid	60 mg	Iron	18 mg
Niacinamide	60 mg	Manganese	10 mg
Inositol	60 mg	Biotin	50 mcg
Vitamin B ₆	260 mg	Chromium	100 mcg
Vitamin B ₁₂	2.5 mg	Molybdenum	300 mcg
Vitamin D	400 units	Choline	60 mg
Vitamin E	800 units	Bioflavonoid complex	300 mg
Folic acid	800 mcg	l-Glutamine	100 mg
		Betaine HCL	150 mg

Botanicals

Chinese Herbal Approaches

In the traditional practice of Chinese medicine, herbal formulas are typically individualized to suit a given patient's condition, rather than standardized as a treatment for a given "disease." In the United States, however, the use of standardized formulas for certain conditions has become quite popular. Earlier, small randomized controlled trials of two such Chinese herbal formulae (Enhance and Clear Heat, formulated by Health Concerns in California) showed a trend (statistically

nonsignificant) toward fewer symptoms in the treatment group than in the placebo group.⁵⁵ However, a more recent, prospective, placebo-controlled, double-blind study of a different Chinese formula in 68 HIV-infected adults with CD4+ cell counts lower than $0.5 \times 10^9/L$ found no significant differences between the intervention and placebo groups regarding viral loads, CD4+ counts, symptoms, or quality of life scores. No significant therapy-related toxicities were reported, although patients taking Chinese herbs reported significantly higher gastrointestinal disturbances (79% vs 38%; $p = .003$) than those receiving placebo. The investigators concluded that this particular Chinese herbal formula was not effective when administered in a Western medicine setting.⁵⁶

A study of 18 volunteers evaluated the safety and efficacy of CKBM-A01, a Chinese herbal medicine (combination of herbs including wu wei zi [*Schisandrachinensis*], ginseng [*Panax ginseng*], hawthorn [*Fructus crataegi*], jujube [*Ziziphus jujube*], soybean [*Glycine max*], and *Saccharomyces cerevisiae* [baker's yeast]), and patients' quality of life. Although CKBM-A01 appeared to be safe, it provided no significant improvement in quality of life in asymptomatic HIV-infected patients and no significant improvement in the treatment of HIV infection based on CD4+ cell counts and viral loads.⁵⁷ Well-controlled, long-term follow-up studies of use of these Chinese herbal preparations are needed before Western practitioners can recommend them with confidence.

Precautions

Significant concerns remain regarding possible herb–drug interactions, given the large number of herbs in most Chinese formulae, especially in those patients concurrently taking conventional antiretroviral medications.

Milk Thistle

Elevation of liver function tests (LFTs) in patients taking ART is common, especially in those coinfecting with hepatitis C. Numerous in vitro studies have found that silymarin speeds the regeneration of hepatocytes after a chemical injury.⁵⁸ A significant improvement in liver function in patients with alcoholic hepatitis was noted after treatment with milk thistle extract.⁵⁹ At present, no firm evidence specifically links the hepatoprotective function of silymarin with liver damage from

antiretrovirals. However, clinical experience suggests that milk thistle may help normalize LFTs allowing patients to continue on an effective ART regimen. Contrary to a widely held popular belief among patients with HIV disease and many practitioners, milk thistle has no documented antiviral effect either in HIV disease or hepatitis C.

TABLE 19.3**Red Flags of Integrative Therapies (Think Twice Before Moving Forward)**

- You are discouraged from consulting others or information you bring to the visit is belittled
- Information about the therapy focuses on financial success or popularity rather than how it works
- Claims that a treatment can be used for a long list of illnesses without explanation of how results vary depending on how the conditions are related
- Rationale relies predominantly on testimonials
- Information is focused on comparisons with similar products, which have not been adequately studied
- Qualifications of practitioners/providers/promoters are not readily offered
- Information packets/handouts mix opinions and facts
- The treatment is unjustifiably expensive, and no clear explanations are given
- Available studies of the product have not been published or are published only in the newsletter/publication created by the manufacturer/seller

Dosage

The dose is 240 mg twice daily of standardized milk thistle (silymarin) extract.

Precautions

Silymarin is well tolerated. It can occasionally have a laxative effect.

Red Rice Yeast Extract

Hyperlipidemia is a common side effect of treatment with PIs. A standardized extract of Chinese red rice yeast can reduce cholesterol levels by up to 20% in certain patients. One randomized controlled trial showed a significant decrease in lipids with the use of this supplement, with no significant toxicity.⁶⁰ Red rice yeast has not been tested specifically in PI-related hyperlipidemia. No significant adverse effects have been reported to date in patients using this supplement (see [Chapter 27](#)).

Dosage

The dose is 1200 mg of red rice yeast orally twice daily.⁶¹

Precaution

Because this supplement can contain statin-like compounds, it is prudent to monitor liver function similarly for red rice yeast extract over the long term.

Herb–Supplement–Medication Interactions

An extremely active and important area of current research covers the questions of possible interactions among herbal medicines, supplements, and anti-HIV medications. In particular, herbs and supplements that induce elements of the cytochrome P-450 system have been found to potentially lead to lowered serum levels of PIs. For example, St. John's wort—an herb commonly recommended for depression—induces cytochrome P-450 activity and can lead to a decrease in indinavir levels of up to 57%; nevirapine levels can also be affected.⁶² Garlic, commonly used for elevated cholesterol levels, can have similar effects through increased cytochrome P-450 activity.

Databases are slowly becoming available that provide information regarding known herb–drug and supplement–drug interactions, and practitioners caring for patients taking antiretrovirals should regularly

consult these sites to provide informed counseling to patients regarding their concomitant use of herbs and supplements. One example of a free online search database is offered by Medscape:

<http://reference.medscape.com/drug-interactionchecker>.

People living with HIV / AIDS on protease inhibitors should use grapefruit juice with caution, if at all.

St. John's wort increases cytochrome P-450 activity and can reduce serum levels of medications metabolized by this system. It can decrease indinavir levels up to 57%.⁵⁴

Mind-Body Therapy

Research in psychoneuroimmunology has clearly linked psychological stress to impaired immune function. Although a specific link between T-cell count or function and stress reduction in HIV disease has not been clearly established, one study did find a trend toward increased T-cell count in subjects practicing a mind-body approach, and other studies found improvement in natural killer cell function and other immune parameters. Stress reduction approaches studied to date in HIV-positive patients include biofeedback, meditation, systematic relaxation, hypnosis, and cognitive-behavioral stress management training. A review of several mind-body applications from the literature follows.

Progressive Muscle Relaxation and Biofeedback

Ten HIV-positive men who were asymptomatic but had T-cell counts lower than 400 were enrolled in a randomized, 10-week study in which the experimental group received a 1-hour training session twice weekly in progressive muscle relaxation and biofeedback-assisted relaxation.⁶¹ The subjects were expected to practice the techniques daily. Follow-up at 1 month after the intervention was completed showed decreased anxiety and improved mood and self-esteem and increased T-cell counts, as shown by the State Anxiety Inventory, the Profile of Mood States, the Self-Esteem Inventory, and a basic T-cell count. The extremely small sample size limits the generalizability of these findings.

The differing effects of guided imagery, progressive muscle relaxation, and no intervention were tested on 69 participants in an uncontrolled study over a span of 6 weeks.⁶³ Subjects were instructed in their

particular intervention and then expected to continue daily practice for the duration of the study. The outcome showed improved quality of life scores for the guided imagery group but no change in the group practicing progressive muscle relaxation.

Mindfulness and Stress Reduction

Forty-eight HIV-1–infected adults were randomized to either an 8-week mindfulness-based stress reduction (MBSR) program or a 1-day control stress reduction education seminar. Findings provided an initial indication that mindfulness meditation training can buffer CD4+ T-lymphocyte declines in HIV-1–infected adults independent of antiretroviral medication use.⁶⁴

A small, nonrandomized study examined the effects of a structured, 8-week, MBSR program on perceived stress, mood, endocrine function, immunity, and functional health outcomes in HIV-positive adults. Although functional and quality of life outcomes were not significantly affected, natural killer cell activity and number significantly increased in the MBSR group compared with the comparison group.⁶⁵

Another study of stress management training focused on both CD4+ counts and quality of life measurements in 45 HIV-infected and AIDS patients (30 in the intervention group and 15 in the control group).⁶⁶ This study found a lower mean stress level and a trend toward higher CD4+ counts in the intervention group. The intervention led to immediate increases in emotional well-being and perceived quality of life, but these outcomes were not sustained at a 6-month follow-up. The presence of illness-related intrusive thinking was higher in the control group at follow-up, whereas that of the intervention group actually decreased.

Further studies are needed to distinguish whether any one of the mind-body approaches is more effective than others in patients with HIV disease. Generally, these strategies are considered extremely safe. The one exception to this general rule is that patients with a history of psychosis or unstable behavior should avoid hypnosis and undertake other deep relaxation approaches with caution because these practices may increase the risk of relapse in certain patients (see [Chapters 94](#) and [100](#)).

Spirituality

Spirituality is an important resource that individuals use to cope with HIV disease. A growing body of evidence is supporting its effect on

disease progression, more positive health behaviors, and quality of life.⁶⁷ An integrated perspective utilizing a spiritual assessment is prudent in assisting PLWHA in coping with the challenges of the disease (see [Chapter 114](#)).

Therapies to Consider

Acupuncture

Acupuncture has been widely used both to enhance immune function and general well-being in HIV-positive patients and to treat specific HIV- or medication-related symptoms. One randomized controlled trial that examined amitriptyline plus acupuncture found no benefit of standardized acupuncture over sham (placebo) acupuncture in the treatment of HIV disease-related peripheral neuropathy.⁶⁸

Methodological challenges in studying acupuncture make it difficult to demonstrate a small positive effect of an acupuncture intervention. Specifically, to construct a valid placebo intervention (i.e., sham acupuncture) that does not in itself carry a therapeutic benefit beyond that of placebo is difficult. In addition, individualized strategies both for specific symptoms and for overall health may have higher efficacy than that of standardized treatment protocols more amenable to study in such trials; however, these individualized strategies are extremely difficult to study in blinded trials. Thus, a trial such as this one examining standardized acupuncture treatment versus individualized choice of points may fail to show efficacy because of the lesser efficacy of the standardized approach.

Massage Therapy

Massage therapy has been shown to reduce anxiety levels. Massage therapy is proposed to have a positive impact on the quality of life and immune function through stress mediation. The ability of massage to produce significant effects in the treatment of PLWHA deserves further study. A randomized trial of massage therapy in HIV-exposed neonates showed a significant benefit; other evidence is all anecdotal.⁶⁹ Although massage therapy has not been proved to affect CD4+ levels per se, evidence showed that daily massage in HIV-positive men improved natural killer cell function and increased CD8+ cell counts.⁷⁰ A Cochrane Systematic Review examined the safety and effectiveness of massage therapy on quality of life, pain, and immune system parameters. The

investigators concluded that some evidence supports the use of massage therapy to improve quality of life among PLWHA, particularly in combination with other stress management modalities, and that massage therapy may have a positive effect on immunological function.⁷¹ The benefits in terms of mood and decreased anxiety and the lack of adverse effects make massage therapy a reasonable choice for the HIV-positive patient.

Hypnosis

Painful HIV distal sensory polyneuropathy (HIV-DSP) is the most common nervous system disorder in HIV patients. The symptoms adversely affect quality of life and often diminish capacity for independent self-care. To date, no interventions have been shown to be consistently effective in treating the disorder.⁶² Volunteers receiving three weekly brief hypnosis interventions were followed for a total of 17 weeks. At exit, 26 out of 36 (72%) had improved pain scores with mean pain reduction in those individuals being 44%. Improvement was found irrespective of whether or not participants were taking pain medications. There was also evidence for positive changes in affective state and quality of life.⁷²

Therapies to Know About

Medical Cannabis

A DEA Schedule 1 substance, medical cannabis cannot be prescribed in the United States; however, 28 states and the District of Columbia (more than 24.6 million Americans) permit, in varying degrees, use of cannabis with a licensed physician recommendation.⁷³ Medical cannabis as a treatment option is not widely accepted in the medical community, yet the best current evidence supports HIV neuropathy with three high-quality randomized controlled clinical trials establishing the pain relieving efficacy of cannabis.⁷⁴⁻⁷⁶ A calculated NNT of 3.6 for herbal cannabis in HIV neuropathy is beaten only by amitriptyline when compared to currently available modalities.⁷⁷ A 2007 article in the *New England Journal of Medicine (NEJM)* stated that “clinicians and patients who are comfortable with the concept of therapeutic cannabis use can explore its usefulness in ameliorating painful peripheral neuropathy, especially in situations in which other approaches have failed.”⁷⁸

Dosage

Start at 1–5 mg mixed major cannabinoids (THC and CBD) depending on patient history of previous cannabinoid use and titrate slowly to alleviate neuropathic pain while avoiding unwanted side effects (see the following).

Precautions

The most common side effects are sedation, dizziness, dry mouth, nausea, and disturbances in concentration. Medical cannabis used for chronic pain over one year appears to have a reasonable safety profile.⁷⁹ The only absolute contraindications are acute psychosis and other unstable psychiatric conditions. Cannabis use during pregnancy is not recommended. Drug interactions are a concern, with special attention paid to other therapies metabolized by CYP1A2, CYP3A4, and CYP2D6.⁸⁰ Smoking should be actively discouraged, and alternative routes of cannabis delivery—tincture, vaporized, sublingual, oral medication—should be used when appropriate on a case-by-case basis.

Dinitrochlorobenzene

Dinitrochlorobenzene (DNCB) is a chemical used to develop color photographs. Some HIV-positive individuals have used a very dilute solution to a small patch of skin to enhance the immune system function. Applying DNCB should produce redness, itching, and even blisters. If symptoms are too intense, the dosage is lowered, and if mild, the dosage is increased. DNCB is absorbed through the skin and has immunomodulatory effects, which may include the stabilization of CD4+ cell levels. A small Brazilian trial of 35 individuals not on ART using DNCB over an 18-month period experienced significant weight gain and increases in CD4+ when compared to control.⁸¹ A DNCB starter kit costs between \$25 and \$50 and is not regulated.

Dosage

DNCB is available as a liquid solution in four strengths: 10%, 2%, 0.2%, and 0.02%. The solution is applied on the skin once a week to a 2-inch square area. Then the area is bandaged and kept dry for 10 hours. After

the first skin response (a red, itchy rash), the strength of the DNCB solution is lowered

Precautions

There is very little research to support the benefits of DNCB, and there has been no recent research. No study on DNCB has started with more than 35 patients, and many patients dropped out of the studies. The first application of DNCB may produce a chemical “burn” in addition to the normal itchy rash. The rash occurs each time DNCB is applied and lasts for a few days. Some people have persistent scarring or rashes where they apply DNCB. It may also cause sensitivity to other chemicals.

Prevention Prescription

- Encourage routine HIV testing for all adults. CDC recommends that health care providers test everyone between the ages of 13 and 64 at least once as part of routine health care. Younger adolescents and older adults who are at increased risk should also be screened. They also recommend screening all pregnant women, including those who present in labor with unknown HIV status.
- Be aware and educate on the prompt treatment of HIV exposure with PEP. Make sure that your practice has a PEP protocol in place.
- Discuss PrEP for those at high risk:
http://www.cdc.gov/hiv/pdf/prevention_PrEP_factsheet.pdf.
- Behavioral risk reduction counseling is an important part of the management of HIV-infected patients. At each visit, review the patient’s understanding of HIV transmission and sexual/drug use activities.
- Inquire about tobacco use and encourage cessation.

Therapeutic Review

It is now recommended that all HIV-positive individuals start ART regardless of CD4 count to reduce the risk of disease progression and prevent transmission of HIV. This approach does not preclude the use

of integrative strategies as supportive adjuncts and to alleviate certain disease- or medication-related symptoms.

Pharmaceuticals

- Consultation with a physician familiar with the rapidly changing range of medication options is recommended for proper choice of pharmaceutical approaches. 

Nutrition

- Nutritional consultation early in the course of HIV infection should be recommended. 
- Adequate calorie consumption and an emphasis on whole foods, Mediterranean diet, and a high intake of omega-3 essential fatty acids are important elements. 
- Absorption issues should be considered as well.

Supplements

- Multivitamin daily, emphasizing vitamins B, C, D, and E and avoiding additional vitamin A or any other unnecessary vitamin supplementation. 
- ALCAR: 2000–3000 mg daily, especially in peripheral neuropathy or lipid disturbance. 
- l-Glutamine: 2000 mg daily, especially in chronic diarrhea or malabsorption syndromes. 
- Calcium carbonate supplementation: 500 mg twice daily for PI-induced diarrhea. 

Botanicals

- Milk thistle extract: 240 mg twice daily in patients with elevated values on LFTs or coinfection with hepatitis C. 
- Red rice yeast: 1200 mg twice daily for hyperlipidemia. 
- High level of awareness among practitioners regarding possible interactions between herbal medicine, especially cytochrome P-450

inducers, and antiretroviral medications. 

- Medical cannabis: 1–5 mg to start; titrate to alleviate neuropathic pain while avoiding side effects. 

Mind-Body Approaches

- Biofeedback, deep relaxation therapy, visualization, cognitive-behavioral stress reduction training, or other mind-body strategies.

- Strongly consider exploring a spiritual assessment.

CHAPTER 20

Herpes Simplex Virus

Maret Rossi, and Bradly Jacobs, MD, MPH, ABOIM

The herpesvirus family is a group of more than 100 double-stranded DNA viruses,¹ eight of which are known to commonly infect humans: herpes simplex 1 (primarily known as herpes labialis), herpes simplex 2 (primarily known as herpes genitalis), human herpesvirus type 3 (varicella-zoster virus), human herpesvirus type 4 (includes Epstein Barr virus), human herpesvirus type 5 (cytomegalovirus), human herpesvirus type 6 (includes roseolovirus), human herpesvirus type 7 (HHV-7), and human herpesvirus type 8 (includes Kaposi's sarcoma-associated virus).² Each form of the virus manifests in different ways, but all have a symptomatic active period followed by a latent or inactive period. The symptom-free latent period can last for months to years to even a lifetime, meaning symptoms may never reappear. In this chapter, we focus on herpes simplex virus as approximately 90% of individuals worldwide are reported to have antibodies against HSV-1, HSV-2, or both.³

Epidemiology

HSV-1 and HSV-2 can infect system of the body; however, generally HSV-1 targets the orolabial regions, while HSV-2 predominantly affects the anogenital region. Although the prevalence of HSV-1 has decreased in recent decades, there is an increased frequency of HSV-1 targeting the genital region, with HSV-1 the more prevalent form of the two. There are approximately 500,000 new primary HSV-1 infections annually in the U.S,⁴ and by the age of 20, approximately 50% of the American population will be infected.⁵

According to the Sexually Transmitted Diseases Surveillance report of the Centers for Disease Control and Prevention (CDC) for 2013, the

prevalence of HSV-2 among the US population decreased from 21% in the years 1988–1994 to 15% in the years 2007–2010.^{6,7} Of note, 87% of 14–49 year olds in the US never received a clinical diagnosis.⁸ Further, prior HSV-1 infection increases the likelihood of asymptomatic HSV-2 infection by three-fold. HSV-2 is a sexually transmitted disease, and its prevalence is positively correlated with sexual activity and inversely with socioeconomic status.⁹ African Americans are at a four-fold higher risk of HSV infection compared with Caucasians, with women at a two-fold higher risk compared with men.¹⁰

Clinical Manifestation

Although generally asymptomatic, HSV-1 infections typically manifest as oral and labial lesions and occasionally as facial lesions.¹¹ Initial areas frequently become erythematous and then develop into a cluster of fluid-filled blisters (vesicles) that eventually weep then crust over (one of the hallmarks of HSV infection).¹² Primary infections resulting in oral viral shedding can last 23 days (mean, 7–10 days), with neutralizing antibodies appearing on days 4–7. Children with symptomatic first infection may have a high fever (101 to 104°F), sore throat and mouth, malaise, tender cervical lymphadenopathy, and inability to eat.¹³ Recurrent oral-labial lesions occur in approximately 30% of individuals with serological evidence of HSV-1 herpes, with 40% of these individuals experiencing more than one recurrence annually. Initial symptoms prior to lesions manifest may include pain, tingling, and itching.¹⁴

In contrast, HSV-2 infections primarily appear in the anogenital region. HSV-2 infection manifests as macules and papules that form small blisters and may transform into painful ulcers that crust over prior to healing.¹⁵ The initial episode is typically the most severe and may last longer than subsequent outbreaks. Symptoms may include fever, malaise, headaches, dysuria, and tender inguinal lymph glands.¹⁶ Lesions and viral shedding may persist for 3 weeks in the initial episode. Recurrent outbreaks are typically less intense and last approximately 8 to 10 days, similar to that of herpes labialis.¹⁷ Individuals can typically expect to have 4–5 recurrent outbreaks within 1 year of the primary infection.¹⁸

As viral titers are 100 to 1000 times greater when visible herpes lesions are present, the rates of transmission via viral shedding increase when an individual is symptomatic. To infect an individual, herpes simplex virus

travels through microscopic breaks in oral or genital mucosal tissue and replicates within epithelial cells upon entry.¹⁹ After this active period, the virus is transported to sensory neurons in regional ganglia where it remains in a dormant phase until reactivation.²⁰ It is important to note that even when latent, herpes virus remains transmissible to others. Known triggers of herpes simplex include facial trauma, surgery, fever, and exposure to UV light, as discussed later in this chapter.²¹

There is no known cure for herpes simplex infections.²² The goal of treatment during acute episodes is to decrease the viral activity, and the goal during recurrent episodes is to prevent the return of an outbreak.

Herpesvirus shedding can be transmitted after the skin lesions have healed, but viral shedding is greatest when an individual is symptomatic. Condoms reduce transmission only by 30% since other skin areas are likely shedding the virus.

Integrative Therapy

Lifestyle

As herpes is highly contagious and sexually transmitted, patients should avoid sexual contact during an outbreak to prevent transmission of genital herpes and kissing to prevent oral herpes infection. Patients should wash hands frequently to reduce self-inoculation of the eyes and face. Should patients have sexual contact, they should be advised to use condoms. However, condom usage is reportedly associated with only a 30% reduction in transmission, most likely because lesions may be located in areas outside the region covered by the condom.²³

When considering triggers that increase viral shedding and/or incident outbreaks, patients should consider all factors that increase allostatic load and/or impair innate immune function, such as enhanced perceived stress, acute infections, excessive exercise, poor sleep quality, and poor nutrition. Other triggers include marked emotional stress, HIV infection, and immunosuppressive medications. In addition, triggers of HSV-1 reactivation include environmental trauma, such as wind exposure; ultraviolet light; and physical trauma, such as local injury to the face or lips.²⁴ Consequently, regular use of sun protection (hats, sunblock) and lip balm are important prevention strategies. See [Table](#)

[20.1](#) for a summary of potential triggers of Herpes simplex virus reactivation.

Nutrition

Lysine and Arginine

Lysine is an essential amino acid that is not naturally produced by the body. Many clinical trials have reported that lysine-rich diets and lysine supplements reduce the recurrence, severity, and healing period of herpes simplex virus infections. Conversely, arginine appears to be an antagonist of lysine. Griffith et al. demonstrated in an in vitro study that herpes simplex virus uses arginine for replication.²⁵ Miller et al. observed that lysine competes with arginine for intestinal absorption, transport to cells, and reabsorption at the renal tubule, and it degrades arginine by activating arginase.^{26,27} Therefore, it is recommended to avoid arginine-rich foods, such as nuts, grains, chocolate, and refined sugars, and increased intake of a lysine-rich diet of meat, fish, and dairy.²⁸ The arginine and lysine ratio of selected foods is presented below³⁰ (see [Table 20.2](#) for dietary considerations in herpes simplex virus infection).

TABLE 20.1

Potential Triggers of Incident Herpes Simplex Virus Reactivation

Acute infection
HIV infection
Immune suppressing medication
High perceived stress
Poor sleep quality
Poor nutrition
High emotional stress
Blunt trauma or burn to face, lip, mouth, or genital area
Excessive exposure to wind, sun, arid climate
Fever

Supplements

Lysine

One may consider supplementing a low-arginine diet with oral lysine. A double-blind, crossover clinical trial, randomly assigned 41 patients to receive lysine hydrochloride (624 mg or 1248 mg per day) or placebo for 24 weeks, and then the alternate treatment for an additional 24 weeks. All patients received a diet high in lysine and low in arginine. Patients in the high-dose group reported significantly fewer recurrences of herpes simplex virus in the lysine period than the placebo period, with lower dose of lysine showing no benefit.³¹ In a separate randomized, double-blind clinical trial, 114 patients with orofacial, genital herpes, or both received 1000 mg lysine hydrochloride or placebo three times a day for 6 months. Of the 52 who completed the trial, 74% in the lysine group reported the treatment to be effective or very effective compared with only 28% in the placebo group. The authors reported that lysine significantly reduced healing time, severity, and incident outbreak frequency.³² Overall, the effectiveness of maintaining a high lysine diet and taking supplemental lysine by mouth is supported by modest clinical evidence.

Dosage

1 g orally, three times daily

Precautions

May cause GI distress at high doses (>10 g daily). May modestly raise LDL cholesterol levels.

Vitamin C

Ascorbic acid (Vitamin C) has been studied since 1936 due to its success in boosting immune function and inactivating a wide range of viruses in vitro, including herpes.²⁶ In a small double-blind clinical trial 42 years later, patients with herpes simplex outbreaks were administered a protocol of 200 mg vitamin C and 200 mg water-soluble flavonoids (apparently from citrus) or a lactose placebo to be taken three times daily for 3 days. Symptom remission was 57% shorter in the active treatment group compared with placebo (4.2 vs. 9.7 days; $p < 0.01$).³⁴ Investigators

and biological plausibility suggest that treatment is most effective when initiated during the prodromal stage.

Dosage

Acute treatment 500 mg two times daily

Precautions

GI distress with single doses greater than 1000 mg

TABLE 20.2

Dietary Considerations in Herpes Simplex Virus Infection

Foods	Quantity of food	Ratio of Arginine to Lysine	Quantity of Lysine
Low Arginine to Lysine Ratio (Helpful foods)			
Yoghurt	1 cup	0.35	700 mg
Cheese	3 oz.	0.4	1650 mg
Milk, whole	1 cup	0.45	600 mg
Cheese, cheddar	3 oz.	0.49	1497 mg
Cheese, ricotta	½ cup	0.50	1600 mg
Avocado	1 medium	0.50	100 mg
Tuna (3 oz)	½ can	0.6	2400 mg
Halibut, baked	3 oz.	0.65	2083 mg
Salmon	3 oz.	0.65	2014 mg
Sardines, canned in oil	3 med.	0.65	814 mg
Chicken (baked light meat)	3 oz.	0.71	2232 mg
Pork	3 oz.	0.83	1586 mg

High Arginine to Lysine Ratio (Foods to avoid)			
Almonds	18 nuts	4.7	145 mg
Peanut	¼ cup	3.0	363 mg
Cashews	10 nuts	2.6	185 mg

Zinc

Zinc is a mineral that is essential in cellular processes such as immunity and protein folding.³⁵ Topical zinc has been considered as a treatment for reducing symptoms, preventing recurrence, and shortening duration of outbreaks of oral and genital herpes. In a 2013 controlled clinical trial, 100 patients with herpes genitalis were allocated to one of four groups: one group of ten people received placebo and the remainder were allocated to receiving one of three groups, each containing a different concentration of topical ZnSO₄ (1%, 2%, or 4%). Treatment was initiated on day 1, then administered every 5 days for 1 month, then every 10 days for 2 months, and finally every 15 days for 3 months for a total of a 6-month protocol. At the end of the study, 80% versus 33%, 20%, and 3% of patients (placebo administration vs. 1%, 2%, and 4% topical ZnSO₄ administration, respectively) experienced recurrent outbreaks over the study period. Out of the three concentrations, 4% ZnSO₄ proved most effective and was well-tolerated.³⁶

A trial of 200 patients with acute herpes simplex lesions applied a 0.25% zinc sulfate in a saturated solution of camphor water eight to ten times per day beginning within 24 hours of an outbreak. Investigators reported that lesions usually disappeared within 3–6 days, and the earlier treatment began the shorter the duration of symptoms.³⁷ A double-blind randomized trial assigned 46 patients with oral or facial herpes with symptoms of less than 24-hour duration to receive either zinc oxide-glycine cream or placebo. Treatment was applied every 2 hours for the lesser of 21 days or symptom resolution. Treatment was associated with a 23% reduction in symptom duration (5.0 vs. 6.5 days; $p < 0.02$) in addition to a statistically significant reduction in symptom severity.³⁸

There is moderate evidence to suggest that topical zinc formulations have utility in reducing the severity and duration of symptoms, and

potentially the recurrence frequency, of oral/facial herpes infection. The greatest evidence is for formulations containing zinc sulfate, and reasonable evidence exists for zinc oxide-glycine and zinc monoglycerolate. There is only limited evidence evaluating oral zinc supplementation. We therefore favor using topical formulations for oral herpes infection.

Dosage

0.25%–4% zinc sulfate topical cream applied at initial onset of symptoms (ideally), then every 5 days for 1 month, then every 10 days for 2 months, and finally every 15 days for 3 months; although this protocol was well tolerated in one study, lower concentrations (0.25% every 30–60 minutes until lesions disappear) have been found to be effective.

Precautions

Zinc sulfate solutions at higher concentrations (e.g., 4%) may cause pain, irritation, itching, and dryness.

Botanicals

Propolis

Propolis is a resin-like substance collected by bees from various plants, such as conifer and poplar trees.³⁹ It has antioxidant effects that boost the immune system, with evidence indicating it may aid in the recovery process of HSV-1 and -2 infection. In a randomized, single-blind, controlled multicenter study, 90 adults diagnosed with recurrent genital herpes (HSV-2) received a specific 3% propolis ointment (Herstat or Cold Sore FX), an acyclovir ointment, or a placebo. Ointments were applied to the affected area four times daily for 10 days. Investigators reported a statistically significant reduction in symptom severity and duration, as well as wound healing as determined by the study dermatologist, with propolis treatment. They further reported reductions in coexisting vaginal superinfections compared with both acyclovir and placebo groups.⁴⁰ In another study, the application of the same specific 3% propolis ointment (Herstat) to areas affected by HSV-1 infections five times daily at the start of symptoms reduced the symptom duration by

3–4 days and reduced pain.⁴¹

Dosage

3% propolis ointment applied four to five times daily for 10 days

Precautions

Do not use for patients with allergies to bee products.

Lemon Balm

The lemon-scented herb, lemon balm (*Melissa officinalis*), belongs to the mint family and has been used therapeutically for centuries.⁴² Due to its antiviral properties, lemon balm has been investigated as a method of treating herpes simplex virus. In a double-blind, randomized clinical trial, 66 patients with herpes labialis (HSV-1) applied a 1% topical ointment of lemon balm oil (70:1 extract) to the affected area four times daily starting with prodromal symptoms and continuing 2–3 days after lesions had healed. The results demonstrated that lemon balm oil ointment not only shortened the healing period (4.94 vs. 4.03 days) but also prevented infection spread and reduced burning, stabbing, and tingling symptoms.⁴³ An in vitro study investigated the phytochemical mechanism of *Melissa officinalis* and its antiviral effects on HSV-1 and HSV-2, finding that its inhibitory activity was due to lemon balm extracts inhibiting the virus prior to adsorption but not after penetration.⁴⁴ Therefore, it is recommended that lemon balm be applied as soon as one experiences prodromal symptoms in order to ensure the most effective and successful results. Finally, an in vitro study conducted in 2014 examined the effects of an aqueous extract of lemon balm and its phenolic compounds caffeic acid, p-coumaric acid, and rosmarinic acid on acyclovir-resistant strains of herpes simplex virus I. The study investigators reported lemon balm extract inhibited cell penetration of drug-sensitive and drug-resistant HSV strains by 80% and 96%, respectively.⁴⁵

Dosage

Apply a topical 1% ointment of lemon balm oil to the affected area four

to five times daily from the start of prodromal symptoms until 2–3 days after lesions have healed. The majority of previous studies used the product, Lomaherpan, which is a 1% dried lemon balm extract cream.

Sangre de Grado

Croton lecheri is a large tree that grows in the upper Amazon region of Colombia, Ecuador, and Peru; a dark red resin, where the name Sangre de Grado is derived, oozes from its bark.⁴⁶ Traditionally, Sangre de Grado has been used orally to treat diarrhea and promote gastrointestinal function. Recently, the powdered dry extract has been found to contain a novel proanthocyanidin called SP-303 that if applied topically may reduce genital and anogenital herpes lesions. A multicenter, double-blind, placebo-controlled clinical trial explored the efficaciousness and safety of Virend, a topical antiviral agent containing 15% SP-303, on recurrent genital herpes of AIDS patients. The trial reported that 41% of patients treated with Virend experienced complete healing of lesions versus 14% of patients in the placebo group ($p = 0.05$), with 50% of patients receiving active treatment compared with 19% of patients receiving placebo found to be culture negative ($p = 0.06$).⁴⁷

Dosage

15% SP-303 ointment applied three times daily for 21 days

Aloe Vera

Aloe vera (*Aloe barbadensis*) is a cactus-like plant that grows in hot, dry climates and has been used for its medicinal properties by many cultures for millennia. A systematic review by Vogler and Ernst reviewed two randomized, double-blind clinical trials by the same author who studied the efficacy of a topical formulation in treating genital herpes. They concluded that there is limited evidence supporting its use.⁴⁸ The first study randomized 120 patients to receive either aloe vera cream (aloe vera extract 0.5% in hydrophilic cream), aloe vera gel, or placebo three times daily for 5 days. The aloe vera cream was associated with a statistically significant reduction in healing time (4.8 days vs. 7.0 days and 14.0 days, respectively) and a higher number of cured patients (70% cured patients vs. 45% and 7.5%, respectively).⁴⁹ The second study

randomized men to aloe vera extract 0.5% in a hydrophilic cream or placebo. The results of this trial corroborated the results of the first trial in finding that the aloe vera cream group experienced significantly shorter healing times (4.9 days vs. 12 days, $p < 0.001$) and a higher number of cured patients (66.7% vs. 6.7%, $p < 0.001$) than those in the placebo group.⁵⁰

Dosage

0.5% aloe vera extract in hydrophilic cream applied three times daily for 5 days

Acupuncture

There is robust evidence regarding the benefits of acupuncture in reducing anxiety, perceived stress, insomnia, depression, pain, and improving overall well-being and quality of life. Each of these factors has been associated with triggering incident HSV outbreaks. Consequently, acupuncture should be considered as an adjuvant therapy that may reduce recurrent infection rates through intermediate pathways.

Mind-Body Therapies

In addition to physical discomfort, receiving a diagnosis of oral and particularly genital herpes can cause emotional, psychological, and psychosexual distress including depression, anger, guilt, and/or anxiety.⁵¹ In fact, the psychological component can become more disruptive to the patient's quality of life than the physical component.⁵²

Relaxation Training

In 1985, adults living in a senior home were taught progressive muscle relaxation three times weekly for 1 month compared with social support, and a reduction in HSV antibodies that persisted 1 month beyond the intervention was documented.⁵³

Hypnosis

In a pilot crossover study, 21 patients with genital HSV received 6 weeks of self-hypnosis using immune function imagery by listening to an

audiotape recording of a live session. The study reported a 40% reduction in recurrent episodes ($p = 0.05$), with patients experiencing improved mood and reduced depression and anxiety.⁵⁴

Other Mind-Body Interventions

In a study, 62 HIV-positive men coinfecting with genital herpes were randomly assigned in a ratio of 2:1 to either a 10-week cognitive behavioral stress management class or wait-list control. Investigators reported that HSV-2 IgG antibodies were significantly reduced within the treatment group and remained unchanged in control group.⁵⁵

There is a paucity of published literature on the effect of meditation, psychotherapy, and social support for people with recurrent HSV infection. Nonetheless, these therapies have been shown to improve quality of life and well-being, and as such will undoubtedly help people living with this condition.

Pharmaceuticals

There is no known curative therapy for HSC infection. Therefore, the mainstay of conventional treatment remains antiviral pharmaceutical medical therapy (acyclovir, famciclovir, valacyclovir) designed to inhibit DNA synthesis and viral replication.⁵⁶ Of note, many of the treatment guidelines for oral herpes have been extrapolated from genital herpes clinical research and guidelines.⁵⁷

Antiviral medications have been shown to significantly reduce the severity and duration of symptoms during primary infection, reduce recurrent outbreaks frequency when taken prophylactically, and are extremely well tolerated. In comparative studies, these medications have been shown to be noninferior in effectiveness. While acyclovir is considerably less expensive, valacyclovir is dosed less frequently and thus associated with greater patient adherence to treatment regimens.⁵⁸

Topical anesthetic agents, such as viscous ziladent, benzocaine, and lidocaine, are available for the management of painful oral lesions resulting from HSV-1 infection and have been shown to provide limited short-term relief. Topical antiviral medications (e.g., penciclovir, docosanol) for HSV-1 oral lesions have demonstrated modest benefit in improving symptom severity and duration.⁵⁹

Herpes simplex is an intracellular virus that responds best to oral

antiviral medications. Topical antivirals have only modest benefit.

Primary Uncomplicated HSV Infection

Dosage

The typical duration of treatment is 7–10 days. For maximal clinical benefit, treatment should commence within 72 hours of symptom onset. Any of the following medications can be prescribed, with factors for consideration including cost and dosing frequency.

Acyclovir: 200 mg five times daily or 400 mg three times daily

Famciclovir: 250 mg three times daily

Valacyclovir: 1000 mg twice daily

Precautions

Dosage adjustments for renal insufficiency.

Recurrent Uncomplicated HSV Infection

Treatment strategies depend on patient's quality of life (i.e., recurrence frequency and severity of symptoms) and risk of exposing an uninfected sexual partner as viral shedding may occur in the absence of symptoms. Treatment options include no treatment, episodic treatment (at onset of recurrence), and chronic suppressive therapy (typically 1-year treatment followed by observational period). No treatment and episodic treatment are typically reserved for individuals with infrequent recurrences of minimal symptom severity, and those with no risk of viral transmission to an unexposed partner. For individuals experiencing frequent outbreaks (arbitrarily defined in research studies as greater than six episodes annually) or at risk of viral transmission, chronic suppressive therapy has been shown to be highly effective in improving overall quality of life and reducing outbreak frequency, symptom duration, and severity when compared with episodic therapy. A study randomized 156 patients with recurrent genital HSV to 12 months of either acyclovir 400 mg twice daily, 200 mg five times daily for 5 days at onset of symptoms, or placebo. Chronic suppressive therapy increased the number of days before recurrent outbreak and reduced symptom duration to 250 days and 0.32 days per month, respectively, compared to 28 days and 4.18 days per month with episodic treatment and 23 days and 4.72 days with

placebo, respectively.⁶⁰

Health professionals should discontinue chronic suppressive antiviral therapy once a year to determine whether continuation is necessary. To optimize the effectiveness of episodic therapy, it is important that patients maintain medication supply on-hand so that treatment can commence within 24 hours of the onset of prodromal symptoms (paresthesia, tingling, pain, redness).

Dosage

Chronic suppressive therapy. A 12-month treatment course of any of the following:

- Acyclovir (400 mg twice daily)
- Famciclovir (250 mg twice daily)
- Valacyclovir (500 or 1000 mg once daily)

Episodic therapy. To increase effectiveness, commence treatment within 24 hours of prodromal symptoms (pain, tingling, paresthesia). Oral herpes treatments differ from genital herpes and are therefore distinguished below. Treatment options include any of the following:

- Acyclovir:
 - Oral herpes: 200 mg or 400 mg five times daily for 5 days
 - Genital herpes: 800 mg three times daily for 2 days; 800 mg twice daily for 5 days; or 400 mg three times daily for 5 days
- Famciclovir:
 - Oral herpes: 750 mg twice daily for 1 day; or 1500 mg as a single dose
 - Genital herpes: 1000 mg twice daily for 1 day; or 500 mg once, then 250 mg twice daily for 2 days
- Valacyclovir:
 - Oral herpes: 2 g twice daily for 1 day
 - Genital herpes: 500 mg twice daily for 3 days or 1000 mg once daily for 5 days

Precautions

Dosage adjustments for renal insufficiency

Therapies to Consider

Black Tea Extract

Black tea, derived from the leaves of the *Camellia sinensis* plant, is rich in theaflavins. Two studies have examined the effect of black tea extract on HSV-1 in vitro. The results of the first found that a concentration of 75 μM was not toxic to cultured cells and yet exhibited potent dose-dependent anti-HSV-1 effects, inhibiting > 99% of viral production.⁶¹ The other observed that black tea extract at concentrations of 0.14 μM reduced HSV-1 virions in human cells by interfering with the attachment, penetration, and DNA replication of HSV-1.⁶² This preliminary evidence is intriguing and supports further research in humans. Given the overall health benefits of black tea, people with HSV may consider drinking black tea daily and observe whether they experience any benefits against herpes virus symptoms.

Rhubarb and Sage

In a double-blind, comparative, randomized trial, 145 patients diagnosed with herpes labialis received rhubarb-sage cream, sage cream, or Zovirax cream (topical formulation of acyclovir). Healing period was 6.7 days in the rhubarb-sage cream group, 7.6 days in the sage cream group, and 6.5 days in the Zovirax cream group.⁶³ Further studies are required to determine the utility of rhubarb and sage together as a topical treatment for herpes simplex virus infection.

Prevention Prescription

Incident Infection Prevention

- Engage in honest dialogue with potential sexual partners regarding HSV status
- Avoid sexual contact during times of excess stress or when other triggers exist that increase the quantity of viral shedding
- Use a condom during sexual encounters to reduce risk of viral transmission

Reduce Recurrent Outbreaks

- Avoid trauma to skin (excessive sunlight and wind, physical trauma)

- Maintain good sleep quality
- Manage perceived and objective stress levels
- Evaluate whether a high lysine and low arginine diet alters outbreak frequency
- Consider daily use of Lysine supplementation, 1000 mg three times daily
- Consider chronic suppressive antiviral pharmaceutical therapy if outbreaks are frequent or quality of life is affected.
 - Acyclovir (400 mg twice daily)
 - Famciclovir (250 mg twice daily)
 - Valacyclovir (500 or 1000 mg once daily)

Elderberry

Hippocrates called the elder tree his “medicine chest” back in 400 CE. In recent years, preliminary evidence indicates favorable antimicrobial and antiviral effects of elderberry. In a 2005 interview Madeleine Mumcuoglu, MD, an Israeli virologist, explained her findings of elderberry neutralizing the activity of hemagglutinin spikes on the surface of the herpesvirus: “When these hemagglutinin spikes are deactivated, the viruses can no longer pierce cell walls or enter the cell and replicate.”⁶⁴ A 2011 study reported that the flavonoids in a standardized elderberry extract (*Sambucus nigra L.*) bound to several bacteria and viruses in vitro.⁶⁵ Elderberry has become a common recommendation for cold and flu relief; however, its effect on herpes simplex virus 1 and 2 has not yet to be elucidated. However, there are anecdotal reports of patients claiming benefit in reducing the duration and severity of herpes genitalis symptoms.

Therapeutic Review

Herpes

Acute Treatment

- Supplements
 - Lysine: 1 g, three times daily 
 - Vitamin C: 500 mg two times daily for 3 days 

- Zinc sulfate. Topical solution 0.0025%–0.25% applied at initial onset of symptoms (ideally) 
 - Apply every 30–60 minutes until lesions disappear—OR—
 - Every 5 days for 1 month, then after every 10 days for 2 months, and finally every 15 days for 3 months
- Botanicals
 - For oral and genital
 - Propolis 3% topical ointment: four times daily for 10 days 
 - For oral
 - Lemon Balm oil 1% topical ointment or cream (70:1 extract) 
 - Apply to affected area four times daily until 3 days after lesions healed.
 - For genital
 - Propolis 3% topical ointment: four times daily for 10 days 
 - Sangre De Grado: 15% SP-303 ointment applied three times daily for 21 days 
 - Aloe vera 0.5% extract in hydrophilic cream: three times daily for 5 days 
- Acupuncture to improve sleep, perceived stress, and anxiety 
 - Once weekly, typically 20–45 minutes per treatment, individualized treatment protocol encouraged.
- Mind-Body Therapies
 - Self-hypnosis once weekly 
 - Progressive muscle relaxation training program 
 - Cognitive behavioral therapy training 
 - Other—meditation, psychotherapy 
- Pharmaceutical
 - Primary infection: Ideally start within 72 hours of symptom onset. Treat for 7–10 days. Choose from following based on dosing and cost: 
 - Acyclovir: 200 mg five times daily or 400 mg three times daily
 - Famciclovir: 250 mg three times daily

- Valacyclovir: 1000 mg twice daily
- Episodic therapy for oral: Prescribe medication for on-demand use. Commence treatment within 24 hours of onset prodromal symptoms (pain, tingling, paresthesia). 
- Acyclovir: 200 mg or 400 mg five times daily for 5 days
- Famciclovir: 750 mg twice daily for 1 day; or 1500 mg as a single dose
- Valacyclovir: 2 g twice daily for 1 day
- Episodic therapy for genital: Treatment options include any of the following: 
- Acyclovir: 800 mg three times daily for 2 days; 800 mg twice daily for 5 days; or 400 mg three times daily for 5 days
- Famciclovir: 1000 mg twice daily for 1 day; or 500 mg once, then 250 mg twice daily for 2 days
- Valacyclovir: 500 mg twice daily for 3 days or 1000 mg once daily for 5 days

CHAPTER 21

Chronic Hepatitis

Tina M. St. John, MD

Pathophysiology

Characterized by hepatonecrosis and inflammatory cell infiltration, hepatitis is most commonly caused by viral and toxic agents. Deemed chronic when persisting for longer than 6 months, hepatitis triggers an ongoing inflammation that often leads to fibrosis and eventually cirrhosis, with a concomitant increased risk of hepatocellular carcinoma.

Chronic hepatitis may develop due to a variety of etiologies, either in isolation or combination ([Table 21.1](#)). The majority of individuals develop chronic hepatitis without a recent recognizable acute clinical illness or obvious symptoms. The condition is typically insidious and slowly progressive, declaring itself clinically only after cirrhosis develops with accompanying signs and symptoms.

Hepatitis C is the most common cause of chronic viral hepatitis in the United States, accounting for approximately 75% of all cases.^{1,2} Given its high prevalence and clinical implications, chronic hepatitis C (CHC) is the focus of this section. Integrative treatments aimed at controlling chronic hepatic inflammation and its sequelae underlying the pathogenesis of CHC are applicable to other liver conditions that share a similar pathophysiology.

The hepatitis C virus (HCV) is hepatotropic but minimally cytopathic. The detrimental effects of chronic infection arise predominantly from ongoing inflammation, which causes marked oxidative stress. In the presence of ongoing hepatonecrosis, connective tissue is laid down as the body attempts repair. Accumulation of extracellular connective tissue leads to fibrosis, which progresses predictably ([Table 21.2](#)). Cirrhosis is the final stage of the fibrotic process, characterized by diffuse hepatocyte damage, nodular regeneration, and aberrant architecture accompanied

by impaired hepatocyte function and impeded portal blood flow. The histological hallmarks of chronic hepatitis are hepatic necrosis, mononuclear infiltration, and fibrosis, which serves as the primary indicator of hepatic injury. Fibrosis and cirrhosis are assessed directly with liver biopsy or indirectly with noninvasive testing, including transient elastography and blood markers, such as platelet count, hyaluronic acid, procollagen type 3 N-terminal peptide, and tissue inhibitor of matrix metalloproteinase-1.³

Chronic inflammation due to *hepatitis infection* results in free radical production, *fibrosis*, *cirrhosis*, and hepatocellular carcinoma.

Advanced fibrosis and cirrhosis are associated with increased risk of hepatocellular carcinoma (HCC). CHC is the leading cause of HCC in the United States, with a 2% to 8% incidence per year among individuals with HCV-related cirrhosis.⁴ Liver cancer incidence in the United States tripled between 1975 and 2005 before stabilizing from 2007 through 2010.^{5,6} Although the 1-year, cause-specific survival for HCC has increased from 25% in 1992 to 47% in 2004,⁵ overall 3-year survival remains at approximately 17%.⁷

With the recent introduction of direct-acting antivirals (DAAs), curative-intent treatment is recommended for all adults with CHC.⁸ Fibrotic stage, however, is a primary consideration in determining the relative urgency of antiviral treatment. Approximately 5% to 20% of individuals with CHC develop cirrhosis over 20 to 30 years.⁹⁻¹¹ The results of prospective observational studies and outcome modeling projections indicate the risk of CHC disease progression to severe fibrosis or cirrhosis is minimal at 10 to 15 years in individuals with persistently normal alanine aminotransferase (ALT) levels, but greater than 30% to 40% in those with elevated serum ALT levels and portal fibrosis.^{9,12} Because clinical findings and liver enzyme levels do not predictably correlate with hepatic histological features, cirrhosis cannot be ruled out based on clinical and laboratory assessments alone.^{13,14} Nonhistological factors associated with accelerated CHC progression are shown in [Table 21.3](#). Viral load is notably absent as it has not been found to correlate with disease progression.

Reducing Free Radicals

The primary care provider has an important role in promoting constitutional, hepatic, and immunological health and wellness. Factors that potentially influence CHC disease progression and may be affected by integrative interventions fall into two primary arenas: oxidative stress and immunological function.²¹⁻³⁰ Chronic inflammation leads to an overabundance of oxygen-derived free radicals. The influence of free radicals in a given inflammatory reaction depends on the balance between the production and inactivation of these reactive metabolites. To the extent that one can influence the balance favorably toward decreased oxidative stress, one can potentially limit or reduce damage caused by an overabundance of free radicals.

Enhancing Liver Detoxification

As the interface between the digestive tract and the rest of the body, the liver orchestrates metabolic homeostasis and detoxifies endogenous waste products and pollutant xenobiotics. A two-phase detoxification process neutralizes and eliminates these chemicals. For optimal function, the phases of detoxification must be balanced and supported by adequate dietary intake to provide the necessary system elements. Phase I of the detoxification pathway is chemical neutralization, predominantly mediated by the cytochrome P-450 system. This system of heme-derived enzymes catalyzes redox reactions for a wide variety of endogenous and exogenous substrates. Enzymatic P-450 neutralization yields free radicals that can damage hepatocytes. These oxygen-derived chemicals are removed by hepatic antioxidants. One of the most important of these is glutathione, which is also used in phase II of the detoxification process. High levels of toxin exposure can deplete hepatic glutathione and hamper both phases of the detoxification process.

TABLE 21.1
Common Etiologies of Chronic Hepatitis

Etiological Category	Specifics
Hepatitis viruses	Hepatitis C Hepatitis B (+/- hepatitis D)
Toxins and medications	Ethanol Methyldopa Isoniazid Nitrofurantoin Amiodarone
Acquired metabolic disorders	Nonalcoholic steatohepatitis

Autoimmune disease	Autoimmune hepatitis
Inborn metabolic disorders	Wilson's disease Hemochromatosis Alpha ₁ -antitrypsin deficiency
Biliary diseases	Primary and secondary biliary cirrhosis Primary sclerosing cholangitis Biliary tree anomalies
Cryptogenic	—

TABLE 21.2
Stages of Liver Fibrosis

Stage Characteristics	
0	No fibrosis
1	Confined to enlarged portal zones
2	Periportal or portal-portal septa with intact architecture
3	Architectural distortion (septal fibrosis, bridging) without obvious cirrhosis
4	Probable or definite cirrhosis

Phase II of the detoxification process is elimination, which typically involves a conjugation reaction that renders the toxin water-soluble, thereby facilitating excretion through bile or urine. The six pathways of phase II detoxification are glutathione conjugation, amino acid conjugation, methylation, sulfation, acetylation, and glucuronidation.³¹ Many experts consider glutathione conjugation the most important of these pathways. [Table 21.4](#) provides a list of substances required for phase II detoxification (see [Chapter 106](#)).

TABLE 21.3
Nonhistological Factors Associated with Accelerated Fibrosis Progression Among People with Chronic Hepatitis C^{8,15-20}

- Genotypic male
- Age > 40 years at the time of initial infection
- Heavy alcohol use
- Daily marijuana use
- Obesity and/or insulin resistance
- Genotype 3 infection
- Coinfection with HIV and/or HBV
- Organ Transplant

HBV, hepatitis B virus; HIV, human immunodeficiency virus.

TABLE 21.4
Substances That Support Phase II Detoxification^{31,32}

Detoxification Pathway	Required Nutrients
Glutathione conjugation	Dietary glutathione Vitamins B ₂ , B ₆ , and C N-acetylcysteine Glycine, cysteine, glutamine, and methionine Zinc, copper, manganese, and selenium
Amino acid conjugation	Glycine, taurine, glutamine, arginine, and ornithine Magnesium
Methylation	S-adenosylmethionine Vitamin B ₁₂ and folic acid Choline Molybdenum
Sulfation	Sulfur-rich foods B vitamins Taurine, methionine, cysteine, and glutathione Zinc, copper, manganese, selenium, and molybdenum
Acetylation	Vitamins B ₁ , B ₂ , B ₅ , and C Acetyl coenzyme A
Glucuronidation	Glucuronic acid and glutamine Magnesium Vitamins B ₃ and B ₆

Integrative Therapy

The choice of therapeutic modalities used in an integrative approach to CHC management depends on numerous factors, including the patient's liver status, goals, and comorbidities. Regardless of the modalities chosen, the fundamental goals of integrative CHC management are as follows: decrease hepatic inflammation to limit disease progression; support and enhance hepatic detoxification capacity; support healthy immune function; decrease the risk of cirrhosis, hepatocellular carcinoma, and extrahepatic complications; and support and enhance quality of life.

Pharmaceuticals

Guidelines from the American Association for the Study of Liver Diseases and the Infectious Diseases Society of America in collaboration with the International Antiviral Society–USA (AASLD/IDSA/IAS–USA) state that, “[Antiviral] treatment is recommended for all patients with chronic HCV infection, except those with short life expectancies that cannot be remediated by treating HCV, by transplantation, or by other directed therapy.”⁸ The benefits of virological cure include reduced hepatic inflammation and morbidity; potential improvement in hepatic fibrosis; reduced risk of HCC and liver-related mortality; and partial or complete remission of extrahepatic manifestations of CHC.³³⁻³⁷

Pharmacological treatment of CHC has evolved rapidly since 2011. Direct-acting antiviral therapy has replaced the previous standard treatment regime of peginterferon plus ribavirin.⁸ Compared to peginterferon plus ribavirin, newer interferon-free DAA regimens are better tolerated with fewer contraindications, require a shorter duration of treatment, and are markedly more effective at inducing sustained viral response (SVR). Clinical trial data indicate that DAA-based CHC treatment leads to an SVR in 80% to 100% of patients.³⁸⁻⁴⁵ The drawbacks of DAA therapy include affordability and drug interactions.⁴⁶⁻⁴⁸

The introduction of direct-acting antiviral therapy has revolutionized the treatment of HCV. Although costly compared to previous regimes, DAA therapy requires a shorter duration, has fewer side effects, and is effective in 80%–100% of patients.

The decision to initiate therapy is based on the following considerations: patient’s personal preferences, liver status, and comorbidities; the likelihood of disease progression; and potential risks and benefits. It is recommended that all people with CHC—treatment-naïve or experienced, including those with compensated or decompensated cirrhosis—should be considered for antiviral therapy. There is differential priority and urgency, however, based primarily on the relative risk of complications and likelihood of HCV transmission to others. Individuals at the greatest risk of complications are considered highest priority for treatment as they are likely to derive the greatest benefit from virological cure ([Table 21.5](#)).

Risk factors can be used to predict the likely natural history of CHC. The clinical course in a given individual, however, is inherently unpredictable. The decision to initiate antiviral treatment and the timing

of such therapy must be individualized. For patients with minimal fibrosis who are asymptomatic, opting to defer curative-intent therapy for a short period is unlikely to represent a major health risk. Supportive management and regular follow-up are the cornerstones of care for all individuals with CHC, regardless of their treatment decisions.

Direct-Acting HCV Antivirals

In the United States, DAAs are the mainstay of recommended first-line CHC treatment. DAAs are used in combination to reduce the likelihood of treatment failure due to preexisting or evolving antiviral resistance.⁴⁹ Ribavirin may be added to combination DAA therapy in some situations for the same reason.⁵⁰ The specific antiviral regimen and duration of treatment for a given patient depends on HCV genotype and subtype, past treatment experience, presence of cirrhosis (with or without decompensation), comorbidities (e.g., HIV, renal disease), and the presence of genetic viral variations that could influence treatment response.^{8,38,51}

TABLE 21.5

Clinical Factors That Increase Priority for Antiviral Hepatitis C Treatment^{8,38,51}

Advanced fibrosis or compensated cirrhosis
Liver transplant candidate or recipient
Coexisting liver disease (e.g., hepatitis B, NASH)
HIV coinfection
Severe or debilitating extrahepatic manifestations
Type 2 diabetes mellitus

—————

HIV, human immunodeficiency virus; NASH, nonalcoholic steatohepatitis.

Since the first HCV DAAs were approved by the U.S. Food and Drug Administration in 2011, additional agents continue to be introduced at a rapid pace. Currently, FDA-approved DAAs for combination treatment

of CHC include protease inhibitors (simeprevir, paritaprevir, and grazoprevir); polymerase inhibitors (sofosbuvir and dasabuvir); and NS5A inhibitors (ledipasvir, ombitasvir, daclatasvir, velapatasvir, and elbasvir). Protease inhibitor ritonavir lacks anti-HCV activity but is used to boost levels of some HCV DAAs by inhibition of CYP3A4 enzymes. The swiftly changing pharmacological landscape in CHC is driving a concomitant flux in treatment recommendations. [Table 21.6](#) summarizes current AASLD/IDSA/IAS–USA recommended and alternative therapies for HCV genotype 1, 2, and 3 infections, which account for 98% of cases of CHC in the U.S.⁵²

Dosage

See [Table 21.6](#).

Precautions

The side effect profile of HCV DAAs is markedly better than peginterferon plus ribavirin. A number of clinically relevant drug interactions, however, warrant scrupulous attention. Interference or enhancement of drug absorption, metabolism, or elimination may affect bioavailability, potentially leading to toxicity or subtherapeutic drug levels. Prescription and over-the-counter medications as well as certain herbs are known to interfere with specific DAAs. Medications and drug classes of particular concern include antiretrovirals, immunosuppressants, proton pump inhibitors, anticonvulsants, statins, phosphodiesterase inhibitors, calcium channel blockers, benzodiazepines, ethinyl estradiol, amiodarone, gemfibrozil, rifampin, azole antifungals, St. John’s wort, and milk thistle.^{38,46,53} As research examining specific DAA and herb or supplement interactions is often lacking, many experts recommend avoiding all such therapeutics during antiviral treatment. As specific interactions vary among the DAAs, it is critical to crosscheck all medications, herbs, and supplements taken against the prescribing information to minimize the risk of drug-related complications during treatment.

TABLE 21.6

AASLD/IDSA/IAS–USA Recommended and Alternative Direct-Acting

Antiviral Regimens for Chronic Hepatitis C due to Genotypes 1, 2, and 3⁸

Genotype		Cirrhosis [‡]	RAV Consideration [†]	Antiviral Regimen Recommendation (R) or Alternative (A) [‡]	Duration (weeks)
Initial Treatment					
1a, 1b	+ or -		Elbasvir RAVs absent (relevant for 1a only)	R: daily fixed-dose sofosbuvir (400 mg)/velparicvir (100 mg)	12
1a	+ or -		Elbasvir RAV present	A: daily fixed-dose sofosbuvir (50 mg)/velparicvir (100 mg) plus weight-based ribavirin [‡]	16

‡ Cirrhosis refers to compensated cirrhosis unless otherwise noted.

† Resistance-associated variants (RAVs) represent HCV genetic variations that can adversely affect treatment response with certain DAA regimens. Pretreatment testing is recommended before using these regimens.

‡ Recommended regimens are favored for most patients in a given subgroup, based on optimal efficacy, favorable tolerability and toxicity profiles, and duration. Alternative regimens are those that are effective but have, relative to recommended regimens, potential disadvantages, limitations for use in certain patient populations, or less supporting data than recommended regimens. For some groups, data are insufficient to recommend a specific regimen; alternatives

are considered equivalent.

§ Weight-based ribavirin: 1000 mg daily if <75 kg or 1200 mg daily if >75 kg in two divided doses.

¶ Daclatasvir dose may need to be adjusted if used with cytochrome P450 3A/4 inducers or inhibitors.

Ribavirin

Ribavirin is a guanosine analog with in vitro and in vivo activity against a variety of viruses. Although it has little in vivo effect against HCV in isolation, adding ribavirin to DAA therapy reduces the risk of developing antiviral resistance during treatment, thereby leading to improved therapeutic response.^{54,55}

Dosage

See [Table 21.6](#).

Precautions

Ribavirin is associated with two serious adverse effects; hemolytic anemia and birth defects. Monitoring hemoglobin and hematocrit throughout therapy is essential, as is scrupulous use of reliable birth control during and for 6 months after the completion of treatment.^{54,55}

Treatment Response

HCV viral load determines virological response. Quantitative HCV RNA testing within the 12 weeks before initiating DAA-based therapy, at week 4 of treatment, and 12 weeks after completion of antiviral therapy is recommended. The majority of individuals have undetectable HCV RNA at week 4 of DAA therapy; however, treatment response may be delayed in those with cirrhosis. In such cases, repeat testing at week 6 is recommended. While evidence-based guidelines for the cessation of DAA-based HCV treatment have not been established, AASLD/IDSA/IAS–USA recommends discontinuing treatment if there is a 10-fold or greater increase in HCV RNA levels from baseline at week 6 of treatment.⁸

Hepatitis A and B Vaccination

Patients with documented CHC not previously immunized and without

serological evidence of immunity should be vaccinated against hepatitis viruses A and B. Superinfection in a patient with CHC may cause acute fulminant disease. In the absence of an acute fulminant episode, new infection superimposed on preexisting chronic liver disease may accelerate disease progression and negatively affect prognosis.

Supplements

Glutathione

The potent antioxidant glutathione serves numerous crucial functions, including detoxification and cytotoxic T lymphocyte (CTL) activation.⁵⁶ Glutathione is predominantly produced intracellularly in the liver from cysteine, glutamate, and glycine. Glutathione levels are frequently below normal levels in patients with CHC.⁵⁷⁻⁵⁹ One study found that CHC patients with the lowest glutathione levels had the highest viral loads and greater degrees of liver damage compared to patients with the highest glutathione levels.⁵⁹

Absorption of intact oral glutathione is limited as it is hydrolyzed by intestinal gamma-glutamyl transferase.

Optimal glutathione levels are achieved by consuming a diet rich in foods with high levels of sulfur-containing amino acids (e.g., asparagus, avocados, broccoli, spinach, garlic, and unprocessed meats) and may be enhanced by supplements that promote glutathione production, such as vitamins C and E, N-acetylcysteine (NAC), selenium, and silymarin.

Vitamin C

Vitamin C is a powerful antioxidant and antiinflammatory, functions that may help limit chronic inflammation and oxidative stress associated with CHC. A study published in 2008 noted an inverse relationship between plasma vitamin C and aspartate aminotransferase (AST) levels among patients with CHC.⁶⁰ Vitamin C also has immunomodulatory and anticarcinogenic functions, and has been found to preserve intracellular reduced glutathione concentrations and improve overall antioxidant capacity.^{61,62}

Dosage

The typical vitamin C dosage is 200 mg to 250 mg twice daily, although recommendations vary widely. The tolerable upper intake limit (UL) is 2000 mg/day.⁶³

Precautions

Vitamin C modulates iron absorption and transport. High doses should be avoided in patients with hemochromatosis or other conditions with the potential for iron overload. High-dose vitamin C is contraindicated in patients with a history of kidney stones or renal insufficiency. Excessive doses may result in bloating and/or diarrhea.

Vitamin E

Vitamin E is a fat-soluble antioxidant that supports optimal glutathione levels. Research data on vitamin E in the setting of chronic hepatitis are mixed. Two small studies of CHC patients found vitamin E supplementation led to reduced ALT levels in roughly one-half of study participants.^{64,65} However, another study in which CHC patients took supplemental vitamin E, selenium, and vitamin C daily found no effect on ALT, HCV viral load, or oxidative markers after 6 months of treatment.⁶⁶ Some studies have indicated that vitamin E may have a role in interrupting the fibrotic process.^{67,68}

Dosage

The typical dose is 400 IU/day of d-alpha tocopherol.

Precautions

High-dose vitamin E may potentiate the effects of antithrombotic drugs and some herbs (e.g., garlic and ginkgo). Patients with vitamin K deficiency should avoid high-dose vitamin E. The UL for vitamin E is 1500 IU/day.⁶³

Selenium

The essential nutrient selenium exerts potent antioxidant activity via its roles in the formation and function of selenium-dependent glutathione

peroxidases. Selenoproteins serve as important regulators of tissue redox status, inflammation, and immune responses. Selenium deficiency has been linked to innate, humoral, and cell-mediated immunosuppression.⁶⁹ Significantly reduced selenium levels have been found among patients with CHC, with greater deficiencies observed in cirrhotics compared to those with lesser fibrosis.⁷⁰⁻⁷³ Thus there is at least a theoretical role for supplemental selenium in limiting CHC-related disease progression, although efficacy has yet to be proven. Similarly, the potential role of selenium in HCC prevention among patients with chronic viral hepatitis remains uncertain. A large Taiwanese study conducted in the late 1980s and early 1990s examining selenium levels in 7342 men with chronic hepatitis B or C and development of HCC found selenium levels were lowest in men with CHC. Participants with the highest selenium levels were 38% less likely to develop HCC compared to participants with the lowest selenium levels.⁷⁴ Another large-scale, contemporaneous Chinese study found a similar protective effect among patients with chronic hepatitis B infection.⁷⁵ Subsequent studies, however, have failed to definitively demonstrate a chemoprotective effect associated with selenium supplementation and HCC risk.^{76,77}

Dosage

The typical selenium dose is 200 mcg/day in the form of high-selenium yeast or L-selenomethionine.

Precautions

The UL for selenium is 400 mcg/day,⁶³ although adverse reactions are uncommon at doses less than 900 mcg/day.⁷⁸ Symptoms associated with selenium toxicity include hair and nail brittleness and loss, rash, fatigue, irritability, nausea, vomiting, and diarrhea.⁷⁹

S-Adenosylmethionine

S-adenosylmethionine (SAME) is synthesized in all body tissues but highly concentrated in the liver. SAME serves as the primary methyl group in transmethylation reactions, which are integral to phase II hepatic detoxification and biosynthesis of nucleic acids, phospholipids, proteins, and other essential molecules. Available in the U.S. as a nutritional supplement, SAME is used medicinally in Europe for liver

disorders, depression, osteoarthritis, and fibromyalgia.

SAMe has been shown to have hepatoprotective effects in animal models of experimental injury; however, the few results from human studies have been less definitive.^{80,81} A placebo-controlled, 2-year study of 123 patients with alcoholic cirrhosis found 200 mg of oral SAMe daily significantly improved survival and delayed the need for liver transplantation.⁸² SAMe has been shown in animal models to protect against the development of HCC,⁸³⁻⁸⁵ although efficacy has not yet been established in humans with cirrhosis. Studies of patients with viral hepatitis and other chronic liver conditions have found that SAMe has utility in alleviating associated symptoms, such as itching, jaundice, and fatigue, and reduces liver enzyme and bilirubin levels.^{86,87} SAMe has also been used for decades in Europe to treat depression, a common complaint among CHC patients. A 2013 literature review concluded that the proof of concept is solid, but additional study data are required before SAMe can be confidently recommended as first-line or adjuvant therapy for depression.⁸⁸

The high cost of SAMe, its relative instability, and lack of conclusive data to support its use in CHC preclude its recommendation for regular use. Some clinicians recommend a combination of methionine, trimethylglycine, vitamin B₁₂, and folic acid to support endogenous SAMe production.

Dosage

The typical dose of SAMe for liver disease is 800 mg twice daily on an empty stomach.

Precautions

Mild gastrointestinal upset, anxiety, hyperactive muscle movement, and insomnia have been reported as side effects of SAMe use. Patients with depression and bipolar disorder should be closely monitored while taking SAMe.

Alpha-Lipoic Acid

Alpha-lipoic acid (ALA) is a fatty acid antioxidant. A key metabolite in mitochondrial energy production and a potent free radical scavenger, ALA is used medicinally in many European countries, primarily to treat

liver disorders and neuropathy. The effect of ALA in raising cellular glutathione levels is thought to be important in CHC due to relative glutathione deficiency.^{89,90} ALA also helps recycle and regenerate other antioxidants, including vitamins E and C.⁹¹ Results from studies of animal models indicate that ALA may impede fibrosis progression associated with chronic hepatitis by reducing production of reactive oxygen species.^{92,93}

ALA is costly and has not been well studied in clinical trials among people with chronic viral hepatitis. Therefore its routine use is not recommended. In patients with unexplained spikes in liver enzymes, however, ALA may be advisable to reduce oxidative stress.

Dosage

ALA dosage is 500 to 600 mg/day.

Precautions

No side effects have been reported with ALA doses up to 1000 mg/day.

Glutamine

Glutamine is a conditionally essential amino acid. Although normally synthesized in adequate amounts, endogenous glutamine production may be inadequate during periods of metabolic stress. Glutamine is crucial for many metabolic functions, including protein and glutathione synthesis, energy production, maintenance of optimal antioxidant status, and immune function. Glutamine regulates the expression of several genes and activates numerous proteins.⁹⁴ L-Glutamine is an immunonutrient and the preferred substrate for energy production in enterocytes and lymphocytes. Glutamine influences production of some T-cell-derived cytokines and is important for optimal lymphocyte proliferation.⁹⁵⁻⁹⁷ Notably, lymphocytes are unable to produce glutamine. If glutamine stores are depleted by ongoing immunological demands, glutathione production will therefore be inadequate. Glutamine is an important nutritional supplement when metabolic stress renders endogenous synthesis inadequate.

Dosage

Glutamine doses of 2 to 4 g/day are used during periods of metabolic stress or poor dietary intake. Glutamine supplements should be taken between meals.

Precautions

Glutamine supplementation should be approached with caution in patients with hepatic or renal insufficiency.⁹⁸

Zinc

The essential mineral, zinc, serves numerous important biochemical roles, including functioning as an essential cofactor in healthy immunological function and supporting antioxidant systems. As zinc deficiency is uncommon in developed countries, routine zinc supplementation is unnecessary for most CHC patients but may be a consideration for individuals who are nutritionally deprived.

Dosage

The typical zinc dosage is 15 mg/day. The UL for zinc is 40 mg/day.⁹⁹

Precautions

Long-term ingestion of high-dose zinc may deplete copper stores, interfere with iron function, and lead to microcytic anemia. Ingestion of large amounts of zinc (>30 mg/day) may cause acute toxicity with nausea, vomiting, diarrhea, anorexia, abdominal cramps, a metallic taste, headache, and drowsiness.

Iron

People with CHC should avoid iron overload. Increased hepatic iron stores are associated with higher degrees of inflammation and more severe hepatic fibrosis in patients with CHC compared to patients without iron overload.^{100,101} Iron supplements should be avoided among patients with CHC except in cases of documented deficiency. Iron-binding supplements may be beneficial in patients with increased serum iron levels.

Botanicals

Milk Thistle (*Silybum marianum*)

Milk thistle is the most commonly used supplement among CHC patients.¹⁰² The active component of milk thistle, silymarin, has reported antioxidant, antiinflammatory, antifibrogenic, antiproliferative, and immunomodulatory effects in addition to stabilizing hepatocyte cell membranes against free radical attack.¹⁰³⁻¹⁰⁵ Silymarin is a potent antioxidant. It has been reported to raise hepatic and intestinal glutathione levels by 50% in animal studies¹⁰⁶ and to increase levels of the antioxidant enzymes superoxide dismutase, glutathione peroxidase, and catalase in other animal models.^{107,108} Silymarin also has antifibrotic properties. Among silymarin users in the Hepatitis C Antiviral Long-Term Treatment against Cirrhosis (HALT-C) trial, researchers found reduced fibrosis progression but no significant difference in clinical outcome compared to nonusers.¹⁰⁹ A separate U.S. multicenter, double-blind, placebo-controlled trial among 154 CHC patients previously unsuccessfully treated with interferon-based therapy found no significant differences in serum ALT levels, viral load, or quality of life between participants taking 420 mg or 720 mg of oral silymarin 3 times daily for 24 weeks compared to those taking a placebo.¹¹⁰ An earlier randomized, double-blind, 12-month trial of 177 Egyptian patients with CHC, however, found patients taking oral silymarin reported improved symptoms and general well-being, although no effect was noted in HCV viremia, ALT, or serum and ultrasound markers of hepatic fibrosis.¹¹¹ Combination treatments with milk thistle as a principal component are currently being evaluated. In a small study of CHC patients treated with a 3-month course of a combination of silybin phospholipids and vitamin E, researchers found a significant reduction in serum aminotransferase levels.¹¹² Other clinical studies of the effects of silymarin on chronic liver disease have yielded mixed results.¹¹³⁻¹¹⁵ A 2005 Cochrane systematic review of 13 randomized trials and a 2014 meta-analysis of randomized controlled trials of silymarin in CHC patients both concluded there is lack of high-quality evidence of efficacy.^{116,117} The difference between laboratory observations and clinical efficacy may be attributable to issues such as limited absorption of oral silymarin, relatively low blood levels, and HCV-specific alterations in hepatic silymarin uptake and enterohepatic cycling.^{103,110,118}

In summary, research data indicate that many actions of silymarin may theoretically be beneficial for chronic hepatitis patients. Clinical data to

support this supposition, however, remain lacking with regard to CHC. Given that milk thistle has no known serious adverse effects, many clinicians believe the potential for benefit justifies use of this supplement despite the current lack of robust, supportive clinical evidence.

Dosage

The typical milk thistle dosage for chronic hepatitis is 300 mg three times daily, or 210 mg of silymarin three times daily. Silymarin-phosphatidylcholine is absorbed more effectively than regular standardized milk thistle and requires less frequent dosing (240 mg twice daily). Alcohol extracts should be avoided in patients with hepatitis.

Precautions

Side effects of milk thistle are reportedly rare. Reported adverse reactions include stomach pain, nausea, vomiting, diarrhea, headache, rash or other skin reactions, and joint pain. Allergic reactions may occur in patients with hypersensitivity to ragweed or plants in the daisy family.

Milk thistle should be discontinued at least 1 week prior to beginning DAA-based antiviral therapy (particularly simeprevir and elbasvir/grazoprevir) and avoided throughout treatment due to the risk of drug-herb interactions.⁸

Licorice Root (*Glycyrrhiza glabra and uralensis*)

Licorice root preparations have been an accepted treatment for hepatitis in Japan since the 1960s. Glycyrrhizin (an aqueous extract of licorice root) acts primarily as an antiinflammatory and cytoprotective agent.¹¹⁹ Although the antiviral properties of glycyrrhizin have been demonstrated in vitro, they do not appear to be clinically relevant.¹¹⁹⁻¹²¹ Some clinical studies reporting benefit have used a form of intravenous glycyrrhizin called Stronger Neo-Minophagen C (SNMC; 0.2% glycyrrhizin, 0.1% cysteine, and 2% glycine). A nonrandomized, retrospective Japanese study reported that long-term SNMC treatment (3

to 5 times weekly for 13 to 15 years) among patients with viral hepatitis led to significantly reduced incidence of cirrhosis and hepatocellular carcinoma.¹²² A review article published in 2005 noted, however, that SNMC “improves liver function in patients with chronic hepatitis” but does not reduce mortality.¹¹⁹ A Cochrane review of medicinal herbs for HCV infection concluded that glycyrrhizin did not demonstrate significant beneficial effects.¹²³ A 2014 review similarly concluded that evidence of clinical efficacy remains lacking.¹²⁴

Despite promising animal model data and anecdotal experience supporting the parenteral use of glycyrrhizin, robust clinical data demonstrating efficacy are scant. Moreover, oral licorice root preparations remain virtually unstudied.

Dosage

The recommended dosage of oral licorice root depends on the form: 250 to 500 mg three times daily for solid dry powder; 1 to 2 g three times daily for powdered root; or 2 to 4 mL three times a day for fluid extracts.

Precautions

High-dose glycyrrhizin may lead to an aldosterone effect with potassium loss, water retention, and hypertension. Use may potentiate the effects of diuretics, certain cardiac medications (e.g., digitalis), and corticosteroids. Glycyrrhizin should be used cautiously in the setting of hypertension, ascites, renal insufficiency, and cardiac failure. A diet high in potassium-rich foods is recommended for patients taking a licorice root preparation. Blood pressure and potassium levels should be monitored regularly.

Schisandra (*Schisandra chinensis*)

Schisandra has long been used in traditional Chinese and Kampo medicine for liver disorders. Medicinal substances derived from the fruit of the plant include schisandrins A, B, and C, and several gomisins. Schisandra is a potent free radical scavenger, a characteristic that may explain the hepatoprotective effects observed with this botanical. Gomisin A has been found to promote hepatocyte growth factor, limit

lipid peroxidation, and inhibit apoptosis in acute hepatic injury animal models.^{125,126} Gomisin A also acts as an antiinflammatory, preventing the release of arachidonic acid by macrophages.¹²⁷ Laboratory evidence suggests that gomisin A may have anticarcinogenic effects^{128,129}; however, published clinical trial data examining schisandra use in CHC patients are lacking.¹³⁰

Dosage

The typical dosage for Schisandra extract is 100 mg twice daily.

Precautions

Schisandra lignans have been reported to induce phase I drug metabolism¹³¹ and competitively inhibit the methylation pathway of phase II detoxification in animal models.¹³² Caution should be used if medications metabolized by the cytochrome P-450 system are given with schisandra. Side effects are uncommon and include dyspepsia, anorexia, and urticaria.

Astragalus (*Astragalus membranaceus*)

Astragalus is an important immunomodulatory herb in Chinese medicine.¹³³ In vitro studies have demonstrated that astragalus promotes B-cell proliferation and antibody production and enhances CTL activity.¹³⁴ Astragalus also acts as an antioxidant, increasing superoxide dismutase and decreasing lipid peroxide activity. Astragalus is reported to have protective effects against toxins in animal models.¹³⁵ An astragalus injection solution was found to have an inhibitory effect on experimental hepatic fibrogenesis, possibly due to its antioxidant properties.¹³⁶ A small trial among patients with chronic hepatitis B found astragalus supplementation was associated with decreased serum fibrosis markers and liver enzymes.¹³⁷ A 2009 meta-analysis of clinical trials from English and Chinese literature concluded that astragalus and certain other traditional Chinese botanicals may have activity against HCC, although the authors noted a potential publication bias due to a lack of randomization in the studies evaluated.¹³⁸ Whether these agents have a chemoprotective role in patients with chronic viral hepatitis at increased risk for HCC remains a matter of conjecture.

Dosage

The typical dosage of astragalus powder is 4 to 7 g daily and typically provided in herbal concoctions.

Precautions

Doses greater than 28 g/day may cause immune suppression. Astragalus should be avoided in patients with autoimmune disease or receiving immunosuppressive therapy due to its immunostimulatory effects. As astragalus may contain selenium, ingestion of large amounts may lead to selenosis. Astragalus may potentiate the effects of antithrombotic and anticoagulant medications. Side effects of astragalus use are uncommon.

Herbal Concoctions and Traditional Chinese Medicine

Traditional Chinese medicine (TCM) has long described healing remedies for chronic liver maladies. Integrative TCM relies on individualized constitutional diagnosis and treatment in parallel with biochemical, histological, and other diagnostic methods. Because constitutional diagnostic methods are used in formulating treatment plans, individualized herbal concoctions containing several botanicals are commonly used. Herbal concoctions for chronic hepatitis are likely to include varying doses and combinations of the botanicals discussed previously in addition to others. Herbal concoction prescriptions are modified according to a patient's changing signs and symptoms. Referral to a qualified TCM practitioner with experience treating chronic hepatitis may be beneficial for patients who opt to forego antiviral therapy.

Mind-Body Therapies

Research is beginning to catch up with clinical experience regarding the negative effects of psychosocial stress on health, particularly with respect to the roles of glucocorticoids and catecholamines. Stress activates the hypothalamic-pituitary-adrenal axis, leading to increased glucocorticoid secretion. The sympathetic nervous system is similarly activated by stress, which increases catecholamine levels.¹³⁹ Both groups of substances

cause specific cytokine responses that influence the inflammatory response, with human studies demonstrating alterations in a number of immunomodulators related to acute experimental stress.^{140,141} A small study in Japan found an association between chronic psychosocial stress related to type 1 personality and increased hepatitis C severity.¹⁴² Stress has been shown to induce interleukin-6 and tumor necrosis factor-alpha within the liver, thus augmenting the hepatic inflammatory response.¹⁴³ Evidence suggests that repetitive stress may aggravate chronic inflammatory diseases to a greater extent than acute stressors.¹⁴⁴ Thus mind-body therapies that alleviate psychosocial stress may enhance the liver-specific and overall health of patients living with chronic hepatitis.

Therapeutic modalities that enhance balance and increase a sense of control, meaning, and purpose may decrease the degree to which psychosocial stress contributes to a patient's disease process. Chronic illness is a stressor in and of itself. Whatever we can do to help patients minimize or alleviate this and other stressors in their lives is healing in the broadest and truest sense (see [Chapter 94](#)).

Examples of modalities that may help alleviate stress and enhance peacefulness include meditation, prayer, journaling, counseling, support groups, behavioral therapy, hypnosis, and visualization, as well as art, music, and dance therapy. Relaxation techniques, such as deep breathing, biofeedback, and others, may also merit discussion. Clinicians should offer therapeutic approaches that suit a patient's personality, culture, and belief system.

Lifestyle Interventions

Measures to Reduce Toxin Exposure

Exposure to exogenous toxins increases hepatic workload and oxidative stress. When the liver is already in a state of chronic inflammation, this additional burden may exacerbate ongoing injury and accelerate disease progression.

Reduce Dietary Toxins

Oral intake of toxic xenobiotics can be minimized by avoiding prepackaged, ready-to-eat foods, processed meats, and canned foods. Encourage organically grown foods, but keep in mind that such products may not be affordable for some patients.

Avoid Alcohol

Alcohol abstinence is one of the most important recommendations a clinician can make for patients with CHC. Even low levels of alcohol intake in patients with HCV has been associated with accelerated fibrosis and increased risk of cirrhosis and HCC.¹⁴⁵⁻¹⁴⁷ Clinicians must be prepared to offer patients with alcohol addiction or dependence with information about local services that provide psychosocial support in becoming alcohol-free. Alcohol in over-the-counter products (e.g., mouthwash, cold preparations, and tinctures) is also to be avoided (see [Chapter 83](#)).

Avoid Tobacco Products

All tobacco products (chewing tobacco, cigars, pipes, and cigarettes) introduce an array of toxins into the body and should be avoided. Smoking reduces glutathione levels due to the additional burden of detoxifying nicotine and neutralizing free radicals produced by tobacco toxins. Smoking increases the risk of hepatocellular carcinoma^{148,149} and has been linked to accelerated CHC fibrosis.¹⁵⁰

Avoid Unnecessary Drugs and Supplements

Pharmaceuticals, botanicals, and supplements that are metabolized by the liver can dramatically increase the xenobiotic burden on the liver. Additionally, some of these products have hepatotoxic potential ([Table 21.7](#)). All products with hepatotoxic potential should be avoided or prescribed with caution and closely supervised.

Recreational drug use is an important topic to discuss with all chronic hepatitis patients as these drugs increase the toxic burden on the liver. Many patients with CHC smoke marijuana to alleviate disease-related symptoms. Daily cannabis use, however, has been reported to significantly accelerate hepatic fibrosis progression.¹⁵¹ Smoking marijuana may also contribute to steatosis, an independent risk factor for CHC progression.¹⁵² A study among HIV–HCV coinfecting patients, however, failed to demonstrate a relationship between marijuana use and CHC progression.¹⁵³ Asking about marijuana use in the same manner as other lifestyle issues opens the door to a candid discussion.

Avoid Environmental and Occupational Toxin Exposure

Pesticides, herbicides, and other toxic chemicals can damage hepatocytes

and elevate liver enzyme levels.¹⁵⁴⁻¹⁵⁷ Home exposure to paint and lacquer, glues, epoxy, and other toxins should be minimized.

Exercise

Exercise enhances portal blood flow, decreases fatigue,¹⁵⁸ improves overall well-being, and may alleviate depression,¹⁵⁹ a common finding in patients with CHC. Moderate exercise has also been shown to improve immune response.^{160,161} Encourage a realistic exercise program that takes into account the patient’s current activity level and interests and progresses gradually.

TABLE 21.7
Common Pharmaceuticals and Botanicals with Hepatotoxic Potential

Type	Specific Agents
Pharmaceuticals	Acetaminophen Alpha-methyl dopa (Aldomet) Amiodarone (Cordarone) Carbamazepine (Tegretol) Diclofenac (Voltaren, Cataflam) Fluconazole or ketoconazole (Diflucan, Nizoral) Hydralazine (Apresoline, Novo-Hylazim) Ibuprofen (Advil, Motrin, Nuprin) Nitrofurantoin (Macrochantin) Phenytoin (Dilantin) Sulfonamides (especially Septra or Bactrim) Amoxicillin (Amoxil) Chlorpromazine (Thorazine) Ciprofloxacin (Cipro) Duloxetine (Cymbalta) Statins/HMG-CoA reductase inhibitors (Caduet, Crestor, Lescol, Lipitor, Mevacor, Pravachol, Simcor, Vytorin, Zocor)
Botanicals	Barberry (<i>Berberis vulgaris</i>) Comfrey (<i>Symphytum officinale</i>)—Should never be taken internally Golden ragwort (<i>Senecio aureus</i>) Groundsel (<i>Senecio vulgaris</i>) Huang qin (<i>Scutellaria baicalensis</i>) Kava-kava (<i>Piper methysticum</i>) Pennyroyal (<i>Mentha piperita officinalis</i>) Sassafras (<i>Sassafras albidum</i>) Senna (<i>Cassia senna</i>) Valerian (<i>Valeriana officinalis</i>) Wall germander (<i>Teucrium chamaedrys</i>) Wood sage (<i>Teucrium scorodonia</i>) Ma-huang (<i>Ephedra equisetina</i>) Jin bu huan (<i>Lycopodium serratum</i>)

Encourage Healthy Body Weight

Steatosis increases the rate of hepatic fibrosis in CHC patients.^{162,163} Although genotype 3 disease is most closely associated with steatosis risk, elevated BMI has been shown to be an independent predictor of nonalcoholic steatosis.¹⁶⁴ Overweight and obese patients should be encouraged to engage in a sensible, sustainable weight-reduction program. Management of metabolic syndrome, high triglycerides, and obesity is a priority as insulin resistance is common among CHC patients.¹⁶⁵

Nutrition

The liver is the master processor of nutrient and metabolic homeostasis, and one's diet can make these jobs easier or more difficult. A diet including a variety of fresh fruit and vegetables supplies the necessary nutrients to support hepatic synthetic and detoxification functions. High-quality protein supports hepatic synthetic functions and the immune system. Low dietary fat helps prevent or counter hepatic steatosis, a condition that accelerates CHC progression. Avoiding excessive carbohydrates helps stabilize glucose metabolism, which is often disturbed in CHC patients due to insulin resistance (see [Chapters 88](#) and [87](#)).

Encourage Regular Consumption of Cruciferous Vegetables

Cruciferous vegetables include cabbage, broccoli, cauliflower, Brussels sprouts, kale, mustard greens, collard greens, kohlrabi, rutabaga, turnips, bok choy, arugula, horseradish, radish, wasabi, and watercress. These vegetables are good sources of vitamin C, selenium, folate, carotenoids, lignans, flavonoids, and indole-3-carbinol, which can increase the activity of certain phase I and II detoxification enzymes.^{166,167}

Encourage Regular Consumption of Fruit

Fruit is a rich source of vitamins C, E, and K, folate, selenium, magnesium, potassium, carotenoids, flavonoids, lignans, terpenoids, and fiber. Adequate amounts of a variety of fruit help ensure an adequate supply of substrates needed for detoxification and biosynthesis. Berries—especially black raspberries, elderberries, blackberries, and blueberries—

contain high concentrations of antioxidants.¹⁶⁸ Peaches, mangoes, and melons are also rich in antioxidants. Citrus fruit contains high concentrations of the phytochemical D-limonene, a strong inducer of phase I and II of the detoxification system.¹⁶⁹

Avoid Foods That Inhibit the Detoxification System

Certain foodstuffs inhibit the detoxification system. Grapefruit contains naringenin, an inhibitor of cytochrome P-450 3A4 of the phase I detoxification system.¹⁷⁰ Capsaicin from hot peppers, eugenol from clove oil, and quercetin from onions also slow phase I detoxification. Patients with chronic liver disease are best advised to limit intake of these foodstuffs accordingly.

Encourage Adequate Protein Intake

Adequate protein intake is essential for healthy immune function and detoxification. Liver disease and chronic inflammation increase the body's requirements for protein, particularly in the presence of cirrhosis. Furthermore, phase II of the detoxification system is especially vulnerable to inadequate protein intake. Healthful sources of complete proteins include eggs, lentils, nuts, lean meats, fish, poultry, and soy. Encourage lean white meat and fish over red meat.¹⁷¹ Recommended daily protein intake (in grams) should be calculated by multiplying body weight (in pounds) by a factor 0.5 to 0.7.

Encourage Healthful Dietary Fat Intake

When counseling patients regarding healthful dietary fat intake, focus on two major points: limiting dietary fat to no more than 30% of caloric intake and limiting intake of omega-6 polyunsaturated fats and trans fats. Limiting overall fat intake is important as high-fat diets—particularly in combination with reduced protein and carbohydrates—increase the risk of steatosis and cirrhosis among patients with chronic hepatitis.^{172,173}

Most primary care clinicians are accustomed to promoting the consumption of unsaturated fats over saturated fats in order to improve cardiovascular health. Patients with chronic liver disease, however, have

additional pathophysiological concerns. Unsaturated fats are more volatile (polyunsaturated fats more so than monounsaturated fats) and prone to oxidation than saturated fats. As hepatic oxidative stress is typically high in patients with CHC, the additional stress of large quantities of unsaturated fats may exacerbate hepatocyte injury. Reduced intake of polyunsaturated omega-6 fatty acids (e.g., safflower oil, sunflower oil, corn oil) is particularly important. Encourage the use of predominantly monounsaturated fats such as olive, canola, and peanut oils for cooking. Also encourage the consumption of omega-3 fatty acids to help reduce inflammation.¹⁷⁴ Finally, all patients should be advised to avoid trans fats (see [Chapter 88](#)).

Encourage Dietary Fiber

Dietary fiber helps bind toxins in the gut, resulting in bowel excretion of toxins without hepatic processing. A European cohort study involving more than 477,000 participants found dietary fiber, particularly from grain and vegetable sources, had a protective effect against the development of HCC in patients with chronic hepatitis B and/or C.¹⁷⁵ Encourage whole-grain and vegetable sources of dietary fiber.

Encourage Green Tea

Catechin polyphenols in green tea have antioxidant, antiangiogenic, and antiproliferative properties that may help reduce hepatic inflammation, slow chronic hepatitis disease progression, and attenuate HCC risk.^{171,176-178} A 2009 meta-analysis found a significantly decreased risk of primary liver cancer associated with long-term consumption of green tea.¹⁷⁹

Dosage

Two or three cups of green tea daily.

Precaution

Caution patients against the use of highly concentrated green tea extracts as cases of fulminant hepatitis have been reported.^{180,181}

Encourage Coffee

Regular coffee contains caffeine, chlorogenic acids, and a broad array of other compounds that collectively have hepatoprotective effects. Drinking coffee is associated with slower CHC disease progression, decreased fibrosis severity,¹⁸²⁻¹⁸⁴ and reduced risk of cirrhosis and HCC.¹⁸⁵

Dosage

Two to four cups of filtered, regular coffee daily.

Precaution

Whereas filtered coffee appears to be hepatoprotective, unfiltered coffee (boiled or pressed) may cause elevations of serum liver enzyme levels.¹⁸⁵⁻¹⁸⁷

Prevention Prescription

Hepatitis C Primary Prevention

- Do not share needles or other drug paraphernalia.
- Do not share personal care items that may be contaminated with blood, including toothbrushes, razors, and manicure and pedicure equipment.
- Do not get a tattoo with an unsterilized stylus; be certain new ink and new or sterilized ink pots are used.
- Avoid contact with blood during sexual activity.
- If you have multiple sexual partners, use latex condoms correctly and consistently at every sexual encounter.
- Use universal body fluid precautions.

Hepatitis C Secondary Prevention

- Abstain from alcohol, tobacco products, street drugs, and unnecessary medications and supplements.
- Avoid environmental toxins, including pesticides, herbicides, and other toxic chemicals.
- Achieve and maintain a healthy body weight.
- Exercise regularly.
- Establish and maintain ongoing health care to include immunizations,

CHC disease progression monitoring, and HCC screening, as indicated.

Therapeutic Review

Screening

The Centers for Disease Control and Prevention recommends one-time, hepatitis C antibody screening for anyone born during 1945 through 1965 due to the high prevalence of the disease in this age group.¹⁸⁸ The CDC also recommends anti-HCV screening for individuals who have one or more of the following risk factors:

- current or former use (even if only once many years ago) of injected street drugs
- receipt of blood, blood products, or an organ transplant before 1992, or clotting factors prior to 1987
- receipt of blood, blood products, or an organ transplant from a donor who later tested positive for hepatitis C
- long-term renal dialysis
- HIV infection
- persistent ALT elevation
- born to a mother with active HCV infection
- accidental exposure to HCV-positive blood

The AASLD/IDSA/IAS–USA recommends annual HCV screening for individuals who currently inject illicit drugs and HIV-positive men who have unprotected sex with men.⁸ Routine screening is not recommended for pregnant women, healthcare workers, first responders, or nonsexual household contacts. Screening is discretionary for individuals who may be at increased risk of hepatitis C related to tissue transplantation; past incarceration; body piercings and/or tattoos; current or former recreational drug use taken other than orally or parenterally (e.g., intranasally or subcutaneously); and a history of multiple sex partners, sexually transmitted infection, or a sexual partner of someone with hepatitis C.

Hepatitis screening tests detect HCV antibodies. A reactive result indicates HCV exposure, but further testing is required to differentiate past versus active infection¹⁸⁹ because approximately 15% to 25% of

people spontaneously resolve HCV infection.¹⁹⁰ People with a positive antibody screen should be tested for HCV RNA, which is typically detectable within 2 to 3 weeks of the initial infection. A positive result indicates active HCV infection, while a negative result indicates there is no active infection.

Initial Evaluation and Management

Individuals newly diagnosed with hepatitis C require additional testing to evaluate current disease status and factors that may influence disease progression and/or treatment decisions.^{8,38}

Laboratory

- HCV genotype testing is recommended for any patient considering antiviral therapy because HCV genotype affects the regimen choice, duration of treatment, and probability of successful viral clearance.^{8,38}
- HIV and hepatitis B testing is recommended as coinfection influences disease progression and treatment.
- Obtain baseline markers of liver status (e.g., AST, ALT, albumin, bilirubin, INR, CBC, and platelet count).
- Order noninvasive blood markers for fibrosis (e.g., Fibrotest, Fibrosure) if there is no clinical evidence of cirrhosis to evaluate hepatic fibrosis.
- Obtain baseline HCV viral load for patients who will begin antiviral treatment within 12 weeks. Defer pretreatment viral load testing if the period between testing and treatment initiation will be > 12 weeks.

Radiology

- Assess hepatic fibrosis with imaging studies (ultrasound, CT, or transient elastography) if there is no clinical evidence of cirrhosis. Consider a liver biopsy if imaging studies are inconclusive and/or inconsistent with noninvasive blood markers of fibrosis.

Lifestyle

- Reduce environmental (e.g., tobacco) and dietary toxin exposure.
- Abstain from alcohol and illicit drug use. Refer for alcohol/drug dependence counseling and treatment as needed.
- Achieve and maintain healthy body weight.

- Exercise regularly.
- Counsel patients about reducing the risk of HCV transmission.

Nutrition

- Include six to seven daily servings of fruits and vegetables (particularly cruciferous vegetables). 
- Limit grapefruit and other inhibitors of the detoxification system. 
- Limit fat intake (no more than 30%; aim for 10%–20%). 
- Eliminate trans fats (hydrogenated and partially hydrogenated oils). 
- Use olive, canola, or peanut oil in cooking. 
- Increase intake of omega-3 fatty acids (cold-water fish, nuts, flaxseed). 
- Decrease intake of omega-6 fatty acids (vegetable oils). 
- Increase fiber intake. Consider supplementation with methylcellulose or psyllium if dietary fiber intake is inadequate. 
- Ensure adequate protein intake. 

Pharmaceuticals

- Vaccinate patients without immunity to hepatitis A or B. 
- Discuss antiviral treatment options with all patients, including duration of therapy, regimens, and potential risks and benefits.
- Encourage antiviral treatment for patients with clinical factors that increase risk of HCV-related complications as they are most likely to realize short-term, high-impact benefits from viral cure (see [Table 21.5](#)). 
- Patients undergoing antiviral treatment should discontinue all nonessential herbs, supplements, and medications during therapy.

Mind-Body

- Encourage lifestyle choices that reduce psychosocial stress.
- Explore relaxation and meditative techniques tailored to the patient's personality, belief system, and culture to help reduce stress.

Supplements

- Selenium: 200 mcg daily 
- Iron-free multivitamin with minerals: one daily 
- B-complex: one daily 
- Vitamin C: 200–250 mg bid 
- Vitamin E (D-alpha tocopherol): 400 IU daily 
- Precautions: Avoid iron supplementation and excess vitamin A.

Botanicals to Consider

- Silymarin-phosphatidylcholine: 240 mg bid 
- Licorice root: 200–500 mg dry powder tid, 1–2 g powdered root tid, or 2–4 mL fluid extract tid 
- Schisandra: 100 mg of extract bid 
- Astragalus: 4–7 g of powder qd 

Monitoring

- See patients who are not receiving antiviral therapy at least twice yearly to monitor for signs of progression and /or extrahepatic disease manifestations.
- Monitor AST/ALT ratio; a ratio > 1 indicates probable disease progression to advanced fibrosis or cirrhosis.¹⁹¹ Refer for gastroenterology or hepatology consult.
- Consider repeat liver fibrosis evaluation as clinically indicated.

Consultations

- Infectious disease consultation and comanagement is highly recommended for patients with HCV–HIV coinfection.
- Hepatology consultation is recommended for CHC patients with decompensated cirrhosis, hepatitis B coinfection, or another comorbid hepatic condition.
- Nutrition consultation is recommended for patients with cirrhosis.

CHAPTER 22

Urinary Tract Infection (UTI)

Amy B. Locke, MD, FAAFP, ABIHM

Pathophysiology and Epidemiology

Urinary tract infections (UTIs) are common, with an estimated life time incidence of approximately 53% in women and 14% in men.¹ The higher prevalence in women is thought to be related to urethral length. For those who have had a prior infection, the risk of another increases dramatically. One study found a recurrence rate of 44% within 1 year among women with a history of UTI.² The most common causative pathogens include gram negative organisms, in particular *Escherichia coli* (*E. coli*), which account for 80% of infections.³ Many recurrent infections may actually represent reinfection with the same organism.⁴ Despite clearing the bacteria from the urine, the colon may act as a reservoir for pathogenic bacteria.

A simple UTI, or cystitis, involves bacterial colonization of the bladder. Complicated UTIs usually involve structural or anatomic factors, underlying disease states such as diabetes that hinder treatment, or drug-resistant bacterial strains. Ascending infections into the kidneys are not uncommon, particularly with complicated UTIs; pyelonephritis requires urgent medical attention to avoid damage to renal structures and sepsis. Factors that increase the likelihood of progression include delayed treatment, unrecognized infection, asymptomatic bacteriuria in pregnancy, anatomical factors, and systemic diseases that lower immune function, such as diabetes.

Asymptomatic bacteriuria does not require treatment outside of pregnancy. Although bacteriuria is more common in diabetics,⁵ treatment has not been shown to alter outcomes.^{6,7} A 2015 Cochrane review found no benefit of treatment across diverse populations and diagnoses.⁸ The United States Preventive Services Task Force (USPSTF)

recommends screening for bacteriuria in pregnancy (A-grade recommendation) and against screening for others (D-grade recommendation).⁹ The rapid treatment of pregnant women with both clinically diagnosed UTI and asymptomatic bacteriuria is essential due to the high risk of pyelonephritis.

Clinical Presentation

The majority of episodes of lower urinary tract infection present with a combination of dysuria, urinary urgency, and frequency. Gross hematuria, suprapubic discomfort, and cloudy urine are not uncommon. Symptoms of fever, myalgia, or low back/flank pain should prompt consideration of pyelonephritis. A history of dysuria, urinary frequency, and absence of vaginal discharge reportedly indicates a 90% probability of UTI.¹⁰ Physical examination findings may consist of suprapubic tenderness; however, a physical examination is not required in the evaluation of UTI.

Laboratory testing frequently comprises urinalysis only. Urinalysis may reveal the presence of nitrites, leukocyte esterase (LE), and/or hematuria. The presence of nitrites with either LE or hematuria has a reported positive predictive value of 92%, but a negative predictive value of 76% when all three are absent.¹¹ Urine culture is not required for the diagnosis and treatment of simple UTI but may be helpful in patients with recurrent symptoms in order to exclude other etiologies, such as interstitial cystitis or when there is concern regarding the presence of drug resistant organisms. If performed, greater than 100,000 colony forming units of a single organism confirms the diagnosis of UTI.

The differential diagnosis of dysuria includes *Chlamydia trachomatis* cervicitis and interstitial cystitis, among others, in women. Prostatitis and urethritis should be excluded in the treatment of men with UTI. Treatment via phone for those with recurrence is generally considered acceptable. Many practices have a nurse triage protocol that allows recommendations, including prescriptions, to be provided without an office visit. Patients with frequent complicated UTIs, women with pyelonephritis in, and men with UTI may benefit from further evaluation by a urologist or further imaging.

Risk Factors

A number of factors that may predispose an individual to recurrent UTIs

that vary across the age spectrum (Table 22.1). Younger women who are sexually active, have a history of UTIs as children, have had a new partner in the last year, use condoms (particularly those with spermicidal lubrication), or use diaphragms are at increased risk.^{12,13} The frequency of intercourse has also been demonstrated to be an independent risk factor.¹² An inverse relationship between voiding after intercourse and risk of UTI has been shown by some studies but not others.¹⁴ Tight clothing, tampon use, and soap preference have not consistently been shown to be related to recurrence in case control trials.¹² Delayed urination in college-age women has been reported to be significantly associated with infection risk in some studies but not others.^{12,15} Physiological changes during pregnancy are associated with a significant increase in the frequency of UTI.

Postmenopausal women with recurrent UTI are more likely to be affected by diabetes, history of premenopausal UTI, urge incontinence, sexual activity, incomplete emptying of the bladder, and the presence of a cystocele.^{16,17} Children may have increased rates with bowel and bladder dysfunction, termed Dysfunctional Elimination Syndrome,¹⁸ as well as vesicoureteral reflux.

TABLE 22.1
Risk Factors for Urinary Tract Infection

Young Women	Older Women	Men	General
Higher frequency of intercourse History of UTI as child Condom use Spermicide use Diaphragm use Pregnancy Delayed urination Lack of voiding after intercourse	Diabetes History of premenopausal UTI Urge incontinence Sexual activity Incomplete bladder emptying Cystocele	Lack of circumcision Penetrative anal intercourse Female partner with UTI Prostatic hypertrophy	Foreign bodies Nephrolithiasis Catheters Family history of recurrent UTI Decreased fluid intake Dysfunctional Elimination

Some risk factors cross all age ranges, including family history of recurrent UTI¹² and foreign bodies, such as renal stones and catheters. Family history of recurrent UTI may be associated with increased risk due to the relationship between specific phenotypes and bacterial adherence to the bladder wall.¹⁹ Antibiotic use is a risk factor for UTI, presumably due to its effect on vaginal flora. Altered vaginal flora from *Lactobacillus* to *E. coli* is associated with an increased risk of recurrent infection.²⁰ This may explain the risk associated with spermicide use, as it increases colonization by *E. coli*.

Risk factors that predispose men to simple UTI include penetrative anal intercourse, a female partner with UTI, and lack of circumcision.²¹ The risk of UTI in uncircumcised males has recently been estimated to be much higher than previously thought, with a relative risk increase of approximately 23%.²² Obstructive symptoms, such as those due to prostatic hypertrophy, predispose to complicated UTI.

Integrative Therapies

Nutrition

In general, a diet high in fruits and vegetables, whole grains, and healthy fats will promote good health and may strengthen the immune system. In addition, some foods and food components are thought to have a direct impact on the frequency of UTI.

Bladder Irritants

Many believe that certain foods cause irritation of the bladder. Lower urinary tract symptoms may increase with consumption of certain foods,²³ however, the relationship with UTI risk has yet to be clearly established, with case-control studies evaluating dietary factors reporting negative results.¹⁴ Possible irritants include caffeine, simple sugars and starches, tobacco, alcohol, and some food additives. For those with recurrent infections, a trial diet to avoid these substances may result in a reduction in the frequency of urinary infections.

Garlic and Onions

Garlic has been used as an antimicrobial agent throughout history for a wide range of conditions. Previous studies have evaluated its effect on a broad range of organisms, including viral, bacterial, fungal, and parasitic infections. Garlic appears to be active against common urinary pathogens.²⁴ The most active ingredient of garlic is thought to be the sulfur-containing compound, allicin.²⁵ There are, however, nearly 100 compounds present that may act synergistically. In animal models of urinary pseudomonas, garlic appears to decrease bacterial counts and prevent renal damage.²⁶ Human trials of garlic for urinary tract infection are currently lacking. Garlic may have utility in the treatment of acute or recurrent infections.

Chopping or mashing garlic cloves 10 minutes prior to eating or

cooking seems to maximize the release of allicin, thereby increasing effectiveness. Raw consumption is preferred to cooking, as the highest allicin content may be found in raw garlic. Cooked garlic, however, may also have significant health benefits.

Onions also contain allicin and may have utility in the treatment and prevention of urinary pathogens, although no trials have so far been reported. Onions contain a large number of compounds thought to promote health, including flavonoids such as quercetin.

Fluids

Many practitioners recommend significant fluid intake to flush the urinary system with the aim of preventing UTIs. The effectiveness of this approach, however, has not been consistently proven by previous literature. Several studies have reported an association between decreased fluid intake and susceptibility to UTI,^{27,28} while others have not supported this finding.^{12,14} A review concluded that combination of fluid intake, frequent voiding, and complete bladder emptying may have greater benefit than simply drinking larger volumes.²⁹ There is no harm in this recommendation, and it may indeed be helpful. Fluid intake may play a role in dealing with constipation, which particularly plays a role in UTIs in children.

Supplements

Probiotics

Due to the colonic bacterial reservoir of pathogenic strains likely involved in recurrent UTIs,⁴ it is a logical extension to maximize intestinal health. Probiotic treatments have been evaluated in a number of studies; however, consistent results are lacking. Theoretically, *Lactobacillus* strains provide a barrier in the vagina and on the perineum that prevents bladder colonization. *Lactobacillus* strains out-compete pathogenic strains and affect their adhesion.³⁰ A 2013 meta-analysis found *Lactobacillus* species to be effective in preventing UTI but noted small study sizes.³¹ The most efficacious strains according to previous literature appear to be *L. rhamnosus* GR-1 and *L. reuteri* RC-14 (previously known as *L. fermentum*).³² A randomized trial comparing these strains (1 billion CFU orally bid) to trimethoprim/sulfamethoxazole (TMP/SMX) found the antibiotic to be superior; however, many regard the results of this study as evidence that these species have benefit in treating UTI.³³

The probiotic arm had no change from baseline in antibiotic resistance, whereas the antibiotic arm developed 100% resistance to TMP/SMX and high resistance rates to a number of other antibiotics.

Several studies have found *L. GG* to be less effective.³² The optimal dosing of probiotics is unclear, but is likely to be at least in the one billion colony forming unit (CFU) range. Probiotics can be given orally or vaginally.

Dosage

Two billion colony forming units daily of *Lactobacillus rhamnosus* and *reuteri*.

Precautions

The risks associated with the use of probiotics in immunocompetent individuals is exceedingly small.

The best studied species of probiotic are *Lactobacillus rhamnosus* and *reuteri*. Products containing these strains are increasingly available. Patients should be counseled regarding identifying products containing these specific species.

Vitamin C (Ascorbic acid)

Vitamin C may or may not have a role in the prevention of recurrent UTI. In a single blind randomized trial of pregnant women, 100 mg of ascorbic acid reduced UTI rates by more than half over 3 months (29.1% vs. 12.7%).³⁴ In a case control study, intake of vitamin C was found to be correlated with protection against UTI in college age women; however, the amounts of vitamin C taken were not noted.¹⁴

Dosage

Optimal dosage is unknown. Consider 100 mg daily.

Precautions

Diarrhea and GI upset may occur with high doses.

D-Mannose

D-Mannose is a simple sugar found in fruits. D-Mannose is not broken down in the bloodstream and is concentrated in the bladder where it prevents bacterial adherence to the bladder wall. The cellular receptors of uroepithelial cells, to which bacteria such as *E. coli* bind, are composed of D-mannose.³⁵ When taken as a supplement, D-mannose binds to bacterial receptors, blocking the ability of bacteria to adhere to the epithelial cell wall.³⁵ Animal studies have reported the efficacy of D-mannose in decreasing bacteriuria within 1 day.³⁶

The safety of D-mannose has been studied in long-term studies in mice without evidence of harm³⁷ and has been used in humans for the treatment of a rare carbohydrate deficient glycoprotein syndrome.

Recent trials have begun to evaluate the efficacy of D-mannose in humans when taken for UTI prophylaxis. No studies have evaluated its efficacy as an acute treatment. A study of 308 women comparing nitrofurantoin and 2 g daily of d-mannose reported equally efficacy compared to no treatment.³⁸ A pilot study evaluated 250 mg d-mannose in combination with 500 mg cranberry extract, a gelling compound made of 1 billion *Streptococcus thermophilus* ST10 and 250 mg tara gum, and two species of *Lactobacillus* (2.5 billion *L. plantarum* LP01 and 1 billion *L. paracasei* LPC09).³⁹ In this small trial of 33 women, there was a statistically significant reduction in symptoms of recurrent UTI with the use of D-mannose. Accordingly, D-mannose is considered to have promise as a potentially safe supplement for the treatment of UTI.

Dosage

Optimal dosage is unknown. Consider 2 g daily for prevention.

Precautions

Loose stools and abdominal bloating may occur at high doses.

Other Supplements

Other supplements that have been evaluated for the prevention of recurrent UTI include weekly to monthly bladder instillation of high dose hyaluronic acid and chondroitin.⁴⁰

Botanicals

Cranberry (*Vaccinium macrocarpon*)

Cranberry juice and powder have successfully been used to prevent urinary tract infection. The use of cranberry dates back to Native American tribes who used it for the treatment of urinary conditions. Historically, cranberry was thought to work by acidifying urine, yet recent studies have shown effects with minimal change in urine pH.⁴¹ The presumed active compounds, proanthocyanidins (PACs), inhibit bacterial adhesion to the bladder wall and decrease bacterial virulence.^{42,43} In a small trial, a dose of 72 mg of PAC was effective against *E. coli* infection, with the effect appearing to be dose dependent.⁴² The optimal dose of cranberry for the treatment of UTI is currently unknown.

Heterogeneity among the results of previous studies has made practical advice difficult, with variations in the dose and type of cranberry product making comparisons particularly challenging. A 2012 Cochrane review evaluated 24 randomized trials using cranberry juice or capsules and found some evidence that cranberry juice may decrease the frequency of UTI in susceptible women but found a high dropout rate, likely related to difficulty adhering to daily juice consumption.⁴⁴ In several trials, cranberry was found to be similarly effective to antibiotics. Optimal dosing could not be determined by these studies, with the authors concluding that cranberry juice should not be recommended and cranberry extract should be studied more thoroughly. A more recent trial in postsurgical patients found a 50% reduction in UTI compared to placebo among women administered two capsules bid (equivalent to two 8-oz glasses of cranberry juice daily).⁴⁵

Other trials have examined recurrent UTI in a more general population of women. In a randomized control trial, cranberry juice was compared to cranberry powder and a placebo in sexually active women.⁴⁶ The incidence of recurrent UTI was found to be reduced by approximately 30% in both cranberry groups. The doses used in this study were 250 mL of cranberry juice three times daily and concentrated cranberry juice tablets twice daily. The size of the tablets used was not disclosed. A separate trial used only 30 mL of cranberry-lingonberry concentrate daily, with a 20% risk reduction in recurrence observed.⁴⁷ Small studies that have shown success with cranberry tablets have used 400 to 800 mg doses twice daily.^{48,49} The size and design of these studies may limit extrapolation to larger populations. A trial randomizing older women to

500 mg of cranberry extract or 100 mg of trimethoprim found equal efficacy in the prevention of UTI⁵⁰; however, a trial in younger women comparing 500 mg of cranberry extract to TMP/SMX found cranberry to be inferior.⁵¹ Cranberry was also associated with a significantly lower rate of antibiotic resistance. Further studies are required to determine the most effective doses and frequency of cranberry supplementation.

Although cranberry products are frequently used to treat acute infection, the efficacy of this approach has not been studied.⁵²

Dosage

16 oz (500 mL) of unsweetened cranberry juice daily or cranberry extract 500 mg daily to 400–800 mg bid.

Precautions

Moderate interaction with warfarin is possible.

Many cranberry beverage products on the market contain only a small amount of cranberry juice and a significant amount of sweeteners. These may have a minimal impact on the urinary tract and a potentially negative impact on overall health.

Uva Ursi (*Arctostaphylos uva ursi*)

Uva ursi, or bearberry, leaf has long been used for urinary symptoms, although there is little human data regarding its efficacy in treating UTI. The active compound of uva ursi is thought to be arbutin, which is converted into hydroquinone following consumption.⁵³ Alkaline urine is thought to be necessary for the efficacy of uva ursi, with in vitro studies indicating activity against typical pathogens.⁵⁴

A preliminary trial reported the effectiveness of uva ursi in preventing recurrent UTI when combined with dandelion root and leaf.⁵⁵ In this trial, women took an extract for 1 month and were then followed for 1 year. During that time, 18% of women in the placebo group (27 individuals) and 0% in the treatment group (30 individuals) developed a UTI.

Dosage

3 g dried herb daily or as one cup of an infusion (3 g dried herb steeped in 150 mL of cold water for 12–24 h) four times daily.

Hydroquinone derivative 400–800 mg up to four times daily.

Precautions

Unfortunately, due to potential toxicity when used long term, uva ursi cannot be recommended for the purpose of prophylaxis. The toxicity of uva ursi may be related to the component hydroquinone and the inhibition of melanin,⁵⁶ although tannins may also play a role. The most common side effects of uva ursi include nausea and gastrointestinal distress. Rarer and more serious side effects may include hepatotoxicity, retinal disease,⁵⁶ seizure, cyanosis, and death. These risks are more pronounced with high doses and prolonged use. Many experts recommend limiting the use of uva ursi to acute infections for no longer than 1 week at a time and no more than five courses per year,⁵⁷ although others have argued that longer use may be safe.⁵⁸ Uva ursi is not considered safe in pregnancy or children. Uva ursi can turn urine a greenish-brown color and interfere with urinalysis.

Berberine

Berberine is an alkaloid found in a number of plants. Common in the traditions of traditional Chinese medicine, Ayurvedic medicine, and Native American healing, plant species that contain berberine include goldenseal (*Hydrastis canadensis*), oregon grape (*Berberis aquifolium*), bayberry (*Berberis vulgaris*), coptis (*Coptis chinensis*), and tree turmeric (*Berberis aristata*). A small number of studies of this compound have been reported. Some have used specific plants and others have used isolated berberine. In vitro studies have demonstrated berberine sulfate causes inhibition of *E. coli* adhesion to epithelial cells.⁵⁹ Studies using berberine for other indications have not reported toxicity or significant side effects.⁶⁰

Dosage

Optimal dose unknown.

Precautions

Berberine is not considered safe in pregnancy or for infants due to the risk of kernicterus.⁶¹ Berberine may also effect the cytochrome P450 system and, subsequently, the serum levels of other substances.

Goldenseal (*Hydrastis canadensis*)

Goldenseal is a woodland herbaceous plant native to North America. There is little data to support the use of goldenseal in the treatment of UTI. However, goldenseal root has been used for antimicrobial purposes. A study of goldenseal extract demonstrated in vitro activity against a number of common urinary pathogens⁶²; however, in vivo studies have not been reported. Flavonoids present in goldenseal have been posited to act synergistically with berberine.⁶³ There is concern of overharvesting and dwindling populations in the forests of Eastern North America.

Other traditional herbal preparations that have been used for urinary tract infections include stinging nettles, marshmallow root, echinacea, burdock, slippery elm, dandelion, and lovage. Some of these, such as *Echinacea angustifolia*, have been studied in the treatment of other conditions. For example, although Echinacea has been identified as an immune stimulator, it has not been studied in UTI. Others have little research regarding their clinical uses.

Pharmaceuticals

Antibiotics

Simple cystitis in women may be treated with 3 days of any of several antibiotics, including TMP/SMX and ciprofloxacin; however, current guidelines⁷ recommend using fluoroquinolones as a second line due to the potential development of resistance and potential harm. Other acceptable antibiotics include nitrofurantoin for 5 days. Amoxicillin is not recommended due to high resistance rates. Optimal therapy often depends on antibiotic resistance rates in the individual's community. Complicated UTIs require a longer course of antibiotics. Pregnant women and those with chronic disease, such as diabetes, should be treated for 7 days. Men with UTI are also typically treated for 7 days.

Recurrent UTI may be treated with prophylactic antibiotics daily or postcoital. Either approach has been shown to decrease the frequency of UTIs. Prophylactic antibiotics are usually continued for 6 to 12 months

before a trial period of cessation. In a Cochrane review, 6 and 12 months of prophylactic treatment were found to have equal efficacy.⁶⁴ Postcoital antibiotics appear to be as effective against recurrent UTIs as daily therapy among individuals with symptoms related to intercourse.⁶⁴

Dosage

Nitrofurantoin ER 100 mg bid for 5 days.

Trimethoprim/sulfamethoxazole one tablet DS (160/800 mg) bid for 3 days. Fosfomycin 3 g one dose. Ciprofloxacin 250 mg bid for 3 days.

Prophylactic doses are typically administered once daily at the same dose used for treatment. Common choices include nitrofurantoin, TMP/SMX, and ciprofloxacin daily.⁶⁵ Postcoital doses are provided as one tablet at the time of intercourse.

Precautions

Frequent or long-term use of antibiotics may be associated with medication side effects, bacterial resistance, and risk of disruption to normal bacterial flora.

Phenazopyridine

Phenazopyridine (Pyridium) can provide pain relief from dysuria and bladder spasms. Phenazopyridine is available over the counter and by prescription.

Dosage

100–200 mg bid for 2 days.

Precautions

This medication may turn urine a dark orange color, which may interfere with urinalysis.

Estrogen

Systemic estrogen replacement does not appear to have an effect on the frequency of UTIs in postmenopausal women^{66,67}; however, topical

estrogens may be beneficial for postmenopausal women with recurrent UTI.^{67,68} Successful studies have used estriol or estradiol in various forms.⁶⁹ Generally, studies have used a daily dose for 2 weeks and then twice weekly.

In a randomized trial, 0.5 mg of vaginal estriol nightly for 2 weeks followed by two times weekly for 8 months compared with placebo resulted in a significant reduction in the frequency of UTI (0.5 vs. 5.9 episodes per patient year). Vaginal estriol was found to be less effective than daily nitrofurantoin in preventing recurrent UTI.⁷⁰

Dosage

25 mcg vaginal estradiol every day for 2 weeks followed by two times weekly. Estradiol vaginal ring inserted every 12 weeks. 0.5 mg vaginal estriol every day for 2 weeks followed by two times weekly.

Precautions

Vaginal estrogen may be absorbed systemically at high doses, prompting the need for endometrial protection. In general, the safest approach is to use the lowest effective dose for the least amount of time needed.

Other Therapies to Consider

Behavioral Changes

Certain behaviors are thought to be associated with an increased risk of urinary tract infection, many of which are associated with irritation of the urethra or reflux of urine back into the bladder from the urethra. These include intercourse, tight clothing, holding of urine, and irritants such as bubble bath, douche, or other products. Many of these associations have no evidence base, but addressing them is associated with little risk of harm. For those with dysfunctional voiding, pelvic floor training is beneficial for improving muscle relaxation.

Acupuncture

In a randomized trial of acupuncture compared to no treatment, women with a history of recurrent UTI had a 50% reduction in UTI compared to

the control group (73% vs. 52% with no UTI over 6 months).⁷¹ The treatment group received biweekly acupuncture sessions over 4 weeks and were followed for 6 months. There was a reduction in bladder residuals in the treatment group of 50% compared to baseline, with no change observed in the control group. An earlier study by the same research team reported similar results with a partial response with sham acupuncture compared to a no-treatment control.⁷²

Mind-Body Skills

Although no specific mind-body skills have been evaluated for the prevention or treatment of UTI, mental and spiritual health are important components of overall health, including a healthy immune system. They, along with other foundations of health such as nutritional status, adequate sleep, and physical activity, are essential for optimal health. Attention to techniques to improve these factors, whether through yoga, mindfulness, social connectedness, or other strategies, will likely help limit susceptibility to infectious processes.

Biofeedback

In a subgroup of women who suffer from dysfunctional voiding, pelvic floor therapy was reported to decrease the frequency of recurrent UTIs.⁷³ Dysfunctional voiding is defined as increased external sphincter activity during voluntary voiding. This occurs in individuals without neurological deficits.

Pelvic floor relaxation training with biofeedback can be a useful intervention for those who have dysfunctional voiding with incomplete bladder emptying.

Children with overactive bladder and/or dysfunctional voiding also respond to biofeedback techniques aimed at decreasing recurrent UTI.⁷⁴ Biofeedback has utility in the treatment of dysfunctional elimination syndrome, which is a frequent cause of childhood UTI.⁷⁵ Diaphragmatic breathing combined with pelvic floor muscle retraining has also been shown to have efficacy in the treatment of children with UTI.⁷⁶

Prevention Prescription

- Encourage a plant-based diet high in garlic and onions.
- Remove possible bladder irritants such as caffeine, alcohol, and simple sugars.
- Encourage adequate fluid intake.
- Monitor stress and focus on foundations of health such as optimal diet, physical activity, sleep, mental, and spiritual health.
- Encourage frequent voiding and avoidance of holding urine.
- Avoid constipation.
- Consider changing method of birth control if frequent UTI is associated with the use of spermicides, condoms, or diaphragm use.
- Urinate after intercourse.

Therapeutic Review

Below is a summary of therapeutic options for acute treatment and prevention of UTI. If a patient presents with severe symptoms or a history suggestive of a complicated UTI, antibiotic therapy should be initiated immediately. For patients with mild to moderate symptoms, a ladder approach may be more appropriate. Patients should be counseled to seek further care if their symptoms worsen or do not resolve.

Acute Infection

Nutrition

- Encourage garlic consumption 

Supplements

- D-mannose: $\frac{3}{4}$ tsp three times daily 

Botanicals

- Cranberry: 16 oz of unsweetened juice daily or extract 400 mg bid 
- Usa ursi, hydroquinone derivative: 400–840 mg up to four times daily or 3 g of dried root daily 

Pharmaceuticals

- Nitrofurantoin ER: 100 mg bid for 5 days 
- Trimethoprim/sulfamethoxazole: one tab DS bid for 3 days 
- Fosfomycin: 3 g for 1 day 
- Ciprofloxacin: 250 mg bid for 3 days 
- Phenazopyridine: 200 mg bid for 2 days 
(Symptom management only)

Recurrent Infections

- Remove exacerbating factors
- Eliminate use of spermicides, trial change of birth control method 
- Urinate after intercourse 

Nutrition

- Encourage garlic consumption 
- Encourage adequate fluid intake 

Supplements

- Probiotics: one billion colony forming units daily of *Lactobacillus rhamnosus* and/or *fermentum* 
- D-Mannose: 2 g daily 
- Vitamin C: 100 mg daily 

Botanicals

- Cranberry: 16 oz of unsweetened juice daily or extract 400 mg bid 
- Uva ursi 
- Other herbal products that have potential benefit include berberine containing plants and echinacea

Pharmaceuticals

- Trimethoprim/sulfamethoxazole: one tablet DS daily 
- Nitrofurantoin: 100 mg daily 

- Ciprofloxacin: 250 mg daily 
- Vaginal estrogen: daily for 2 weeks, followed by twice weekly 

Other Therapies

- Biofeedback for those with dysfunctional voiding 
- Acupuncture

CHAPTER 23

Lyme Disease

Ather Ali, ND, MPH, MHS

Epidemiology

Lyme disease is a multisystem infection caused by the spirochetal bacterium *Borrelia burgdorferi*.^{1,2} *B. burgdorferi* sensu lato is the only species known to cause human infection in North America, whereas pathogenic species in Europe and Asia include *B. burgdorferi* sensu stricto, *B. garinii*, and *B. afzelii*, among others.^{1-3,3a} A number of other genospecies of *B. burgdorferi* have been identified, although the public health importance of these is not well defined.³

In 1977, Lyme disease was characterized by Steere et al. and named for the geographic area (Lyme, Old Lyme, and Haddam, Connecticut) where 39 patients presented with arthritic symptoms of previously unknown cause,⁴ although individual cases of Lyme borreliosis were described in Europe as early as 1883.³

Lyme disease is the most common vector-transmitted disease in the United States.³ Approximately 30,000 cases of Lyme disease are reported to the Centers for Disease Control and Prevention (CDC) each year, although the CDC notes that these rates reflect overdiagnosis of cases as well as overall underreporting, noting that approximately 300,000 diagnoses of Lyme disease are made in the United States each year.³ The vast majority (95%) of reported cases occur in the northeastern and midwestern areas of the United States in 14 states (Connecticut, Delaware, Maine, Maryland, Massachusetts, Minnesota, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, Virginia, and Wisconsin), with higher rates among children aged 5–15 years and adults older than 50 years.³ [Fig. 23.1](#) illustrates the distribution of Lyme disease in the United States; Vermont has the highest incidence of Lyme disease (108 cases per 100,000).⁶ Lyme

borreliosis also occurs in some Asian countries and throughout Europe.^{1,3}

The principal vectors for transmission of *B. burgdorferi* in the United States are nymphal deer ticks (*Ixodes scapularis* and *pacificus*) during the late spring or summer months.⁸ Infected ticks need to be attached for at least 24–48 hours to be able to transmit the organism.⁸ Bites from *Ixodes* ticks are usually painless and are often unrecognized. [Fig. 23.2](#) illustrates stages in the life cycle of the deer tick.

Ixodes ticks may also transmit *Anaplasma phagocytophila*, *Babesia microti*, *Borrelia miyamotoi*, *Ehrlichia* species, and Deer tick virus (a type of Powassan virus), either separately or in conjunction with *B. burgdorferi*.⁹ The impact of coinfections on the clinical course of Lyme disease can range from self-clearing fevers to life-threatening illnesses.²

Infected persons do not transmit Lyme disease to others; no epidemiological or clinical data currently confirm sexual or congenital transmission of *B. Burgdorferi* between humans,¹⁰ despite widespread concern. Uncomplicated Lyme disease is generally treatable, with a favorable prognosis.³

Clinical Course

Lyme disease is classified into three stages; early localized Lyme disease, early disseminated Lyme disease, and late Lyme disease.¹⁰ Early localized Lyme disease is characterized by a rash (erythema migrans, see [Fig. 23.3](#)) appearing at the site of the tick bite typically between 7 and 14 days following the bite.¹⁰ Erythema migrans is usually asymptomatic but may become pruritic or painful.² Systemic symptoms sometimes may accompany the rash and include fever, myalgia, headache, fatigue, and localized lymphadenopathy.¹⁰

Early disseminated Lyme disease may manifest as multiple erythema migrans, usually appearing 3–5 weeks following the tick bite. Neurological findings, including meningitis and cranial nerve palsies, may present. Other symptoms can include fatigue, flulike symptoms, carditis (manifested as heart block), and syncopal episodes.^{2,10}

Late Lyme disease occurs weeks to months after initial infection and is characterized by arthritis, usually affecting the large joints including the knee, and can be mono- or oligoarticular. Neurological complications may develop, including polyneuropathy, encephalitis, and encephalopathy.^{10,12}

Chronic Persistent Symptoms, Chronic Lyme Disease, Posttreatment Lyme Disease Syndrome, and Medically Unexplained Symptoms

Fatigue, arthralgia, and myalgia may persist after initial treatment for Lyme disease,² with reported frequencies varying between 0%–50% in published studies¹¹ and reported rates of 10%–20% in recent trials. Steere reports that 10% of patients with Lyme arthritis develop persistent synovitis that can last for months or years after initial antibiotic treatment.¹³ The impact of persistent symptoms is great; health-related quality of life is often severely compromised.^{14,15}

Risk factors for posttreatment Lyme disease syndrome include delays in initial diagnosis, higher severity of symptoms at treatment, and the presence of neurological symptoms at the time of initial treatment.¹¹

In a cohort in Westchester County, NY, Asch et al. found that 53% of patients reported persistent symptoms following initial treatment for Lyme disease, and noted that antibiotic treatment within 4 weeks of initial infection was associated with a greater likelihood of full symptom resolution.¹⁶ In a pediatric cohort, 23% of children developed refractory arthritis after initial treatment.¹⁷ These children were subsequently treated with nonsteroidal antiinflammatory drugs, intraarticular steroid injections, or disease-modifying antirheumatic drugs. None developed chronic arthritis or recurrent infections.¹⁷ Of note, polymerase chain reaction (PCR) testing of joint fluid can detect *B. burgdorferi* DNA for several weeks after spirochetes are killed¹⁸ and thus may not be a good test for effectiveness of treatment. Chandra et al. found significantly higher levels of antineural antibody reactivity in persons with persistent Lyme symptoms compared with post-Lyme healthy and normal healthy controls, suggesting chronic symptoms may be related to a differential immune response¹⁹; however, a recent follow-up study did not find similar proportions of antineural antibodies in chronic fatigue patients with similar symptomology.²⁰ Other potential mechanisms of posttreatment symptoms include autoimmunity, potential genetic predisposition, and inflammatory genotypes of *B. burgdorferi* as well as speculation regarding antibiotic-tolerant persistent organisms.¹¹

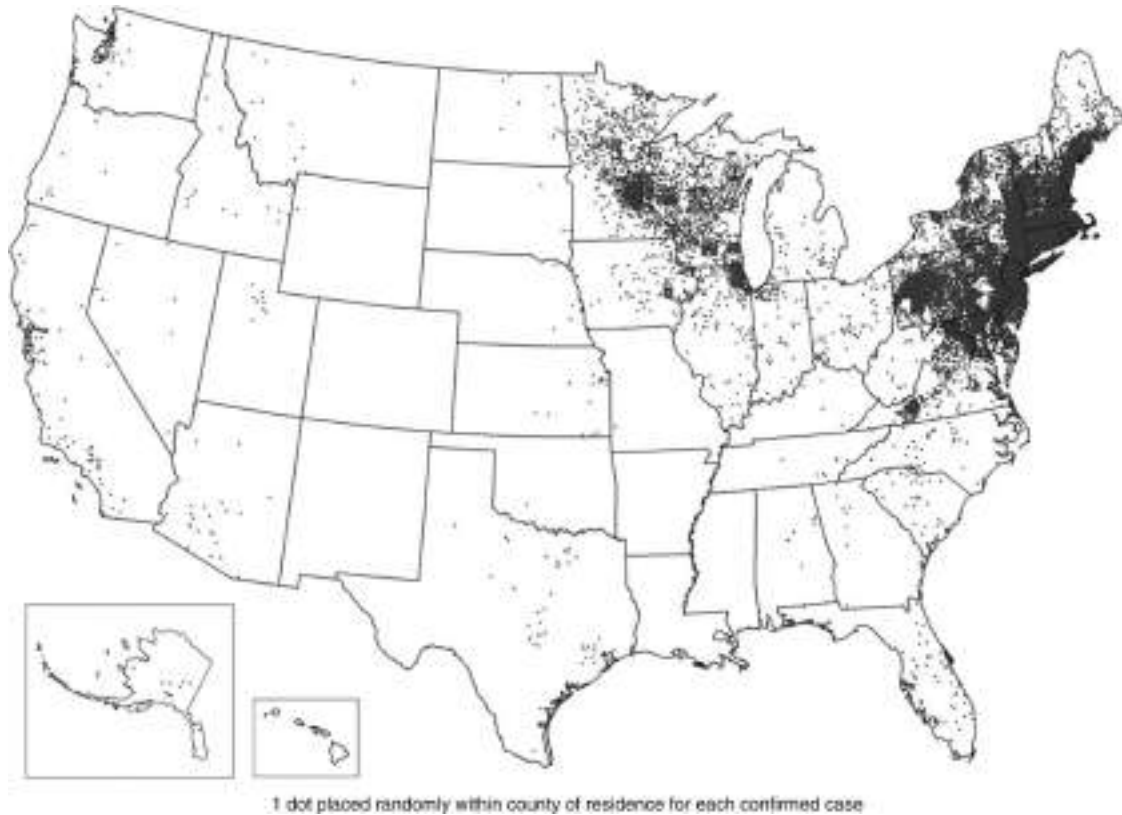

FIG. 23.1 Distribution of Lyme Disease.

The distribution of Lyme disease corresponds to the distribution of the Ixodes ticks that transmit *Borrelia burgdorferi*. (From the Centers for Disease Control and Prevention, Division of Vector-Borne Diseases: Lyme disease maps: <http://www.cdc.gov/lyme/stats/maps/map2013.html> .)

FIG. 23.2 Various stages of the life cycle of the deer tick *Ixodes scapularis*, the vector for Lyme disease in the northern United States. The larval stage is shown on the left, followed by the nymphal stage, the adult female, and the adult male on the right. Most infections are transmitted from ticks at the nymphal stage. (Originally published in Murray TS, Shapiro ED. Lyme disease. *Clin Lab*

Med . 2010;30:311).

FIG. 23.3 *Erythema migrans* Rash of Lyme Disease.

A, Typical macular lesion on left shoulder. B, Bull's eye lesion on lateral thigh with central punctum. C, Multiple lesions on back. D, Lesion with vesicular center on posterior thigh. (Courtesy Juan Salazar, MD, University of

Connecticut Health Center. In: Ferri FF, editor: *Ferri's Clinical Advisor*. Philadelphia, Elsevier; 2016:755.)

Chronic Lyme disease is a label used for a constellation of nonspecific symptoms, such as fatigue, night sweats, sore throat, lymphadenopathy, arthralgia, myalgia, palpitations, abdominal pain, nausea, diarrhea, sleep disturbance, poor concentration, irritability, depression, back pain, headache, and dizziness, with or without serological or clinical evidence of previous infection by *B. burgdorferi*.²¹⁻²⁵ The diagnosis of chronic Lyme disease is nebulous; no standard definition exists, though it is understood to be distinct from “post-Lyme disease syndrome” or “late Lyme disease” in which arthralgia and other symptoms persist after documented *B. burgdorferi* infection.^{21,26,27}

Patients are frequently diagnosed with chronic Lyme disease based on nonstandard interpretations of serology or other testing that has limited validity and reliability, or more often, based on clinical symptoms alone²⁶ or occasionally attributing symptoms to chronic coinfections.²⁸ Chronic Lyme disease is diagnosed throughout the United States, including areas where Lyme disease is not endemic.^{24,29,30} Often, persons self-diagnose using lists of multiple nonspecific symptoms found on the internet. Treatment usually includes regimens of multiple antibiotics, often administered parenterally, frequently continuing for months or years in opposition to standard guidelines for treatment of Lyme disease.²⁶ This approach is far longer in duration and associated with substantially greater risks than standard treatment for any other spirochetal infection and virtually all infectious agents treated with antibiotics. Chronic Lyme disease regimens often result in considerable out-of-pocket expenses (often amounting to tens of thousands of dollars per year), patient distress, and potential harm,³¹ as well as increasing risk of selecting for antibiotic resistant bacteria.²⁴ Some attribute chronic Lyme disease symptoms to drug-resistant reservoirs of *B. burgdorferi*, including atypical intracellular cystic or spherical forms.^{32,33} However, no research has correlated the presence of these organisms with persistent symptoms, nor has the eradication of these been associated with improvement in symptoms.³⁴

Despite the challenging political controversy regarding persistent Lyme symptoms, research has been unable to associate chronic symptoms with the presence of spirochete infection. Further, no association between the eradication of Lyme infection and improvement of symptoms has been observed.

One survey found that 2.1% of Connecticut-based primary care physicians diagnose and treat chronic Lyme disease, while the majority were unsure or did not believe in the existence of chronic Lyme disease.⁴ A 2014 survey found that less than 5% of Public Health faculty members reported expertise in Lyme disease or posttreatment Lyme disease syndrome.³⁵ The predominant infectious disease, pediatric, and neurology organizations discount chronic Lyme disease as a distinct clinical entity, while other academic, professional, and advocacy organizations argue the contrary. This issue has become politicized with acrimonious debate among academic organizations and advocacy

groups.³⁶

Chronic Lyme disease symptoms may resemble other medically unexplained symptoms (also known as functional somatic syndromes), including chronic fatigue syndrome, irritable bowel syndrome, fibromyalgia, sick building syndrome, and chronic unexplained pain,^{15,37,38} as well as neurological conditions such as amyotrophic lateral sclerosis³⁹ or multiple sclerosis.⁴⁰ The lack of clear pathophysiology in medically unexplained conditions often results in extensive and expensive diagnostic workups and significant iatrogenic complications.^{41,42} Like many chronic conditions in which persons are suffering from pain, psychiatric comorbidities are prevalent and often overlooked.^{29,42-44} At least 13% of outpatient visits are attributable to medically unexplained symptoms.^{42,45} Suffering is often exacerbated by a self- or provider-validated cycle that attributes common somatic complaints to serious conditions.⁴⁴ Significant symptomatic and objective overlap occurs in these conditions in addition to high rates of cooccurrence of different syndromes.^{44,46,47}

In one qualitative study, patients identifying with chronic Lyme disease reported significant declines in health status and dissatisfaction with healthcare in mainstream settings.¹⁵ In one sample, nearly half of chronic Lyme disease patients were diagnosed with fibromyalgia.⁴⁸ Occasionally, persons with other defined medical conditions (including cancer) are misdiagnosed as having chronic Lyme disease.⁴⁹ Many syndromes present with similar constellations of nonspecific symptoms such as muscle weakness, arthralgias, and general fatigue.⁵⁰ Patients with these conditions regularly seek out complementary and alternative medicine (CAM) therapies and providers.^{15,51-54}

1. Persons suffering from chronic persistent symptoms often present with debilitating and severe symptoms. Patients should not be dismissed or disregarded because the pathophysiology of their symptoms is unknown. Effective symptomatic treatments can significantly improve quality of life.
2. In most conditions, CAM patients and providers are promoting less-invasive therapies than the mainstream standard-of-care. Lyme disease is an unusual case where CAM patients and providers are often seeking more invasive and elaborate interventions than conventionally provided.

Diagnosis

Lyme disease is diagnosed according to historical and physical findings; serology is used to support the diagnosis in persons without erythema migrans. Early Lyme disease is generally diagnosed based on the presence of erythema migrans; persons at this early state will likely be seronegative, as erythema migrans appears before an adaptive immune response develops.⁵⁵ In a case series in Maryland, 87% of patients with early Lyme disease presented with erythema migrans⁵⁶; 70% of the Lyme disease cases reported to the CDC between 2003 and 2005 presented with erythema migrans.⁵⁷ The FDA does not recommend serological testing in early Lyme disease because of the low sensitivity of tests in early manifestations.⁵⁸

The CDC criteria for diagnosis of Lyme disease are (1) erythema migrans alone or (2) at least one late manifestation plus laboratory confirmation of infection. Laboratory confirmation, by this definition, includes isolation of *B. burgdorferi* from a clinical specimen or the presence of IgM or IgG antibodies to *B. burgdorferi* in serum or cerebrospinal fluid.⁵⁹ The CDC recommends a two-tier process when testing blood for evidence of Lyme disease. Initial testing using an enzyme-linked immunosorbent assay (ELISA) or immunofluorescent assay (IFA) is followed by a Western blot for confirmation.⁵⁹ It is important to note that the CDC criteria for Lyme disease are not intended for use by clinicians to make a diagnosis of Lyme disease. Rather, they are intended for national surveillance data,⁶⁰ although the majority of cases in practice do fulfill this definition.⁵⁵

ELISA testing is associated with many false positives,⁶¹ thus the need for confirmation of a positive or equivocal ELISA by Western Blot. A negative ELISA, on the other hand, does not warrant further serology.^{26,59,62} Western blot testing is more specific, that is, it will likely be positive when a person is truly infected. IgM antibodies will appear first, typically within 1–2 weeks of initial infection. IgG antibodies appear later, usually within 2–6 weeks after the onset of erythema migrans. At least 90% of persons with late Lyme disease have positive IgG antibodies.⁶³ These may remain elevated following successful antibiotic treatment and symptom resolution.⁵⁵ Steere et al. reported that 16% of a large cohort had systemic symptoms of Lyme disease without initially presenting with erythema migrans that later demonstrated positive serology.⁶⁴ Of note, persons who fit into this rubric should have objective symptoms, such as arthritis or facial palsy, as opposed to arthralgia.

The sensitivity of two-tier testing is greatest in late Lyme disease. In the acute phase of erythema migrans, sensitivities range from 29% to 40% and increase to 97% in those with arthritis (with specificity at 99%).¹ Of note, there is considerable variability between the different commercial assays that are FDA-cleared, especially for the detection of IgM antibodies.¹

It is not recommended to screen persons without objective evidence of Lyme disease for possible exposure to Lyme disease.^{55,62} Seropositivity indicates past exposure and does not prove an active infectious process⁶⁵ and should not be used to diagnose active Lyme disease. Serological testing is most useful in persons with a high pretest probability: persons in which Lyme disease is likely based on history and clinical presentation. In this population, positive serology supports the diagnosis of Lyme disease. In late Lyme disease, a positive IgG result is nearly always observed. In persons with low prior probability of Lyme disease, serological testing will result in more false positive results.

Testing of ticks for *B. burgdorferi* is generally advised to determine whether antibiotic therapy should be initiated.⁶⁶

Strict use of the standard diagnostic criteria will minimize false positives but may result in atypical presentations being missed.⁶⁷ Less stringent diagnostic criteria incorporating broader clinical symptoms have been proposed and are in use by a minority of clinicians⁶⁸; however, no literature is available assessing the diagnostic accuracy of these alternative criteria.

Recent advances in Lyme disease testing can potentially improve the sensitivity and specificity of current diagnostic methods, although these advances have not translated to better standards of care.⁶² A number of unconventional (not FDA-cleared) direct-to-practitioner lab tests exist that claim to improve upon standard Lyme disease assessment and diagnosis; however, it is beyond the scope of this chapter to review them all. These are often propriety tests developed and marketed by a single laboratory. These tests are regularly paid for out-of-pocket by patients, often with extensive markups by practitioners. Besides marketing materials from the laboratories themselves, there is minimal independent data assessing the validity of these tests. Literature from one representative test included an advertisement for the test that superficially resembled a peer-reviewed journal article. The article promoted incorporating the lab's novel testing into existing diagnostic algorithms, and claiming that the novel tests have relevance by "... clarifying clinically ambiguous cases, and confirming therapeutic

success.” No data justifying these claims are presented, although the choices of immunological markers appeared reasonable.

The alternative tests report positive results at much higher rates than conventional serology. Despite the documented shortcomings of conventional serology (such as low sensitivity during early infection and subjective interpretation of bands)⁶² that can result in false negatives and the appeal of tests that claim more sensitivity, the alternatives cannot be endorsed at this time. Tests that provide unique interpretations of Western blot results do not increase sensitivity, but rather decrease specificity.⁶² It is unknown whether the higher rates of positive results from alternative tests are due to more true positives or whether the results are (1) impacted by selection effects (where people more likely to be infected are sent to alternative labs), (2) less precise or accurate than conventional testing, (3) false positives,⁶² (4) affected by confirmation bias, or (5) a combination thereof. Unfortunately, no independent data is available that assesses these factors.

Due to the high out-of-pocket cost and uncertain benefit of these tests, none of these invalidated tests⁶⁹ can be recommended without documenting adequate human testing, at minimum ensuring (1) high sensitivity and specificity in diagnosing Lyme disease according to established criteria, (2) minimal intrasample variability, assessed independently,^{63,70,71} and (3) comparative effectiveness in relation to and in addition to standard ELISA and Western blot testing.

If a tick is engorged or likely attached for >72 hours, consider treating with a single dose of 200 mg of doxycycline. This can reduce the risk of Lyme by 87%. Only 1%–3% of tick bites in endemic areas result in infection. The number of tick bites needed to be treated to prevent one case of erythema migrans is 50 (number needed to treat, NNT = 50). If the tick is not engorged or is known to be attached for less than 72 hours, consider reassurance.²

Integrative Therapy

Persons with Lyme disease typically seek CAM for three major reasons. Some seek CAM therapies in addition to conventional therapies—a *complementary* or *integrative* approach. Some believe that conventional therapies are ineffective or dangerous and seek more “natural”

alternatives to mainstream therapies. Some present after learning about chronic Lyme disease through the internet or advocacy groups promoting treatment protocols employing a myriad of long-term antimicrobials (often parentally),^{68,72} nutritional supplements, botanicals, and other unconventional therapies, such as hyperbaric oxygen⁷³ or antifungals.^{15,74}

Since the evidence that differentiates chronic Lyme disease from other medically unexplained conditions is unclear, this section will focus on acute Lyme disease as defined and diagnosed using standard criteria.²⁶

Risk Reduction

Reducing the risk of tick bites in endemic areas and proper removal of ticks within 48 hours following a bite are the most effective means to reduce the incidence of Lyme disease (see *Prevention Prescription*).

No major lifestyle interventions such as specific diets or exercise regimens have been shown to reduce risk of contracting Lyme disease.⁷⁵ “Immune boosting” formulas or other natural products have not been shown to affect the incidence of Lyme disease.

Acute Infection

Pharmaceuticals

Lyme disease is best treated with antibiotics. Treatment within 4 weeks of symptom onset is strongly associated with complete recovery.¹⁶ Coinfections should be addressed as warranted. Persons experiencing late Lyme disease symptoms with neurological, rheumatological, or cardiac manifestations should be treated by an appropriate specialist. It is important to note that no credible alternatives exist to prompt antibiotic treatment; the risks of inadequate treatment are progression to more severe symptomology and greater risk of long-term sequelae.

Antibiotics

Doxycycline is the first-line therapy in early Lyme disease; it is effective for the treatment of erythema migrans as well as for human granulocytic anaplasmosis (HGA) that may occur concurrently with early Lyme disease. Patients experiencing carditis or arthritis can use these regimens as well.²

In persons with early Lyme disease with cranial nerve palsy (without clinical evidence of meningitis), oral doxycycline, amoxicillin, or cefuroxime axetil can be used.^{2,76}

Dosage (Adults)^{2,26}

Doxycycline: 100 mg twice per day for 14 days (range: 10–21 days)

Amoxicillin: 500 mg three times per day for 14 days (range: 14–21 days)

Cefuroxime axetil: 500 mg twice per day for 14 days (range: 14–21 days)

Precautions

Doxycycline should not be used in children aged <8 years or in pregnant or lactating women. Amoxicillin and cefuroxime axetil have also demonstrated efficacy in treating early Lyme disease, are effective for the treatment of early Lyme disease, and can be used in children aged <8 years.^{2,26}

Late Lyme arthritis can be treated with somewhat longer regimens than those used in early Lyme disease. Some persons may not respond or require intravenous antibiotics. For persons with recurrent or persistent arthritis, the Infectious Disease Society of America recommends additional 4-week courses of oral antibiotics for persons whose symptoms have improved with initial oral treatment and intravenous therapy for persons not experiencing substantial improvement on oral antibiotics.²⁶

Dosage

Doxycycline: 100 mg twice per day for 14 days (range: 14–21 days)

Amoxicillin: 500 mg three times per day for 14 days (range: 14–21 days)

Cefuroxime axetil: 500 mg twice per day for 14 days (range: 14–21 days)

Precautions

Doxycycline can increase photosensitivity; avoid exposure to sunlight, sunlamps, or tanning beds while using doxycycline. A sunscreen (minimum SPF 15) can also be helpful. Do not take iron supplements, multivitamins, calcium supplements, antacids, or laxatives within 2 hours before or after taking doxycycline.

Supplements

Probiotics

Antibiotic-associated diarrhea occurs in approximately 25% of patients⁷⁷; probiotic therapy may mitigate this.⁷⁸ As probiotic effects vary by indication and strain, recommendations generally need to be strain specific. The strains most likely to be effective in treating antibiotic-associated diarrhea are *Lactobacillus* GG, *Bifidobacterium lactis* Bb-12, *Lactobacillus acidophilus* La-5,⁷⁹ *Lactobacillus sporogenes*, and *Saccharomyces boulardii*.⁷⁸ Some evidence supports the use of *S. boulardii* in treating *Clostridium difficile* colitis.⁸⁰

Dosage

Five to forty billion colony forming units/day⁷⁸ throughout the duration of antibiotic treatment⁸¹ or 200 g of a specific yogurt product containing *Lactobacillus rhamnosus* GG, *Bifidobacterium lactis* Bb-12, and *Lactobacillus acidophilus* La-5⁷⁹

Precautions

Probiotics are generally safe; however, case reports of endocarditis and sepsis in immunocompromised patients exist.⁸² In addition, caution should be exercised in patients with a central venous catheter or who have compromised intestinal mucosa.⁷⁷

Chronic Persistent Symptoms

It is important to assess whether Lyme disease has been adequately treated and that the patient actually had objective evidence of Lyme borreliosis. Persons without an initial diagnosis of Lyme disease using

objective criteria should be discouraged from pursuing a diagnosis of chronic Lyme disease. Persistent symptoms may not be due to continued active borreliosis; rather, such patients can be treated with symptomatic and antiinflammatory measures. Antibiotic-refractory arthritic symptoms may also be autoimmune in origin or attributed to persistent infection.^{11,18}

For persons with unexplained symptoms with a low prior probability of Lyme disease, the value of alternative testing is minimal as true positives will be rare. If test results are positive, there are psychological benefits from a diagnosis supporting a defined medical process, whether or not the diagnosis is accurate. This potential benefit may be outweighed by the high possibility of negative externalities from identifying with cases of severe, lifelong debilitation (prevalent in the popular media)^{83,84} coupled with highly-invasive and potentially harmful treatments of unclear benefit. Clearly, there is benefit in a true positive identification of Lyme disease with subsequent treatment resulting in symptomatic relief, thereby reducing the likelihood of long-term sequelae.

A number of unconventional methods are purported to treat acute, or more often, persistent infection. Some, purporting to detect “vibrations” in the body (such as the Rife machine) or electrodiagnostic devices (such as the Vegatest) have no scientific basis nor any validity in treating Lyme disease (or any other disorder). Some elaborate alternative protocols exist^{85,86} but have not been systematically assessed in controlled trials. Other common herbal therapies with some evidence for antimicrobial activity that are safe include *Artemisia annua*, olive leaf, goldenseal (*Hydrastis canadensis*), and grapefruit seed extract, although they have not demonstrated antispirochetal activity. Some other common interventions in Lyme disease protocols include chaparral (*Larrea divaricata*)⁸⁷ and colloidal silver⁸⁸ that have significant risks of toxicity and harm; these should be actively discouraged.¹⁵

The following are a sampling of integrative therapies that can be antiinflammatory or analgesic with a high potential benefit-risk ratio. As there are a paucity of clinical trials assessing CAM interventions in persons with persistent symptoms following Lyme borreliosis, therapies that are safe and have demonstrated efficacy in inflammatory conditions or medically unexplained conditions (such as fibromyalgia) that symptomatically resemble chronic Lyme disease were chosen. A more comprehensive list of potential therapies can be found in the fibromyalgia and chronic fatigue syndrome chapters ([Chapters 47](#) and [48](#)).

It is critical to acknowledge and address the real suffering and debilitating symptomology of patients,^{83,84} regardless of whether the etiology of their symptoms is clear or ambiguous.¹⁵ The benefits of a salutogenic patient-practitioner relationship are described in [Chapter 3](#).

Pharmacological

Antiinflammatory Treatments

Nonsteroidal antiinflammatory drugs (NSAIDs), intraarticular steroid injections, or disease-modifying antirheumatic drugs (DMARDs) have all been used to treat persistent symptoms associated with Lyme disease.¹⁷

Antibiotics

Five randomized controlled trials have been conducted in patients with post-Lyme disease syndrome using long-term antibiotic regimens.^{14,24,89-91} Krupp et al. demonstrated improvements in fatigue in persons treated with intravenous ceftriaxone after 28 days compared to placebo, without improvement in cognitive function or a laboratory measure of infection.⁸⁹ Six of the 52 patients that began the interventions (11.5%) discontinued the study due to adverse events; of these, four patients (three on placebo) required hospitalization due to line sepsis.⁸⁹ None of the other studies have demonstrated significant benefit for long-term antibiotic treatment in patients with ongoing subjective symptoms following standard treatment of initial Lyme disease.^{14,91a}

Case reports documenting symptomatic relief using long-term antibiotic therapy are common,⁹² and Cameron et al. reported significant improvements in quality of life in patients experiencing persistent Lyme disease symptoms when treated with amoxicillin for 3 months,⁹³ although this study has been criticized for a number of methodological flaws that may render its conclusions moot.⁹⁴ Of note, a number of antibiotics used to treat Lyme disease exhibit antiinflammatory effects, including macrolides and tetracyclines,⁹⁵ while B-lactams⁹⁶ and tetracyclines⁹⁷ exhibit neuroprotective effects. Thus symptomatic relief using antibiotics can be achieved through other pharmacological actions besides antimicrobial effects.

Precautions

The risks of long-term antibiotic therapy are well documented including anaphylaxis and biliary complications, resulting in cholecystectomy⁹⁸ as well as fatal sepsis³¹ and infection of intravenous catheters.²⁴ Longer courses of antibiotics increase the risk of adverse events.¹⁸ NSAIDs, DMARDs, and intraarticular injections also pose considerable risk and may be undesirable if treatments with a better risk-benefit ratio exist.

If the presence of persistent borreliosis cannot be established using objective criteria, nonpharmacological therapies are initially recommended for symptomatic relief. Pharmaceuticals can be considered if nonpharmacological means do not provide adequate relief. Antibiotics should only be used if active borreliosis is confirmed.

Gabapentin

In an open pilot study in 10 patients with neuroborreliosis, 10 patients were treated with gabapentin (starting at 300 mg/day and increasing to a maximum tolerated dose). Weissenbacher et al. reported that pain symptoms improved in 90% of patients and sleep quality and general health improved in 50% of patients.⁹⁹

Dosage

300 mg/day titrating up to a maximum tolerated dose within 4–12 weeks. In the study by Weissenbacher et al., the average dose associated with pain reduction was 700 mg.⁹⁹

Precautions

Gabapentin is associated with a variety of adverse effects, including depression and increasing the risk of suicide.¹⁰⁰ Abrupt discontinuation of gabapentin can cause withdrawal symptoms.⁹⁹

Herbal

The herb *Uncaria tomentosa* (*Cat's claw*) is prominent in a number of alternative protocols for Lyme disease.⁸⁵ It has antioxidant, antiinflammatory, and immunostimulant activity.¹⁰¹ No evidence exists for specific antispirochetal activity. In a randomized trial in persons with

rheumatoid arthritis, a specific extract of *Uncaria tomentosa* demonstrated efficacy in reducing painful joints.¹⁰²

Dosage

60 mg daily in three divided doses of an extract free of tetracyclic oxindole alkaloids.¹⁰²

Precautions

Can cause headache, vomiting, and dizziness.

Lifestyle

Antiinflammatory Diet (See [Chapter 88](#))

The antiinflammatory diet is characterized by emphasizing omega-3 fatty acids (found primarily in deep-water fish) and minimizing omega-6 fatty acids, with an emphasis on unprocessed whole grains, beans, and fruits and vegetables. Fish oil, especially EPA, is often added as a supplementary measure. There is significant overlap between the antiinflammatory diet and the Mediterranean diet in reducing risk of cardiovascular disease.^{103,104}

Antiinflammatory diets have demonstrated clinical benefits in persons with inflammatory diseases such as rheumatoid arthritis.^{103,105} More extensive antiinflammatory dietary measures, such as a gluten-free vegan diet, have been shown to reduce inflammatory markers in patients with rheumatoid arthritis¹⁰⁶ as well as improve symptoms.¹⁰⁷

Aerobic and Weight-Bearing Exercise

Moderate aerobic exercise has been shown to improve physical function, mood, symptom severity, and self-efficacy in fibromyalgia patients,¹⁰⁸ as well as energy in patients with unexplained fatigue.¹⁰⁹ Other trials have confirmed the benefits of aerobic exercise and muscle strengthening for fibromyalgia,¹¹⁰⁻¹¹² as well as hydrotherapy¹¹³ and walking.¹¹⁴ Pain, the most characteristic symptom of fibromyalgia, was reduced in persons exercising at low-to-moderate intensity two or three times per week with positive effects on depressed mood, quality of life, and physical fitness.¹¹⁵ Aerobic exercise, performed twice weekly over 8 months, can alleviate

symptoms as well as demonstrate antiinflammatory effects.¹¹⁶

Multiple systematic reviews indicate that, among myriad treatments proposed for fibromyalgia, mild-to-moderate intensity aerobic and weight-bearing exercise (including aquatic exercise)¹¹⁷ has consistently shown to be effective in alleviating, pain, fatigue, depression, and improving health-related quality of life in persons with fibromyalgia.¹¹⁸⁻¹²²

Dosage

Mild aerobic exercise with weight training two to three times weekly for at least 4 weeks.¹¹⁸ Initiate at 15 minutes and increase to 30 minutes as tolerance grows.

Supplements

Probiotics

Preliminary studies suggest the efficacy of probiotic strains in treating chronic fatigue syndrome-associated anxiety¹²³ using *Lactobacillus casei* strain Shirota (LcS). Some chronic Lyme disease protocols include probiotics.⁷² Some probiotics have antiinflammatory properties that are strain- and species-specific and may be used symptomatically.^{124,125}

Dosage

24 billion colony forming units of *Lactobacillus casei* strain Shirota (LcS); available in a fermented milk commercial product (Yakult).

Omega-3 Fatty Acids

Omega-3 fatty acid intake is inversely associated with major depression,^{126,127} a strong comorbidity with chronic fatigue syndrome and fibromyalgia.¹²⁸ Further, serum levels of EPA are significantly lower in chronic fatigue syndrome patients than in normal controls.¹²⁹ Omega-3 fatty acid supplementation has some evidence for efficacy in treating a number of nonspecific symptoms associated with persistent Lyme disease, including fatigue, arthralgias,¹³⁰ depression,¹³¹ and anxiety.⁶⁹

Dosage

2500 mg of omega-3 fatty acids (with 50% or more EPA), consistent with a case series¹³² documenting clinically significant pain reduction and improved function associated with a variety of conditions including fibromyalgia.

Intravenous Micronutrient Therapy

A clinical trial of a popular intravenous formula (the Myers' cocktail)¹³³⁻¹³⁵ found both a large treatment effect and a large placebo effect in improving pain, mood, and global function, with effect sizes comparable to FDA-approved drugs for fibromyalgia.¹³⁴ Contextual factors and the therapeutic relationship are important factors in the overall effectiveness of a therapy, especially with subjective outcomes such as in chronic pain syndromes,^{136,137} and perhaps stronger with alternative therapies associated with elaborate rituals and distinct contexts.¹³⁸ There is an ethical imperative to provide therapeutic options that are safe and effective for symptomatic relief, with appropriate informed consent, without endorsing approaches that are unsafe or ineffective.¹³⁹ There is emerging literature on the psychobiology of the placebo effect, with clinically significant effects demonstrated in a variety of contexts.^{138,140} Intentional use of placebo in clinical practice is routine¹⁴¹ with complex ethical implications.¹³⁸

Dosage

Weekly slow intravenous infusions (over 10 minutes) of Myers cocktail. Persons responding to the Myers' cocktail should experience significant symptomatic relief within 4 weeks. The Myers' cocktail contains 5 mL magnesium chloride hexahydrate (20%), 3 mL calcium gluconate (10%), 1 mL Hydroxocobalamin (1000 mcg/mL), 1 mL pyridoxine hydrochloride (100 mg/mL), 1 mL dexpanthenol (250 mg/mL), 1 mL B-complex 100 (contains 100 mg thiamine HCl, 2 mg riboflavin, 2 mg pyridoxine HCl, 2 mg panthenol, 100 mg niacinamide, 2% benzyl alcohol, 5 mL vitamin C [500 mg/mL], and 20 mL sterile water).

Acupuncture

Acupuncture^{142,143} (and sham acupuncture¹⁴⁴) have been shown to symptomatically improve pain associated with fibromyalgia. Although analgesic effects often do not differ from placebo acupuncture,¹⁴⁵ the therapy has minimal risk,¹⁴⁴ reduces anxiety,¹⁴⁵ and may be effective for fatigue¹⁴⁶ in chronic disease.¹⁴⁷

Dosage

20-minute individualized session weekly.

Massage Therapy

Various forms of massage have demonstrated short-term beneficial effects in treating fibromyalgia symptoms in randomized trials.^{148,149} Despite the lack of a complete understanding of the mechanisms, massage has clearly been shown to improve osteoarthritis pain.¹⁵⁰⁻¹⁵⁵ Massage therapy has been evaluated and found efficacious as an adjunct treatment for pain secondary to cancer,¹⁵⁶⁻¹⁶⁸ low back pain,¹⁶⁹⁻¹⁷² procedural pain,^{173,174} rheumatoid arthritis,^{175,176} and fibromyalgia.^{177,178} It also has been shown to be beneficial for patients with chronic pain following spinal cord injury.¹⁷⁹ In a randomized, open-label clinical trial, a series of classical Swedish massage therapy sessions was found to be as effective as conventional analgesia for chronic rheumatic pain.¹⁷⁵

Dosage

Swedish or other massage approach (30–60 minutes) one to two times weekly.

Mind-Body Therapy

Psychological trauma is associated with persistent Lyme disease symptoms¹⁸⁰ and fibromyalgia,¹⁸¹ and chronic stress tends to exacerbate symptoms.^{182,183} Mind-body therapies are especially attractive in cases where psychological trauma predates the onset of symptoms, as both

somatic and psychological benefits are often seen.¹⁸⁴ Cognitive-behavioral therapy has demonstrated good evidence in improving function in adults¹⁸⁵ and adolescents with fibromyalgia.¹⁸⁶

Tai Chi

Two randomized trials demonstrated significant benefits of tai chi, a Chinese mind-body practice involving meditation, deep breathing, and slow, gentle, graceful movements^{187,188} for fibromyalgia. Tai chi has also shows promise in improving symptoms of rheumatoid arthritis.^{74,189}

Dosage

Group course with experienced teacher twice weekly for at least 12 weeks.

Mindfulness Meditation

A number of trials have assessed the effects of various regimens of mindfulness meditation with promising results in outcomes ranging from pain severity, physical function, and tender point threshold¹⁹⁰⁻¹⁹⁴ in persons with fibromyalgia.

Mindfulness-based stress reduction (MBSR) is a standardized protocol of mind-body therapies that involves mindfulness meditation, patient education, and group support¹⁹⁵⁻¹⁹⁷ developed by Kabat-Zinn et al. at the Stress Reduction Clinic of the University of Massachusetts Medical Center. Several randomized trials have demonstrated the benefit of MBSR for a variety of chronic conditions with improvements in psychological and somatic measures.¹⁹⁸⁻²⁰⁸

Dosage

The standard 8-week course of MBSR consists of an instructor delivering group instruction for 2.5 h/wk (consisting of meditation practice, group discussions, and mindfulness skill-building activities),¹⁹⁷ a single half-day meditation retreat, and daily practice of 30–45 minutes 6 days per week.¹⁹⁵ Internet-delivered interventions have also demonstrated promise.^{209,210}

Therapies to Consider

If chronic persistent symptoms continue without resolution and other conditions are definitively ruled out, other complementary therapies can be considered such as trigger-point injections, chiropractic manipulation, and myofascial release therapy, all of which demonstrate some evidence of efficacy.¹⁸⁵

Prevention Prescription for Lyme Disease

Reduce Risk for Tick Bites in Endemic Areas

- Clear brush and trees, remove leaf litter and woodpiles, and keep grass mowed.
- Wear light-colored clothing that covers the skin to aid in identifying and protecting from tick bites. Tuck pant legs into socks when outdoors in vegetated areas.
- Apply tick and insect repellents containing 20%–30% DEET [N,N-diethyl-3-methyltoluamide],³ although excessive doses have been reported to cause neurological complications in children.²¹¹
- Permethrin, a synthetic pyrethroid applied to clothing, is effective in killing ticks. Toxicities have been reported at high doses.^{211,212}
- A plant-based insect repellent containing oil of lemon eucalyptus has been shown to protect from mosquitoes but has not demonstrated efficacy against ticks.²¹¹
- The most effective methods shown to reduce risk of Lyme disease in endemic areas are the use of protective clothing and using tick repellents on the skin and clothing.²¹³
- Check skin for ticks after being outdoors in the late spring and summer months in endemic areas. [Fig. 23.4](#) illustrates the life cycle of ticks that can transmit Lyme disease.
- Bathe within 2 hours after spending time in vegetation.^{3,214}
- Pesticides are effective, but recommendations are tempered due to environmental concerns and risk of harm to children and wildlife.

Reduce Risk for Lyme Disease After a Tick Bite

- Remove ticks using fine-tipped tweezers and a steady motion, grasping the tick as close as possible to the skin. Pull directly away

from the skin. Do not use petroleum jelly, nail polish, or heated instruments to remove a tick.

- Monitor for signs and symptoms of Lyme disease after a tick bite.
- Consider antimicrobial prophylaxis (200 mg doxycycline in a single dose for adults or 4 mg/kg up to a maximum dose of 200 mg for children aged >8 years, and 250 mg of amoxicillin in children aged <8 years) if a tick is attached for more than 48 hours in an endemic area, although risk of *B. burgdorferi* infection is low; 1.2% of untreated children in a large cohort developed Lyme disease after a tick bite in a highly endemic area. Treatment subsequent to symptom onset is associated with complete recovery.²¹⁵

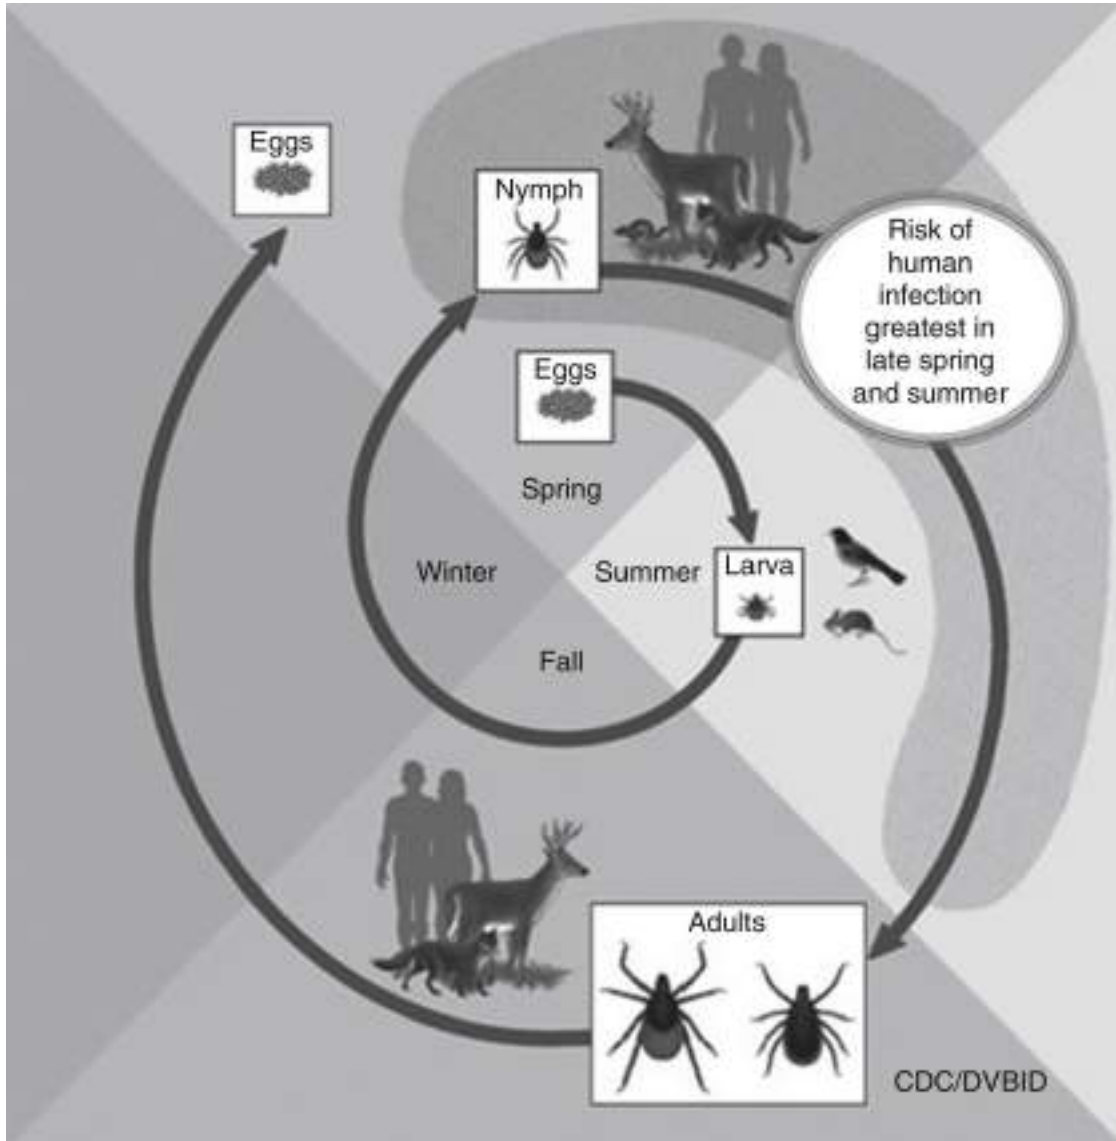

FIG. 23.4 Life cycle of blacklegged ticks that can transmit anaplasmosis, babesiosis, and Lyme disease. (From the Centers for Disease Control and Prevention, Division of Vector-Borne Diseases: Life cycle of hard ticks that spread disease: http://www.cdc.gov/ticks/life_cycle_and_hosts.html .)

Therapeutic Review

Early Lyme Disease	Adult Dosing
Doxycycline 	100 mg twice per day for 14 days (range, 10–21 days)
Amoxicillin 	500 mg three times per day for 14 days (range, 14–21 days)

Cefuroxime axetil  500 mg twice per day for 14 days (range, 14–21 days)

Early Lyme Disease With Neurological Manifestations	Adult Dosing
Doxycycline 	100 mg twice per day for 14 days (range, 14–21 days)
Amoxicillin 	500 mg three times per day for 14 days (range, 14–21 days)
Cefuroxime axetil 	500 mg twice per day for 14 days (range, 14–21 days)
Probiotics: <i>Lactobacillus GG</i> , <i>Lactobacillus sporogenes</i> , <i>Bifidobacterium lactis Bb-12</i> , <i>Lactobacillus acidophilus La-5</i> , or <i>Saccharomyces boulardii</i> 	5–40 billion CFU/day throughout the duration of antibiotic treatment or 200 g of a specific yogurt product containing <i>Lactobacillus rhamnosus GG</i> , <i>Bifidobacterium lactis Bb-12</i> , and <i>Lactobacillus acidophilus La-5</i> ⁷⁹

Chronic Persistent Symptoms	Adult Dosing
NSAIDs, intraarticular steroid injections, DMARDS 	Varies as needed
Antibiotics (long term, intravenous) 	Varies, only when borreliosis is confirmed
Gabapentin 	300 mg/day titrating up to a maximum tolerated dose within 4–12 weeks (average dose, 700 mg)
<i>Uncaria tomentosa</i> (cat's claw) 	60 mg daily in three divided doses of an extract free of tetracyclic oxindole alkaloids
Antiinflammatory diet 	
Aerobic and weight-bearing exercise 	15–30 minutes two to three times weekly for at least 4 weeks
Probiotics: <i>Lactobacillus casei</i> strain Shirota 	24 billion colony forming units of available in a fermented milk product
Omega-3 fatty acids 	2500 mg of omega-3 fatty acids (with 50% or more EPA) per day
Intravenous micronutrient therapy 	37 CC infused weekly of the Myer's cocktail
Acupuncture 	20-minute individualized session weekly
Massage therapy 	Swedish or other massage approach (30–60 minutes) one to two times weekly
Tai chi 	Group course with experienced teacher twice weekly for at least 12 weeks
Mindfulness meditation, mindfulness-based stress reduction 	Group course with weekly meeting and daily practice

CHAPTER 24

Hypertension

Gregory A. Plotnikoff, MD, MTS, and Jeffery Dusek, PhD

Hypertension is the most important risk factor for cardiovascular morbidity and mortality in industrialized countries. At least 65 million Americans have blood pressures that place them at significantly higher risk of coronary artery disease, heart failure, renal failure, thoracic and abdominal aneurysms, myocardial infarction, and stroke. Hypertension is also associated with cognitive dysfunction, erectile dysfunction, and loss of vision. The higher the pressure, the greater the risk of complications.¹

However, hypertension frequently is asymptomatic; in the absence of symptoms, elevated blood pressure may not hold particular significance for patients. In many cultures of the world, if there is no pain, there is no disease. This means that clinicians face three key challenges. First, is there a shared awareness? Is hypertension even an issue for the patient? Second, will the patient accept any intervention to treat an abstract number? Third, will the patient accept a long-term intervention with no immediate benefit? For these reasons, patients benefit when integrative clinicians initially explore the meanings, beliefs, and interpretations the patient brings to their experience of numbers from ambulatory blood pressure measurements. The patient's answers should both guide the clinician's approach and foster a working partnership (see also [Chapter 3](#)).

Hypertension prevention and treatment represents an ideal opportunity to codevelop a customized action plan that addresses logical options regarding diet, exercise, supplementation, smoking cessation, and mind-body self-care skills development. Additional insights may also come from both Ayurvedic and traditional East Asian medicine traditions. This chapter will address how each of these individual interventions can contribute to improved health and well-being.

A reduction in systolic blood pressure of 5 mmHg is reportedly associated with a 7% reduction in all-cause mortality.

There is no question that every clinician must be well versed in the treatment of hypertension. However, at the time of writing this chapter, considerable confusion exists regarding optimal hypertension management. For this reason, a brief review of the controversies is warranted.

In 2014, JAMA published the eighth report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 8).² This was greatly anticipated as the previous report, termed JNC 7, was published in 2003. Nine new recommendations were made, the most controversial of which was to redefine the goal blood pressure for those greater than 60 years of age to < 150/90 mmHg. For all others aged over 18 years, the goal blood pressure was recommended as < 140/90. This same goal was recommended for patients with chronic kidney disease or diabetes.

Significant confusion followed the publication of JNC 8. Critics noted the marked lack of consistency with JNC 7; the lack of consensus among the JNC 8 committee members, with 5 of 17 authors quickly publishing a dissent³; and the lack of clarity in definable quality measures in hypertension by which to grade physicians. The American Heart Association (AHA) and American College of Cardiology (ACC) continue to recognize JNC 7 and are currently preparing their own guidelines.

The confusion follows from the mixed conclusions of the two JNC reports. The 2003 JNC 7 report defined a normal BP as less than 120 mmHg systolic and less than 80 mmHg diastolic. The report similarly defined stage 1 hypertension as 140–159 mmHg systolic and 90–99 mmHg diastolic. In between normal and stage 1 values is a category the JNC 7 report termed prehypertension. This new term was introduced to heighten awareness of both risk and opportunities for prevention. The JNC 7 report also noted that the BP treatment goal is less than 130/80 mmHg for persons with diabetes or renal disease and hypertension¹ ([Table 24.1](#)). In marked contrast, JNC 8 did not define a “normal” blood pressure, eliminated the stages of hypertension, and revised upward the thresholds for treatment, including for those persons with comorbidities.

How could this happen? JNC 7 recommendations were based upon expert consensus derived from a thorough but nonsystematic literature review that included observational studies. In contrast, JNC 8 recommendations followed from a formal systematic review by

methodologists who were restricted to consideration of randomized controlled trials (RCTs) with more than 100 hypertensive participants who were followed for at least 1 year. This eliminated approximately 98% of all previously published clinical studies of hypertension treatment, including observational studies, systematic reviews, and meta-analyses.⁴ The JNC 8 committee also restricted their analysis to three questions. First, does initiation of antihypertensive pharmacological treatment at a specific threshold improve health outcomes? Second, do attempts to reach specified blood pressure goals lead to improvements in health outcomes? And, third, do various antihypertensive drugs or drug classes differ in regards to health outcomes? The panel did not address whether therapy-associated adverse effects and harms resulted in significant changes in important health outcomes.

TABLE 24.1
JNC 7 and JNC 8: Goal Blood Pressures

	JNC 8	JNC 7
Ages 18–59 years	< 140/90	< 140/90
Ages ≥60 years	< 150/90	< 140/90
Diabetes mellitus or chronic kidney disease	< 140/90	< 130/80

The JNC 8 recommendations were graded based upon the quality of evidence reviewed. Not considered for the first two questions were any RCTs that included participants with a normal blood pressure (such as persons with diabetes). Studies considered for the third question were limited to those that examined one class of medication versus another. This eliminated all single agent placebo-controlled trials from consideration.

Based upon such a rigorous evidence-based review, only two grade A “strong” recommendations could be made. First, for those ≥ 60 years of age, antihypertensive pharmacological therapy should be initiated at a threshold of ≥ 150 mmHg systolic blood pressure or ≥ 90 mmHg diastolic blood pressure with a goal blood pressure of < 150 mmHg systolic and < 90 mmHg diastolic. Second, for those < 60 years of age, pharmacological therapy should be initiated at a diastolic blood pressure ≥ 90 mmHg with a treatment goal of achieving a pressure < 90 mmHg.

Likewise, only three Grade B “moderate” recommendations could be

made. For the general nonblack population, including those with diabetes, initial therapy should include a thiazide diuretic, a calcium channel blocker (CCB), an angiotensin converting enzyme inhibitor (ACEi), or an angiotensin receptor blocker (ARB). For the general black population, initial therapy should be a thiazide diuretic or CCB. For those aged ≥ 18 years with chronic kidney disease, the initial or add-on pharmaceutical should be an ACE or ARB to improve kidney outcomes.

Grade C or “weak” recommendations were based upon RCTs with major limitations, such as the presence of post hoc analyses of non-prespecified subgroups. Only one recommendation was possible; for blacks with diabetes, initial therapy should be a thiazide diuretic or a CCB.

Every other recommendation made by the JNC 8 committee was labeled grade E, the category representing consensus expert opinion. This means that the evidence base from the gold standard of randomized-controlled trials was too weak to make a definitive recommendation. Further, any other clinical intervention for the prevention and treatment of hypertension fails the strictest definition of “evidence-based” practice. Given contradictory clinical trial data, these guidelines will likely remain controversial.⁵

JNC 8 recommends blood pressure treatment for those ≤ 60 years of age at 140/90 mmHg. For those older than 60 years, treatment is recommended at 150/90 mmHg. First line therapy can be with a thiazide diuretic, ACE, ARB, or CCB. In the black population, a thiazide or CCB should be used. In those with kidney disease, an ACE or ARB is recommended.

Although observational studies and association studies have demonstrated a strong relationship between lower blood pressures and reduced risk, all the way down to very low blood pressures, evidence from RCTs does not indicate any patient benefit from treatment *with pharmaceuticals* to achieve lower blood pressures. Two significant implications exist for integrative practitioners and their patients. First, JNC 8 widens the range of acceptable blood pressures for patients. Second, JNC 8 reduces the pressure to prescribe pharmaceuticals for patients who decline or wish to avoid pharmaceuticals. In fact, JNC 8 explicitly supports the role of conventional risk modifications including reducing sodium intake, increasing exercise, moderating alcohol

consumption, losing weight, and following the Dietary Approaches to Stop Hypertension (DASH) eating plan. The American Heart Association has gone even farther. In 2013, it affirmed that all individuals with blood pressure levels > 120/80 mmHg should consider trials of alternative approaches as adjuvant methods to help lower blood pressure when clinically appropriate.⁶

Because many persons wish to avoid pharmaceutical therapies, integrative clinicians are often sought who can counsel from an evidence base regarding the most appropriate treatment options available. This chapter's purpose is to expand the range of logical, nonpharmaceutical for both the prevention and treatment of hypertension. The intent is to support integrative clinicians in their capacity to codevelop an evidence-informed, customized action plan with their patient.

Nonpharmaceutical approaches to the treatment of hypertension, which include and go beyond the basic lifestyle modification recommendations found in the JNC 8 report, are provided in the following.

Integrative Therapy

Lifestyle Modification

Smoking Cessation

Smoking cessation should be part of every comprehensive lifestyle modification plan. Cigarette use is reportedly associated with a 4 mmHg increase in systolic blood pressure and a 3 mmHg increase in diastolic blood pressure compared with placebo.⁷ Persons with hypertension who smoke, however, are at an additional increased risk of cardiovascular events compared with those with hypertension that do not smoke. This risk includes both ischemic and hemorrhagic stroke, and correlates directly with the number of cigarettes smoked.^{8,9} Progressive muscle relaxation training,¹⁰ hypnotherapy,¹¹ and acupuncture¹² may have utility in assisting smoking cessation. Electronic cigarettes are not considered smoking cessation devices.¹³

Nutrition

Mediterranean Diet

The efficacy of the Mediterranean diet in preventing or treating

hypertension was evaluated among 9408 men and women enrolled in a prospective cohort study from 1999–2005. The study documented that, after adjustment for major hypertension risk factors and nutritional covariates, the degree of adherence to the Mediterranean diet over 6 years was associated with modest blood pressure reduction. For those with high adherence, mean systolic pressure declined by 3.1 mmHg (95% confidence interval [CI], –5.4 to 0.8) and mean diastolic blood pressure by 1.9 mmHg (95% CI, –3.6 to –0.1).¹⁴

Beyond hypertension, a systematic review of 35 different experimental studies demonstrated that the Mediterranean diet has favorable effects on lipoprotein levels, endothelium vasodilatation, insulin resistance, metabolic syndrome, antioxidant capacity, myocardial and cardiovascular mortality, and cancer incidence in obese patients and in those with previous myocardial infarction.¹⁵ Additionally, the NIH-AARP study of 214,284 men and 166,012 women demonstrated that, over 10 years, adherence to the Mediterranean diet was associated with approximately a 20% reduction in all-cause mortality in both men and women. In comparing high to low conformity adherence in men, hazard ratios of cardiovascular and cancer mortality were 0.78 (95% CI, 0.69–0.87) and 0.83 (95% CI, 0.76–0.91), respectively. Similarly, a 12% reduction in cancer mortality was demonstrated in females ($P = 0.04$).¹⁶ From the HALE (Healthy Aging: Longitudinal Study in Europe) study of persons aged 70–90 years, adherence to the Mediterranean diet and a healthful lifestyle was associated with a more than 50% lower rate of all-cause and cause-specific mortality¹⁷ (see [Chapter 88](#)).

The Dietary Approaches to Stop Hypertension (DASH) Diet

The DASH diet (Dietary Approaches to Stop Hypertension) trial enrolled 459 participants and provided each with all food for 11 weeks. For the first 3 weeks, the participants were provided a control diet low in fruits, vegetables, and dairy products, with a fat content typical of the average diet in the United States. Participants were then randomly assigned to receive either 8 weeks of the control diet rich in fruits and vegetables or a “combination” diet rich in fruits, vegetables, and low-fat dairy products with reduced saturated and total fat. Sodium intake and body weight were maintained at constant levels. For the 326 participants with prehypertension, the DASH diet resulted in reduced systolic and diastolic pressures of 3.5 mmHg ($P < 0.001$) and 2.1 mmHg ($P = 0.003$), respectively. Among the 133 subjects with level I hypertension, the DASH diet reduced systolic and diastolic blood pressure by 11.4 and 5.5

mmHg more than the control diet ($P < 0.001$ for each).¹⁸ These results have since been replicated in numerous settings (see [Chapter 89](#)).

Olive Oil

One of the main components of the Mediterranean diet is olive oil, which provides both high levels of monounsaturated fatty acids (MUFA), principally oleic acid, and healthy polyphenols. Oleic acid has been shown to have antihypertensive effects in laboratory animals.¹⁹ Phenolic compounds in olive oil prevent lipoperoxidation, induce favorable changes in lipid profile, improve endothelial function, and have antithrombotic properties.²⁰ In the *Prevención con Dieta Mediterránea* (PREDIMED) study of 772 asymptomatic persons 55 to 80 years of age at high cardiovascular risk, participants allocated to Mediterranean diets supplemented with either nuts or virgin olive oil demonstrated mean reductions in systolic pressure of 5.9 mmHg compared to those allocated a control low-fat diet (CI, -8.7 to -3.1 mmHg) and 7.1 mmHg (CI, -10.0 to -4.1 mmHg), respectively.²¹

Olive oil represents a logical substitute for butter and partially hydrogenated vegetable oils. The Food and Drug Administration (FDA) allows manufacturers to state on labels that consuming approximately two tablespoons (23 g) of olive oil a day may reduce the risk of heart disease. As a general recommendation, use organic, cold-pressed, extra-virgin olive oil for cold cooking, such as salad dressings and vegetable dips.

The consumption of a diet rich in polyphenols, including those found in olive oil and cocoa beans, appears to be important for hypertension prevention and control.²² Polyphenols can induce nitric oxide (NO)-mediated endothelium-dependent relaxation in most arteries, including the coronary arteries. Polyphenols can also induce endothelium-derived hyperpolarizing factor (EDHF)-mediated arterial relaxation.^{23,24}

Cocoa (*Theobroma cacao*)

In observational studies, regular intake of cocoa-containing foods has been shown to be associated with lower cardiovascular mortality. In a cohort of 470 Dutch men followed for 15 years, cocoa intake was inversely associated with blood pressure and positively associated with reduced risk of both cardiovascular and all-cause mortality. The first published meta-analysis of cocoa reviewed five randomized controlled studies of cocoa administration ($n = 173$) with an average intake of 100 g

daily (500 mg of polyphenols) for a median duration of 2 weeks demonstrating reductions in pooled mean systolic and diastolic blood pressure values of 4.7 mmHg (95% CI, -7.6 to -1.8 mmHg; $P = 0.002$) and 2.8 mmHg (95% CI, -4.8 to -0.8 mmHg; $P = 0.006$), respectively, compared with controls. Of the five studies cited, only two trials enrolled hypertensive patients.²⁵

Following this report, the authors enrolled 44 adults with untreated upper-range prehypertension or stage 1 hypertension in a prospective 18 week randomized-controlled trial of either 6.3 g (30 kcal) per day of dark chocolate containing 30 mg of polyphenols or matching polyphenol-free white chocolate. Low-dose dark chocolate intake reduced the prevalence of hypertension from 86% to 68%, with mean systolic BP decreasing by 2.9 (1.6) mmHg ($P < .001$) and diastolic BP by 1.9 (1.0) mmHg ($P < 0.001$). This was accomplished without changes in body weight or plasma levels of lipids, glucose, and 8-isoprostane (a measure of oxidative stress). The decrease in BP was also accompanied by a sustained increase in vasodilative nitric oxide donor S-nitrosoglutathione levels by 0.23 (0.12) nmol/L ($P < 0.001$). In comparison, the polyphenol-free white chocolate intake was not associated with any changes in BP or plasma biomarkers.²⁶

The benefit of flavanol-containing cocoa appears to also extend to persons with diabetes. A 30-day, thrice-daily consumption of flavanol-containing cocoa (321 mg flavanols per dose) versus a matched product with 25 mg of flavanols per dose in 41 persons treated for diabetes reportedly increased baseline brachial artery flow-mediated dilatation by 30% ($P < 0.0001$) without evidence of tachyphylaxis or decline in glycemic control.²⁷

A 2010 pooled meta-analysis included 13 trials (15 treatment arms) and reported the most significant findings in hypertensive and prehypertensive subgroups (SBP, -5.0 ± 3.0 mmHg; $P = 0.0009$; DBP, -2.7 ± 2.2 mmHg, $P = 0.01$) compared to placebo. However, blood pressure was not reduced below 140 mmHg systolic or 80 mmHg diastolic. Daily flavanol dosages ranged from 30 mg to 1000 mg in the active treatment groups (dark chocolate with 50%–70% cocoa).²⁸

Consider recommending $\frac{1}{4}$ of a standard-sized dark chocolate bar consisting of 70% cocoa daily to help lower blood pressure.

Red Wine

Although alcohol consumption may cause multiorgan damage and raise blood pressure, red wine consumption is inversely associated with mortality due to cardiovascular diseases.²⁹ Previous studies have shown this effect even intakes as high as 300 mL of wine per day.³⁰ Risk reduction is greatest for red wine at low to moderate intake.³¹ One possible explanation is that red wine is an extremely rich source of bioactive polyphenols. Noteworthy compounds include the flavonoids (quercetin, catechin, and epicatechin), proanthocyanidins, anthocyanins, and phenolic acids including gallic, caftaric, and caffeic acid in addition to the trihydroxystilbene termed resveratrol. These compounds are not found in white wines as the fermentation process for white wines, unlike for red wines, does not include the polyphenol-rich grape skins, seeds, and stems.³² Each polyphenol may play some role in preventing or treating hypertension. For example, quercetin, catechin, and resveratrol promote nitric oxide production by vascular endothelium. Although animal studies have reported many potentially beneficial effects with oral administration of quercetin or resveratrol, they have not documented a reduction in blood pressure.^{33,34}

Omega-3 Fatty Acids

A diet rich in cold-water fatty fish or grass fed animals is also rich in omega-3 polyunsaturated fatty acids (PUFA) that may prevent the development of hypertension. Omega-3 fatty acid deficiency contributes to development of hypertension in animal models.³⁵ This also appears to be true for humans. A 20-year follow-up study of a cohort of 4508 adults aged 18–30 years without hypertension at baseline documented an inverse association between long-chain omega-3 intake and development of hypertension. For the highest intake quartile compared to the lowest, after adjustment for potential confounders, the hazard ratio was just 0.65 (95% CI, 0.53–0.79; P [trend] < 0.01).³⁶ A double-blind, placebo-controlled intervention of 4 g of omega-3 fatty acids for 8 weeks in patients with chronic kidney disease with an initial mean supine blood pressure of 125.0/72.3 mmHg demonstrated significant reductions in 24 hour systolic (-3.3 ± 0.7 mmHg) and diastolic (-2.9 ± 0.5 mmHg) blood pressures in addition to a 24% reduction in serum triglyceride levels.³⁷ A recent meta-analysis of 70 RCTs confirmed blood pressure reduction in both hypertensive and normotensive subjects, with the strongest effects of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) supplementation observed in untreated hypertensive subjects (systolic blood pressure, -4.51 mmHg, 95% CI, -6.12 to -2.83 ; diastolic blood

pressure, -3.05 mmHg, 95% CI, -4.35 to -1.74). A confounder to randomization for clinical trials is that blood pressure reduction may be most pronounced in persons with the CYP4F2 V33M polymorphism.³⁸

Supplementation of ≥ 2 grams per day of EPA + DHA (fish oil) appears necessary to reduce diastolic pressure.³⁹

Fiber

A meta-analysis of 25 randomized controlled trials published up to the year 2004 documented that supplemental intake of dietary fiber significantly reduced both systolic and diastolic in hypertensive patients. The degree of reduction was significant: systolic -5.95 mmHg, (95% CI, -9.50 to -2.40) and diastolic -4.20 mmHg, (95% CI, -6.55 to -1.85). The authors suggested that at least 8 weeks of supplementation was required to achieve the maximal blood pressure reduction.⁴⁰ A 2007 study in hypertensive, overweight patients of psyllium powder dosed at 3.5 grams 20 minutes before each meal documented significant systolic and diastolic pressure reduction compared to controls.⁴¹

Flax Seed

Flax seed is a common dietary supplement that contains short-chained omega-3 fatty acids, lignans, and fiber. A 2013 prospective, double-blinded, placebo-controlled, randomized trial ($n = 110$) evaluated daily ingestion of 30 g of milled flaxseed or placebo over 6 months. The mean reduction in systolic blood pressure was approximately 10 mmHg and in diastolic was 7 mmHg. Participants with an initial systolic blood pressure ≥ 140 mmHg had significantly greater reductions.⁴² A 2015 meta-analysis of 11 studies (14 trials) did not demonstrate as profound a reduction in blood pressure following flax seed supplementation. The data reviewed indicated that flaxseed supplementation slightly reduced systolic blood pressure (-1.77 mmHg; 95% CI, -3.45 to -0.09 mmHg; $P = 0.04$) and diastolic blood pressure (-1.58 mmHg; 95% CI, -2.64 to -0.52 mmHg; $P = 0.003$).⁴³

Inorganic Nitrates

Both the Mediterranean and the DASH diets contain foods that are rich in inorganic nitrates, a source of the vasodilator, nitric oxide, via

transformation by symbiotic bacteria. Reduced nitric oxide production has been linked to hypertension, endothelial dysfunction, and insulin resistance.⁴⁴ Foods that support nitric oxide production via nitrate content include root vegetables, such as beets, carrots, and turnips in addition to dark greens, celery, and leeks ([Fig. 24.1](#)). Four weeks of a beetroot juice intervention in a randomized, placebo-controlled study of 68 patients with hypertension aged 18–85 years reduced 24-hour ambulatory systolic and diastolic BP by 7.7 mmHg and 5.2 mmHg, respectively, (95% CI, 4.1–11.2 and 2.7–7.7; $P < 0.001$ for both) as well as blood pressures measured in clinic and at home.⁴⁵ No tachyphylaxis was observed. The authors also noted that the intervention, compared to placebo, improved endothelial function by $\approx 20\%$ ($P < 0.001$) and reduced arterial stiffness by 0.59 m/s (95% CI, 0.24–0.93; $P < 0.01$). Supplementation with 250 mL a day of beetroot juice was well tolerated. The necessary dose and time required for the effect of beetroot on blood pressure is currently unknown. A follow-up 1-week intervention with nitrate-rich beetroot juice reported increases in all measures of serum and urinary nitrates but did not reduce blood pressure.⁴⁶

Exercise

Both JNC 7 and JNC 8, as well as the American Heart Association and the American College of Sports Medicine, recommend aerobic endurance exercise for the primary prevention, treatment, and control of hypertension. Blood pressure reductions of approximately 5–7 mmHg systolic can follow an isolated exercise session (acute) or following exercise training (chronic). Reductions in blood pressure can last up to 22 hours following endurance exercise. The higher the initial blood pressure is, the greater the response.

The American College of Sports Medicine recommends the following exercise prescription for those with high BP:

- Frequency: on most, preferably all, days of the week. Intensity: moderate intensity (40%–60% VO_2R).
- Time: ≥ 30 min of continuous or accumulated physical activity per day.
- Type: primarily endurance physical activity supplemented by resistance exercise.⁴⁷

Weight Loss

A 2008 meta-analysis of all weight loss studies demonstrated that dietary interventions to reduce body weight resulted in better blood pressure reduction than either of the prescription drugs orlistat and sibutramine. Weight loss of 4 kg (10 pounds) by diet was associated with a mean reduction in systolic blood pressure of approximately 6 mmHg. Similar weight loss with orlistat reduced systolic blood pressure by approximately 2.5 mmHg. Sibutramine treatment reduced body weight but did not lower and may have even elevated, blood pressure. The authors noted that no prospective studies demonstrate mortality or other patient-relevant end points can be lowered by weight reduction.⁴⁸

Dietary Supplements

Dietary supplements represent low-cost, low-toxicity interventions that may be helpful in reducing blood pressure. However, when reviewing the medical literature, one must be aware of several limitations in the

quality of research in this area. First, few studies measure and report serum levels at baseline and following the study period. This failure to document the presence or absence of a serum or intracellular deficiency or functional insufficiency means dosing is blind. If one size does not fit all, then studies are at high risk of false negative results due to underdosing. Additionally, treatment of a patient population with preexisting sufficient levels presumably means that additional dosing is unlikely to confer benefit. Further, adherence to the intervention protocol cannot be assessed without measurement of serum levels. Second, few studies intervene with a dose based on the achievement of a targeted serum level. Most dosing is extrapolated from in vitro or epidemiological studies of intake in large populations. Individual variability in uptake and metabolism are not considered when calculating dosing. Third, differences in the bioavailability and function of different forms of a dietary supplement may exist. Accordingly, the majority of interventional nutrition research does not answer the very important clinical question, “does replenishment of a deficiency to a given serum level result in an improved clinical outcome?” Evidence-based, patient-centered care requires significantly better clinical studies.

CoQ10

Coenzyme Q₁₀ (CoQ₁₀, ubiquinone, or ubiquinol) is a crucial cofactor in the electron transport chain and oxidative phosphorylation for production of adenosine triphosphate (ATP). The highest tissue concentration of CoQ10 is found in the heart, with the highest cellular concentration on the inner membrane of the mitochondrion. CoQ10 has been shown to be a potent antioxidant. Reduced levels are associated with aging, hyperthyroidism, cardiovascular disease, total parenteral nutrition, aerobic training, and ultraviolet exposure.⁴⁹ Statins and some beta blockers, such as propranolol, can reduce endogenous production of CoQ10 by as much as 40%.⁵⁰ A 2015 meta-analysis of eight clinical trials documented significant reduction in serum levels of CoQ10 with the use of all statins.⁵¹ Supplementation can reduce oxidative stress and hyperinsulinemia, two significant drivers of hypertension.⁵²

Low serum levels of CoQ10 were first associated with hypertension in 1975.⁵³ Since then, several studies have reported that supplementation can significantly reduce both systolic and diastolic hypertension without affecting aldosterone, sodium, or potassium levels or plasma renin activity. A trial involving 109 symptomatic hypertensive patients supplementation with CoQ10 (75–360 mg/day) to achieve a serum level

of $> 2.0\mu\text{g}/\text{mL}$ reported a substantial reduction in mean systolic (from 159 to 147 mmHg) and diastolic (94 to 85 mmHg) blood pressures with concomitant improvement in New York Heart Association (NYHA) functional class and medication requirements. After an average of 4.4 months, 37% of patients were able to discontinue one antihypertensive drug, 11% discontinued two drugs, and 4% discontinued three drugs. Only 3% required the addition of one antihypertensive drug, and none required the addition of more than one antihypertensive drug. Importantly, 25% of all patients were able to control their blood pressure with only CoQ10 supplementation.⁵⁴

Statin drugs and some beta-blockers (propranolol) can reduce the endogenous production of CoQ10 by as much as 40%.

A 2007 meta-analysis of 12 clinical trials ($n = 352$ patients) concluded that CoQ10 supplementation in hypertensive patients can lower systolic blood pressure by up to 17 mmHg and diastolic blood pressure by up to 10 mmHg without significant side effects. In three randomized, double-blind controlled trials ($n = 120$), mean systolic pressure in the treatment group decreased by 16.6 mmHg ($P < 0.001$) from a mean of 167.7 mmHg (95% CI, 163.7–171.1 mmHg). The mean diastolic blood pressure decreased by 8.2 mmHg ($P < .001$) from 103 mmHg (95% CI, 101–105 mmHg) before treatment. In comparison, the placebo arms demonstrated minimal and statistically insignificant reductions in systolic and diastolic pressures. In the open-label, uncontrolled trials included in the analysis, patients were treated at doses of 60 to 120 mg daily for 6 to 12 weeks. Mean systolic blood pressure declined by 13.5 mmHg (95% CI, 9.8–17.1 mmHg; $P < 0.001$) and mean diastolic by 10.3 mmHg (95% CI, 8.4–12.3 mmHg; $P < 0.001$). This meta-analysis noted that in many of the studies included, patients were able to discontinue medication.⁵⁵

Dosage

Dose to achieve a serum level of $> 2.0\mu\text{g}/\text{mL}$. This will require 75–350 mg a day taken with meals that contain some fat.

Precautions

Side effects are infrequent and include abdominal discomfort, nausea,

vomiting, diarrhea, anorexia, rash, and headache. CoQ10 has an antiplatelet effect so can theoretically increase the risk of bleeding with antiplatelet or anticoagulant agents. As excretion is via the bile, accumulation may occur in patients with hepatic impairment or biliary obstruction.

Vitamin D

Calcitriol, also known as 1,25-dihydroxyvitamin D, is the activated secosteroid hormone form of vitamin D that has receptors on nearly every tissue, including vascular smooth muscle cells⁵⁶ and renin-producing juxtaglomerular cells.⁵⁷ Calcitriol regulates hundreds of genes including the renin gene and thus the renin–angiotensin system (RAS) that controls blood pressure. Observational data from both the Health Professionals Followup Study (613 men) and the Nurses Health Study (1198 women) found low vitamin D status with was significantly associated with increased risk of incident hypertension over 4–8 years. For those with a serum 25 (OH) D level < 15 ng/mL compared to those with a level > 30 ng/mL, the RR for men was 6.13 (95% CI, 1.00–37.8) and for women was 2.67 (95% CI, 1.05–6.79).⁵⁸ In 2010, the Intermountain Heart Collaborative Study Group of 41,504 patients reported that vitamin D deficiency (<30 ng/mL) was associated with highly significant ($P < 0.0001$) increases in the prevalence of hypertension and associated cardiac risk factors of diabetes, hyperlipidemia, and peripheral vascular disease. Vitamin D deficiency was also strongly correlated ($P < 0.0001$) with coronary artery disease, myocardial infarction, heart failure, stroke, and death.⁵⁹

Despite the potential benefits of vitamin D in improving cardiovascular health, few prospective trials support the hypothesis that vitamin D replenishment to normal levels reduces blood pressure. Among 148 elderly women with a mean 25-(OH) D serum level of 10 ng/mL (severe deficiency), 800 IUs of vitamin D3 supplementation per day for 8 weeks raised serum levels by 12 ng/mL and reduced systolic pressure by 7 mmHg compared to placebo. In contrast, among 189 men and women with a mean baseline level of 13 ng/mL, a single dose of 100,000 IU of vitamin D3 raised serum levels to a mean of 20 ng/mL at 5 weeks compared to placebo but had no effect on blood pressure.

Prior to the 2015 DAYLIGHT study with 534 participants, the largest prospective trial had enrolled 438 participants with a mean BMI of 35, mean 25 (OH) D level of 23.2 ± 8.5 ng/mL, systolic pressure of 124 ± 15

mmHg, and diastolic pressure of 75.4 ± 9.7 mmHg and randomized participants into three treatment groups: placebo, 20,000 IUs, or 40,000 IUs of oral cholecalciferol per week. At the end of 1 year, the low dose group had increased serum 25 (OH) D to a mean of 40 ng/mL, and the high dose group increased levels to a mean of 55 ng/mL with no significant change in blood pressure.⁶⁰ Of note, the main objective for this study was to study the effect of vitamin D supplementation on weight change, so the study was not designed and powered to detect effects on blood pressure. In the DAYLIGHT study, participants with prehypertension or stage I hypertension were enrolled and randomized to 400 IU or 4000 IUs per day. The median 25-hydroxyvitamin D level at baseline was 15.3 ng/mL. After 6 months, both the low-dose and high-dose arms demonstrated significantly improved vitamin D status but no significant reductions in either systolic or diastolic blood pressures.⁶¹ Of note, vitamin D supplementation does not appear to reduce adiposity.

Future studies will need to address whether there is a threshold serum level needed to reduce the risk of incident hypertension or reduce already elevated pressures. Additionally, the duration of vitamin D sufficiency required for the prevention or reduction of hypertension needs to be defined.

Magnesium

Magnesium is a well-understood and frequently used intervention for hypertension in preeclampsia. Neither the JNC 7 nor JNC 8 guidelines recommend oral supplementation of magnesium. However, in addition to the potentially high magnesium intake associated with either a Mediterranean or DASH diet, several studies have reported that low dietary intake of magnesium correlates strongly with high blood pressure. The Women's Health Study followed 28,349 female United States health professionals aged ≥ 45 years without hypertension for almost 10 years. Magnesium intake, after adjustment for age and randomized treatment, was found to be inversely associated with the risk for incident hypertension. The highest quintile of intake (median, 434 mg/day) had a relative risk of 0.87 (95% CI, 0.81–0.93; P for trend < 0.0001) compared with those in the lowest quintile (median, 256 mg/day). Further adjustment for other risk factors slightly attenuated this inverse association.⁶² The Honolulu Heart Study reported that of 61 nutritional substances studied, magnesium intake had the strongest inverse association with BP.⁶³

Despite the inverse relationship between dietary magnesium and

hypertension prevalence observed in epidemiological studies, clinical intervention studies have failed to demonstrate consistent benefit. As noted above, several limitations exist in the literature. For magnesium, few studies have measured baseline serum levels, with even fewer measuring intracellular magnesium levels. Serum magnesium levels do not reflect intracellular magnesium.⁶⁴

Additionally, there are many forms of magnesium that may have different bioavailability and physiological activity. Accordingly, “one-size fits all” magnesium studies of varying dosing and varying type of magnesium prevent any meta-analysis of existing randomized trials. Despite these limitations, magnesium appears to be beneficial in reducing blood pressure and to be nontoxic.

A recent clinical trial enrolled 48 patients with mild uncomplicated hypertension and randomized them to 12 weeks of 600 mg/day of oral magnesium pidolate and lifestyle recommendations or lifestyle recommendations as a control. Mean 24-hour systolic pressures declined by 5.6 ± 2.7 mmHg ($P < 0.001$) and diastolic pressures declined by 2.8 ± 1.8 mmHg ($P = 0.002$) compared to controls.⁶⁵ In 82 diabetic hypertensive adults with documented hypomagnesemia receiving captopril but not diuretics, supplementation with 2.5 g magnesium chloride over 4 months decreased systolic pressure by 20.4 ± 15.9 mmHg compared to 4.7 ± 12.7 mmHg with placebo ($P = 0.03$). The magnesium intervention reduced diastolic pressure by 8.7 ± 16.3 mmHg versus 1.2 ± 12.6 mmHg in the placebo group. The adjusted odds ratio between serum magnesium and blood pressure was 2.8 (95% CI, 1.4–6.9). A threshold serum level for effect was not reported.⁶⁶

Dosage

Natural sources of magnesium include pumpkin seeds, nuts, coffee, quinoa, spinach, bran cereal, buckwheat, and beans.

Dietary or supplementation intake doses of 400–800 mg of nonoxide forms of magnesium (malate, glycinate, taurate, etc.) are required to achieve normal intracellular and serum potassium levels.

Precautions

Magnesium supplementation may cause loose bowel movements. Start at a low dose (120–200 mg) and slowly increase as tolerated.

Botanicals

Garlic (*Allium sativum*)

Garlic has been widely promoted for antihyperlipidemic effects; however, the results of both animal and human studies have indicated a blood pressure-lowering effect. Two separate meta-analyses published in 2008 demonstrated significant blood pressure lowering effects in persons with hypertension. The first meta-analysis included 11 of 25 studies from the systematic review. These demonstrated a mean decrease in the hypertensive subgroup of 8.4 ± 2.8 mmHg for SBP ($P < 0.001$) and 7.3 ± 1.5 mmHg for DBP ($P < 0.001$).⁶⁷ The second meta-analysis included 10 trials in the analysis, of which three had patients with elevated blood pressures. For hypertensive participants, the garlic interventions reduced systolic pressure by a mean of 16.3 mmHg (95% CI, 6.2–26.5) and diastolic pressure by a mean of 9.3 mmHg (95% CI, 5.3–13.3) compared with placebo.⁶⁸ Since then, the results of a 12-week randomized controlled trial of aged garlic extract in 79 patients with uncontrolled systolic hypertension indicated 480 mg (1.2 mg of S-allylcysteine) is both acceptable and effective at lowering systolic blood pressure (reduced by 11.8 ± 5.4 mmHg compared with placebo; $P = 0.006$).⁶⁹

Dosage

The dose for raw garlic cloves is half to two cloves per day. Supplements may help avoid garlic breath. Consider a standardized dose containing 4000 mcg of allicin or 1.2 mg of S-allylcysteine.

Precautions

Adverse effects include the following: diaphoresis; dizziness; mouth, esophagus, and stomach irritation; nausea; and vomiting. Allergic reactions are rare. Dosages greater than for culinary use may increase the risk of bleeding if taken with anticoagulants or antiplatelet agents.

Hawthorn (*Crataegus monogyna*)

Hawthorn as an herbal extract is a cardiovascular tonic popular in Europe that has been in use since at least the first century AD. Hawthorn is a short deciduous tree whose leaves, berries, and flowers contain high concentrations of flavonoids. Extracts are used for their positive inotropic

and vasodilatory properties. Three clinical trials for blood pressure reduction have demonstrated very mild effects.⁷⁰⁻⁷² Hawthorn is most often used for early-stage congestive heart failure.

Dosage

The German Commission E Monographs cites the use of standardized extracts containing 30–169 mg of proanthocyanidins (18.75%) calculated as epicatechin or 3.5–19.8 mg of flavonoids (2.2%) calculated as hyperoside taken in two to three individual doses for a total dose of 750–1500 mg of Hawthorn per day.⁷³

Precautions

Transient side effects including dizziness, gastrointestinal complaints, headaches, and heart palpitations have been reported.⁷⁴ Results from the HERB-CHF trial of Crataegus extract WS1442 documented that participants treated with hawthorn extract were 3.9 times more likely to experience progression of heart failure at the start of hawthorn therapy compared to placebo. The observed increase in risk diminished over time.⁷⁵

Herbs that require close monitoring in the treatment of patients with hypertension include licorice, ephedra, and Panax ginseng, which all have the capacity to significantly raise blood pressure.

Mind-Body Therapy

Despite numerous historical reports of decreases in BP attributed to mind-body practices,⁷⁶⁻⁸¹ a Cochrane Review⁸² raised concerns regarding the impact of these interventions on blood pressure as many studies were conducted in the 1980s and 1990s, and the methodological quality of these studies was inconsistent. Specifically, not all studies were randomized controlled trials, the enrollment criteria were not specific to age group, cardiovascular risk factors, or type of hypertension, and the degree of blood pressure reduction varied widely. This important meta-analysis of randomized controlled trials concluded, somewhat

surprisingly, that mind-body practices produced only modest benefits in reducing SBP, even though the investigators reported a roughly 5.5 mmHg reduction in SBP and a 3.5 mmHg reduction in DBP. Regarding the potential clinical significance of this reduction, SBP reductions between 2 and 5 mmHg have been shown to result in decreased mortality from stroke (14%), coronary heart disease (9%), and total mortality (7%).⁸³

Since 1995, additional well-designed randomized controlled trials have demonstrated the efficacy of mind-body interventions, including relaxation response elicitation,^{84,85} biofeedback,⁸⁶⁻⁸⁹ transcendental meditation,^{90,91} mindfulness based stress reduction (MBSR)^{92,93} yoga,^{94,95} qi gong,^{96,97} and tai chi,⁹⁸ on reducing systolic blood pressure (SBP) or diastolic blood pressure (DBP). Although several of the more recent studies are limited by small sample sizes, many now address the mechanistic and biological mechanisms by which these approaches reduce BP. Additionally, the overall consistency of positive results indicates that, as a whole, mind-body interventions do positively affect both SBP and DBP. Aggregating the findings of these studies shows average reductions of approximately 10 mmHg and 7 mmHg for SBP and DBP, respectively.

Relaxation Response

Relaxation response (RR) is one of the most accessible means of discovering and developing mind-body self-care skills.⁸³ The efficacy of RR in treating hypertension has been demonstrated by a 8-week intervention trial in older adults (mean age, 66.8 years) with elevated SBP and normal DBP who were taking at least two antihypertensive medications.⁸⁴ Participants were blinded to hypothesis and were randomly assigned to one of two interventions to reduce BP: group 1 (relaxation response intervention; n = 61) or group 2 (intensive lifestyle modification; n = 61). Clinic SBP decreased by 9.4 mmHg and 8.8 mmHg in the relaxation response and lifestyle modification groups, respectively ($P < 0.0001$), without a difference observed between groups. In a second phase of the study, participants who achieved a clinic assessed SBP of less than 140 mmHg and had at least a 5 mmHg reduction from baseline entered an antihypertensive medication elimination protocol, with 44 subjects in the relaxation response group and 36 in the lifestyle modification group qualifying for the protocol. Participants in the relaxation response group were more likely to eliminate an antihypertensive medication successfully than were those in the lifestyle

modification group (odds ratio, 4.3; 95% CI, 1.2–15.9; $P = 0.03$). The relaxation response intervention not only led to an important decrease in BP comparable to that of intensive lifestyle modification, but also resulted in a significantly greater capacity for participants to eliminate an antihypertensive medication without increasing BP (see [Chapter 94](#)).

Biofeedback

Reduced blood pressure is presumed to be a treatment effect of biofeedback training due to increased parasympathetic tone and/or reduction in adrenal hormone production. The first clinical trial to suggest that biofeedback was effective in persons with hypertension was published in 1981. In this 8-week study of 38 persons, the intervention group demonstrated significantly lower blood pressure, muscle tension, serum aldosterone, and urinary cortisol levels compared to controls.⁷⁸ However, a 2010 systematic review of 36 biofeedback trials found no persistent effectiveness in hypertension management.⁹⁹ Since then, the results of one pilot study have indicated that biofeedback training was effective at attenuating blood pressure elevations due to psychosocial stressors and emotional activation.⁸⁷ This interpretation was supported by an earlier clinical trial of biofeedback for 4 weeks with 20 participants.⁸⁸ A 2015 randomized trial enrolled 59 adults for 16 weeks of biofeedback training with real-time BP feedback signals or, as the control group, training with pseudofeedback signals. A large percentage of both groups demonstrated a greater than 5 mmHg reduction by 9 weeks that persisted for 8 weeks after completing the study.⁸⁵ The investigators interpreted this as the result of repeated practice in BP self-regulation (see [Chapter 96](#)).

Reducing the breathing rate to 6 breaths per minute lowers blood pressure and enhances heart rate variability. This is considered the ideal breathing rate for inducing cardiovascular benefits.

Transcendental Meditation

Two studies examined the effect of a 12-week proprietary transcendental meditation (TM) intervention on BP in medicated African Americans. In the first study,⁸⁹ 111 individuals (mean age, 67 years) were randomized to TM, progressive muscle relaxation (PMR), or health education. The findings indicated that TM resulted in a clinic-based 10.6 mmHg

reduction in SBP and a 6.6 mmHg reduction in DBP, significantly greater than the 4.0 mmHg and 2.1 mmHg reduction for PMR and greater than the 1.5 mmHg reduction in SBP and 0.6 mmHg increase in DBP among the health education group. In a more recent study enrolling younger subjects (mean age, 48.5 years),⁹⁰ the TM intervention (n = 54) resulted in a clinic-based 1.6 mmHg reduction in SBP and a 4.2 mmHg reduction in DBP at the end of the 12-week intervention. PMR (n = 52) led to a 1.77 mmHg increase in SBP and a 1.4 mmHg reduction in DBP, whereas health education (n = 44) resulted in a 2.0 mmHg increase and a 0.5 mmHg decrease in DBP. Overall, the results of these well-controlled trials indicate a significant effect of the TM intervention on BP (see [Chapter 100](#)).

Mindfulness-Based Stress Reduction

Two recent studies examined the impact of mindfulness-based stress reduction (MBSR) on unmedicated individuals with elevated blood pressure or prehypertension but not reaching the stage 1 hypertension designation (140 mmHg/80 mmHg). In the first study,⁹¹ adults were randomized to either 8 weeks of MBSR or progressive muscle relaxation (PMR). Both MBSR (n = 21) and PMR (n = 17) were conducted in group settings for 2.5 hours per week with 45 minutes of mandatory homework practice. Results indicated a 4.8 mmHg reduction in SBP with MBSR, which was significantly larger than the 0.7 mmHg reduction in the PMR group (P = 0.016). Results indicated a 1.9 mmHg decrease in clinic DBP with MBSR, which was significantly larger than the 1.2 mmHg increase in the PMR group (P = 0.008). No significant differences in daytime ambulatory measures of either SBP (3.1 mmHg decrease vs 1.5 mmHg decrease in MBSR and PMR groups, respectively) or DBP (4.1 mmHg decrease vs 2.2 mmHg decrease in MBSR and PMR groups, respectively) were observed between interventions. In the second study, termed HARMONY,⁹² unmedicated, stage 1 hypertensive adults were randomized to MBSR (n = 46) or a wait-list (WL; n = 41), with ambulatory BP at 12 weeks serving as the primary outcome. The 24-hour ambulatory measures of SBP (MBSR, -0.4 ± 6.7 mmHg vs WL, $-.04 \pm 7.8$ mmHg) and DBP (MBSR, 0.04 ± 4.9 mmHg vs WL, -0.4 ± 4.6 mmHg) did not significantly differ between groups. The pattern of these results provides some doubt as to whether MBSR has a measurable impact on clinic blood pressure and any impact on ambulatory blood pressure.

Yoga

The first study to explore whether a yoga intervention could affect BP was conducted in unmedicated persons with hypertension who were 35 to 65 years old.⁹³ The 33 subjects were equally randomized to yoga intervention, treatment with antihypertensive medications, or a no-treatment control. Yoga resulted in large reductions in clinic-based SBP (33.3 mmHg) and DBP (26.3 mmHg), comparable to the impact of antihypertensive medications on SBP (24.0 mmHg) and DBP (9.9 mmHg). Both active interventions were superior to the smaller reductions exhibited in the no-treatment group (SBP, 4.2 mmHg; DBP, 2.0 mmHg). Since then, several small studies have been conducted, which suggest that yogic practices, as a daily discipline, reduce blood pressure; however, clinical significance has not been demonstrated. A recent study of iyengar yoga versus dietary modification reported significant reductions in blood pressure in both arms at 12 weeks.⁹⁴ A recent systematic review noted that 17 trials met the inclusion criteria but only two RCTs were of acceptable methodological quality. Significant reductions in systolic or diastolic blood pressures were reported by 11 and 8 trials, respectively, compared with pharmacotherapy, breath awareness, no treatment, or usual care. The authors noted that the evidence for yoga was supportive but inconclusive and needed more rigorous studies.¹⁰⁰

Qi Gong

Numerous studies have examined the effect of a qi gong intervention on BP. However, only two have been published in English. In the first study,⁹⁵ 58 unmedicated individuals (mean age, 56 years) were randomized to either a 10-week qi gong intervention or a wait list control group. Qi gong led to a significant reduction in clinic-based SBP and DBP (approximately 10 mmHg and approximately 3 mmHg, respectively) compared with increases in SBP and DBP (approximately 3 mmHg and approximately 1 mmHg, respectively) in the wait list control group. In the second study,⁹⁶ 36 unmedicated participants were equally divided randomly to a 8-week qi gong intervention or a wait list control. Qi gong was associated with significant reductions in clinic-based SBP and DBP (approximately 12 mmHg and approximately 10 mmHg, respectively) compared with increases in SBP and DBP (approximately 2 mmHg and approximately 2 mmHg, respectively) in the wait list control group. As both studies included a wait list control group, further placebo-controlled studies are now required. Nevertheless, particularly if one considers the numerous studies published in Chinese, some support

exists for considering a qi gong intervention for hypertension as recommended in a recent systematic review.¹⁰¹

Tai Chi

The impact of a tai chi intervention has been evaluated in a group of 76 people with stage 1 hypertension or high-normal BP and no medications (mean age, 51.6 years).⁹⁷ The 12-week intervention had a large impact on SBP (15.6 mmHg reduction) and DBP (8.8 mmHg reduction) relative to the sedentary control condition (n = 37; 6.4 mmHg increase in SBP and 3.4 mmHg increase in DBP). Tai chi resulted in significant reductions in BP relative to a sedentary control.

Despite important methodological concerns raised by meta-analyses of earlier studies, more recent evidence examining the impact of various mind-body approaches on BP supports clinically relevant and persistent reductions. Although several of the more recent studies were limited by small sample sizes, the overall consistency of the positive reported results indicates that, as a whole, mind-body interventions do positively affect both SBP and DBP. Many mind-body studies now address the mechanistic and biological mechanisms underlying the efficacy of these approaches in reducing BP. Understanding the antihypertensive effects of these therapies may increase the appropriate use of these therapies in clinical contexts.

Therapies to Consider

Earthing

Electrical grounding, also referred to as “earthing,” represents an easy and comfortable therapy with potential benefit in enhancing overall health, including blood pressure. Grounding follows from direct physical contact with the earth, such as walking barefoot on grass or a beach, or indirect contact through use of a grounded blanket. Either means results in rapid transfer of electrons from the earth to the body and equalization of the electrical potential of the body with that of the planet. Proponents assert that such equalization may have antiinflammatory activity because reactive oxygen species (ROS), also known as free radicals, have one or more unpaired electrons and damage DNA and/or cellular proteins and lipids by creating chain reactions of electron stealing in order to satisfy their need for a paired electron. The lack of antioxidants (electron

donors) is believed to worsen cellular damage. Thus proponents claim that electron replenishment via grounding to the negatively charged earth may minimize the impact of oxidative stress.¹⁰²

Evidence of the association between hypertension / cardiac health and grounding comes from small studies reporting improvements in blood viscosity,¹⁰³ parasympathetic tone, diurnal rhythms, inflammation, and heart rate variability.^{104,105} No definitive benefits or harms have been documented.

Ayurveda

Practitioners may use diet, lifestyle adjustments, herbs, breathing exercises, massage, and yoga to balance doshas pertinent to the experience of hypertension, such as a state of excess pitta. For many persons with hypertension, a pitta-pacifying diet of cooling foods may be beneficial. Foods that may lead to imbalanced pitta states include coffee, alcohol, hot, spicy, and oily foods, which can include many nuts and fermented or pickled foods. These may be particularly challenging in hot summer months. Yoga may also have beneficial effects on hypertension. A recent systematic review of 17 qualifying RCTs noted that 11 reported significant reductions in systolic blood pressure and 8 reported significant reductions in diastolic blood pressure, with yoga compared to pharmacotherapy, breath awareness or reading, health education, no treatment, or usual care.¹⁰⁶

Traditional Chinese and East Asian Medicine

Practitioners may identify persons with the Western diagnosis of hypertension as having one or more Eastern diagnoses, such as yin deficiency of liver and kidney, ascendant liver yang, phlegm stagnation, or blood stagnation. Persons with a Western diagnosis of hypertension may be treated for an Asian pattern with acupuncture, moxibustion, or herbs in order to tonify, expel phlegm and wind, clear heat, resolve blood stasis, or clear dampness. Commonly used herbs in multiherb formulas include gou teng (*Uncaria* species), niu xi (*Cyathula* species), tian ma (*Gastrodia* species), chuanxiong (*Ligusticum sinense*), fu ling (*Poria cocos* wolf), zexie (*Alismatis* species), and ju hua (chrysanthemum). The Chinese herb danshen (*Salvia miltiorrhiza*), commonly used for cardiovascular issues, should not be used concurrently with warfarin.¹⁰⁷ Use of any herbal medicines with Western cardiovascular

pharmaceuticals warrants close monitoring. Acupuncture may provide positive effects with enhanced regulation of the autonomic nervous system and achievement of a balanced constitutional state. Currently, insufficient evidence exists to support the use of acupuncture,^{108,109} moxibustion,¹¹⁰ or ancient multiherb formulas^{111,112} in the treatment of the Western diagnosis of hypertension.

Prevention Prescription

Per Michael Pollan: “Eat food. Not too much. Mostly plants.” These three guidelines minimize intake of unhealthy fats including hydrogenated vegetable oils, limit intake of unhealthy sugars including high fructose corn syrup, and significantly increase intake of potassium, magnesium, calcium, inorganic nitrate, and soluble fiber.

- Exercise for at least 30 minutes a day at least 4 days per week.
- Limit alcohol consumption.
- Do not smoke.
- Breathe: incorporate mind-body practices into your daily routine.

Therapeutic Review

Dietary

- Follow the DASH diet eating plan with its emphasis on foods rich in potassium, magnesium, calcium, and nitrates 
- Reduce dietary sodium to less than 2.4 grams per day (1 tsp) 
- Limit alcohol to two drinks or less per day for men and one drink or less per day for women 
- Consider 10 to 30 grams per day of 70% cacao dark chocolate 
- Consider 30 grams per day of flax seed 
- Consider 30 grams per day of dietary fiber 

Exercise

- Aim for 30 minutes a day of aerobic exercise 

Weight Loss

- Aim for a weight loss of at least 10 pounds (4.5 kg) if overweight 

Dietary Supplements

- Maintain a serum 25-OH-vitamin D greater than 40 ng/mL 
- Ensure 1000 mg a day of EPA and DHA by fish or krill oil 
- Consider CoQ10 to achieve a serum level > 2.0 µg/mL 
- Consider absorbable magnesium at 6 mg/kg. 

Botanical

- Consider a trial of garlic at 4000 mcg allicin or 1.2 mg of S-allylcysteine 
- Consider the tonifying effect of hawthorn 750–1500 mg per day 

Mind-Body

- Attempt to practice any of these approaches for approximately 20 minutes daily. Overall evidence for each intervention are as follows:

- Mind-body 
- BBA 
- Biofeedback 
- TMA 
- Yoga 
- Qi gong 
- Tai chi 

Pharmaceutical

- Follow the JNC 7 guidelines that emphasize thiazide diuretics as first line agents or JNC 8 guidelines that also allow the use of calcium channel blockers, angiotensin converting enzyme inhibitors, or

angiotensin receptor blockers 

Other Therapies

- Consider Ayurvedic assessment for dietary and other means of balancing one's dosha (constitutional state) 
- Consider traditional East Asian medicine, including acupuncture, for balancing one's constitutional state 

Note

- With use of all therapies, including pharmaceuticals, an organized system of regular follow-up and review with self-monitoring and appointment reminders appears to be effective adjuncts for blood pressure control¹¹³

CHAPTER 25

Heart Failure

Russell H. Greenfield, MD

Much has changed within a relatively short time span with respect to the management of chronic heart failure (HF). Sadly, much remains largely unchanged. Pharmacological and technological advances for the treatment of HF have helped set the stage for the most recently updated treatment guidelines developed jointly by the American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) in 2013.¹ Promising research findings have provided much needed hope for a breakthrough; however, the reality remains that the morbidity, mortality, and escalating financial burden to society associated with HF continue to be unacceptably high. The statistics are sobering: at 40 years of age, the lifetime risk of developing HF for both men and women is 20%.² Incidence rates worsen with advancing age, increasing from approximately 20 per 1000 persons aged 65–69 years to more than 80 per 1000 persons aged ≥ 85 years.³ It is estimated that over 5 million individuals in the U.S. currently have clinical HF,⁴ with one in five Americans predicted to be aged >65 years by the year 2050.⁵ Thus the prevalence of HF in the U.S. is expected to increase dramatically, particularly as more people survive heart attacks. HF is the most frequent Medicare diagnosis-related group.⁶ A conservative estimate of the direct and indirect costs associated with HF in the United States in 2010 was \$39.2 billion.⁷ Experts believe that renewed attention and energy should be applied towards addressing HF, at least equal to that directed towards cancer.

Few, if any, medical problems represent as substantial a burden on our health care system as HF yet offer so true a picture of both the need and potential benefit of an integrative approach to care. The single best way to treat HF is to prevent its development because once established, HF follows an inexorable progression toward greater infirmity and death,

typically within a few short years. Prevention, prevention, prevention must be our mantra with respect to HF management. Lifestyle and dietary measures that promote optimal heart health should be encouraged early in life, and improved access to preventive medical care across socioeconomic strata should be mandated. Careful surveillance for early signs of hypertension, diabetes, obesity, mood disorders, and coronary artery disease is essential in addition to aggressive treatment of these comorbidities with the use of safe and effective available interventions.

Integrative treatment of heart failure focuses primarily on prevention.

For people who have already developed symptomatic HF, the emphasis rests squarely on conventional medical therapy with physiological goals of lowering both preload and afterload, maintaining stable left ventricular function, limiting activation of the renin-angiotensin-aldosterone system, and inhibiting release of neurohormonal factors. Therapeutic goals should emphasize optimizing both functional capacity and quality of life. Complementary medical therapies with promise of efficacy and evidence of safety can be employed as adjuncts, to the benefit of some patients.

HF is a complex clinical syndrome that results from structural or functional impairment of ventricular filling or ejection of blood,¹ and exists in various different forms including acute and chronic, congestive, right- and left-sided, in addition to systolic and diastolic. Cardinal manifestations of HF include fatigue, shortness of breath, and fluid retention. As a proportion of patients present without signs or symptoms of fluid overload, the term “heart failure” is generally preferred over “congestive heart failure.” While many different disorders may cause or contribute to the development of HF, the majority of cases involve left ventricular dysfunction. This chapter focuses exclusively on chronic systolic HF, a disorder marked by impaired left ventricular ejection fraction (<45%) in which cardiac output is insufficient to meet metabolic demands. This condition is now referred to as HF_rEF (heart failure with reduced ejection fraction), as opposed to HF_pEF (heart failure with preserved ejection fraction).¹

HF_rEF most commonly develops as a consequence of long-standing cardiovascular disease, particularly hypertension or coronary artery disease, leading to ischemic cardiomyopathy. Once considered to be

solely a manifestation of the mechanical inability of the heart to pump blood adequately throughout the body, the pathophysiology of HFrEF is now recognized to be multifactorial. Initially positive neurohormonal compensatory mechanisms, believed to involve angiotensin II, norepinephrine, aldosterone, natriuretic peptides, vasopressin, and endothelin⁸ among other compounds, ultimately become maladaptive and contribute to clinical deterioration ([Table 25.1](#)).⁹⁻¹² In the most severe form of HFrEF, pulmonary edema develops as backward pressure within congested capillaries becomes high enough to allow fluid leakage into lung tissue thereby compromising gas exchange and creating a life-threatening situation. Death most often results from progressive cardiac decompensation, respiratory failure, or cardiac dysrhythmia (sudden cardiac death).

Several classification systems for HF have been proposed, owing in part to myriad clinical presentations. The New York Heart Association (NYHA) system ([Table 25.2](#))¹³ defines the level of illness according to exercise capacity and symptoms, whereas the ACCF/AHA stages of HF ([Table 25.3](#))¹⁴ emphasize development and progression of the disease, and can be used to describe both individuals and populations.¹ Together, the NYHA functional classification and the ACCF/AHA stages of HF provide complementary diagnostic information regarding the presence and severity of HF, and serve to help guide therapeutic intervention.

TABLE 25.1
Pathophysiological Features

- Increased calcium entry into myocytes
- Myocyte hypertrophy and loss with interstitial fibrosis, with resulting ventricular hypertrophy and dilation (structural remodeling)
- Reduced wall motion
- Increased myocardial energy expenditure
- Systemic vasoconstriction
- Sodium retention and circulatory congestion
- Increased circulating catecholamines
- RAAS activation
- Increased levels of tumor necrosis factor-alpha and atrial and B-type natriuretic peptides

RAAS, renin-angiotensin-aldosterone system.

Data from references ⁶⁻⁹.

TABLE 25.2

New York Heart Association Functional Classification System

NYHA Class	Description
I	Physical activity not limited by symptoms such as shortness of breath, fatigue, or palpitations
II	Physical exertion mildly limited, with symptoms of shortness of breath, fatigue, or palpitations developing with typical daily activities
III	Physical activity severely curtailed; symptoms of shortness of breath, fatigue, or palpitations developing with almost any kind of activity
IV	Symptoms and physical discomfort present even at rest

NYHA, New York Heart Association.

From The Criteria Committee of the New York Heart Association. *Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Great Vessels*. 9th ed. Boston, Mass: Little & Brown; 1994.

Integrative Therapy

The critical message regarding management of HF_rEF cannot be overemphasized—do everything to prevent the disease from developing in the first place. Integrative means to help prevent or, at least, aggressively treat disorders that contribute to development of HF (including hypertension, coronary artery disease, diabetes, mood disorders, and dyslipidemia) can be found under the appropriate chapter headings in this text. The aims of treatment for established HF_rEF are straightforward: prevent progressive cardiovascular deterioration; minimize symptoms; enhance quality of life; and increase survival rates. [Fig. 25.1](#) is a flow chart of approaches to the treatment of HF_rEF. [Fig. 25.2](#) is a treatment algorithm for HF_rEF according to disease stage.

TABLE 25.3

2005 ACCF/AHA Stages of Heart Failure

ACCF/AHA Stage	Description
A	At risk for HF but without structural heart disease or HF symptoms
B	Structural heart disease but without signs or symptoms of HF
C	Structural heart disease with prior or current symptoms of HF
D	Refractory heart failure requiring specialized intervention

ACCF, American College of Cardiology Foundation; AHA, American Heart Association; HF, heart failure.

From Hunt SA, Abraham WT, Chin MH, et al. 2009 focused update incorporated into the ACC/AHA 2005 guidelines for the diagnosis and management of heart failure in adults: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. *J Am Coll Cardiol* 2009; 53:e1-e90.

Herbs and Supplements

Be sure to advise patients that the agents discussed in the following paragraphs do not act quickly, and that 4 to 6 weeks or more may pass before clinical benefit, if any, is evident. These remedies offer the greatest promise of clinical benefit in patients with less severe disease (ACCF/AHA stages A to C, NYHA classes I to III). Thus the use of these agents is not considered appropriate for acutely worsening HF.

Botanicals

Hawthorn (*Crataegus oxycantha*)

Long a favored herbal remedy in Europe, hawthorn is a slow-acting cardiac tonic whose active constituents are considered to be flavonoids, such as vitexin and rutin, and oligomeric proanthocyanidins. The German Commission E specifically recommends only the leaf and flower of the hawthorn plant be used therapeutically.

Numerous beneficial effects have been ascribed to hawthorn based on both animal and human studies,¹⁵⁻¹⁷ including:

- Increased coronary artery blood flow
- Enhanced pumping efficiency of the heart (improved contractility)
- Antioxidant activity
- Phosphodiesterase inhibition
- Angiotensin-converting enzyme (ACE) inhibition
- Antidysrhythmic effects (lengthens the effective refractory period, unlike many cardiac drugs)
- Mild reduction in systemic vascular resistance (lowered blood pressure)

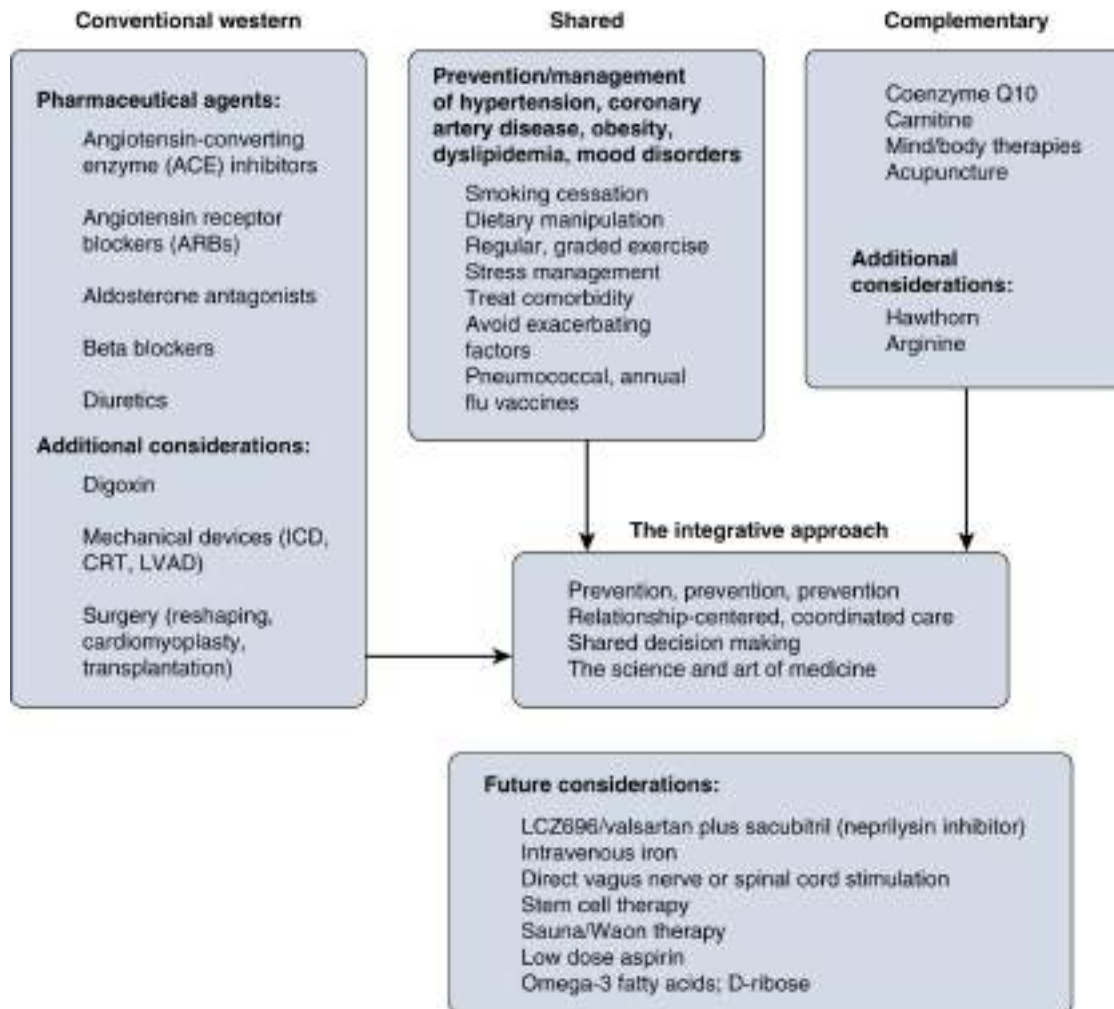

FIG. 25.1 Therapeutic Options for HFrEF.

CRT, cardiac resynchronization therapy; ICD, implantable cardioverter-defibrillator; LVAD, left ventricular assist device. Data for this figure was found from references [202-210](#).

Reviews of placebo-controlled trials have reported both subjective and objective improvement in patients with mild forms of HF (NYHA classes I and II).^{16,18,19} In one study, hawthorn was compared to the ACE inhibitor, captopril, for the treatment of HF. At the end of the trial period, improved exercise capacity compared with baseline measurements was observed in both treatment groups, with no statistically significant difference between the two treatments. However, a relatively low dosage of captopril was administered in this study.²⁰ Other studies of hawthorn in patients with HF have reported improvements in clinical symptoms, pressure-rate product, left ventricular ejection fraction, and patients' subjective sense of well-being.²¹⁻²⁵ A 2008 systematic review suggested

significant improvements in symptoms and physiological outcomes associated with the use of standardized extracts of hawthorn among patients with HF.²⁶ However, the majority of the studies with positive results did not include treatment with drugs now accepted as standard medical therapy, such as ACE inhibitors and beta blockers. Subsequent studies evaluating hawthorn in the setting of chronic HF in combination with current standard medical therapy have reported less successful outcomes. In one trial, the standardized hawthorn extract, WS 1442, was added to conventional medical therapy for HF that included ACE inhibition and beta blockade over 6 months. No significant improvement following treatment with hawthorn was observed in a 6-minute walking test, the primary end point, or secondary end points including quality of life and NYHA classification. However, a modest improvement in left ventricular ejection fraction was observed.²⁷ The results of the SPICE study, a large 24-month, randomized clinical trial of hawthorn in patients with NYHA heart failure classes II and III and left ventricular dysfunction, indicated no statistically significant benefit of hawthorn on the composite end point of cardiac death, nonfatal myocardial infarction, and hospitalization for worsening disease. There was a trend toward reduced cardiac mortality in the treatment group, most notably for those with significantly impaired left ventricular function.²⁸ Most concerning, however, are the results of a retrospective safety analysis of the use of hawthorn in NYHA class II to III HF over 6 months.²⁹ The analysis revealed that hawthorn not only failed to impede progression of disease but appeared to increase the risk of early HF progression. Hospitalization rates were higher, and death rates were slightly higher, in those receiving hawthorn compared with placebo.²⁹ In light of the previously good safety record of hawthorn, these findings are puzzling and quite concerning.

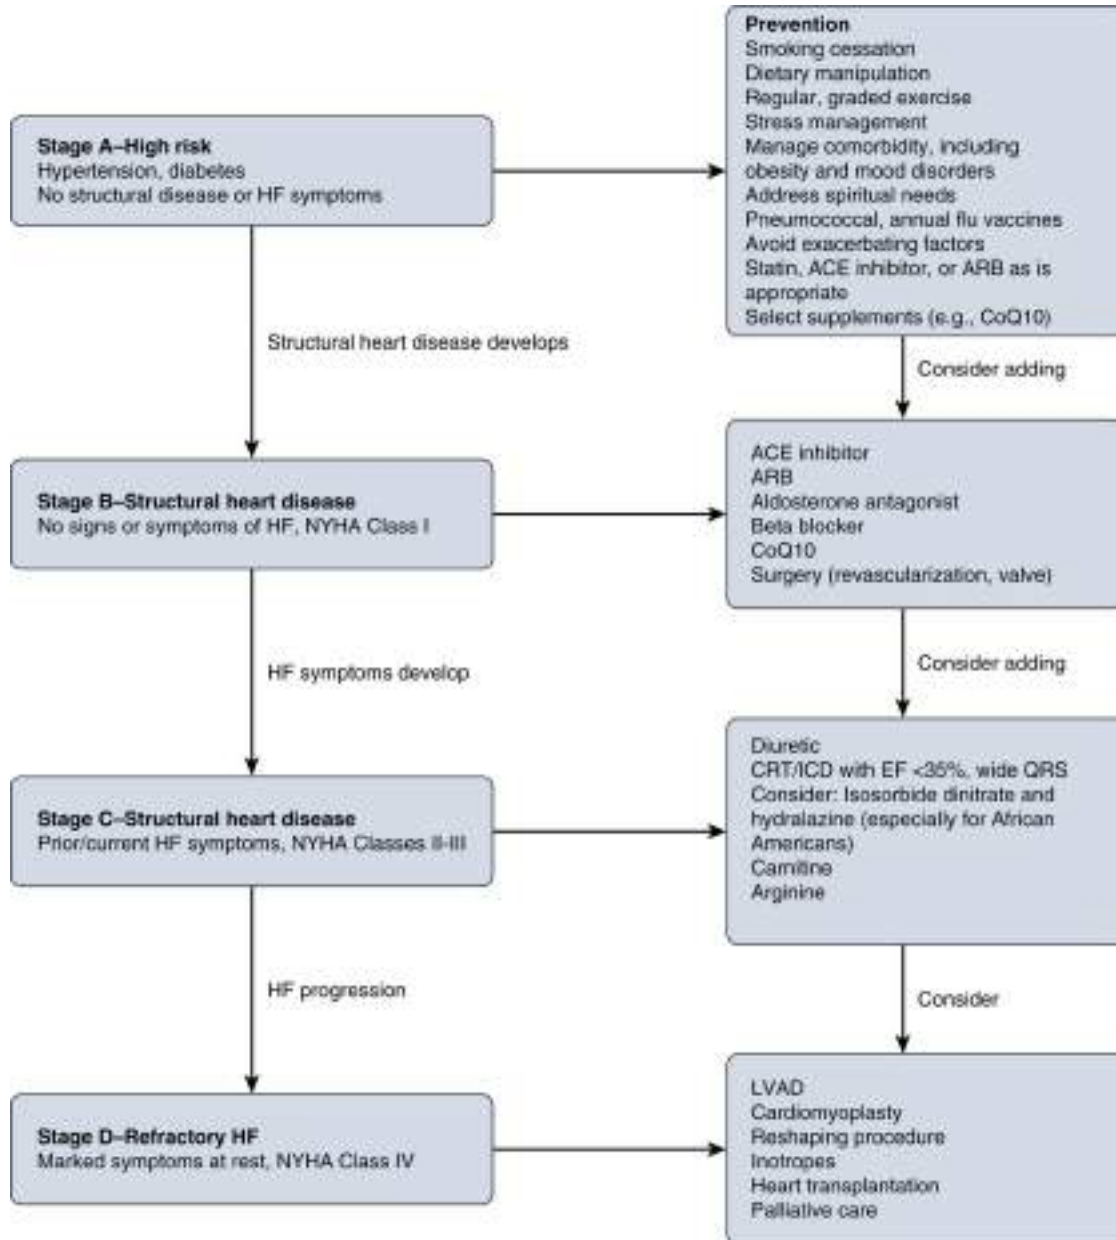

FIG. 25.2 Clinical Pathway of HF/EF Management.

ACE, angiotensin converting enzyme; ARB, angiotensin receptor blocker; CoQ10, coenzyme Q10; CRT, cardiac resynchronization therapy; EF, ejection fraction; HF, heart failure; ICD, implantable cardioverter-defibrillator; NYHA, New York Heart Association. (Adapted from: Yancy CW, Jessup M, Bozkurt B, et al. 2013 ACCF/AHA guideline for the management of heart failure: executive summary.

Circulation . 2013;128:1810-1852.)

Dosage

Hawthorn is usually standardized to its content of flavonoids (2.2%) or oligomeric proanthocyanidins (18.75%). The recommended daily dose, according to previously reported studies, ranges from 160 to 1800 mg; however, most practitioners believe therapeutic efficacy is greater with higher doses (600 to 1800 mg/day). Noticeable improvement may not occur for 6 to 12 weeks.

Precautions

With the exception of the one study described previously where hawthorn was associated with early HF progression, few side effects have been associated with the use of hawthorn. Practitioners should remember that hawthorn has a mild hypotensive effect. A previous significant concern regarding a potential herb–drug interaction has largely been allayed. It had been suggested that hawthorn may enhance the activity of digitalis glycosides, thus increasing the risk of side effects despite the hawthorn plant not containing digitalis-like substances. A study found no significant interaction between hawthorn and digitalis³⁰; however, the investigators noted that these agents should still be combined with caution until more definitive data becomes available. Most conventional medical practitioners reflexively state that hawthorn should not be given to people taking digitalis for heart failure. A far more integrative perspective would consider the possibility of lowering the therapeutically effective dosage of digitalis, thereby minimizing the side effects associated with its use, by combining digitalis with an appropriate dose of hawthorn. Similarly, combination therapy may permit the use of lower doses of hawthorn with no reduction in therapeutic effectiveness as the purported beneficial actions of hawthorn overlap those of other commonly used medications in HF, such as ACE inhibitors and beta blockers. In each instance, however, there is a paucity of data available to help guide combination therapy. Accordingly, further research is required in this area. Until the safety and effectiveness of hawthorn in the setting of guideline-directed medical management of HF^rEF are clearly proven, its clinical indications should be considered rare.

Hawthorn, a long-favored herbal remedy for mild forms of chronic HF, possesses actions largely supplanted by conventional medications, and has been associated with untoward risk of harm.

Supplements

Coenzyme Q10

Coenzyme Q10 (sometimes abbreviated as CoQ10) has long been used as a nutritional supplement for cardiovascular disease, and at one time was one of the top six pharmaceuticals consumed in Japan under the name ubiquinone.³¹ More recently, coenzyme Q10 has become increasingly used in the United States, with significant attention paid to published research examining the potential role of this agent in HF management. A naturally occurring substance that behaves like a vitamin, coenzyme Q10 is present in small amounts in most diets. Coenzyme Q10 is also synthesized within the body from tyrosine, partially through a pathway shared with cholesterol synthesis. Coenzyme Q10 is found in highest concentrations within the mitochondrial membranes of organs with significant energy requirements, particularly the heart, where it acts as a carrier of both electrons and protons, and interacts with enzymes intricately involved with energy production.³²⁻³⁵ Coenzyme Q10 also possesses antioxidant³⁶ and membrane-stabilizing³⁷ effects.

The concentration of coenzyme Q10 within the plasma and myocardium is lower in patients with cardiac failure compared to controls, regardless of etiology.³⁸⁻⁴⁰ The more severe the degree of HFrEF according to the NYHA functional classification system, the greater the deficiency of coenzyme Q10.⁴¹⁻⁴⁴ Whether a reduced coenzyme Q10 concentration is causal, as may be the case in idiopathic dilated cardiomyopathy, or secondary, as is likely with ischemic cardiomyopathy, remains unclear. Regardless, demonstrated myocardial deficiency of coenzyme Q10, the knowledge that exogenous administration can correct the deficiency,^{40,45} and an appreciation of its necessity for adequate myocardial energy provision together initially formed the rationale for coenzyme Q10 administration in the broad setting of HF.

The first clinical application of coenzyme Q10 in cardiovascular disease was reported in 1967.⁴⁶ Since that time, numerous studies evaluating the utility of coenzyme Q10 use in the setting of chronic HF have been published. Unfortunately, the studies are of highly variable

quality due to the following limitations: uncontrolled or of short duration (weeks to a few months); inclusion of a small number of subjects; conducted before the widespread use of ACE inhibitors, beta blockers, and aldosterone antagonists; or measured only functional parameters. Nonetheless, published data predominantly indicates a supportive role for coenzyme Q10 in HF, with beneficial effects on ejection fraction,⁴⁷⁻⁴⁹ end-diastolic volume index,^{48,50} development of pulmonary edema and hospitalization rate,⁵¹ and symptoms.^{49,52,53} Research suggests that withdrawal of CoQ10 supplementation results in worsening cardiac function and symptoms,⁵⁴ and at least two studies have reported a survival benefit when coenzyme Q10 is added to a conventional therapeutic regimen^{55,56}; however, some studies have failed to demonstrate clinical efficacy.^{57,58} More recently, the authors of a 12-week observational trial combining coenzyme Q10 with a proprietary maritime pine bark extract in a small number of patients with NYHA class II to III HF reported improvements in ejection fraction and treadmill walking distances.⁵⁹ The Q-SYMBIO trial reported benefits of 300 mg of CoQ10 daily in the setting of HF at both 16 weeks and 2 years of follow-up.⁶⁰ A separate study of coenzyme Q10 combined with 10 mg of atorvastatin reported a mildly beneficial effect on ejection fraction and NYHA functional status compared to atorvastatin alone.⁶¹ A 2013 analysis suggested that CoQ10 has a therapeutic role in the management of HF,⁶² while a Cochrane Database review suggested no firm conclusions could yet be made due to the poor quality of existing research.⁶³ CoQ10 may help reduce the incidence of atrial fibrillation in patients with HF.⁶⁴ Clearly, however, large multicenter trials are required to determine the true efficacy of coenzyme Q10 in the treatment of HF.

Dosage

Most CoQ10 supplements are provided in the oxidized state (ubiquinone), which is reduced to ubiquinol following ingestion. While no clear advantage of one over the other has been proven, both oxidized and reduced forms of coenzyme Q10 are available in supplement form.⁶⁵ The optimum dosage of coenzyme Q10 in the setting of HF has yet to be undetermined. Studies have used doses ranging from 30 to 600 mg/day; however, most practitioners initially prescribe 100 to 200 mg daily. Softgel capsules of coenzyme Q10 may

provide superior bioavailability.⁶⁶

Precautions

Coenzyme Q10 appears to be remarkably free of significant side effects. The most common adverse reaction is gastrointestinal upset (epigastric discomfort, loss of appetite, nausea, and diarrhea), occurring in less than 1% of all studied subjects.⁶⁷ Caution is advised for patients receiving anticoagulation therapy because there are case reports of possible procoagulant activity in patients taking warfarin, perhaps due to the structural similarity of coenzyme Q10 to menaquinone.⁶⁸⁻⁷⁰ On the other hand, patients taking 3-hydroxy-3-methyl-glutaryl-coenzyme A (HMG-CoA) reductase inhibitors (statins) may benefit from supplementation with coenzyme Q10. As alluded to earlier, cholesterol and coenzyme Q10 partially share the mevalonate pathway, the biosynthetic pathway disrupted by statin drugs. Cholesterol production and the endogenous pathways for coenzyme Q10 production may both be compromised by HMG-CoA reductase inhibition.⁷¹⁻⁷⁵ Studies have indicated that supplemental CoQ10 may help reduce the incidence of statin-associated myopathy^{76,77}; however, this approach remains controversial.

Carnitine

Carnitine, another vitamin-like substance, acts as a carrier of the fatty acids required for energy production from the cytoplasm to mitochondria. Carnitine is synthesized from the amino acid, lysine, but it is also available in small amounts from foods such as red meat (see brief discussion under Precautions). Organs with the highest concentrations of carnitine (those with high levels of fatty acid metabolism, including the heart and skeletal muscle) are incapable of synthesizing carnitine.⁷⁸ Myocardial carnitine is concentrated within the left ventricle.^{79,80} Levels of carnitine are reportedly low in patients with HF,^{81,82} and depletion of myocardial L-carnitine appears to affect cell membrane function adversely, leading to impaired myocardial contractility.⁸³⁻⁸⁵

Only the L-form of carnitine should be used therapeutically; the DL-form has yet to be proven safe. Investigators have suggested that propionyl L-carnitine (PLC; created through the esterification of L-carnitine) is most effective in the setting of heart disease due to its highly lipophilic nature.⁸⁶ PLC has been shown to improve muscle metabolism,⁸⁷

to stimulate the Krebs's cycle,⁸⁸ and to improve heart contractility^{89,90} in animal models. Studies of L-carnitine in humans with ischemic heart disease or peripheral vascular disease have reported enhanced cardiac performance and increased exercise tolerance.⁹¹⁻⁹³

Preliminary human trials using PLC in the setting of HF have provided promising results.⁹⁴ Long-term administration of PLC has been shown to improve ventricular function, reduce systemic vascular resistance, and increase exercise tolerance.^{95,96} Acute administration of PLC reportedly lowered pulmonary artery and capillary wedge pressure in a study of patients with HF,⁹⁷ while a statistically significant reduction in 3-year mortality was reported in a separate study.⁹⁸ A well-conducted study reporting no significant benefit of PLC in HF did, however, reveal a trend toward beneficial effects in patients with relatively preserved heart function (ejection fraction between 30% and 40%) and demonstrate the safety of PLC.⁹⁹

Dosage

The dosage of PLC used in the majority of previous study was 2 g/day (range, 1 to 3 g/day) in two to three divided doses.

Precautions

Current literature strongly suggests that PLC is safe for patients with HF. L-Carnitine has been reported to cause an unpleasant body odor at extremely high doses. However, the majority of studies using PLC have reported no significant side effects or major toxicity,⁷⁸ although an effect on peripheral thyroid hormone action has been posited.¹⁰⁰

Concerns over the safety of carnitine have focused on dietary sources, including meat and eggs, and the production of TMAO (trimethylamine-N-oxide) by gut bacteria. TMAO has been linked to increased risk of acute coronary events and the progression of HF.^{101,102} The contribution of carnitine supplementation toward the production of TMAO has yet to be elucidated.

L-Arginine

L-Arginine is an essential amino acid with vasodilatory effects that may enhance coronary artery blood flow and lessen cardiac workload. Use of

L-arginine has been associated with improved hemodynamics and decreased endothelial dysfunction,¹⁰³⁻¹⁰⁷ improved exercise tolerance,^{103,108,109} improved kidney function,¹¹⁰ and enhanced quality of life.¹¹¹ L-arginine may protect against the development of cardiorenal syndrome, a condition where kidney or heart dysfunction adversely affects the other organ system in the setting of HF.¹¹² There is promising evidence supporting a role for arginine in the management of HFrEF¹¹³; however, there is a lack of data to support its regular use in clinical practice.

Dosage

The typical dose recommended in HF is 2 g three times daily.

Precautions

L-Arginine increases potassium levels when used in combination with other potassium-sparing drugs¹¹⁴ and may increase the incidence of recurrent herpetic lesions. The results of a clinical trial cast doubt on the utility of arginine therapy after myocardial infarction, and even indicated such an intervention may increase mortality in older patients.¹¹⁵

Pharmaceuticals

Angiotensin-Converting Enzyme Inhibitors

Early institution of maximal therapy with ACE inhibitors saves lives. Numerous studies have shown that treatment with ACE inhibitors slows progression of HF and can improve quality of life and long-term prognosis.¹¹⁶⁻¹¹⁸ The biggest limitation of this class of agents is that many patients are not receiving maximal beneficial dosages. Such undertreatment stymies anticipated therapeutic benefits. ACE inhibitors should strongly be considered in all patients with reduced ejection fraction to help prevent symptomatic HF, as well as in those with HFrEF unless contraindicated.

Dosage

Initial and maximal dosages for commonly used agents are as follows¹:

- Captopril: 6.25 to 50 mg three times daily
- Enalapril: 2.5 to 20 mg twice daily
- Fosinopril: 5 to 40 mg daily
- Lisinopril: 2.5 to 40 mg daily
- Perindopril: 2 to 16 mg daily
- Quinapril: 5 to 20 mg twice daily
- Ramipril: 1.25 to 10 mg daily
- Trandolapril: 1 to 4 mg daily

Precautions

Many physicians remain wary of the potential side effects of ACE inhibitors, such as hypotension, kidney problems (increased creatinine levels), and electrolyte disorders (hyperkalemia). A safe and effective approach is to start at a low dose before slowly increasing the dosage and periodically checking electrolyte levels. All patients with a verified diagnosis of HF able to tolerate ACE inhibitors should be prescribed these agents, with dosage maximized appropriately. Some patients may develop a chronic, dry cough with ACE inhibitor therapy that may limit utility. In this instance, angiotensin receptor blockade and vasodilator therapy are appropriate considerations. Efforts should first be made to ensure that cough is not secondary to the development of HF with congestion.

Angiotensin Receptor Blockers (ARBs)

Angiotensin II subtype I receptor blockers provide more complete blockade of the renin-angiotensin system than ACE inhibitors and have been shown to decrease morbidity and mortality to a degree similar, but not superior, to that of ACE inhibitors. ARBs have fewer side effects than ACE inhibitors and, in carefully selected cases, may be of benefit when combined with ACE inhibitors as part of standard therapeutic regimens.¹¹⁹⁻¹²³ This last point bears a warning; ACE inhibitors should only be combined with ARBs with considerable caution as studies have reported increased morbidity and mortality, and no significant all-cause mortality benefit, particularly among patients also receiving an aldosterone antagonist.^{1,122,123} ARBs are a reasonable alternative for patients who are unable to tolerate ACE inhibitor therapy.^{122,124}

Dosage

Initial and maximal dosages for commonly used agents are as follows¹:

- Candesartan: 4 to 32 mg daily
- Losartan: 25 to 150 mg daily
- Valsartan: 20 to 160 mg twice daily

Precautions

Aside from the cautions noted above, ARBs are typically well tolerated.

Aldosterone Antagonists

Aldosterone mediates sodium retention, cardiac remodeling, myocardial fibrosis, and baroreceptor dysfunction.¹²⁵ Studies evaluating spironolactone, a diuretic and nonselective aldosterone antagonist, have reported reductions in both the need for hospitalization and the risk of sudden death when spironolactone is added to standard conventional medical therapy.¹²⁶⁻¹²⁹ Eplerenone is a more selective aldosterone antagonist that has also been shown to reduce morbidity and mortality in HF. Although the benefits of aldosterone antagonism in HF are well established, this form of therapy remains underused by physicians, perhaps due to concerns regarding hyperkalemia.¹³⁰ Data indicate an important role for spironolactone even in patients with NYHA class I to II HF.¹³¹ All patients with advanced HF_rEF (left ventricular ejection fraction <35%) should be considered for aldosterone antagonist therapy.^{132,133}

Dosage

Initial and maximal dosages for commonly used agents are as follows¹:

- Spironolactone: 12.5 to 50 mg daily
- Eplerenone: 25 to 50 mg daily

Precautions

Spironolactone and eplerenone are known to promote potassium and magnesium retention. Adequate kidney function should be confirmed prior to the initiation of aldosterone antagonists, with frequent electrolyte level monitoring. Avoid concomitant use of these agents

with trimethoprim-sulfamethoxazole or ciprofloxacin in elderly patients due to increased risk of hyperkalemia.¹³⁴

Beta Blockers

Once considered contraindicated in the setting of HF, beta blockade has clearly been shown to have benefit in all but the most severe functional classes of HF when added to a regimen of ACE inhibitors or ARBs. Beta blockers enhance left ventricular systolic function and have been shown to decrease hospitalization rates and reduce the incidence of sudden cardiac death.¹³⁵⁻¹⁴¹ They not only affect the mechanical action of the heart but also provide autonomic balance and counteract specific neurohormonal processes that contribute to progressively worsening heart function through cardiac remodeling.¹⁴²⁻¹⁴⁴ Beta blockade combined with ACE inhibition is considered a cornerstone of HFrEF management.

Three beta blocking agents have been shown to have benefit in the clinical setting of HF, although the most beneficial agent in specific instances remains unclear. Treatment should be initiated at low doses and gradually titrated upward.¹⁴⁵

Dosage

Initial and maximal dosages for commonly used agents are as follows¹:

- Bisoprolol: 1.25 to 10 mg daily
- Carvedilol: 3.125 to 50 mg twice daily
- Carvedilol CR: 10 to 80 mg daily
- Metoprolol succinate extended release: 12.5 to 200 mg daily

Precautions

Side effects include hypotension and bradycardia.

Angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), beta blockers, and aldosterone antagonists are each associated with positive impacts on HF-related mortality.

Cardiac Glycosides (Digoxin)

Digoxin has been a mainstay of the conventional Western medical

armamentarium since the days of William Withering, who first explored the benefit derived from use of the leaves of the common foxglove plant (*Digitalis purpurea*) more than 100 years ago. Until relatively recently, digoxin was commonly employed in the treatment of supraventricular dysrhythmias (atrial fibrillation) and HF, particularly when HF was associated with hypertension, valvular disease, or coronary artery disease.

Digoxin is known to be a positive inotrope (increases the pumping efficiency of the heart); however, more recent work has demonstrated beneficial neurohormonal activity. Administration of digoxin does not appear to affect overall mortality when added to current standard medical therapy, although digoxin may improve symptoms, enhance exercise capacity, improve patient quality of life and clinical status, and reduce hospitalization rates in some instances.¹⁴⁶⁻¹⁵⁰

However, the use of digoxin in the setting of HF_rEF is not without risk, with a 2013 study reporting a major increase in all-cause mortality (72%) in a community cohort of patients with new systolic HF who were administered digoxin in combination with beta blockers.¹⁵¹

Dosage

The initial and maximal dose is as follows¹:

- Digoxin: 0.125 to 0.25 mg daily in most patients

Precautions

Although useful, digoxin has a very narrow therapeutic window and toxicity is common. Few physicians initiate digoxin therapy early in the course of HF, with most prescribing it only in moderate to severe disease, and then only as second- or third-line therapy. Digoxin can be used both in the setting of acute cardiac decompensation and as part of chronic maintenance therapy. Digoxin should not be prescribed as monotherapy—patients with HF should almost always be taking an ACE inhibitor in combination with other medications as previously described. Lower doses of digoxin are often necessary in patients with renal insufficiency.

Isosorbide Dinitrate and Hydralazine

Few therapies underscore the notion that no two people are alike as

clearly as the combination of nitrates and hydralazine. Combined use of hydralazine and isosorbide dinitrate was the first treatment shown to improve survival in HF, though it was subsequently found to be less effective than ACE inhibition in direct comparisons.¹⁴⁵ African Americans with HF, however, generally do not respond as favorably to ACE inhibitors or beta blockers as nonAfrican-Americans, and appear to have less nitric oxide activity than nonAfrican-Americans. The Reevaluation of the Veterans Administration Cooperative Study on Vasodilator Therapy of Heart Failure (V-HeFT trial)¹⁵² reported a significant reduction in mortality among African Americans receiving nitrates and hydralazine. Subsequently, the African-American Heart Failure Trial (A-HeFT) evaluated the same fixed combination of isosorbide dinitrate and hydralazine in addition to standard therapy.¹⁵³ The study was stopped early due to a reduction in mortality with combination therapy of 43%. The vasodilatory effects of this therapy are mediated by increased nitric oxide levels as a result of the effects of isosorbide dinitrate as a nitric oxide donor and hydralazine as an inhibitor of the breakdown of nitric oxide. In 2005, the U.S. Food and Drug Administration approved the use of BiDil (a fixed-dose combination of isosorbide dinitrate and hydralazine) for the treatment of HF in African Americans. More recent data indicate a possible role for isosorbide dinitrate and hydralazine as an add-on therapy for patients of any race with advanced HF.¹⁵⁴

Dosage

Initial and maximal dosages is as follows¹:

- Hydralazine/isosorbide dinitrate (BiDil): 37.5 mg hydralazine/20 mg isosorbide dinitrate to 75 mg hydralazine/40 mg isosorbide dinitrate three times daily

Precautions

Headaches and dizziness have been reported, as has hypotension.

Diuretics

Diuretics help lessen cardiac workload by decreasing preload yet the efficacy of these agents in prolonging survival was not demonstrated until 2006.^{155,156} The most commonly used diuretics in the setting of HF are loop diuretics, such as furosemide, which are especially beneficial

once fluid retention has developed.

Dosage

Initial and maximal dosages for commonly used agents are as follows¹:

- Bumetanide: 0.5 to 10 mg daily
- Furosemide: 20 to 600 mg daily
- Torsemide: 10 to 200 mg daily

Precautions

Periodic blood tests are required to evaluate electrolyte balance, particularly potassium and sodium levels. Diuretics may increase renin and aldosterone levels, thereby worsening the neurohormonal milieu. Benefits of therapy usually outweigh risks, however, because diuretic therapy may reduce morbidity and mortality in addition to improving the symptoms of HF.¹⁵⁵

Biomechanical Therapy

The risk of sudden cardiac death in the setting of HF is markedly increased, likely due to an increased incidence of ventricular dysrhythmias. With an eye toward preventing sudden cardiac death, biomechanical approaches are increasingly being used in the treatment of HF. Evidence supporting the use of cardiac resynchronization therapy (CRT, a form of biventricular pacing) to correct dyssynchronous ventricular contraction and associated incomplete ventricular filling, and implantable cardioverter defibrillators (ICDs) either separately or combined, is compelling with data strongly suggesting improved quality of life and reduced mortality, particularly among patients with stage C disease.¹⁵⁷⁻¹⁶⁷ The use of CRT combined with an ICD in asymptomatic or mildly symptomatic patients with heart disease, reduced ejection fraction, and a wide QRS complex was associated with a 34% reduction in the risk of death or HF events as compared with the use of ICD alone.¹⁶⁷ CRT and ICD are recommended for patients with a left ventricular ejection fraction of less than 35%, NYHA class III to IV symptoms, and a QRS complex duration of more than 0.12 seconds.^{1,6,145} The utility of this approach may be expanding in light of evidence indicating potential health benefits across the spectrum of HF

presentations, even among patients with mild disease.¹⁶⁸ Drugs remain the mainstay of HF_rEF treatment; however, mechanical device therapy is now offering significant benefits to a major subset of patients. The placement of left ventricular assist devices (LVADs), cardiomyoplasty, revascularization for ischemic heart failure, reshaping procedures utilizing titanium anchors, and heart transplantation represent some of the most drastic surgical interventions for the treatment of HF. LVADs may have utility in prolonging life in patients with advanced HF_rEF; however, there is concern that LVADs may contribute to declines in cognitive function and impair health.¹⁶⁹

The most significant recent change in conventional medical treatment for chronic HF is the increased reliance on device therapy, particularly mechanical circulatory support.

Bioenergetics

Acupuncture

Investigators have posited that acupuncture may ameliorate conditions that worsen the prognosis for patients with HF, particularly among those with high sympathetic activity.^{170,171} A pilot study of acupuncture offered to 17 subjects with stable NYHA class II to III HF receiving appropriate medical therapy reported no benefit with respect to ejection fraction but a marked improvement in 6-minute walk test results in the active group.¹⁷² These results are intriguing; however, further studies are required to validate the use of acupuncture in the treatment of HF.

Mind-Body Therapy

Depression is an independent risk factor for HF and is extremely prevalent among patients with established disease.^{173,174} Depression-specific activation of inflammatory cytokines occurs in people with HF and may lead to worsening morbidity and mortality rates.^{175,176} Norwegian data indicate that moderate to severe depression increases the risk of HF by 40%.¹⁷⁷ Numerous studies have reported that providing adequate means of stress reduction can help relieve depression and anxiety, reduce the risk of developing cardiovascular disease, and improve the health and well-being of patients with established HF.¹⁷⁸⁻¹⁸⁴

Some of the benefits of mind-body therapies may be related to impacts on the autonomic nervous system.¹⁸⁵ Despite a lack of studies evaluating the treatment of depression among patients with HF, this is becoming an active area of interest.¹⁸⁶ A study evaluating the utility of biofeedback in treating advanced HF reported increased cardiac output and reduced systemic vascular resistance compared with controls.¹⁸⁷ A more recent small trial examining the effects of transcendental meditation compared with health education in African Americans with HF reported improvements in 6-minute walk scores, depression scores, and measures of quality of life after 6 months, in addition to a reduced hospitalization rate.¹⁸⁸

Health benefits of mind-body therapy were reported by the SEARCH (Study of the Effectiveness of Additional Reductions in Cholesterol and Homocysteine) trial, which examined the effect of training in mindfulness meditation and coping skills in association with support group discussion in more than 200 adults with HF_rEF.¹⁸⁹ Although medical management was not maximized in a small percentage of subjects, measures of anxiety and depression were significantly lower in the active group at the end of the study period. The study found no impact on hospitalization or death rates, but symptom improvement persisted to a 12-month follow-up. A small study of older patients with HF receiving maximal medical therapy reported improvements in neurotransmitter levels and quality of life measures after listening to 30-minute meditation tapes twice daily at home for 12 weeks.¹⁸⁵

Additional studies supporting the benefits of mind-body approaches for patients with HF include those focusing on freeze-frame stress management,¹⁹⁰ behavior modification,¹⁹¹ relaxation response training,^{192,193} and tai chi.^{194,195}

Lifestyle

Community education regarding the adverse effects of smoking, excessive alcohol intake, and obesity must continue and expand. Assistance with tobacco and alcohol cessation, as well as weight management planning, should be made readily available across socioeconomic classes. It is worth noting that recent data indicate moderate alcohol intake (defined as up to one glass of wine, one 12-ounce beer, or a single shot of liquor each night) is associated with reduced risk of HF in both women and men. Higher intakes are associated with increased all-cause mortality, although not specifically an

increased risk of HF.¹⁹⁶

A diagnosis of HF is not a contraindication to participating in exercise. Studies have shown that appropriate, graded exercise programs can improve function and quality of life among patients with HF.¹⁹⁷⁻²⁰⁰ Lack of improvement after fitness training is associated with a poor prognosis.²⁰¹ Results of the HF-Action trial²⁰² were disappointing, reporting at best a modest impact on hospitalization and mortality rate with regular exercise; however, the results reinforced the safety of regular exercise and cardiac rehabilitation for patients with HF. The combination of physical exertion and a healthy diet can help patients maintain optimal body weight and thereby lessen strain on the heart. Sufficient rest is also important, with a target of at least 7 hours of sleep each night considered prudent. The diagnosis and treatment of obstructive sleep apnea can help reduce morbidity and mortality in the setting of HF.²⁰³

Regular participation in spiritual or religious practices may protect against heart disease.²⁰⁴⁻²⁰⁷ Many patients struggle with their spirituality once a diagnosis of HF is made, a struggle that adds to an already stressful situation and perhaps leads to increased morbidity.^{208,209} The burden of symptoms, mood disorders, and spiritual challenges associated with HF has been equated to those experienced by people with cancer.²¹⁰ Attention to spiritual needs can help patients adjust to their new circumstances, address specific regrets with regard to prior lifestyle choices, and search for present meaning and future hope.^{211,212} Religious practice is one of many aspects of spiritual care; in one study it was gratitude, rather than religiosity per se, that was found to account for improved mood, better sleep, reduced fatigue, and lower levels of inflammatory markers related to cardiac health in people with asymptomatic (stage B) HF.²¹³ Patients who come to accept their diagnosis of HF appear to enjoy better quality of life compared with those who have not.²¹⁴

Nutrition

Adhering to an antiinflammatory diet (see [Chapter 88](#)) may help prevent the development of HF and slow progression of established disease. While avoidance of red meat is not necessary, processed meats may be harmful. A recent study demonstrated an increased risk of incident HF and HF-related mortality among patients with a high intake of processed meats, such as cold cuts and sausage.²¹⁵ Patients with stage C HF

typically require additional measures to maintain health. Fluid and sodium (salt) restriction has long been believed to positively affect cardiac function and symptoms in patients with HF; however, sodium restriction is currently the subject of intense debate. In fact, the most recent HF guidelines consider sodium restriction reasonable but not mandatory for patients with symptomatic HF to help reduce congestive symptoms.¹

Supplementation with B vitamins, especially thiamine, should be considered,²¹⁶⁻²¹⁸ as should micronutrient supplementation, including magnesium.²¹⁹⁻²²² The safety of high-dose vitamin E in patients with established cardiovascular disease remains unknown.²²³

Prevention Prescription

- Do not smoke. If you do smoke, get help to quit.
- Follow an antiinflammatory or Mediterranean-style diet.
- Participate in regular physical fitness activities.
- Manage stress in healthy ways.
- Aim for ~7 hours of sleep each night.
- Maintain a healthy weight for height.
- Work with your doctor to manage medical conditions that may lead to heart failure, especially high blood pressure, coronary artery disease, high cholesterol levels, mood disorders, and diabetes.
- Attend to your spiritual side.
- Have the pneumococcal vaccination and annual flu vaccination.
- Avoid overuse of nonsteroidal antiinflammatory medications (NSAIDs).

Therapeutic Review

All patients with heart failure should be started on a combination of an angiotensin-converting enzyme (ACE) inhibitor and beta blocker where appropriate, with consideration given to aldosterone antagonist therapy and ARBs. *Be careful to avoid complications such as hyperkalemia.* Aggressive treatment of comorbidities should be considered.

Removal of Potential Exacerbating Factors

- Try to discontinue nonsteroidal antiinflammatory drugs and first-generation (nondihydropyridine) calcium channel blockers.

Stress Management and Mind-Body Therapy

- Promote proper attention to mood and stress management, and offer instruction in tools such as meditation, relaxation response, and tai chi. 

Sleep

- Consider the possible presence of obstructive sleep apnea and manage appropriately. 

Graded Exercise

- Enroll patients in a certified cardiac rehabilitation program. 

Nutrition

- Encourage an antiinflammatory diet or Mediterranean-style diet. 
- Urge fluid and salt restriction. 

Spirituality

- Inquire about and address needs in an open fashion, and use pastoral care services as appropriate. 

Bioenergetics

- Acupuncture 

Supplements

- Coenzyme Q10: 100 to 200 mg daily 
- Propionyl-L-carnitine: 1 to 3 g daily 
- Arginine: 2 g three times daily 

Botanicals

- Hawthorn: 600 to 1800 mg daily (exercise caution of using with

digoxin) 

Pharmaceuticals

- ACE inhibitors 
- ARBs 
- Beta blockers 
- Aldosterone antagonists 
- Isosorbide dinitrate in combination with hydralazine 
- Diuretics 
- Digitalis 

Surgery

- Cardiac resynchronization therapy or implantable cardioverter defibrillator 
- Left ventricular assist device 
- Cardiomyoplasty 
- Reshaping procedures 
- Heart transplantation

CHAPTER 26

Coronary Artery Disease

Stephen Devries, MD, FACC, FAHA

Integrative Approaches to Cardiovascular Disease

Despite the many advances in treatment and prevention, cardiovascular disease remains the leading cause of premature death and disability in the United States.¹ Nevertheless, 70% of cardiovascular disease is preventable through lifestyle changes alone.² Clearly, we have work to do.

An integrative approach acknowledges the great value and potentially life-saving benefits of modern pharmacology and procedures while also recognizing the limitations of these approaches when used in isolation. An integrative approach is ideally suited to the prevention and treatment of coronary disease because it addresses many of the root causes, especially those influenced by lifestyle. The goal of this chapter is to provide a perspective on the utility of a broader spectrum of therapies beyond those that constitute conventional cardiovascular care.

Pathophysiology

What triggers a cardiovascular catastrophe? For many years, it was believed that a cardiovascular event occurred after many years of progressive narrowing of the coronary artery. According to this view, myocardial infarction develops as a result of progressive accumulation of cholesterol deposits on the lining of the coronary arteries, leading to complete cessation of blood flow. This theory held that over time, cholesterol deposits accumulate and ultimately stop blood flow, leading to myocardial infarction. In more recent years, this paradigm has been

largely upended and replaced by a more complex, and less intuitive, picture.

Angiographic studies have revealed, quite surprisingly, that acute coronary events often arise from “mild” coronary lesions that are far less than 50% obstructive.³ The explanation for this paradoxical finding is that vulnerable plaques, those most likely to rupture and evolve into a complete thrombotic occlusion, are those with large lipid cores and thin fibrous caps.⁴ Surprisingly, the majority of plaques with the largest lipid cores are not severely stenotic (lipid-laden deposits may enlarge the artery and do not always reduce blood flow). Conversely, some of the most severely stenotic plaques are not necessarily the ones with the largest lipid cores and therefore may not be the most “vulnerable.”

A useful way of thinking about this concept and conveying it to patients is that a mild coronary lesion can be considered a “fault line” that appears quite passive and harmless in a quiescent phase. However, like any fault line, these seemingly harmless plaques may erupt at any moment, causing a potentially lethal cardiac event.

This scenario has implications for both the detection and treatment of coronary disease. With regards to detection, a mildly stenotic coronary lesion is not flow limiting and therefore would not be expected to result in chest pain or provoke abnormal findings on cardiac stress testing. This is the explanation for the anecdote familiar to most clinicians and patients about the individual who sailed through a stress test with “normal” results only to suffer a cardiac catastrophe a short time later.

The fact that a coronary event can rapidly develop from “mild” angiographic lesions emphasizes the need to prevent coronary lesions from developing rather than focus on reducing the severity of stenoses with interventional procedures.

The triggers of coronary artery disease are both genetic and environmental. Genetic factors include inherited metabolic disorders, including dyslipidemia and diabetes. Environmental and lifestyle factors include nutritional imbalance; sedentary lifestyle; stress and depression; smoking; and air pollution. These areas will be explored in detail later in this chapter.

A mild coronary lesion can be considered a “fault line,” which may appear quite passive and harmless in a quiescent phase. However, like any fault line, these seemingly harmless plaques may erupt at any moment causing a potentially lethal cardiac event.

Integrative Therapy

Nutrition

Nutrition is perhaps the most powerful therapy available for the prevention and treatment of coronary disease.

Mediterranean Diet

The power of nutritional therapy is highlighted by the striking results of the Lyon Diet Heart study.⁵ In this study of individuals who survived myocardial infarction, patients were divided into two groups distinguished only by dietary intervention. The control group was advised to consume a “prudent” diet consisting of reduced cholesterol and total fat. The intervention group was advised to eat a Mediterranean-style diet. Patients in this group were counseled to eat more vegetables and fruit, to eat more nuts and fish, to use olive oil and the canola-based margarine as their predominant cooking oils, and to reduce intake of red meat and refined carbohydrates.

The study was intended to last 5 years but was stopped short at 27 months due to a strikingly helpful effect in the Mediterranean diet group.

At that point, a 73% reduction in cardiovascular events, including myocardial infarction and cardiac death, was observed in the Mediterranean-style diet group. A longer-term follow-up study was published 5 years later, demonstrating a durable benefit of the Mediterranean-style diet with a 72% reduction in cardiovascular events after 5 years.⁶

A Mediterranean-style diet has also proven beneficial for primary prevention of cardiovascular disease. A study stratified 7447 individuals at increased risk of, but without manifest, heart disease to one of two dietary arms (either added nuts or added olive oil) with comparisons to a control group (planned to be a low fat diet but, ultimately, resembled the baseline diet). No significant difference in fruit and vegetable intake was observed between the Mediterranean diet groups and controls. The study was terminated prematurely due to the finding of a clear benefit in the two Mediterranean diet groups, with a 30% reduction in cardiovascular events observed thought to be predominantly attributable to fewer strokes.⁷

The substantial benefits of the Mediterranean diet are not surprising given the proven benefits of its component parts. High consumption of vegetables and fruit are the cornerstones of the Mediterranean-style diet.

Daily consumption of vegetables in the Lyon study averaged 427 g (approximately five servings).⁸ Increased intake of vegetables, particularly dark green leafy vegetables, has been shown to be associated with substantially reduced risk of coronary heart disease. Each daily serving of dark green leafy vegetables, for example, has been linked to a 23% reduction in coronary heart risk.⁹ Fruit intake in the Lyon study averaged 271 grams (approximately two servings; see [Chapter 88](#)).

The results of the Lyon Mediterranean diet study underlie my personal recommendation of five servings of vegetables per day and two servings of fruit.

Whole Grains

Another key constituent of the Mediterranean diet is the avoidance of refined grains and an emphasis on the consumption of whole grains. Refined grains, typically void of fiber, are deleterious in a number of ways. As compared to whole-grain, refined grains result in greater release of glucose into the circulation, triggering higher insulin levels and a greater tendency toward atherosclerosis. Higher sugar intake is associated with reduced levels of HDL and increased levels of the more atherogenic small dense LDL¹⁰ (see [Chapter 87](#)).

The method of grain preparation has important health implications. Boiled whole grains (i.e., oat, quinoa, barley) are typically a healthier choice than bread made from the flour of whole grains. Examples of whole grains include barley, buckwheat, quinoa, polenta, and brown rice. A meta-analysis demonstrated a 21% lower risk of cardiovascular events with 2.5 servings per day of whole grains consumed compared to the absence of whole-grain foods in the diet.¹¹ Consuming pulverizing grains, even whole grains, results in higher blood glucose levels than intact grains.¹² Therefore, boiled whole grains are typically a healthier choice than bread made from the flour of whole grains.

Fish

Fish is another component of a healthy diet, with benefits for both primary and secondary prevention of heart disease. In the Chicago

Western Electric Study, more than 35 grams of fish intake per week (approximately three servings) was associated with a 38% reduced risk of cardiac death.¹³ The Diet and Reinfarction Trial (DART) similarly demonstrated a 29% reduction in all-cause mortality among males instructed to eat fish compared to those who did not after only 2 years.¹⁴ Accordingly, substituting chicken or fish for red meat has been shown to reduce the risk of coronary heart disease.¹⁵

Nuts

Nuts have potent benefits for the reduction of coronary heart disease. Increased nut consumption has been linked to longevity, with a 21% improved survival over 5 years in those with the highest versus lowest levels of nut consumption.¹⁶ Four servings of nuts per week (30 g/serving, or ~1 large handful/serving) have been shown to reduce the risk of coronary heart disease by 37%.¹⁷ Increasing consumption of nuts to two handfuls per day reduces LDL cholesterol by as much as 10% in those with baseline values of greater than 160 mg/dL.¹⁸

The success of nutritional interventions is greatly enhanced when patients perceive nutrition as a priority of their health care practitioner. At every clinical encounter with a patient, I recommend inquiring about the number of servings of vegetables and fruit consumed every day and the type of grains, quantity of fish, and number of servings of nuts consumed on a weekly basis. Emphasizing the importance of diet during each clinic visit allows obstacles to be identified and progress to be celebrated.

Exercise

Patients often inquire about “natural” methods for prevention and treatment of heart disease. In concert with dietary changes, there is no therapy more potent than the addition of regular exercise. Surprisingly, exercise intensity appears to be less important than frequency and consistency. In the Health Professionals Follow-Up Study, walking for 30 minutes per day was associated with an 18% reduction in the occurrence of cardiovascular disease.¹⁹ In the Women’s Health Initiative observational study, exercise of as little as 4.2 metabolic equivalent (MET) hours per week resulted in a 27% reduction in heart disease risk.

The benefits of exercise were even greater for a higher levels of exercise (32.8 MET hours per week).

Although aerobic exercise is generally emphasized for cardiovascular health, resistance training also adds considerable benefit. Resistance training for at least 30 minutes per week resulted in a 23% lower risk of heart disease compared no resistance training in males.¹⁹

Therefore, a reasonable prescription for exercise could start at 30 minutes of brisk walking every day in addition to two to three sessions per week of light resistance training interspersed with stretching. More vigorous workouts of longer duration are likely to be of even greater benefit. Of course, individual prescriptions need to take into account the patient's general health history and cardiovascular status. Stress testing prior to beginning a program may be appropriate for those with a history of heart disease or those with multiple cardiovascular risk factors, particularly those who have been previously sedentary.

Pharmaceuticals

In addition to nutrition and exercise as “foundations” of heart health, patients with symptomatic coronary artery disease should receive treatment informed by American Heart Association/ American College of Cardiology (AHA/ACC) guidelines. Proven medical therapy for symptomatic coronary disease includes aspirin, nitrates, beta-blockers, and calcium channel blockers. Angiotensin-converting enzyme inhibitors are also potent antihypertensives and may provide additional cardiovascular prevention above and beyond their antihypertensive properties. Statin therapy should be considered an essential component of treatment for patients with established vascular disease and those at high risk of vascular disease due to its lipid-lowering effects and a host of “pleiotropic” or nonlipid beneficial metabolic effects. A detailed discussion of these therapies is beyond the scope of this chapter but can be found in the AHA/ACC guideline statements (<http://my.americanheart.org/professional/guidelines.jsp>).

[Tables 26.1](#) and [26.2](#) provide information on the interactions of pharmaceuticals and supplements.

Antiplatelet and Anticoagulant Therapies

Aspirin is the most widely prescribed over-the-counter therapy in cardiology. Aspirin is a mainstay of therapy for patients with established cardiovascular disease, and is frequently recommended for individuals

at high risk of cardiovascular disease. However, dosing remains a challenge because higher doses have greater antiplatelet activity and are associated with an increased risk of gastrointestinal bleeding. A useful tool to balance the benefits and risk of aspirin therapy is provided by the Agency for Healthcare Research and Quality (see [Key Web Resources](#)).²⁰

Patients receiving warfarin may consult integrative practitioners for recommendations regarding alternative options, including those in atrial fibrillation wishing to discontinue warfarin. Patients frequently inquire about the possibility of replacing warfarin with over-the-counter products, including nattokinase, fish oil, and vitamin E, among others. Unfortunately, no studies reported to date have supported the use of botanicals or herbs as replacements for warfarin in patients considered to be at high thrombotic risk.²¹

Angioplasty/Stenting

Angioplasty and stenting are commonly regarded as the most potent interventions available in cardiology. It would be logical to assume that mechanical opening of a severely stenotic coronary artery would reduce the likelihood of myocardial infarction. Surprisingly, however, angioplasties and stents have not been shown to reduce the risk of myocardial infarction or prolong life in the vast majority of patients who receive these therapies (those who are asymptomatic or with stable coronary disease). Survival benefit from angioplasties and stents appears to be confined to patients in the midst of acute myocardial infarction or unstable angina. In the more chronic setting, the benefit of angioplasty and stenting is restricted to the amelioration of chest pain.

This counterintuitive finding was demonstrated by the COURAGE trial, where treatment of stable coronary patients with a catheter-based intervention did not prevent myocardial infarction or improve survival compared to initial treatment with medical therapy alone.²² The absence of a survival benefit for catheter-based interventions in stable coronary patients was confirmed in a subsequent meta-analysis of eight trials including a total of 7229 patients.²³

The explanation for the lack of expected outcomes following angioplasty and stenting in patients with stable disease has yet to be elucidated; however, this lack of efficacy is likely due to mechanical interventions generally being directed at one or two of possibly hundreds of “vulnerable” plaques that exist in an individual’s coronary tree.

Research shows that when conversations regarding the risks and

benefits of catheter-based interventions are more fully explained by cardiologists, patients are less likely to choose an invasive approach.²⁴

Lipid Management

Lifestyle changes are the foundation of a solid prevention program, and it should be recognized that the role of lipid management is subordinate to optimizing lifestyle measures.

Nevertheless, lipid management is an extremely important consideration for both primary and secondary prevention. Of the lipid parameters, the priorities for prevention in order of importance are LDL, HDL, and triglycerides. Total cholesterol is not considered the most useful endpoint as it is a summated term that may either underestimate or overestimate risk. Note that a third of heart attacks occur in individuals with a total cholesterol under 200 mg/dL²⁵ (see [Chapter 27](#)).

TABLE 26.1

Important Herbal and Supplement Interactions with Antiplatelet Drugs and Warfarin

Agents	Herb or Supplement	Effects of Interaction
Antiplatelet drugs (aspirin, ticlopidine, NSAIDs, clopidogrel)	Caffeine	Antiplatelet effect
	<i>Cordyceps</i> fungus	Platelet antagonism
	Curcumin	Antiplatelet effects
	Dong quai	Platelet antagonism
	Feverfew	Inhibition of platelet aggregation
	Fish oil	Platelet antagonism
	Garlic	Inhibition of platelet aggregation
	Ginger	Prolongation of bleeding time
	Ginkgo	Antiplatelet activity, hemorrhage
	Green tea	Antiplatelet effects
	Guggul	Antiplatelet activity
	Horse chestnut	Antiplatelet activity
	Policosanol	Antiplatelet activity
	Resveratrol	Inhibition of platelet aggregation
Vitamin E	Antiplatelet activity	
Warfarin	Coenzyme Q10	Decrease in INR
	Dong quai	Elevation of PT and INR
	Fenugreek	Possible increase in INR
	Fish oil	Elevation of INR
	Garlic	Elevation of INR
	Ginkgo	CNS hemorrhage
	Ginseng	Decrease in INR
	Green tea	Decrease in INR
	L-Carnitine	Potential increase in INR
	St. John's wort	Decrease in INR

CNS, central nervous system; INR, international normalized ratio; NSAIDs, nonsteroidal antiinflammatory drugs; PT, prothrombin time.

From Burleson K. Coronary artery disease. In: Rakel D, ed. *Integrative Medicine*, 2nd ed. Philadelphia: Saunders; 2007:302.

Low Density Lipoprotein

Among all lipid parameters, control of LDL is of primary importance because it is most closely associated with cardiovascular risk. Nevertheless, the optimal method of measuring LDL for determining cardiovascular risk remains controversial. Low-density lipoprotein is an apolipoprotein that carries the bulk of circulating cholesterol. Traditional measurement of LDL-C, the basis for most treatment decisions, assesses only the cholesterol content of this complex molecule.

However, mounting evidence suggests that the cholesterol content of LDL may not be the best indicator of cardiovascular risk. Instead, quantification of the number of LDL particles appears to more closely

correlate with cardiovascular risk than conventional measurement of LDL cholesterol.

TABLE 26.2

Important Herbal and Supplement Interactions with Other Cardiovascular Drugs

Cardiovascular Drug	Herb or Supplement	Effects
Digitalis	Hawthorn	Potentially increased serum levels
	Herbal laxatives	Decreased absorption
	Psyllium	Hypokalemia
	St. John's wort	Decreased serum levels
Amiodarone	—	See precautions for digoxin, warfarin, statins, or herbs with hepatic effects
Propranolol	Guggul	Decreased bioavailability
Clonidine	Yohimbine	Both alpha ₂ -antagonists
Calcium channel blockers	Guggul	Decreased bioavailability
Cyclosporine	St. John's wort	Decreased serum levels
Statins	Red rice yeast	Magnified side effects

From Burleson K. Coronary artery disease. In: Rakel D, ed. *Integrative Medicine*, 2nd ed. Philadelphia: Saunders; 2007:303.

In order to better understand how cholesterol concentration relates to LDL particle number, consider the following example: imagine filling two bathtubs with cholesterol to the same level designated by the LDL-C value. For the purpose of this example, we will designate an LDL-C of 125 mg/dL as corresponding to filling the bathtub halfway with cholesterol balls. In one tub, 100 large balls are used to fill the tub halfway. In the second tub, 2000 small marbles are used to fill the tub to the exact same halfway mark. At first glance, both tubs, filled halfway to the same level of 125 mg/dL, might appear to represent equal cardiovascular risk. However, the person with 2000 smaller particles has a much higher risk of cardiovascular disease than the other individual with an identical LDL-cholesterol but with many fewer particles. In other words, risk is much more closely associated with the number of LDL particles than the concentration of cholesterol.²⁶

Several tests are available for the quantification of atherogenic particles (the vast majority of which are LDL particles). The most readily available method for estimating the number of atherogenic particles is non-HDL cholesterol, a simple term that is calculated by subtracting HDL-C from total cholesterol. Calculation of non-HDL cholesterol is particularly helpful when triglycerides exceed 200 mg/dL, an environment where the

formation of small, dense LDL is more likely. A more accurate reflection of the number of atherogenic particles, however, is ApoB. ApoB takes advantage of the fact that each atherogenic particle contains exactly one molecule of ApoB.²⁷ Therefore ApoB has been shown to be closely associated with cardiovascular risk than LDL-C. Another option for quantification of atherogenic particles is LDL particle number, a proprietary test that has been shown in the Framingham Offspring Study to more closely predict cardiovascular risk than LDL-C.²⁶ Treatment goals for ApoB and LDL particle numbers are not currently well established but are commonly set as percentile rankings for the given population (i.e., <5th percentile for a very high-risk patient).²⁸

The most potent treatment available for reducing LDL cholesterol, ApoB, and LDL particle number are prescription HMG-CoA reductase inhibitors, or statins. These medications are capable of lowering LDL cholesterol by more than 50% and have been proven to reduce the likelihood of a cardiovascular event by approximately a third in both primary and secondary prevention studies. Studies of statins have reported an overall but inconsistent mortality benefit.²⁹

Statin-Related Myalgias

Despite the proven benefits of statins in high-risk individuals, statin therapy is not without risk. Myalgias are a particularly frequent adverse reaction that may be more common than described in the package inserts of these medications. An observational study of statins in clinical practice revealed that muscle-related adverse reactions occur in as many as 11% of patients receiving statins.³⁰ The potential for adverse muscle-related symptoms increases with increased doses.

A survey of patients who reported muscle-related symptoms to their physician while taking statins revealed a sobering finding: in only 29% of cases did physicians consider the possibility of a link between the patient complaining of muscle pain and the use of statins.³¹ In 47% of cases, the clinician dismissed the possibility of such a link. Patients feeling that their symptoms are not being acknowledged by their physician may explain why more than 50% of patients stop taking statins after only 1 year.³²

Alternatives to the use of prescription statins can play an important role when:

- Patients are unable to tolerate prescription statins due to adverse reactions
- Patients are philosophically opposed to the use of prescription statins

Options for the treatment of patients with intolerance to prescription statins include (1) reducing the dose of the prescription statin; (2) changing to a different prescription statin; or (3) using nonprescription lipid therapy.

Surprisingly, cutting the dose of a statin in half generally reduces the efficacy of the statin to lower LDL-C by only 7%.³³ Nevertheless, adverse reactions, particularly myalgias, are often improved or eliminated by lowering statin dose.³⁰ Therefore, for mild myalgias related to statin use, dosage modification may eliminate adverse reactions without sacrificing appreciable lipid control.

Prolongation of the dosing frequency of prescription statins may also have benefit. Rosuvastatin, which has the longest half-life of any available statin, has been shown to retain potent effectiveness in lowering LDL-C levels when dosed as infrequently as one or two dosages per week.^{34,35} In one study, a mean rosuvastatin dose of 10 mg given once a week resulted in a mean reduction in LDL-C of 23%.³⁵

Another option for patients unable to tolerate prescription statins is to switch to a different statin. Reactions can be idiosyncratic, and one brand may be well tolerated when others are not. Rosuvastatin and pravastatin may be better tolerated in some individuals, possibly due to their hydrophilic nature. Fluvastatin may also be considered as it has a unique metabolic pathway among statins (mostly by 2C9), which may explain the findings of a large survey reporting fluvastatin to have the lowest risk of myalgias of all statins.³⁰

Water soluble statins, such as rosuvastatin and pravastatin, may cause a lower frequency of statin-related myalgia in some patient population. Fluvastatin may also cause fewer muscle symptoms due to its unique metabolism.

High Density Lipoprotein

HDL is protective against atherosclerotic disease due to its role in removing LDL from plaque (reverse cholesterol transport) in addition to its antioxidant function. The average serum HDL-C levels in men and

women are 40–45 mg/dL and 50–55 mg/dL, respectively. Low HDL is associated with significantly increased cardiovascular risk, even in individuals with low LDL.³⁶ However, studies evaluating the efficacy of pharmacological therapies in raising HDL, including niacin and cholesteryl ester transfer protein (CETP) inhibitors, have been disappointing.³⁷

Lifestyle measures are the primary strategies to raise HDL and include weight loss, exercise, and smoking cessation.³⁸ Reducing intake of added sugar and food with high glycemic load also has utility in raising HDL.¹⁰

Alcohol is effective at raising HDL levels, and this effect may explain the lower risk of cardiovascular events associated with moderate alcohol intake (one serving/day).³⁹ All forms of alcohol, including white and red wine, beer, and hard liquor, have been shown to raise HDL. The cardiovascular benefits of alcohol need to be balanced against the potential for accidents and abuse, as well as the increased risk of breast cancer associated with alcohol intake in women.

The most potent pharmacological agent available for boosting HDL-C is niacin. The HDL-raising effect of niacin is dose-related, with an increase of 20%–30% observed at the highest doses of around 2000 mg/day.^{40,41} The ability of niacin to further reduce vascular risk in patients already receiving a statin, however, has yet to be demonstrated. Despite an increase in HDL levels when niacin was added to background statin therapy, no improvement in cardiovascular outcomes was observed in two large studies.^{42,43}

TABLE 26.3
Nonprescription Therapies for Reducing LDL-C

Product	LDL-C Reduction
Psyllium (10 g/day)	7% ⁴⁸
Sterol/stanol (2.0 g/day)	12% ⁵³
Niacin (up to 2 g/day)	15%–20%
Red yeast rice (2400 mg/day)	20%–30%

Supplements

When none of the dosing options for prescription statins are tolerated (or the patient refuses to consider a prescription statin), nonprescription therapies may be particularly useful. In order of increasing efficacy, the following nonprescription therapies are useful for control of LDL cholesterol: fiber, stanols/sterols, niacin, and red yeast rice ([Table 26.3](#)).

In contrast, herbal or botanical preparations often used for cholesterol management that have been shown to have modest or no benefit include policosanol,⁴⁴ garlic,⁴⁵ and guggulipids.⁴⁶

Fiber

The water-soluble fraction of fiber, soluble fiber, reduces the absorption of cholesterol in the intestinal tract. Therefore additional fiber, either in food or in supplements, can aid in cholesterol management. Each gram of dietary fiber reportedly decreases LDL-C by approximately 2 mg/dL.⁴⁷

Dosage

Supplementation with psyllium, totaling 10 g per day, can reduce LDL-C by 7%.⁴⁸

Stanols/Sterols

Plants do not contain cholesterol but are rich in phytosterols and stanols. Stanols and sterols reduce cholesterol by competing with dietary and biliary cholesterol for intestinal absorption. These agents are capable of reducing LDL-C by up to 12%, when used either as monotherapy or as an adjunct to statin therapy.⁴⁹ There is no significant difference in the LDL-lowering effect of stanols/sterols when administered in supplement form or as enriched foods.⁵⁰

Dosage

Stanols/sterols 2.0 g/day as a single dose.

Precautions

Generally well-tolerated but may cause GI distress.

Niacin

Niacin, a B vitamin, has favorable effects on serum lipids. At higher doses, niacin can reduce LDL cholesterol by 15%–20%, increases LDL particle size to more favorable forms, increases serum HDL, and lowers serum levels of Lp(a). “No flush” or “flush-free” niacin (inositol hexaniacinate) should be avoided because these products do not contain the active form of niacin and, consequently, have no significant lipid-altering properties for most individuals.⁵¹ Care should be taken to avoid niacinamide and nicotinamide, products whose name resembles niacin but have no lipid-altering properties. As previously noted, evidence to date does not support the addition of niacin to statin therapy. The use of niacin as monotherapy in patients unable to tolerate statin therapy remains a therapeutic option.

Dosage

The typical starting dose is 500 mg per day, titrated upward in 500-mg increments every 6–8 weeks as required to a maximal daily dose of 2000 mg per day. Liver function should be checked after each dose adjustment.

Precautions

Although niacin has ideal lipid-altering properties, its use is limited by frequent adverse reactions, which are typically annoying but harmless. The most common adverse reaction to niacin is flushing, which can occur in up to 50% of individuals and is particularly common when initiating therapy or increasing dosage. The best strategy to reduce the risk of flushing involves taking niacin with food, typically dinner, and to use aspirin or nonsteroidal antiinflammatory agents immediately prior to its use. Additional relief from flushing may be possible by taking niacin with applesauce as an after dinner snack. The reason why applesauce may be beneficial in reducing flushing is unknown, but may be attributable to a high concentration of pectin, a soluble fiber known to delay gastric emptying.⁵²

Strategies to Reduce Niacin Flush

- Take niacin with dinner, or after dinner with apple sauce
- Take aspirin or a nonsteroidal antiinflammatory with niacin
- Avoid “no flush” niacin as it is ineffective

Red Yeast Rice

Red yeast rice is the most effective over-the-counter therapy for the treatment of elevated LDL cholesterol and reduces LDL-C levels by 20%–30%.^{53,54} The combination of red yeast rice, fish oil, and therapeutic lifestyle changes has been proven to lower LDL-C by 42%, a reduction comparable to simvastatin 40 mg. This supplement, taken in pill form, is a fermentation product resulting from growing the yeast, *Monascus purpureus*, on rice. Red yeast rice contains a family of cholesterol-lowering molecules known as monacolins, the most prevalent of which is monacolin K (better known by the chemical name lovastatin).

The concentration of monacolins varies widely between different preparations of red yeast rice.⁵⁵ Further, some brands have been shown to contain citrinin, a potentially nephrotoxic fermentation by-product.⁵⁵ Therefore it is recommended that practitioners become familiar with a particular brand of red yeast rice and advise patients to continue taking the same brand to increase the likelihood of a consistent result.

Red yeast rice may be a useful option for patients who are not able to tolerate prescription statins, typically due to myalgias. In a study of patients unable to take prescription statins due to the development of myalgias, 93% of those taking red yeast rice were free of significant muscle symptoms with an average LDL-C reduction of 21%.⁵⁶ A multicenter trial of 116 patients demonstrated a 27% overall reduction in LDL-C (combined results from doses of 1200 and 2400 mg/day). Doubling the dose of red yeast rice from 1200 to 2400 mg/day has been shown to confer an additional 4.6% reduction in LDL-C.⁵⁴

Long-term studies of red yeast rice have also been reported. A Chinese study of 4870 patients who suffered myocardial infarction were followed for nearly 5 years, with a significant reduction in cardiovascular events and a 33% reduction in total mortality compared to placebo observed at the end of the study period.⁵⁷

Dosage

1200 mg twice daily is the typical (and maximal) dose. A lower starting

dose of 600 mg twice daily can be used in patients with a history of statin intolerance.

Precautions

The amount of active ingredient varies between brands. In addition, a few brands have been shown to contain citrinin, a potential nephrotoxin. Obtain baseline liver and renal function tests and repeat labs 2 months after initiating therapy and twice a year thereafter.

Consumerlabs.com has evaluated red yeast rice brands for potency and the presence of citrinin.

Fish Oil

High triglycerides are associated with an increased risk of cardiovascular disease in both men and women but, interestingly, the risk is higher in women.⁵⁹ The mechanisms underlying this increased risk is not well understood, but likely related to an association between high triglycerides and a predominance of small, dense LDL particles.

Beyond lifestyle changes, the most effective pharmacological treatments for elevated triglycerides include fibrates (gemfibrozil and fenofibrates) and fish oil. Fish oil has been shown to reduce triglyceride levels by 50% in patients with baseline levels exceeding 500 mg/dL.

Results from studies evaluating omega-3 for the prevention of cardiovascular disease have been mixed.^{60,61} The lack of an observed benefit of omega-3 in recent meta-analyses may be confounded by the inclusion of studies using low dose therapy, as well as an overall increase in background dietary omega-3 intake.

Currently, the effectiveness of fish oil in preventing cardiovascular disease remains uncertain. A strong recommendation should be made for intake of at least two fish meals per week. Fish oil supplementation is considered a stronger recommendation for patients who do not regularly eat fish.

Dosage

If fish oil is used for the prevention of cardiovascular disease, approximately 1000 mg of combined eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) is recommended. For treatment of elevated triglycerides, doses of 1000 mg to 4000 mg of combined EPA

and DHA are required. This can be achieved with either over-the-counter fish oil or prescription omega-3 products. Particularly with over-the-counter preparations, care should be taken to dose fish oil according to combined EPA and DHA content rather than the amount of “total” fish oil listed on the front of over-the-counter products. For example, if the label lists EPA 300 mg and DHA 200 mg and the serving size is two capsules, then the dose would be four capsules daily to obtain 1000 mg of EPA/DHA.

Vegan preparations of long chain omega-3 fatty acids are available, typically consisting of DHA alone. Vegan omega-3 preparations are usually not highly concentrated and may require multiple pills to achieve the desired total DHA dose.

Precautions

Fish oil may have a mild anticoagulant effect and should be used with caution in patients taking warfarin. Fish oil may cause mild GI upset, which may be relieved by storing fish oil in the freezer prior to use.

Fish Oil Dosing

- Dosage should specify EPA and DHA content (rather than total fish oil).
- Advise patients to check the nutrition label of products to confirm EPA and DHA content.
- The typical dosage for prevention is approximately 1000 mg of combined EPA and DHA.
- The typical dosage for treatment of hypertriglyceridemia is 1000–4000 mg of combined EPA and DHA.

Coenzyme Q10 (CoQ10)

- **Not controversial:** CoQ10 is a mitochondrial membrane bound compound involved in electron transport and energy production. Therapy with statins lowers the level of circulating CoQ10.
- **Controversial:** Supplementing patients who take statins with CoQ10 reduces the risk of statin-related adverse side effects. Despite the logic inherent in correcting deficient levels of CoQ10, most

reported studies to date have not supported treatment with CoQ10 for the prevention of statin-related adverse reactions.^{62,63} Nevertheless, study findings remain inconclusive due to small sample sizes that may be inadequate to demonstrate benefit. The few studies reported benefit have used CoQ10 at doses of 100–200 mg/day.⁶²

Further confounding the potential role of CoQ10 is uncertainty regarding the diagnosis of statin intolerance, with only 36% of patients with a diagnosis of statin intolerance found to have reproducible statin-related side-effects with repeat challenges.⁶³

Evaluation of the effect of CoQ10 deficiency on statin-related myalgias is difficult because blood levels of CoQ10 typically decrease with statin therapy, while tissue levels are not consistently affected.⁶⁴ The majority of circulating CoQ10 is found in LDL, and therefore any intervention that lowers LDL will obligatorily also lower CoQ10.⁶⁴

Therefore, the role of CoQ10 in patients treated with statins remains questionable. What does appear clear is that no significant adverse reactions have been reported with CoQ10 at dosages that far exceed the most common dose range of 100 to 200 mg/day.⁶⁵

Dosage

100–200 mg/day can be considered for treatment of mild myalgias in patients taking statins (although lowering the dose of statin or changing to a different type of statin is likely to be more effective). CoQ10 has no intrinsic lipid-altering properties and has not been reported to reduce the likelihood of developing coronary artery disease.

There is, however, stronger evidence that CoQ10 may be useful as an adjunct in the treatment of systolic heart failure. A prospective, randomized trial of 420 patients conducted over 2 years reported that CoQ10 100 mg three times daily resulted in a significant improvement in total mortality, cardiovascular mortality, and New York Heart Association functional class⁶⁶ (see [Chapter 25](#)).

Vitamin D

Receptors for vitamin D have been identified in heart muscle cells and within arterial walls. Activation of these receptors has many beneficial

functions related to blood pressure regulation and normal arterial function.⁶⁸

Accordingly, vitamin D deficiency has been associated with increased cardiovascular risk. The Framingham Offspring Study evaluated individuals without known cardiovascular disease and found that a vitamin D level less than 15 ng/mL was associated with a 62% increase in cardiovascular risk. The link between vitamin D deficiency and cardiovascular risk was especially prominent in those with hypertension.⁶⁹

Vitamin D deficiency also appears to play a role in statin intolerance. The development of myalgias appears to be more prevalent among vitamin D deficient patients. In one study, the average vitamin D level in those with statin-related myalgias was 21 ng/mL, as compared to those without myalgias with an average level of 30 ng/mL.⁷⁰ This finding was supported by the observation that patients with statin-related myalgias may experience resolution of their symptoms with vitamin D replacement.^{71,72}

Dosage

Although the relationship between vitamin D and cardiovascular disease remains incompletely understood, available data indicate levels above 30 ng/mL are desirable. For patients who are vitamin D deficient, replacement can be achieved with daily dosing of over-the-counter vitamin D₃ (doses of 1000 to 5000 IU per day, depending on severity of baseline deficiency).

Precautions

Excess vitamin D may cause hypercalcemia, and levels should be rechecked to assess adequacy of treatment and reduce toxicity.

Folic Acid

Folic acid, vitamin B₆, and vitamin B₁₂ have been studied in patients with coronary disease because they reduce the circulating level of homocysteine. Elevated homocysteine levels have previously been linked to increased risk of both coronary heart disease and stroke.⁷³

Unexpectedly, randomized trials of folic acid, B₆, and B₁₂ have failed to demonstrate a benefit for secondary prevention despite the

achievement of reduced homocysteine levels (the NORVIT trial, 3749 individuals following myocardial infarction given regimens containing folic acid 800 mcg; and HOPE-2 trial, 5522 patients with vascular disease or diabetes taking folic acid 2500 mcg).^{74,75} Of note, a trend toward harm in the group administered a combination of folic acid, B6, and B12 was observed in the NORVIT trial.

It is unclear why folic acid has failed to reduce the occurrence of cardiovascular events. One explanation is that folic acid is simply a marker, as opposed to a target, of increased risk. An alternative explanation is that folic acid causes harm by unknown mechanisms that offset the benefits of homocysteine reduction.

Although folic acid supplementation has not proven useful, foods rich in folate, particularly dark green leafy vegetables, are strongly associated with cardiovascular benefit. One study reported a 23% reduction in the development of coronary heart disease with each daily serving of green leafy vegetables.⁹ Therefore foods rich in folate should be encouraged.

Folic acid supplementation has not proven useful for the prevention of cardiovascular events. However, foods rich in folate, particularly dark green leafy vegetables, are associated with significant benefit.

Vitamin E

Vitamin E has been postulated to reduce the risk of coronary disease due to its potent antioxidant properties. An early study, the Cambridge Heart Antioxidant Study (CHAOS), showed benefit in reducing nonfatal myocardial infarction with a median follow-up of approximately 1.5 years.⁷⁶ Subsequent studies of longer duration (3.5–8 years) and larger sample sizes (9541–14,641 patients), have failed to confirm a beneficial effect, with no reduction in cardiovascular events with vitamin E.⁷⁷⁻⁷⁹ These trials have used 400–800 IU of alpha tocopherol per day, predominantly from synthetic sources.

Vitamin E exists in eight isomers: four tocopherols and four tocotrienols. One concern in vitamin E studies is that they generally evaluated only the isolated alpha tocopherol fraction of vitamin E. Some experimental data suggest that gamma and delta tocopherol may be more beneficial than the alpha isomer used in clinical trials.^{80,81}

Evidence to date does not support the use of the synthetic alpha tocopherol isomer of vitamin E for the prevention of cardiac disease. Additional research is required to evaluate the effect of mixed tocopherols and tocotrienols on the incidence of cardiovascular events.

Mind/Body

One of the areas where an integrative approach stands to contribute most to the field of cardiology is in appreciation of the role of the mind/body connection in heart health. Although many people are intuitively aware that thoughts and emotions can influence the body, most conventional medical encounters do not include assessment of the patient's emotional state, let alone offer therapies directed at mind-body interventions.

The emotional states most commonly linked to heart disease are stress, anxiety, and depression. Of equal importance is the known association between happiness and heart health.

The link between stress and anxiety with heart disease is strong and far reaching. So much so that anxiety disorders diagnosed early in life, by age 20, independently predict a doubling of heart risk more than 30 years later.⁸²

The mechanism by which stress affects cardiac function is unclear but knowledge is increasing rapidly in this area. Stress clearly leads to an increase in catecholamine levels, which are known to increase blood pressure and heart rate, and therefore increase cardiac work.⁸³ Psychological stress provoked by mental arithmetic produced severely reduced coronary blood flow, identical to that typically observed with strenuous exercise.⁸³ The cortisol response to mental stress has also been linked to plasma levels of cardiac troponin T, a marker of cardiac injury.⁸⁴

A particularly extreme manifestation of stress on heart health is the recently described Takotsubo cardiomyopathy. In this fascinating but potentially lethal condition, psychological stress has been shown to lead to marked increases in circulating catecholamine levels.⁸⁵ The increase in circulating catecholamine triggers acute heart failure typically requiring maximal cardiac support. Antecedent psychological stressors documented to trigger "stress cardiomyopathy" include death of a parent, surprise birthday party, fear of a medical procedure, and public speaking.⁸⁶ Interestingly, cardiac function often completely recovers, following the acute phase of Takotsubo cardiomyopathy.

Perhaps less well recognized is the influence of stress on circulating

serum lipid levels. Both acute and chronic stress have been linked to unfavorable lipid responses. Within hours of acute psychological stress, total cholesterol levels have been shown to increase by 7 mg/dL and LDL cholesterol by 5 mg/dL.⁸⁷ Furthermore, the acute lipid response to stress was observed in individuals diagnosed with hypercholesterolemia 3 years later, suggesting stress may be a contributing cause to chronic dyslipidemia.⁸⁷

Just as emotional factors may contribute to the development of heart disease, they can also be harnessed to promote heart health. Meditation practiced by individuals with coronary disease over 5 years has been demonstrated to reduce the combined risk of a cardiovascular event or death by 48%.⁸⁸ The mechanism of risk reduction by meditation likely includes a decrease in cardiovascular workload, as demonstrated by the ability of meditation to ameliorate the expected increase in heart rate associated with infusion of isoproterenol⁸³ (see [Chapter 100](#)).

A separate study reported that patients assessed as “optimists” had a 55% reduced risk of cardiovascular death, adjusted for traditional risk factors, compared to their less upbeat peers.⁸⁹

A wide range of therapies are available to assist patients with cardiac disease to better manage their stress and anxiety. In addition to more conventional treatments with psychoactive medication or referral for cognitive behavioral therapy, the palette available to the integrative practitioner includes meditation, yoga, biofeedback, healing touch, Reiki, massage, and acupuncture. There is no one resource that is generically superior to another. Instead, referral should be made based on individualized assessments including the patient’s prior knowledge or history with a particular approach, the patient’s philosophical inclination, local expertise, and cost. This “matching” process is truly one of the arts of integrative medicine.

Other Therapies

Enhanced External Counterpulsation (EECP)

Enhanced external counterpulsation is a noninvasive method of improving blood flow to the heart and reducing anginal symptoms. This treatment involves repetitive leg compressions with a pneumatic device

that drives blood backward into the aorta and increases coronary blood flow. A study of 1097 patients with coronary disease reported 73% of patients had improvement in the severity of angina at the completion of treatment, with sustained benefit observed after 2 years.⁹⁰ A separate study examined 363 patients with severe angina and depressed left ventricular function. After treatment, 72% of patients had a reduction in the severity of angina from severe to mild or none with benefit maintained after 2 years.⁹¹

Protocols generally involve 35 one-hour sessions of treatment over 5 weeks. Patients referred for this treatment historically have been those with refractory angina who have exhausted medical therapy and mechanical revascularization options.

Chelation Therapy

Chelation therapy has been proposed as a treatment for atherosclerotic vascular disease. The hypothesized mechanisms of benefit include the binding of calcium to atherosclerotic plaques and reduced oxidative stress leading to improved vascular function. A double-blind, placebo-controlled chelation trial jointly sponsored by the National Institute of Health and National Center for Complementary and Alternative Medicine studied 1708 patients with past history of myocardial infarction. Chelation therapy was found to significantly decrease the primary endpoint by 18% (combined total mortality, cardiovascular events, revascularization, and hospitalization for myocardial infarction).⁹² Diabetics, a prespecified subgroup, had particular benefit with a 39% reduction in the primary end-point. These provocative study results are clearly hypothesis-generating. Additional studies are required to determine the reproducibility of these results and elucidate the underlying mechanisms (see [Chapter 107](#)).

Prevention Prescription

- Nutrition (Mediterranean diet)
- Weight management
- Smoking cessation if needed
- Social connection
- Exercise (aerobics and resistance training)
- Tools for management of stress/anxiety

- Lipid management

Therapeutic Review

Nutrition

Mediterranean-Style Diet

- 5 servings of vegetables/day
- 2 servings of fruit/day
- Whole grains, eliminate refined carbohydrates
- 2 servings of fish/week
- Reduce red meat
- Nuts frequently

Exercise

- 30 min/day walking or a minimum of 30 min 3×/week of more intensive aerobics 
- Resistance training at least 30 min/week 

Smoking Cessation

Lipid Management

For LDL-C

- Fiber supplements: (e.g., Psyllium, 10 g/day) 
- Stanols/sterols: 2.0 g/day 
- Niacin: 500–2000 mg/day 
- Prescription statins: dose varies 
- Red yeast rice: 1200–2400 mg/day divided BID 

For HDL-C

- Exercise 
- Weight loss 
- Reduced intake of carbohydrates 

- Niacin 500–2000 mg/day 

For Triglycerides

- Exercise 
- Weight loss 
- Reduced intake of carbohydrates 
- Fish oil: 1000–4000 mg EPA/DHA per day 
- Fibrates: fenofibrate 45–150 mg/day 

To Reduce Statin Related Myalgias

- Consider CoQ10 100–200 mg/day 
- Replete vitamin D deficiency
- Goal is level > 30 ng/mL 

Stress/Anxiety Reduction

- Breathing exercises 
- Biofeedback 
- Meditation 
- Yoga 
- Acupuncture 
- Cognitive behavioral therapy 
- Anxiolytics 

Antianginal Therapy

- ASA 81–325 mg daily 
- β -Blockers (e.g., metoprolol succinate, usual dose 50–200 mg daily) 
- Nitrates (e.g., isosorbide mononitrate, usual dose 30–120 mg daily) 
- Calcium channel blockers (e.g., amlodipine 2.5–10 mg daily) 

- Angioplasty / stent (A³ for angina)
- EECF (B²)

CHAPTER 27

Dyslipidemia

Mark Houston, MD, MS, MSc

Introduction

The combination of a lipid-lowering diet and scientifically proven nutraceutical supplements significantly reduces total low-density lipoprotein (LDL) cholesterol, triglycerides (TG), and very low density lipoprotein (VLDL); decreases LDL particle number (LDL-P); increases LDL particle size and total and type 2 b high-density lipoprotein (HDL); and improves HDL functionality. In addition, inflammation, oxidative stress, and vascular immune dysfunction are decreased. Prospective clinical trials demonstrated reductions in coronary heart disease (CHD) and cardiovascular disease (CVD) with optimal nutrition and/or administration of nutraceutical supplements, such as omega-3 fatty acids (FAs), red yeast rice (RYR), alpha-linolenic acid (ALA), and niacin. A combined program of nutrition and nutraceutical supplements represents a scientifically valid alternative for patients who prefer nondrug therapies or who are intolerant to statins or other drugs for the treatment of dyslipidemia. This will be the primary focus of this chapter.

This approach to decrease dyslipidemia-induced vascular disease recognizes and treats the various steps that are involved in the development of atherosclerosis and CHD.

Pathophysiology

Dyslipidemia is one of the top five risk factors for CVD, along with hypertension, diabetes mellitus (DM), smoking, and obesity.¹

There are an infinite number of vascular insults, but only three finite responses of the vascular endothelium, vascular smooth muscle (VSM), and cardiac smooth muscle to these insults. These three responses

include inflammation, oxidative stress, and vascular immune dysfunction.²⁻⁴ These pathophysiological processes lead to endothelial dysfunction (ED) and VSM and cardiac dysfunction.

The vascular consequences include CVD, CHD, myocardial infarction (MI), and cerebrovascular accidents (CVAs).⁴

Genetics, epigenetics, chronic inflammatory micro- and macronutrient intake, obesity (visceral obesity), chronic infections, toxins, tobacco products, DM, lack of exercise, and some specific pharmacological agents, including many of the older beta-blockers and thiazide or thiazide-like diuretics, contribute to dyslipidemia.^{5,6}

Several genetic phenotypes, such as apolipoprotein E (APOE), result in variable serum lipid responses to diet, as well as contribute to CHD and MI risk.^{7,8} In addition, HDL proteomics that affect paraoxonase-1 (PON-1) and scavenger receptor B-1 (SR-B1) increase CVD.⁹ The sortilin I allele variants on chromosome 1p13 increase LDL and CHD risk by 29%.¹⁰

Recent studies suggest that increasing dietary cholesterol intake will not significantly alter serum total or LDL cholesterol levels or CHD risk.^{5,6}

Some saturated fats, depending on their carbon chain length, may have minimal influences on serum lipids and CHD risk, whereas mono- and polyunsaturated fats have a favorable influence on serum lipids and CHD risk. Reducing refined carbohydrate intake, such as sugars, bread, white potatoes, white rice, starches, and low-fiber carbohydrates, may be more important in improving serum lipids and lipid subfractions than saturated fats and cholesterol. Refined carbohydrates have more adverse effects on insulin resistance, atherogenic LDL, small LDL, LDL-P, VLDL, TG, total HDL, HDL subfractions, and HDL particle number (HDL-P), thus contributing to CHD risk more than saturated fats.^{5,11-17}

Postprandial hyperglycemia, hypertriglyceridemia, and endotoxemia coupled with inflammation, oxidative stress, and immune vascular dysfunction are highly associated with atherosclerosis.¹⁸⁻²¹ This is metabolic endotoxemia.

The validity of the “Diet–Heart Hypothesis,” implicating dietary saturated fats, cholesterol, and eggs as causative of CHD and MI, has been questioned.¹²⁻¹⁴ Trans-FAs have definite adverse effects on serum lipids and increase CVD, CHD, and MI risk, but omega-3 FAs and monounsaturated fats improve serum lipids and reduce CVD risk.^{5,11-17} Trans fats suppress transforming growth factor beta (TGF-β) responsiveness, which increases the deposition of cholesterol into cellular plasma membranes in vascular tissue.¹⁶

Testing

Expanded lipid testing is the best method to determine risk for CHD and the optimal treatments.

Expanded lipid profiles that measure lipids, lipid subfractions, particle size and number, and APOB and APOA are preferred over standard lipid profiles that measure only the total lipid levels.

These expanded lipid profiles, such as lipoprotein particles (LPP, Spectracell Laboratories, Houston, Texas), nuclear magnetic resonance (NMR, Liposcience, Burlington, North Carolina), Berkeley Heart Labs, Boston Heart Labs, and vertical auto profile (VAP, Atherotech, Birmingham, Alabama), improve serum lipid analysis and CHD risk profiling.^{24,25}

LDL-P is the primary lipid parameter that drives the risk for CHD and MI as well as coronary artery calcification as measured by computed tomography (CT) angiography.^{26,27} Dense LDL type B or LDL type 3 and type 4 have secondary roles in CHD only if the LDL-P is elevated.

Dysfunctional HDL²⁸⁻³¹ may be inflammatory and atherogenic and lose its atheroprotective effects especially in patients with DM, metabolic syndrome, and obesity.³¹

LDL-P drives the risk for CHD and MI. Once the LDL-P is normal, the LDL size is not important as a risk factor ([Fig. 27.1](#)).

Oxidation and inflammation of APOA-1 often result in higher levels of HDL that are dysfunctional and not protective.³¹ The ability to evaluate HDL functionality, either directly or indirectly, measuring reverse cholesterol transport, cholesterol efflux capacity,²⁹ or myeloperoxidase (MPO)³⁰⁻³¹ will improve the assessment and treatment of dyslipidemia-induced vascular disease, CHD, and MI. At this time, only serum MPO is available clinically to measure HDL function.

An understanding of the pathophysiological steps in dyslipidemia-induced vascular damage is mandatory for optimal and logical treatment ([Fig. 27.2](#)). The ability to interrupt all of the various steps in this pathway will allow more specific treatments to reduce vascular injury, improve vascular repair systems, and maintain and restore vascular health.

Native LDL, especially large type A LDL, is not usually atherogenic until modified. However, there exists an alternate pinocytosis mechanism that allows macrophage ingestion of native LDL, which accounts for up to 30% of foam cell formation in the subendothelium during chronic inflammation or infections.³²⁻³³ LDL must be modified from its native form in most clinical circumstances for it to be atherogenic. This modification makes the LDL a foreign substance that is recognized by macrophages, which then mount an immunological and inflammatory response that damages the vascular system.

Decreasing LDL modification, the atherogenic form of LDL cholesterol, by lowering the various forms of LDL modification such as oxidized LDL (oxLDL), glycated LDL (glyLDL), glycooxidized LDL (gly-oxLDL), and acetylated LDL (acLDL), modifying the uptake of modified LDL into macrophages by the scavenger receptors (CD36 SR), and decreasing the inflammatory, oxidative stress, and autoimmune responses will reduce vascular damage beyond treating the LDL cholesterol level.³⁴⁻⁴⁰ There are numerous mechanistic pathways that can be treated to interrupt dyslipidemia-induced vascular damage and disease ([Table 27.1](#)). Reduction in high-sensitivity C-reactive protein (hs-CRP), an inflammatory marker, reduces vascular events independent of reductions in LDL cholesterol through numerous mechanisms.³⁹

Modified LDLs, such as oxidized and glycated LDL, are atherogenic, whereas native LDL is not in most clinical situations. The one exception is that even native LDL may be atherogenic due to pinocytosis by macrophages in the setting of chronic infections or inflammation.

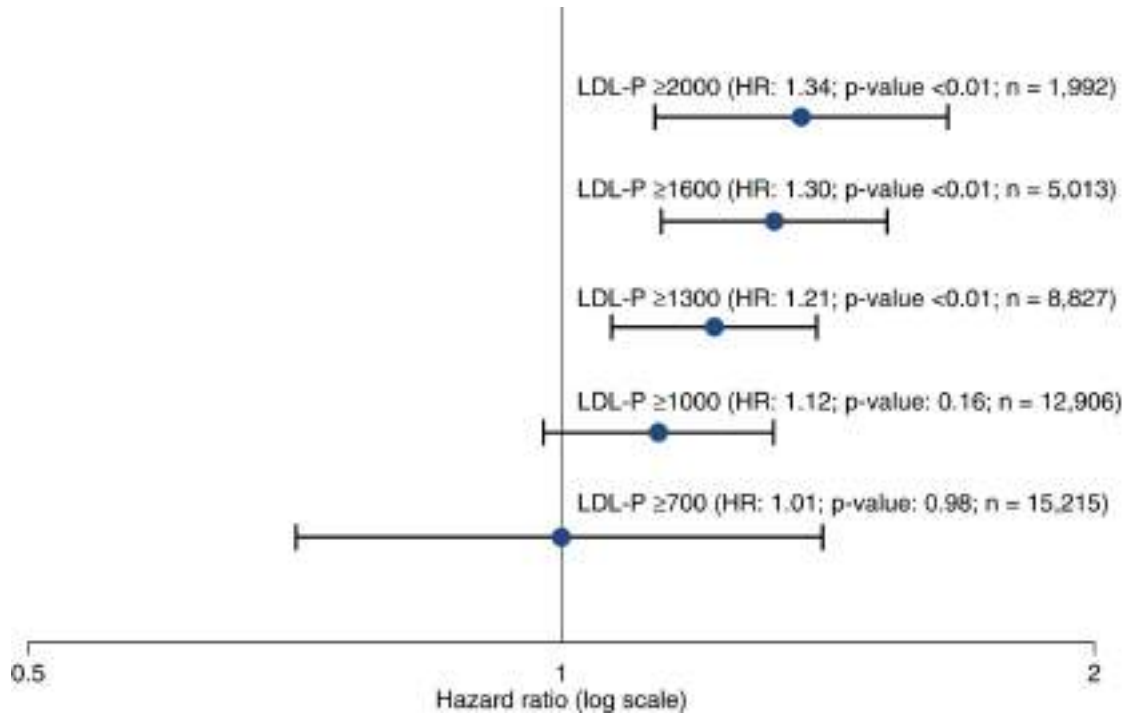

FIG. 27.1 Risk for future CHD events by LDL-P.

Hazard ratios (HRs) for future CHD events across LDL-P thresholds are adjusted for baseline demographics, comorbidities, and LDL-C. Median follow-up was 10.1 months. Sample sizes indicate the number of patients with LDL-P levels at or above the designated thresholds. (Part 1: assessment of CHD incidence by LDL-P). (From Toth PP, Grabner M, Punekar RS, et al. Cardiovascular risk in patients achieving low-density lipoprotein cholesterol and particle targets. *Atherosclerosis* . 2014;235:585-591.)

Mechanism	Treatment/Nutrient
Decrease LDL signaling	Plant sterols
Decrease modified LDL macrophage uptake by scavenger receptors	Resveratrol, N-acetyl cysteine (NAC), aged garlic
Decrease CARM, macrophage recruitment, and migration	NAC, resveratrol, luteolin, glutathione, and curcumin
Alter macrophage phenotype	Omega-3 fatty acid, plant sterols, sterols, and glycosides
Modify signaling pathways	Plant sterols and phytochemicals
Increase reverse cholesterol transport	Lycopene, lutein, plant sterols, glutathione, rosgonin, resveratrol, vitamin flavonoids and anthocyanins, alpha-lipoic acid
Increase total HDL, at all HDL 2 h levels and convert HDL 3 to HDL 2 and 3 h (increase size)	Niacin, omega-3 fatty acids, parolisin, red yeast rice, MUFAs, resveratrol, curcumin, polyphenols, amino acids, citrus bergamot
Improve HDL function. Reduce inflammation, oxidized stress, and immune dysfunction	Quercetin, polyphenols, EGCG, resveratrol, glutathione, lycopene
Increase Apo A-1 lipoprotein	Niacin
Increase PON-1 and PON-2	EGCG, quercetin, polyphenols, resveratrol, glutathione
Decrease VLDL and TG	Niacin, RFE, omega-3 fatty acids, parolisin, citrus bergamot, flavonols, MUFAs, resveratrol, antioxidants
Lower Lp(a)	Niacin, NAC, gamma-oryzanol isochlorogenic, omega-3 fatty acids, flavonols, CoQ10, vitamin C, L-carnitine, L-lysine, L-arginine, almonds
Reduce foam cell and fatty streak formation	Resveratrol, NAC, phytochemicals
HMG-CoA reductase inhibition	RFE, parolisin, gamma-oryzanol isochlorogenic, rosgonin, EGCG, omega-3 fatty acids, citrus bergamot, garlic, curcumin, GLA, plant sterols, lycopene, soy, statins

Integrative Therapy

Many patients cannot or will not use pharmacological treatments, such as statins, fibrates, bile acid resin binders, or ezetimibe, to treat dyslipidemia.⁵ Statin-induced or fibrate-induced muscle disease with myalgias or muscle weakness, abnormal liver function tests, neuropathy, memory loss, mental status changes, gastrointestinal (GI) disturbances, glucose intolerance, and DM are some of the reasons that patients may require the use of nutritional supplements.⁴¹⁻⁴⁵ Many patients who are on prolonged, high-dose statins have other clinical symptoms and/or lab abnormalities such as chronic fatigue, exercise-induced fatigue, decrease in lean muscle mass, reduced exercise tolerance, and reductions in coenzyme Q10, carnitine, vitamin E, vitamin D, omega-3 FAs, selenium, free T3 levels (hypothyroidism), and steroid or sex hormones.^{5,41-53}

Treatment approaches that combine weight loss, reductions in visceral and total body fat, increases in lean muscle mass, optimal aerobic and resistance exercise, use of scientifically proven nutrition, and nutraceutical supplements alone or integrated with drug therapies offer not only improvement in serum lipids but also reductions in inflammation, oxidative stress, immune dysfunction, and ED and VSM dysfunction. In addition, surrogate markers for vascular disease or clinical vascular target organ damage, such as CHD and carotid intimal medial thickness (IMT), were reduced in many clinical trials using a nonpharmacological approach.⁵

Nutrition

Nutrition is an important treatment for dyslipidemia, CHD risk factors, and the prevention and treatment of CVD. Numerous epidemiological studies and prospective clinical trials,⁵⁴⁻⁸¹ including the Framingham Heart Study,^{54,55} Seven Countries Study,^{56,57} Pritikin diet studies,⁵⁸⁻⁶⁰ Ornish Lifestyle Heart Trial,⁶¹⁻⁶⁴ Omni Heart Trial,⁵⁵ Portfolio diet,⁶⁵⁻⁶⁸ Mediterranean diet,⁶⁹⁻⁷³ Lyon Diet Heart Study,⁷² Indian Heart Study,⁷⁴ PREDIMED study,⁷³⁻⁷⁶ and Paleolithic diet, have clearly established the relationship between diet, serum lipids, inflammation, and CVD, including CHD and stroke. The reader is referred to these excellent studies for review as this information will not be included in this chapter.

Although many questions still exist regarding optimal intakes of fats, which types of fats, types and quality of protein, as well as the dietary intakes of complex and refined carbohydrates, most studies clearly indicate that trans-FAs and refined carbohydrates have an adverse effect on serum lipids and cardiovascular outcomes.⁸¹ Some saturated fats may be adverse, others neutral, and some potentially beneficial. The monounsaturated FA (MUFA) and omega-3 FA are consistently beneficial for dyslipidemia and CVD. A vegetarian diet with increased complex carbohydrates and fiber and lower dietary cholesterol is also beneficial. Intake of lean, wild, and organic types of protein and cold-water fish improves lipids and CHD risk factors (see [Chapter 88](#)).

THE MAMMALIAN CELL MEVALONATE CHOLESTEROL PATHWAY AND PP (PYROPHOSPHATE)

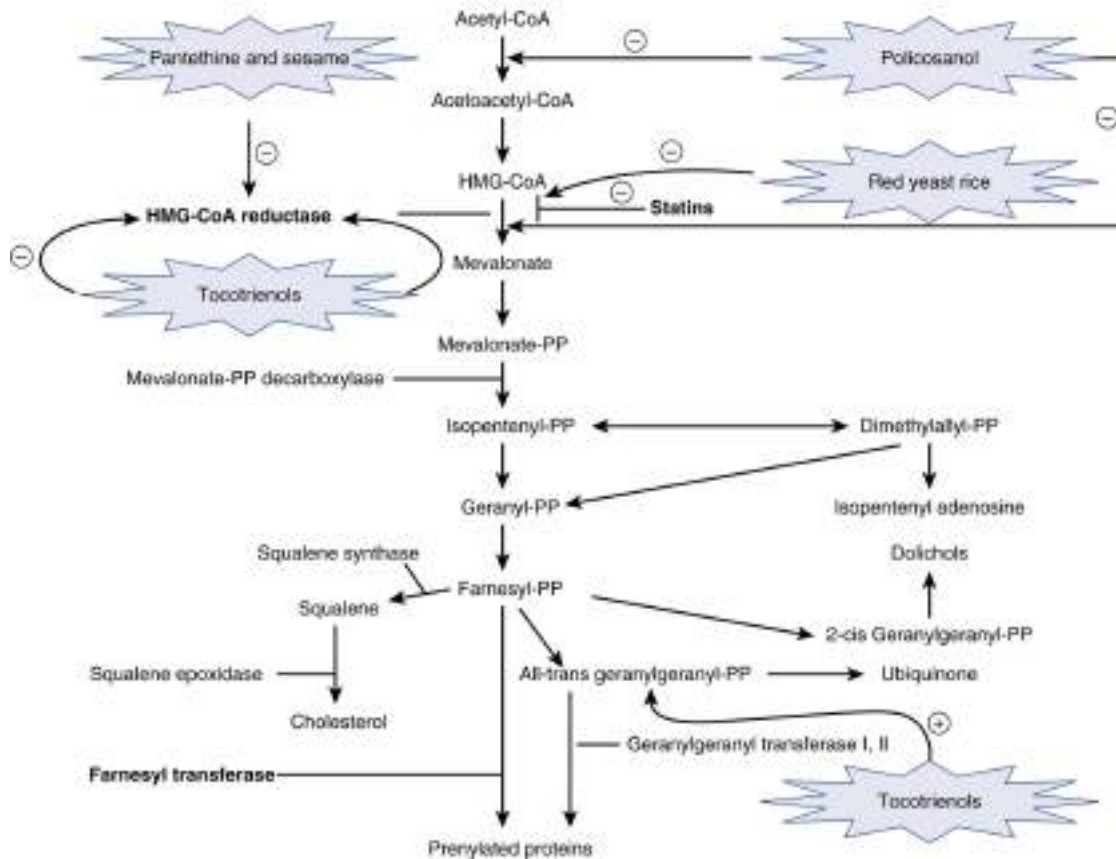

FIG. 27.3 Proposed mechanisms of action of nutraceuticals and statins in the cholesterol pathway.

Nutraceutical Supplements

Nutraceutical supplement management of dyslipidemia has not been frequently reviewed.^{5,6,82} New important scientific information and clinical studies are required to understand the present role of these natural agents in the management of dyslipidemia.^{5,6,82}

Clinical trials showed excellent reductions in serum lipids and CHD with niacin, omega-3 FAs, RYR, fiber, and ALA.

Smaller studies that have used surrogate vascular markers showed improvements in carotid IMT and obstruction, coronary artery plaque progression, coronary artery calcium score by electron beam tomography (EBT) and CT angiography, as well as a decrease in generalized atherosclerosis and improvement in endothelial function.^{5,82-84} The proposed mechanisms of action of some of the nutraceutical supplements

on the mammalian cholesterol pathway are shown in [Fig. 27.3](#).

Niacin (Vitamin B3)

Niacin has a dose-related effect (1–4 g/day) in reducing total cholesterol (TC), LDL, APOB, LDL-P, TG, and VLDL and increasing HDL and LDL size from small type B to large type A, especially the protective and larger HDL 2 b particle and APOA-1.⁵ Niacin also increases the HDL-P (the predominant protective lipid parameter) and HDL function with improvements in reverse cholesterol transport.⁵⁷⁻⁵⁹ Niacin has a logarithmic dose-response on HDL, with smaller doses having a large effect. The effect on LDL reduction is a linear dose-response that requires higher doses.⁸⁵

The changes are dose related, varying from 10% to 30% for each lipid level.^{5,86,87} Niacin inhibits LDL oxidation, increases TG lipolysis in adipose tissue, increases APO-B degradation, and reduces the fractional catabolic rate of HDL APO A-1. Niacin inhibits platelet function, induces fibrinolysis, decreases cytokines and cell adhesion molecules (CAMs), lowers Lp(a), increases adiponectin, inhibits cholesterylester transfer protein (CETP), and increases reverse cholesterol transport.^{5,85-87} However, despite an improved lipid profile, there is variable improvement in endothelial and microvascular function.⁹⁰

Randomized clinical trials such as the Coronary Drug Project, HATS trial, ARBITER 2, Oxford Niaspan Study, FATS, CLAS I and CLAS II, and AFRS have shown reductions in coronary events, decreases in coronary atheroma (plaque), and decreases in carotid IMT.^{5,86,87,90-94} The recent negative findings in the AIM-HIGH study^{95,96} do not detract from these positive clinical trials, as this study has numerous methodological design flaws and was not powered to statistically determine CVD endpoints. The recent HPS-THRIVE trial of 26,000 patients using 2 grams of extended-release niacin plus the antiflushing agent laropiprant daily or placebo on top of a background therapy of simvastatin with or without ezetimibe did not reduce cardiovascular events despite a 17% increased HDL and 20% decreased LDL.^{97,98} Whether the inhibition of flushing by laropiprant or some other unknown effect of this agent interfered with the HDL function and the cardiovascular (CV) outcomes is not clear. However, the recommendation not to use niacin in the face of the other many positive studies is clearly premature.

Dosage

The effective dosing range is from 500–4000 mg/day. It should be titrated slowly starting at 100 mg/day and increased each week by 100–200 mg/day. Sustained-release niacin is preferred. Only vitamin B3 niacin is effective in dyslipidemia.

The nonflushing niacin (inositol hexanicotinate; IHN) does not improve lipid profiles and is not recommended.^{5,99}

Precautions

The side effects of niacin include hyperglycemia, hyperuricemia, gout, hepatitis, flushing, rash, pruritus, hyperpigmentation, hyperhomocysteinemia, gastritis, ulcers, bruising, tachycardia, and palpitations.^{5,86,87} Elevations in homocysteine should be treated with vitamin B6, B12, and folate. Niacin-induced flushing is minimized by increasing the dose gradually, taking it on a regular basis without interruption, consumption with meals, avoiding alcohol within 4 hours of ingestion of niacin, consumption of 81-mg baby aspirin, and supplemental quercetin (500 mg), and apples, apple pectin, or applesauce.

Red Yeast Rice

RZR (*Monascus purpureus*) is a fermented product of rice that contains monacolins, which inhibit cholesterol synthesis via 5-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase and thus has “statin-like” properties (13 natural statins).^{5,82,102-124} RZR also contains ergosterol, amino acids, flavonoids, trace elements, alkaloids, sterols, isoflavones, and monounsaturated FAs that improve the lipid profile.

RZR administered orally to adult subjects with dyslipidemia at 2400 mg/day reduced LDL-C by 22% ($p < 0.001$) and TG by 12% with little change in HDL.^{5,82,102} RZR reduces the risk of abdominal aortic aneurysms (AAA) by suppressing angiotensin II levels.¹⁰³ RZR also is effective in mouse models against obesity-related inflammation, insulin resistance, and nonalcoholic fatty liver disease (NAFLD).¹⁰⁴ RZR in conjunction with berberine improves insulin resistance, glucose, and lipids in subjects with or without metabolic syndrome.^{114,117,123} RZR, policosanol, and artichoke leaf extract decrease and RZR with plant stanols reduce LDL-C significantly.^{105,111,112} RZR with berberine,

policosanol, astaxanthin, coenzyme Q10, and folic acid reduced LDL cholesterol (LDL-C) by 21.1%, similar to pravastatin 10 mg/day, with a simultaneous 4.8% increase in HDL cholesterol (HDL-C) over 8 weeks.¹²⁰

RYR inhibits tumor necrosis factor (TNF)-alpha and metalloproteinase (MMP)-2 and MMP-9,¹⁰⁷ suppresses caveolin-1, increases endothelial nitric oxide synthase (eNOS) expression, improves abnormal hemorheology,¹⁰⁶ increases adiponectin,¹¹³ improves the leptin-to-adiponectin ratio,¹²⁰ lowers hs-CRP, improves vascular remodeling parameters such as MMP-2 and MMP-9,¹¹⁵ reduces expression of tissue factor oxLDL, and reduces thrombosis in animal models by suppressing nicotinamide adenine dinucleotide phosphate oxidase and extracellular signal-regulated kinase activation.¹¹⁸ In a recent placebo-controlled Chinese study of 5000 subjects over 4.5 years, an extract of RYR reduced LDL by 17.6% ($p < 0.001$) and increased HDL by 4.2% ($p < 0.001$).¹²⁴ CV mortality fell 30% ($p < 0.005$) and total mortality fell 33% ($p < 0.0003$) in the treated subjects. The overall primary endpoint of MI and death was reduced by 45% ($p < 0.001$). A recent meta-analysis and clinical trials of RYR for dyslipidemia and CVD endpoints confirmed these positive findings.^{109,110,121,122}

Dosage

The recommended dose is 800–4800 mg/day of a standardized RYR.

Precautions

A highly purified and certified RYR must be used to avoid potential renal damage induced by a mycotoxin, citrinin.^{5,82,102} No adverse effects have been reported such as myalgias or liver dysfunction with long-term use nor is there any interference with the cytochrome (CY)P450 enzymes.¹¹⁸ Although reductions in coenzyme Q10 may occur in predisposed patients and those on prolonged high-dose RYR, because of its weaker “statin-like” effect, this is not as likely as with statins. RYR is an excellent alternative for patients with statin-induced myopathy^{5,82,102,116,124} and for statin-intolerant patients with or without type 2 DM in conjunction with the Mediterranean diet to effectively manage their dyslipidemia.¹¹⁹

Plant Sterols (Phytosterols)

The plant sterols are naturally occurring sterols of plant origin that include B-sitosterol (the most abundant), campesterol and stigmasterol (4-desmethyl sterols of the cholestane series), and the saturated stanols.^{5,82,125-129} The plant sterols are much better absorbed than the plant stanols. The daily intake of plant sterols in the United States is about 150–400 mg/day mostly from soybean oil, various nuts, and tall pine tree oil.⁸² These have a dose-dependent reduction on serum lipids.¹²⁶ TC is decreased 8%, and LDL is decreased 10% (range, 6%–15%) with no change in TG or HDL on doses of 2–3 g/day in divided doses with meals.^{5,82,125-129} A recent meta-analysis of 84 trials showed that an average intake of 2.15 g/day reduced LDL by 8.8% with no improvement in serum lipids at higher doses.¹²⁶

The mechanism of action is primarily to decrease the incorporation of dietary and biliary cholesterol into micelles due to the lower micellar solubility of cholesterol, which reduces cholesterol absorption and increases bile acid secretion. In addition, there is an interaction with enterocyte adenosine triphosphate (ATP)–binding cassette transport proteins (ABCG8 and ABCG5) that directs cholesterol back into the intestinal lumen.^{5,82,125} The only difference between cholesterol and sitosterol consists of an additional ethyl group at position C-24 in sitosterol, which is responsible for its poor absorption. The plant sterols have a higher affinity than cholesterol for the micelles. The plant sterols are also antiinflammatory and decrease the levels of proinflammatory cytokines such as hs-CRP, interleukin (IL)-6, IL-1b, TNF-alpha, phospholipase (PLA) 2, and fibrinogen, but these effects vary among the various phytosterols.^{129,130}

Some studies have shown a reduction in atherosclerosis progression and reductions in the progression of carotid IMT and carotid plaque, but the results have been conflicting.^{5,82} Patients that have the rare homozygous mutations of the ATP-binding cassette are hyperabsorbers of sitosterol (absorb 15%–60% instead of the normal 5%) and will develop premature atherosclerosis.⁸² This is a rare autosomal recessive disorder termed *sitosterolemia*. There are no studies on CHD or other CVD outcomes to date with phytosterols.

Dosage

The recommended dose is 2–2.5 g/day (average, 2.15 g/day).

Precautions

The plant sterols can interfere with absorption of lipid-soluble compounds such as fat-soluble vitamins and carotenoids like vitamins D, E, and K and alpha-carotene.^{5,82}

Soy

Numerous studies have shown mild improvements in serum lipids with soy at doses of 30–50 g/day.^{5,82,131,132} TC falls 2%–9.3%, LDL decreases 4%–12.9%, TG decreases 10.5%, and HDL increases up to 2.4%. However, the studies are conflicting due to differences in the type and dose of soy used in the studies, as well as nonstandardized methodology.^{5,82,131,132} Soy decreases the micellar content and absorption of lipids through a combination of fiber, isoflavones (genistin, glycitin, diadzin), and phytoestrogens.^{5,82,131,132} Soy also reduces sterol regulatory element-binding protein (SREBP) and HMG-CoA reductase, increases LDL receptor density, and increases the antioxidant activity of superoxide dismutase (SOD) and catalase.¹³³ The greatest reduction is seen with soy-enriched isoflavones with soy protein.

Dosage

The dose is 30–50 g/day.

Precautions

None.

Green Tea Extract and Green Tea (EGCG)

Catechins, especially EGCG, may improve the lipid profile by interfering with micellar solubilization of cholesterol in the GI tract and reducing absorption.⁵ In addition, EGCG reduces FA gene expression, inhibits HMG-CoA reductase, increases mitochondrial energy expenditure, reduces oxLDL, increases PON-1, upregulates the LDL receptor, decreases APO-B lipoprotein secretion from cells, mimics the action of insulin, improves ED, activates nuclear erythroid 2-related factor 2 (Nrf2), increases heme oxygenase-1 (HO-1) expression, decreases inflammation, displaces caveolin-1 from cell membranes, increases nitric oxide, reduces endothelial inflammation, and decreases body fat.^{5,134-137}

A meta-analysis of 14 trials shows that EGCG at 224–674 mg/day or 60 oz of green tea a day reduced TC by 7.2 mg/dL and LDL by 2.19 mg/dL ($p < 0.001$). There was no significant change in HDL or TG level.¹³⁸

Dosage

The recommended dose is a standardized EGCG extract at 1000 mg/day or 60 oz brewed green tea a day.

Precautions

Caution regarding the stimulatory effects of caffeine if tea is consumed.

Omega-3 Fatty Acids

Observational, epidemiological, and controlled clinical trials have shown significant reductions in serum TG, VLDL, decreased LDL-P, increased LDL and HDL particle size, as well as major reductions in all CVD events.^{5,139-146} The DART trial demonstrated a decrease in mortality of 29% in men post-MI, and the GISSI prevention trial found a decrease in total mortality of 20%, in CV deaths of 30%, and in sudden death of 45%. The Kuopio Heart Study demonstrated a 44% reduction in fatal and nonfatal CHD in subjects in the highest quintile of omega-3 intake compared to the lowest quintile.^{5,139,140} Omega-3 FA reduced CHD progression, stabilized plaque, and reduced coronary artery stent restenosis and coronary artery bypass grafting (CABG) occlusion.^{5,141} In the JELIS study, the addition of 1.8 grams of omega eicosapentaenoic acid (EPA) to a statin resulted in an additional 19% relative risk reduction (RRR) in major coronary events and nonfatal MI and a 20% decrease in CVA.^{5,142}

There is a dose-related reduction in VLDL of up to 50% and in TG of up to 50% with little to no change or decrease in TC, LDL, or APO-B and no change to a slight increase in HDL.^{5,143-146} However, the number of LDL particles decreases and LDL particle size increases from small type B to large type A (increase of 0.25 nm). The antiatherogenic HDL 2 b also increases by up to 29%. The rate of entry of VLDL particles into the circulation is decreased and APOCIII is reduced, which allows lipoprotein lipase to be more active.²⁷ There is a decrease in remnant chylomicrons and remnant lipoproteins.^{5,144} Patients with LDL more than 100 mg/dL have reductions in total LDL, and those that are below 80

mg/dL have mild increases.¹⁴⁵ However, in both cases, the LDL-P decreases, the dense LDL-B increases in size to the less atherogenic LDL-A particle, and APO-B levels decrease. There is a net decrease in the concentration of cholesterol carried by all atherogenic particles and decreases in nonHDL cholesterol. Omega-3 FA are antiinflammatory, antithrombotic, lower blood pressure (BP) and heart rate, improve heart rate variability,^{5,139} decrease FA synthesis, increase FA oxidation, and reduce body fat and weight.⁵ Omega-3 FAs are one of the only substances that lower lipoprotein-associated phospholipase A2 (Lp-LPA2).²⁷ Insulin resistance is improved without any significant changes in fasting glucose or hemoglobin A1c with long-term treatment.¹⁴⁷ Doses of 3 g/day of combined EPA and docosahexaenoic acid (DHA) at a 3:2 ratio with gamma linoleic acid (GLA) at 50% of the total EPA and DHA content and 700 mg of gamma/delta tocopherol at 80% and 20% alpha tocopherol per 3 grams of DHA and EPA are recommended.⁵ DHA and EPA may have variable but favorable effects on the various lipid levels.^{5,143,144,147} EPA does not usually increase LDL, is less effective in lowering TG than DHA, and does not alter the LDL or HDL particle size.

Although DHA may increase total LDL, it increases LDL and HDL size and lowers TG more.¹⁴⁶ New free FA forms of omega-3 FAs have a fourfold greater area under the plasma n-3 polyunsaturated FA (PUFA) curve than prescription Lovaza and thus a more potent reduction in TG levels.¹⁴⁷ The data on krill oil and dyslipidemia are limited to only two studies in humans.^{148,149} The first study¹⁴⁸ showed a dose-related response of LDL-C reduction of up to 39%, TG reduction of 27%, and HDL elevation of 60%.¹⁴⁸ Another study¹⁴⁹ showed minimal reductions in TG of 10%, but the decrease was not sustained during long-term treatment. These findings with krill oil are very disparate, and the studies are not confirmatory. Krill oil is not recommended at this time for the treatment of dyslipidemia.

Dosage

The dose is 1000–4000 mg/day with a 3:2 ratio of EPA to DHA.

Precautions

High doses for prolonged periods can have a prooxidant effect.

The combination of plant sterols and omega-3 FAs is synergistic in improving lipids and inflammation.⁹⁸

Flax

Flax seeds and flax lignan complex with secoisolariciresinol diglucoside (SDG) and increased intake of ALA from other sources such as walnuts have been shown in several meta-analyses to reduce TC and LDL by 5%–15%, Lp(a) by 14%, and TG by up to 36% with either no change or a slight reduction in HDL.^{5,150-152} These properties do not apply to flaxseed oil. In the Seven Countries Study, CHD was reduced with increased consumption of ALA. In the Lyon diet trial at the end of 4 years, intake of flax reduced CHD and total deaths by 50%–70%.⁵ Flax seeds contain fiber, lignins, and phytoestrogens, which decrease the levels of 7 alpha-hydroxylase and acyl-CoA cholesterol transferase.^{5,150-152} Flax seeds and ALA are antiinflammatory, reduce hs-CRP, decrease TG, increase HDL, decrease insulin resistance and the risk of type 2 DM, reduce visceral obesity and systolic BP, increase eNOS, and improve ED. Flax decreases VSM hypertrophy, reduces oxidative stress, and increases cholesterol efflux in macrophage-derived foam cells by decreasing stearyl-CoA desaturase-1 expressions and farnesoid X receptor's mechanisms of action, which retard the development of atherosclerosis.^{5,150-154}

Dosage

The dose of flaxseed is 14–40 g/day.^{5,150-154} Chia seeds (*Salvia hispanica*) are the richest botanical source of ALA at 60% weight/volume.¹⁵³ The dose of chia seeds is 25 g/day.

Precautions

None.

Monounsaturated Fatty Acid

MUFAs, such as olives, olive oil, and nuts, reduce LDL by 5%–10%, lower TG by 10%–15%, increase HDL by 5%, decrease oxLDL, reduce oxidation and inflammation, improve ED, lower BP, decrease thrombosis, and reduce the incidence of CHD (Mediterranean diet).^{5,155-159} MUFA reduce CD40L gene expression and its downstream products

(IL23A, adrenergic B-2 receptor, oxLDL receptor 1, IL-8 receptor) and related genes involved in atherogenic and inflammatory processes in vivo in humans.¹⁵⁹ MUFA are one of the most potent agents to reduce oxLDL in humans.

Dosage

The equivalent of 3–4 tablespoons (50 grams) a day of extra-virgin olive oil (EVOO) in MUFA content is recommended for the maximum effect in conjunction with omega-3 FAs.

Precautions

None. The caloric intake of this amount of MUFA did not result in any weight gain in the PREDIMED study and resulted in a significant reduction in CVD.⁷³

Sesame

Sesame at 40 g / day reduces LDL by 9% through inhibiting intestinal absorption, increasing biliary secretion, decreasing HMG-CoA reductase activity, and upregulating LDL receptor gene expression, 7 alpha-hydroxylase gene expression, and SREBP 2 gene expression.^{161,162}

Dosage

A randomized placebo-controlled crossover study of 26 postmenopausal women who consumed 50 grams of sesame powder daily for 5 weeks had a 5% decrease in TC and a 10% decrease in LDL-C.¹⁶¹

Precautions

None.

Tocotrienols

Tocotrienols are a family of unsaturated forms of vitamin E termed *alpha*, *beta*, *gamma*, and *delta*.⁵ The gamma and delta tocotrienols lower TC by up to 17%, LDL by 24%, APO-B by 15%, and Lp(a) by 17% with minimal

changes in HDL and APO A-1 in 50% of subjects at doses of 200 mg/day given at night with food.^{5,163-165} The gamma/delta form of tocotrienols are antioxidants and also inhibit cholesterol synthesis by suppression of HMG-CoA reductase activity by two posttranscriptional actions.^{5,163-165} These include increased controlled degradation of the reductase protein and decreased efficiency of translation of HMG-CoA reductase mRNA. These effects are mediated by sterol binding of the reductase enzyme to the endoplasmic reticulum membrane proteins called INSIGs.¹⁶⁴ The tocotrienols have natural farnesylated analogs of tocopherols, which give them their effects on HMG-CoA reductase.¹⁶⁴ In addition, the LDL receptor is augmented. Increased intake of alpha-tocopherol (>20% of total tocopherols) may interfere with the lipid-lowering effect.^{5,163} Tocotrienols are metabolized by successive beta oxidation then catalyzed by the CYP450 enzymes 3A4 and CYP4F2.

The combination of a statin with gamma/delta tocotrienols further reduces LDL cholesterol by 10%.¹⁶³ The tocotrienols block the upregulation of HMG-CoA reductase secondary to competitive inhibition by the statins.^{5,163} Carotid artery stenosis regression has been reported in about 30% of subjects given tocotrienols over 18 months. They also slow progression of generalized atherosclerosis.^{5,165}

Dosage

The recommended dose is 200 mg of gamma and delta tocotrienol at night with food.

Precautions

The tocotrienol dose is very important, as increased dosing will induce its own metabolism and reduce effectiveness, whereas lower doses are not as effective.⁵ Also, concomitant intake (less than 12 hours) of alpha-tocopherol reduces tocotrienol absorption.

Pantethine

Pantethine is the disulfide derivative of pantothenic acid and is metabolized to cystamine-SH, which is the active form in treating dyslipidemia.^{5,166-170} More than 28 clinical trials have shown consistent and significant improvement in serum lipids. TC was decreased by 15%, LDL by 20%, APO-B by 27.6%, and TG by 36.5% over 4–9 months. HDL

and APO A-1 was increased by 8%.^{5,166-171}

The effects on lipids are slow, with peak effects at 4 months, but may take up to 6–9 months.^{5,166-171} In addition, pantethine reduces lipid peroxidation of LDL and decreases lipid deposition, intimal thickening, and fatty streak formation in the aorta and coronary arteries.^{5,166-171}

Pantethine inhibits cholesterol synthesis and accelerates FA metabolism in the mitochondria by inhibiting hepatic acetyl-CoA carboxylase, increases CoA in the cytoplasm, which stimulates the oxidation of acetate at the expense of FA and cholesterol synthesis, and increases Krebs cycle activity.^{5,166-171} In addition, cholesterol esterase activity increases and HMG-CoA reductase activity decreases.^{5,166-171} There is 50% inhibition of FA synthesis and 80% inhibition of cholesterol synthesis.⁵ The lipid effects are additive to statins, niacin, and fibrates.

Dosage

The recommended effective dose is 300 mg thrice a day or 450 mg twice a day with or without food.^{5,166-171}

Precautions

None.

Garlic

Numerous placebo-controlled clinical trials and a meta-analysis in humans show reductions in TC of 17 mg/dL and reductions in LDL of about 9 mg/dL at doses of 600–900 mg/day over 2 months with a standardized extract of allicin and ajoene.^{5,175-182} Many studies have been poorly controlled and used variable types and doses of garlic, which have given inconsistent results.^{5,175,176} Aged garlic (AGE) has shown the best results related to improvement in serum lipids as well as lowering BP, improving endothelial function and arterial elasticity, decreasing coronary artery calcium and plaque progression, and lowering hs-CRP.^{5,84,175-182} Eating whole crushed garlic may also be effective, but the most recent studies have used an AGE, which maintains potency and reduces odor. Garlic reduces intestinal cholesterol absorption, inhibits enzymes involved in cholesterol synthesis, and deactivates HMG-CoA reductase.^{5,175} In addition, AGE reduces VSM proliferation and transformation, decreases oxidative stress and inflammation, decreases

oxLDL, prevents entry of lipids into the arterial wall and macrophages, increases eNOS and NO, increases glutathione, glutathione reductase, and superoxide dismutase, has fibrinolytic activity, and has antiplatelet activity.^{5,84,175} AGE has been used in these studies alone or in conjunction with B vitamins, folate, arginine, and statins.¹⁷⁶⁻¹⁷⁹

Dosage

The preferred dose of aged garlic (AGE; Kyloic acid) is 600 mg twice a day.

Precautions

Common side effects include bad breath, body odor, and GI distress. Garlic can inhibit platelet function and should be used with caution in those on anticoagulant medications.

Resveratrol

Resveratrol reduces oxLDL; inhibits acyl-coA cholesterol acyltransferase (ACAT) activity and cholesterol ester formation; increases bile acid excretion; reduces TC, TG, and LDL; increases PON-1 activity and HDL; inhibits NADPH oxidase in macrophages; and blocks the uptake of modified LDL by CD36, a scavenger receptor (SR).^{183,184} N-acetyl cysteine (NAC) has this same effect on CD36 DR and should be used in conjunction with resveratrol.¹⁸³

Dosage

The dose of trans-resveratrol is 250 mg/day and that of NAC is 1000 mg twice a day.

Precautions

None.

Curcumin

Curcumin, a phenolic compound in turmeric and curry,^{5,185} induces changes in the expression of genes involved in cholesterol synthesis such

as the LDL receptor mRNA, HMG-CoA reductase, SREBP, cholesterol 7 alpha-hydroxylase, peroxisome proliferator-activated receptor (PPAR), liver X receptor (LXR), and affects the expression of genes involved in leukocyte adhesion and transendothelial migration to inhibit atherosclerosis.^{5,185-188} In one human study of 10 patients consuming 500 mg/day of curcumin, HDL increased by 29% and TC fell by 12%.^{5,185} A recent meta-analysis of five studies of 133 subjects did not indicate a significant effect of curcumin on any of the lipid parameters.¹⁸⁸ Larger randomized clinical trials are needed to determine the lipid-lowering effects and potential reduction in CV effects with curcumin.

Dosage

The dose is 500–1000 mg twice a day.

Precautions

High doses can cause GI upset.

Berberine HCl

Berberine HCl is an alkaloid present in roots, rhizomes, and stem barks of selected plants.¹⁸⁹⁻¹⁹¹ In a study of 32 dyslipidemic patients, 500 mg/day of berberine HCl decreased TC by 29%, LDL-C by 25%, and TG by 35% in 3 months.¹⁹⁰ Berberine increases hepatic LDL-R and suppresses PCSK9 expression that increases hepatic LDL excretion and is additive to statins in its lipid-lowering effect.^{189,190} Berberine has additive LDL-lowering effects with statins¹⁸⁹ and ezetimibe.¹⁹¹ A meta-analysis of berberine that included 11 randomized trials of 874 subjects showed significant reductions in TC, LDL, and TG and an increase in HDL without any serious adverse effects.¹⁹²

Dosage

The recommended dose is 500 mg qd to bid.

Precautions

Can cause kernicterus in newborns. Nursing mothers should avoid it. Berberine is more effective and has fewer adverse effects compared

with ezetimibe monotherapy.¹⁹¹

Pomegranate

Pomegranate increases PON-1 binding to HDL and levels of PON-2 in macrophages. It is a potent antioxidant that increases total antioxidant status (TAS), lowers oxLDL, decreases antibodies to oxLDL, inhibits platelet function, reduces glycosylated LDL, decreases macrophage LDL uptake, and reduces lipid deposition on the arterial wall.¹⁹³⁻¹⁹⁸

These changes impede the progression of carotid artery IMT and lower BP especially in subjects with the highest oxidative stress, known carotid artery plaque, and the greatest abnormalities in TG and HDL levels.¹⁹³⁻¹⁹⁸

Dosage

The recommended dose is 8 oz of pomegranate juice or 1–2 cups of pomegranate seeds a day.

Citrus Bergamot

Citrus bergamot has been evaluated in several clinical prospective trials in humans. At doses of 1000 mg/day, this compound lowers LDL by up to 36%, TG by 39%, and increases HDL by 40%.¹⁹⁹⁻²⁰³ Citrus bergamot inhibits HMG-CoA reductase, increases cholesterol and bile acid excretion, binds to the ACAT receptor, and lowers oxLDL.¹⁹⁹⁻²⁰³ Favorable effects on glycemic parameters include reductions in glucose via AMPK and the GLUT4 receptor, reduction in reactive oxygen species (ROS), and weight loss. The active ingredients include naringin, neoeriocitrin, neohesperidin, poncerin, rutin, neodesmin, rhoifolin, melitidine, brutelidine, and vitamin C.¹⁹⁹⁻²⁰⁵

Dosage

The dose is 1000 mg daily.

Lycopene

Lycopene is an acyclic carotenoid with a high concentration in tomatoes and other rose-colored vegetables and fruit. It has been shown in tissue

culture to inhibit HMG-CoA reductase; induce Rho inactivation; increase PPAR gamma, LXR receptor, and RXR activities; increase reverse cholesterol transport and efflux with ABCA1, APO A-1 expression, and caveolin-1 expression; increase HDL 2 and 3; improve HDL functionality; reduce serum amyloid A; decrease CETP; increase PON-1; and reduce inflammation in humans.²⁰⁶⁻²⁰⁸ This reduces intracellular cholesterol and lowers cholesterol in lipid domains, which alter membrane-induced cellular signal transduction. The two unconjugated double bonds in the lycopene molecule have high activity against ROS. Higher serum lycopene levels are associated with reductions in carotid IMT and carotid atherosclerosis.²⁰⁹

Dosage

The doses are lycopene 20 mg/day and astaxanthin 15 mg/day.

Probiotics

Mixed high-dose probiotics at 60–100 billion organisms a day reduce TC by 9%, LDL-C by 8%, and TG by 10%.²¹¹⁻²¹⁴ Probiotics precipitate bile salts and deconjugate bile salts with bile salt hydrolase (BHL). They are also incorporated into cell membranes as well as being assimilated into cholesterol itself.

Combinations

A prospective open-label human clinical trial of 30 patients for 2 months showed significant improvement in serum lipids using a proprietary product with a combination of pantethine, plant sterols, EGCG, gamma/delta tocotrienols, and phytolens.²¹⁵ TC fell 14%, LDL decreased 14%, VLDL dropped 20%, and small dense LDL particles fell 25% (types III and IV).²¹⁵ In another study using the same proprietary product with RYR 2400 mg/day and niacin 500 mg/day, TC fell 34%, LDL decreased by 34%, LDL-P fell 35%, VLDL dropped 27%, and HDL increased 10% (verbal communication, unpublished data).²¹⁶

Studies indicate an RRR of CVD mortality with omega-3 FAs of 0.68, with resins of 0.70, and with statins of 0.78.²¹⁷ Combining statins with omega-3 FAs (EFA) decreases CHD 19% more.¹⁴² The combination of gamma/delta tocotrienols and a statin reduces LDL cholesterol an additional 10%.¹⁶³ Plant sterols with omega-3 FAs have synergistic lipid-

lowering and antiinflammatory effects.¹⁴⁶ A combination of RYR, bitter gourd, chlorella, soy protein, and licorice resulted in significant reductions in TC, TG, and LDL as well as BP in 228 subjects in a controlled clinical trial.²¹⁸ AGE alone or in combination with B vitamins, folate, arginine, coenzyme Q10, or statins improves lipids and other markers of endothelial function, vascular elasticity, NO, inflammation, hs-CRP, coronary artery calcium, and plaque regression.^{5,84,175-179} Future studies are needed to evaluate various other combinations on serum lipids, surrogate vascular endpoints, and CHD and CVD morbidity and mortality.

Prevention Prescription

- Nutrition: encourage a traditional Mediterranean diet
- Exercise: 60 min/day for at least 4 days/week with 40 minutes of resistance training and 20 minutes of interval aerobic training
- Maintain an ideal weight

Therapeutic Review

This approach to lipid management to decrease vascular disease utilizes a more functional and metabolic medicine approach with a broader treatment program that addresses the multitude of steps involved in dyslipidemia-induced vascular damage (see [Table 27.1](#)). This is a valid alternative for patients who are statin-intolerant, cannot take other drugs for the treatment of dyslipidemia, or in those who prefer alternative treatments.

Testing

- Evaluate global CV risk with a risk scoring system (see [Key Web Resources](#) for a risk calculator)
- Use advanced lipid testing that evaluates LDL-P, LDL particle size, HDL-P, MPO, SAA, and hs-CRP ([Table 27.2](#)).
 - LDL-P drives CHD risk
 - Reverse cholesterol transport (RCT) and cholesterol efflux capacity (CEC) and HDL-P drive reductions in CHD risk
 - HDL is often dysfunctional with inflammation and oxidative stress

- HDL levels more than 85 mg/dL are often dysfunctional
- Measuring MPO and hs-CRP help define dysfunctional HDL

Lifestyle

- Identify underlying causes of dyslipidemia; remove and treat them

Nutrition

- Encourage a Mediterranean-style diet 

Exercise

- 60 min/day for at least 4 days/week with 40 minutes of resistance training and 20 minutes of interval aerobic training 

Nutritional Supplements

Start with RYR, plant sterols, berberine, and omega-3 FAs. Others are added as needed based on specific needs for lipids as discussed.

- RYR 2400–4800 mg at night with food 
- Plant sterols 2.5 g/day 
- Berberine 500 mg/day to twice a day 
- Omega-3 FAs with EPA/DHA at a 3:2 ratio 4 grams/day with GLA at 50% of the total EPA and GLA and gamma/delta tocopherol 
- Niacin (nicotinic acid B3) 500–3000 mg/day as tolerated pretreated with quercetin, apples, and aspirin 81 mg. Take with food and avoid alcohol. Never interrupt therapy. 
- AGE Kyolic standardized 600 mg twice a day 
- MUFA 20–40 g/day (EVOO 4 tablespoons a day) 
- Gamma/delta tocotrienols 200 mg hs 
- Sesame 40 g/day 
- Pantethine 450 mg bid 
- Lycopene 20 mg/day and astaxanthin 15 mg/day 
- Trans-resveratrol 250 mg/day with NAC 500 mg twice a day 

- Citrus bergamot 1000 mg/day 
- Probiotics standardized 15–50 billion organisms bid 
- Curcumin 500–1000 mg twice a day 
- EGCG 500–1000 mg bid or 60–100 ounces of green tea a day 
- Pomegranate 1 cup of seeds/day or 6 ounces of juice a day 

Pharmaceuticals

- Integrative treatment with statins such as rosuvastatin or a bile acid sequestrant such as colestevam hydrochloride may be added to the previous nondrug therapies and lifestyle suggestions. 

TABLE 27.2
Expanded Lipid Testing

Test	Reference Range	Notes
LDL Particle Number	High risk pt: goal < 1000 nmol/L Mod risk pt: goal < 1300 nmol/L See Fig. 27.1	Most important. If normal, no need to measure LDL particle size.
Apolipoprotein B (APOB)	High risk pt: goal < 90 mg/dL Mod risk pt: goal < 110 mg/dL Low risk pt: goal < 130 mg/dL	An indirect test of LDL-P. Order this if LDL-P is not available. Does not require fasting. Best for those with normal or slightly high total LDL and high TG.
Lipoprotein (a) (LPa)	Goal < 14 mg/dL	A genetic marker for risk. Think of this as the glue that traps APO-B or LDL into a plaque. Treat with niacin, ASA, or a statin.
Small LDL-P (Type B)	Goal < 117 nmol/L	The most atherogenic LDL. Can also be associated with prediabetes. Size increased by niacin, omega-3 fatty acids, plant sterols, and statins.
HDL Myeloperoxidase (MPO)	Goal < 400 pmol/L	Mediates vascular inflammation and promotes plaque formation. If elevated, HDL loses its beneficial effects. Fasting is not needed. To improve function, see Table 27.1 .
HDL Particle Number	Goal > 35.0 nmol/L	To improve, consider niacin, omega-3 fatty acids, pantethine, red yeast rice, MUFA, resveratrol, curcumin, pomegranate, astaxanthin, and citrus bergamot.

CHAPTER 28

Arrhythmias

Brian Olshansky, MD

Cardiac arrhythmias are slow (brady), fast (tachy), or irregular heart rhythm disturbances (ectopy, atrial fibrillation, and others). Arrhythmias may be a normal phenomenon related to change in autonomic tone; examples include sinus arrhythmia, sinus bradycardia, and sinus tachycardia. Arrhythmias should be evaluated and treated for the following interrelated reasons: (1) to eliminate symptoms, (2) to prevent imminent death and hemodynamic collapse, and (3) to offset long-term risk of serious symptoms and death. This chapter focuses on an approach to evaluate and treat arrhythmias by using an integrative approach.

Common arrhythmias encountered in an office-based setting include atrial premature beats, ventricular premature beats, bradycardias, supraventricular tachycardia, nonsustained ventricular tachycardia, atrial fibrillation, and follow-up of already treated sustained ventricular tachycardia or ventricular fibrillation. Potentially symptomatic and dangerous (potentially life threatening) arrhythmias that require evaluation for possible acute and chronic therapy include (1) sustained ventricular tachycardia in the setting of heart disease, (2) ventricular fibrillation (cardiac arrest), (3) atrial fibrillation, (4) supraventricular tachycardia, (5) sinus bradycardia (and pauses), and (6) atrioventricular (AV) block. Junctional rhythm, AV dissociation, and ectopic beats are common; they may cause concern and may require special attention, further evaluation, and therapy. These latter arrhythmias are generally not serious enough to necessitate long-term aggressive treatment unless they are associated with severe symptoms.

Pathophysiology

Types and Mechanisms

Heart rhythm disturbances have multiple potential mechanisms and causes. The heart rhythm is a mechanical response to electrical activation of specialized fibers and the atrial and ventricular myocardia. Electrical activation is generally initiated in the sinus node and then leads to activation through various atrial conductive pathways to the AV node, the His–Purkinje system, and the ventricles. The sinus node may be activated slowly as a result of damage to this structure or because of autonomic effects. Increased vagal tone, for example, slows the sinus node rate. Abnormalities in conduction disturbances throughout the normal pathways can also lead to heart block and bradyarrhythmia.

The autonomic nervous system can influence the sinus node either to slow it or to speed it. The autonomic nervous system can also influence other tissue in the heart to make it more automatic, accelerate faster, and overtake normal sinus node activation. This influence can lead to activation resulting from an ectopic focus.

Tachyarrhythmia

Common rhythm disturbances causing an increase in heart rate are known as tachycardias. Tachycardias include sinus tachycardia, which can be a normal response to stress and exercise or an inappropriate acceleration for no apparent reason. Supraventricular tachycardias are less common but require tissue above the His bundle to propagate ([Fig. 28.1](#)). Supraventricular tachycardias occur in various forms: atrial flutter, atrial fibrillation, those resulting from abnormal areas in the atria, those secondary to rhythm disturbances in the vicinity of the AV node, and those caused by rhythm disturbances related to extra pathways that connect the atria to the ventricles. These tachycardias are, in part, related to the underlying mechanisms for arrhythmias that include reentry, triggered automaticity, and normal and abnormal automaticity.

Tachyarrhythmias can result from abnormally fast ventricular activation independent of atrial activation. This arrhythmia is known as ventricular tachycardia. Ventricular tachycardia is often associated with underlying structural heart disease, and the prognosis is often concerning because this arrhythmia can lead to cardiac arrest. This is not always true, however, because in patients with no underlying heart disease (idiopathic cause), ventricular tachycardia can have a benign prognosis. Another serious ventricular arrhythmia is ventricular fibrillation. This rhythm disturbance causes cardiac arrest and, without electrical countershock, is fatal.

Other arrhythmias include ventricular ectopic beats, which can

manifest as single ectopic beats; bigeminy (every other beat); trigeminy; quadrigeminy; in a fixed coupled fashion; or unrelated to other beats, couplets, triplets, and other forms of nonsustained ventricular tachycardia.

Many potential problems are related to heart rhythm disturbances. Abrupt change in the heart rate, especially with marked slowing or acceleration, can lead to hemodynamic compromise, syncope, and other related symptoms. Rhythm disturbances that are extraordinarily fast or that originate in the ventricles and are associated with structural heart disease can be premonitory signs of cardiac arrest. However, most rhythm disturbances that are seen in clinical practice are benign.

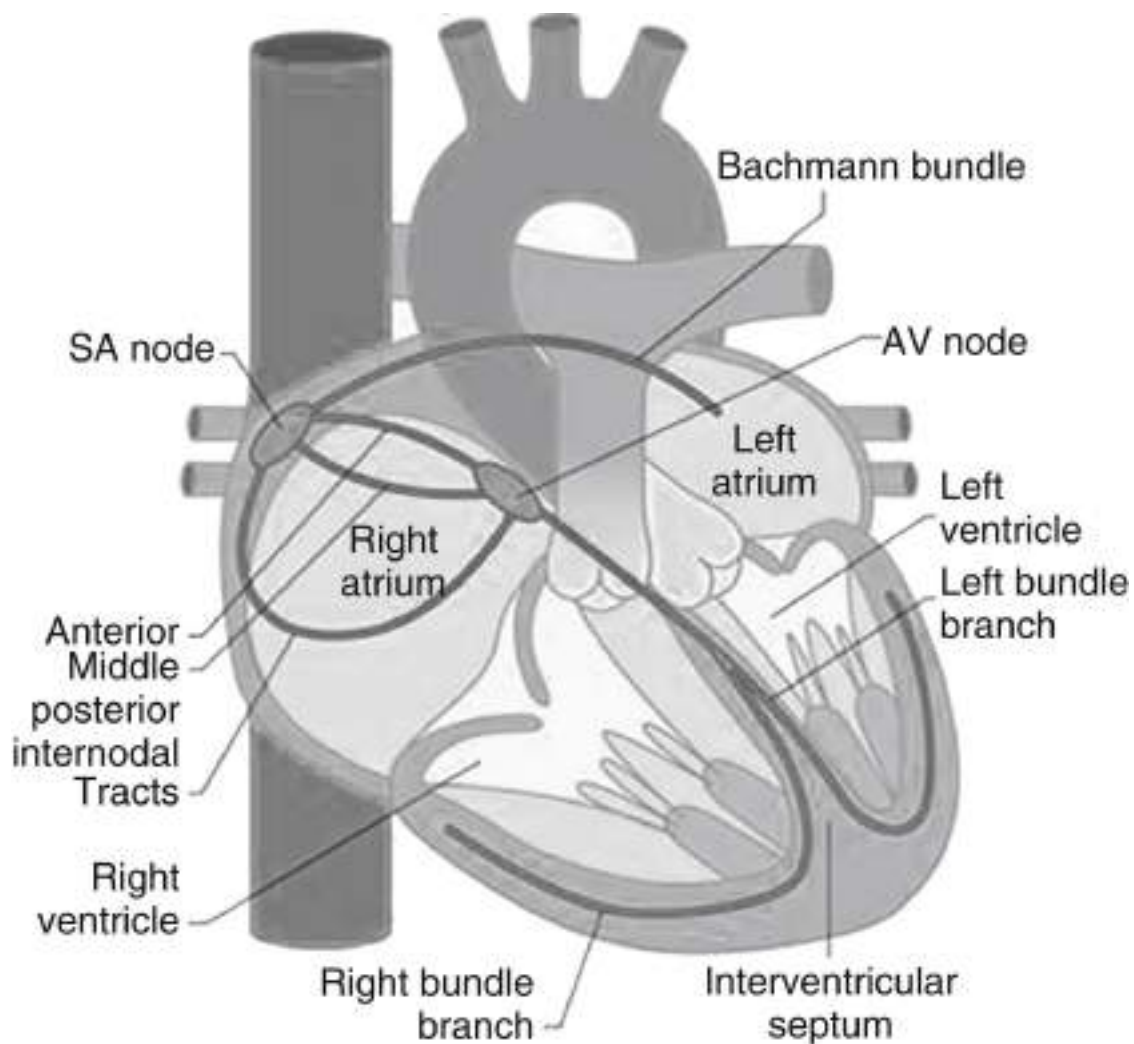

FIG. 28.1 Cardiac anatomy.

Cardiac anatomy comprises electrical and structural components. The

electrical impulse that directs cardiac contraction originates in the sinoatrial (SA) node and is rapidly conducted through the atria by specialized conduction tracts. The impulses merge at the atrioventricular (AV) node, where, after a brief pause, they are rapidly conducted into the ventricles through the bundle of His, which is composed of specialized Purkinje cells. Blood moves from the atria into the ventricles through the tricuspid and mitral valves, respectively, during diastole. During systole, blood from the ventricles is pumped into the pulmonary artery and aorta through the pulmonary and aortic valves, respectively. (From Marks AR. Cardiac function and circulatory control. In: *Goldman-Cecil medicine*. Philadelphia, Elsevier; 2016:53, 262-267.e3)

Ectopic Beats

Ectopic beats that trigger palpitations frequently are the result of ventricular ectopic activity (premature ventricular contractions [PVCs]), atrial ectopic activity (premature atrial contractions [PACs]), and atrial arrhythmias such as atrial fibrillation. Ventricular ectopy and atrial ectopy, when not associated with serious underlying structural heart disease, are relatively benign. Although the risk of death may be slightly increased in any patient with PVCs (up to doubling of mortality), the risk remains low in persons with a normal heart. The reason to treat ectopic beats is not to prevent death, but rather to prevent symptoms. Asymptomatic atrial and ventricular ectopy in a patient with no underlying heart disease does not require treatment.

In a study of 1139 patients with normal ventricular ejection fraction and no history of heart failure, participants with the most PVCs compared to those with the least had a 31% increased risk of death.¹

Symptomatic atrial and ventricular ectopy, however, becomes a major problem to treat in clinical practice for several reasons. First, no good, safe, medical therapies are available.²⁻¹⁴ Drugs used to suppress ectopy frequently can be proarrhythmic and increase the risk of sudden death or increase the severity of the arrhythmias, and these agents can have numerous other serious complications. Second, the problem can be highly symptomatic and concerning to the patient, with potentially a tremendous impact on quality of life. Third, the degree of symptoms from benign arrhythmias varies tremendously, and patients who are highly symptomatic may require several types of therapeutic interventions, which can extend as far as drug therapy and even

radiofrequency catheter ablation approaches. In some patients, caffeinated beverages, chocolate, and even high sugar levels can trigger ectopic activity.^{15,16}

Atrial Fibrillation

Atrial fibrillation is a complex arrhythmia with myriad presentations and therapeutic intervention possibilities. The general approach to atrial fibrillation is threefold: (1) cardiac ventricular rate control, (2) rhythm control, and (3) prevention of thromboembolic events. Although atrial fibrillation is associated with a doubling in mortality, this is not generally the reason for treatment. However, treatment is directed at prevention of symptoms, with treatment of the arrhythmia alone yet to be shown to decrease mortality (it may even increase mortality). Atrial fibrillation occurs in more than 2.2 million U.S. residents.

The most important aspect of the history is to inquire about the ingestion of stimulants such as caffeine, simple sugars, chocolate, pseudoephedrine, ephedra, guarana, ginseng, gotu cola, yohimbe, and others.

People with paroxysms of atrial fibrillation, or at least those patients who present to physicians, are highly symptomatic. Perhaps these patients do not represent the great majority of patients with atrial fibrillation; however, the number of patients with paroxysmal fibrillation who never frequent a health care provider is unknown. In addition, patients with symptomatic atrial fibrillation are not always symptomatic during atrial fibrillation. They often have symptoms when they are in normal sinus rhythm and can be asymptomatic during atrial fibrillation. The presence of persistent paroxysmal or permanent atrial fibrillation frequently inspires long-term treatment and consideration of the threefold treatment approach.

Palpitations

Palpitations are among the most common complaints associated with arrhythmias; the differential diagnosis is extensive. Palpitations can be intermittent or sustained, regular or irregular, and even unrelated to an arrhythmia. Catecholamine excess alone can cause a sensation of palpitations without an arrhythmia even being present.¹⁷

Some causes of palpitations include the following: anxiety; severe viral syndrome; alcohol; stimulants (cocaine, methamphetamine); stimulant medications including pseudoephedrine; drinks containing caffeine, theobromine, or theophylline; poor sleep (or an irregular sleep cycle); and several supplements (including *Ginkgo biloba*, ephedra, ginseng, guarana, horny goat weed, yohimbe, and others). Hormonal changes and excess thyroid hormone can also lead to palpitations.

Palpitations can represent somatization of a psychiatric disorder. Of 125 outpatients referred for ambulatory electrocardiographic monitoring to evaluate palpitations, 34% had an arrhythmia, whereas 19% had a psychiatric disorder, particularly major depression or a panic disorder.¹⁸ Those with psychiatric disorders were younger, more disabled, and more hypochondriacal about their health. Their palpitations were more likely to last longer than 15 minutes, were accompanied by other symptoms, were more intense, and were associated with more emergency room visits. Several reports have confirmed the high incidence of psychiatric conditions in association with palpitations.^{19,20} Nevertheless, careful evaluation of palpitations must rule out organic disease.

Palpitations are only rarely the result of a life-threatening process, although they can be associated with or represent manifestations of underlying ventricular dysfunction or other structural heart disease. Palpitations in a patient with heart disease, especially coronary artery disease, should raise suspicion that the palpitations are the result of an arrhythmia.^{21,22}

Approach to the Patient

Perspective

Arrhythmias may have little meaning if they have no prognostic significance, do not alter hemodynamics or cardiac function, and are not symptomatic. Routine screening of an asymptomatic patient is not recommended. Patients typically seek medical care for palpitations, an arrhythmia associated with symptoms, a symptom thought to be caused by an arrhythmia, or nonspecific symptoms that may result from an arrhythmia.

Initial Evaluation and Diagnosis of the Arrhythmia

The initial evaluation includes a careful, circumspect, and complete history (directed toward the symptoms and any potential relationship

with an arrhythmia, as well as an assessment of potential responsible conditions), a physical examination, and a 12-lead electrocardiogram at baseline and, if possible, during the arrhythmia. An unhurried, careful, and complete history is the key to appropriate further evaluation, and the clinician should resist the urge to perform expensive, unnecessary, or potentially risky tests. Several issues should be addressed in the history ([Table 28.1](#)).

The electrocardiogram recorded during the arrhythmia or while the patient is symptomatic determines the need for further evaluation and treatment. An ambulatory monitor or an event monitor may be needed, in selected patients, to secure a diagnosis. If the symptoms are sporadic, but occur daily, use of an ambulatory (Holter) monitor is the best approach.²³⁻²⁶ An event recorder or transtelephonic monitor can help make the diagnosis in a patient with less frequent palpitations. Transtelephonic devices are small, lightweight, and inexpensive. The memory feature allows recording of data without the need for immediate access to telephone transmission. One such device is a small patch (*Zio Patch*) that is worn for 2 weeks with a summary of the results sent to the clinician.²⁷ An implantable monitor (Reveal, Medtronic, Minneapolis, MN) is also available.²⁸ The device can record events triggered by the patient or by preselected criteria automatically. The device can record up to 42 minutes of data. If episodes are associated with exercise or physical or mental stress, or when an arrhythmia cannot be documented with ambulatory or transtelephonic monitoring, exercise testing may secure a diagnosis.

TABLE 28.1**Historical Features of Importance in the Evaluation of the Patient**

- Which arrhythmia is present?
- Does the arrhythmia cause symptoms?
- Does the arrhythmia have prognostic significance?
- Is the problem life threatening?
- Does the patient require hospital admission or extensive testing?
- Is specialist consultation required and, if so, how urgently?
- Is treatment required?

Risk Assessment

The clinician should determine whether an arrhythmia has prognostic importance: Is it a premonitory sign of death? Several conditions, including ventricular tachycardia and the Wolff-Parkinson-White syndrome ([Fig. 28.2](#)), are potentially life threatening. Not all ventricular tachycardias are life threatening; a patient without heart disease, for example, who has idiopathic sustained ventricular tachycardia (*not* idiopathic ventricular fibrillation) has little chance of dying. In contrast, even a single episode of nonsustained ventricular tachycardia in a patient with coronary artery disease and poor left ventricular function, as a result of prior myocardial infarction, may be associated with a poor prognosis.²⁹

Rarely, an asymptomatic arrhythmia must be urgently treated. Symptoms and their relationship with the arrhythmia require careful assessment. A correlation of the arrhythmia and symptoms is preferred, although not always possible.

Indications for Inpatient Management

Hospital admission is required if the patient has significant underlying heart disease (e.g., cardiomyopathy with congestive heart failure or coronary heart disease with active ischemia), if the arrhythmia is life threatening and requires rapid reversion (e.g., rapid tachyarrhythmias, polymorphic ventricular tachycardia, prolonged QT interval in a patient with syncope), or if the arrhythmia is uncontrolled or highly symptomatic. Hospital admission is preferred for older patients, who may have not only underlying heart disease, but also other chronic illnesses, such as kidney or liver disease that may affect antiarrhythmic therapy.

FIG. 28.2 Six leads of an echocardiograph of a patient with Wolff-Parkinson-White syndrome showing delta waves.

Referral to a Specialist

A cardiologist is frequently needed to help manage the complex patient with an arrhythmia; for example, a temporary pacemaker may be needed for a patient with symptomatic bradycardia. Referral to an electrophysiologist may be necessary to institute aggressive acute therapy, such as intravenous amiodarone for life-threatening ventricular tachycardia, antitachycardia pacing for acute reversion of an arrhythmia, for placement of an implantable cardioverter defibrillator (ICD), or to reprogram a pacemaker or an ICD ([Table 28.2](#)).

Integrative Therapy

The need for long-term therapy must be carefully individualized to each patient because the severity and importance of symptoms are highly variable. The symptoms associated with any arrhythmia can have an impact on lifestyle, occupation, driving, and other important daily activities. These issues must be considered for every patient and are evaluated as part of a diagnostic and therapeutic approach.

Diet

Gastric Distention

Dietary interventions in some cases can influence some arrhythmias. A large meal can distend the stomach and stimulate vagal afferents thus leading to vagal efferent activation, causing atrial fibrillation in patients who have vagally mediated atrial fibrillation, hypotension, and bradycardia.

Food as a Trigger

Some foods may even act as triggers, and patients will often report some evidence for this. Alcohol is one of the major triggers for atrial fibrillation and ventricular ectopy.^{30,31} Caffeine is frequently another trigger for ectopic beats but not necessarily atrial fibrillation.^{15,16} Restriction of alcohol and caffeine may have no effect on arrhythmias. If this is the case, restriction will be of no benefit and may adversely influence the patient's lifestyle. Specific food allergies can trigger a reaction and cause palpitations. Trans fats, particularly of the 18-2 type (found in doughnuts, fried foods, and artificial cheese such as in processed pizza), have been associated with cardiac arrest.^{32,33} In contradistinction,³⁴ omega-3 fatty acids may improve outcomes^{34,35}; however, current data do not indicate an antiarrhythmic effect.³⁶ Fat balance appears to have an effect on cardiovascular health.³⁷ Alcohol consumption may enhance the effects of omega-3 fatty acids while also potentially triggering atrial fibrillation.^{38,39}

TABLE 28.2

Reasons for Referral to a Specialist

- Resuscitated ventricular fibrillation
- Sustained ventricular tachycardia
- Atrial fibrillation that is difficult to control or refractory to standard therapies
- Nonsustained ventricular tachycardia
- Symptomatic supraventricular tachycardia that is difficult to control
- Sinus bradycardia (sick sinus syndrome, tachy-brady syndrome)

- Second-degree atrioventricular block
- Unexplained ventricular ectopy in the athlete or in a symptomatic patient
- Syncope with a suspected arrhythmic mechanism
- Patients with devices (pacemakers, implantable defibrillators) who are unstable
- Uncontrolled rhythm problems

The effects of diet on the autonomic nervous system are complex. Several foods increase sympathetic nervous system tone. High levels of sodium also increase the effects of catecholamines and influence ventricular ectopy.⁴⁰⁻⁴⁵ Caffeine, theophylline, and theobromine present in coffee, tea, and chocolate may be inciting factors, or they may possibly have positive benefits.⁴⁶⁻⁴⁹ Data indicating that coffee causes atrial fibrillation are questionable.^{50,51} Trial and error with these food substances is worthwhile; however, there's no particular reason to eliminate all these foods if they do not have an effect on the arrhythmia. Patients may complain that a specific food triggers a rhythm disturbance by an unknown mechanism. This is not uncommon and is possibly related to some type of allergic reaction or other related issue.

Gastric distention from large meals, excessive caffeine, alcohol, high levels of sodium, trans fats, severe fluctuations in blood sugar levels, and, possibly, food allergies are potential dietary triggers of cardiac arrhythmias.

Botanical Stimulants of Arrhythmia

Specific supplements can trigger arrhythmias. Ma huang, from the Chinese ephedra plant, contains catecholamines including ephedrine that can initiate ectopic rhythm disturbances and cause life-threatening problems.^{52,53} Investigators have even suggested that ambrotose, ginkgo, and other commonly used substances may exacerbate or even cause arrhythmias.

Diet and Anticoagulation

Diet is very important in arrhythmia management, especially in patients who require anticoagulation for atrial fibrillation or other arrhythmias. If the diet changes markedly with significant alterations in vitamin K levels, the prothrombin time will fluctuate tremendously ([Table 28.3](#)).

A balanced diet, low in fat and high in roughage that will lead to a moderate level of blood sugar and as little stress as possible on the gastrointestinal tract, may improve the arrhythmias.

Exercise

Exercise and physical exertion can trigger various arrhythmias. Maintaining excellent physical health through exercise, however, decreases the effects of the sympathetic nervous system on the heart and heart rhythm and improves outcomes in almost all circumstances. The sympathetic nervous system often has a major contributory role in the genesis of serious and benign atrial and ventricular arrhythmias. Exercise performed regularly, with enhancement of aerobic capacity, decreases sensitivity to catecholamines, reduces circulating catecholamine levels, decreases sympathetic nervous system tone, and enhances vagal tone. All these effects increase heart rate variability, which decreases the risk of sudden death and the potential for catecholamine-initiated or sympathetically initiated atrial and ventricular arrhythmias (see [Chapter 96](#)). Exercise can also modulate other potential rhythm disturbances, such as sinus tachycardia. Especially in young women, inappropriate sinus tachycardia and postural orthostatic tachycardia syndrome are potential problems.⁵⁴ Inappropriate sinus tachycardia is a condition in which the sinus node appears to be hyperactive; the cause is not completely known. It may be, in part, related to abnormal sympathetic nervous system stimulation but may also be an intrinsic problem with the sinus node. Increasing exercise decreases the potential for this problem. Exercise appears to be beneficial in treating many arrhythmias, but it must be used with caution. For patients with malignant arrhythmias, exercise therapy must be prescribed and supervised by a qualified physician who is knowledgeable about the risks, benefits, and methods of monitoring the patient.

TABLE 28.3**Therapeutic Review for Nonvalvular Atrial Fibrillation**

1. Address underlying triggers

The most important triggers are hyperthyroidism, hypertension, obesity, alcohol toxicity, obstructive sleep apnea, and a recent pulmonary infection. Also perform an echocardiogram for structural heart disease or congestive heart failure (CHF).

2. Everyone needs rate control

Have a goal of <80 beats/min at rest and <110 beats/min with activity. A 24-hour ambulatory monitor is the most accurate tool to assess this. Rate control will improve symptoms and prevent tachycardia-associated cardiomyopathy.

- Use a beta-blocker if your patient has CHF or coronary artery disease (CAD)
- Use a nondihydropyridine calcium channel blocker (verapamil, diltiazem) in those with lung disease (chronic obstructive pulmonary disease [COPD] and asthma)
- If more rate control is needed, consider adding digoxin, which can work synergistically with beta-blockers and calcium channel blockers.

3. Should I refer to cardiology for rhythm control?

Two large studies on rate vs. rhythm control (the AFFIRM and RACE trials) reported mortality was slightly better with rate control; however, there are some exceptions.

Rhythm control should be considered for the following:

- Younger individuals (<65 years)
- CHF
- Persistent symptoms despite rate control

4. If rhythm control is required, should drugs or ablation be used?

Ablation is more successful but is associated with greater risk. If drugs are not successful, follow with ablation.

Amiodarone has the benefit of providing both rate and

rhythm control but has liver, lung, and thyroid toxicity.

5. **When should I anticoagulate and which anticoagulation drug should I use?**

Use the CHA₂DS₂-VASc and HAS-BLED scores found in “Key Web Resources” to determine the need and risk of anticoagulation. A CHA₂DS₂-VASc score of 2 or more and a HAS-BLED score of ≤ 3 warrants anticoagulation with warfarin or a novel oral anticoagulant (NOAC).

- Use warfarin in those with end-stage kidney disease or on dialysis.
- If a NOAC is used in those with chronic kidney disease, the dose needs to be reduced.
- Dual antiplatelet therapy (e.g., aspirin [ASA] and clopidogrel) is no longer recommended due to the risk of bleeding.

Lifestyle

Lifestyle has a major impact on arrhythmias.⁵⁵⁻⁵⁷ Cigarette smoking and other forms of nicotine have no potential benefit and may be harmful for any individual.^{56,58} Nicotine use can exacerbate the risk of sudden death and malignant and benign arrhythmias of all types. Although alcohol may have a beneficial effect on cardiovascular mortality, myocardial infarction, and cholesterol, it has no benefit on any form of arrhythmia. The combination of alcohol and nicotine is even more likely to trigger an arrhythmia.

Mind-Body Therapy

Autonomic variations can occur with numerous lifestyle interventions, including meditation and other mind-body therapies.^{59,60} The influence can be profound and may occur by several potential mechanisms: (1) change in autonomic function, (2) placebo effect, (3) direct effect on the rhythm, (4) change in perception of the importance of the arrhythmias to the patient, and (5) shifting of the attention from the arrhythmia to some other issue.

Biofeedback can decrease the number, frequency, and severity of palpitations related to arrhythmias. The effects of biofeedback have been known for some time.⁶¹⁻⁶⁵ Another issue is the simple process of developing awareness that a patient can learn to identify a rhythm disturbance as not a potentially noxious experience. The interpretation of the severity of the rhythm disturbance amplifies the severity of the effects on symptoms. Having a patient face the problem can actually empower the patient to improve his or her perception of the arrhythmia and its implications. Ultimately, properly used psychosocial therapy can reduce the risk of death.⁶⁶ Biofeedback devices can also be used to enhance heart rate variability (see [Chapter 96](#)).

Meditation

Meditation has been shown to be associated with a decreased risk of sudden death in high-risk patients because of a reduction in ventricular fibrillation.^{59,60} Meditation may affect the autonomic nervous system in a beneficial way.⁶⁷ It may also change the perception of the arrhythmia for patients who have a benign problem.

Meditation and relaxation techniques may also be useful for individuals who have an ICD for life-threatening rhythm disturbances. If the device is activated frequently, it can cause tremendous grief. Meditation and relaxation techniques can improve outcomes in such patients. These techniques may also allow for better patient acceptance of the shocks (see [Chapter 100](#)).

Relaxation appears to have a positive benefit. For years, physicians have used benzodiazepines to treat rhythm disturbances, such as atrial fibrillation and supraventricular tachycardia, by inducing relaxation. If a patient comes into an emergency room with such an arrhythmia and is allowed to relax, the rhythm will often stop spontaneously (see [Chapter 94](#)).

Acupuncture

Data suggest that acupuncture may be antiarrhythmic for atrial fibrillation.⁶⁸ Although acupuncture may affect other arrhythmias beneficially, current data are far from definitive.⁶⁹ Acupuncture can also trigger inappropriate shocks in patients with ICDs, and this therapy should be avoided in these patients.⁷⁰

Supplements

Coenzyme Q10

Coenzyme Q10, at a dose of 100–300 mg a day, may decrease episodes of atrial fibrillation by an unknown mechanism. Coenzyme Q10 can also have an effect on ventricular and atrial ectopy.⁷¹

L-Carnitine

l-Carnitine, at a dose of 3 g a day or more, can improve mitochondrial function and left ventricular function and may prevent some atrial and ventricular arrhythmias. Several small randomized controlled trials of carnitine have reported a reduction in risk of sudden cardiac death and total death in patients with cardiomyopathy. The mechanism is not clear, but it may be attributable to carnitine improving the mitochondrial and myocardial function.⁷²⁻⁷⁴ Carnitine has no known adverse effects. It may reduce ischemia and reperfusion-induced arrhythmias and raise the ventricular fibrillation threshold (of unclear significance).⁷⁵

Magnesium

Magnesium, approximately 1 g a day as a salt (e.g., magnesium sulfate), has been associated with a decrease in arrhythmias. Magnesium can decrease triggered activity and can slow conduction in the AV node.

Magnesium supplementation administered to patients in congestive heart failure in a double-blind, placebo-controlled trial showed improvements in arrhythmias. Individuals taking 3.2 g per day of magnesium chloride equivalent to 384 mg per day of elemental magnesium had between 23% and 52% fewer occurrences of specific arrhythmias over a 6-week follow-up period.⁴⁵ Although some data suggested that magnesium had a beneficial effect on atrial fibrillation,⁷⁶ other data did not support its use.⁷⁷ Magnesium may also be associated with reduced risk of sudden death in women.⁷⁸

Copper and Zinc

Three cases were reported in which ventricular premature beats disappeared, and PVCs decreased, after copper supplementation at a dose of 4 mg per day.⁴³ Investigators discovered that zinc made the arrhythmias worse and that extra zinc can lead to copper deficiency. The use of copper has a potential problem, however, in that high copper

levels can lead to atherosclerosis.

Selenium

A deficiency in selenium can cause heart problems including arrhythmias. No good data, however, are available to suggest that selenium supplementation in patients with low selenium levels will improve arrhythmia status.^{40,79}

Potassium

Potassium supplementation is extraordinarily important, especially if a patient is taking drugs that lower potassium levels. Potassium has been implicated in all types of rhythm disturbances, and potassium deficiencies can lead to torsades de pointes. Anyone with long QT interval syndrome, and specifically those patients who take drugs that lower potassium levels, clearly should take potassium supplements. This can also be done through potassium in the diet, including fruits and vegetables that contain high potassium concentrations (see [Chapter 89](#)).

Omega-3 Fatty Acids

Omega-3 fatty acids appear to influence several myocardial channels that can affect arrhythmias.⁸⁰⁻⁸⁴ Specifically, omega-3 fatty acids appear to have an effect on calcium and potassium channels.⁸⁵ In men with symptomatic PVCs, omega-3 fatty acids were shown to decrease the risk of PVCs by approximately 70% when supplementation was in the form of fish oil,^{86,87} but data are conflicting.⁸⁸

Fish oil was also shown in the second Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarto Miocardico (GISSI2) prevention trial to be associated with a decreased risk of total death and sudden death. This study included 11,324 Italians who had had a myocardial infarction within the preceding 3 months. These patients were randomized to approximately 850 mg of omega-3 polyunsaturated fatty acids (n = 2836), vitamin E (n = 2830), or neither (n = 2828). Patients who were given fish oil had a 45% reduction in sudden death and a 20% decrease in mortality.⁸⁵

The Lyon Diet Heart Study and the Physicians' Health Study both showed a benefit to the use of fish oil. The Diet and Reinfarction Trial (DART) included 2033 men with acute myocardial infarction who were randomized to receive or not to receive advice on diets: decreased fat intake to 30% of total energy, at least two weekly portions (200–400 g) of

fatty fish (or 1.5 g fish oil capsules if unable to take fish), and cereal fiber to 18 g daily. Patients who were given “fish advice” survived substantially longer and significantly better.⁸⁹

These data inspired the Fatty Acid Antiarrhythmia Trial, a randomized, placebo-controlled trial of 3 g of fish oil compared with cod-scented olive oil, to look at the incidence of recurrent ventricular arrhythmias in patients who had ICDs and were at risk for sudden death. Many of these patients had malignant ventricular arrhythmias leading to shocks from their device. The aim of this study was to decrease the number of shocks. Fish oil was found to be effective in this study, but data were conflicting.⁹⁰

The data on fish oil in arrhythmias and improving outcomes in patients with heart disease are extensive.⁹¹⁻⁹³ Although the data in some cases conflict, fish oil is associated with improved autonomic influences,⁹⁴⁻⁹⁶ reduction in atrial fibrillation⁹⁷ (especially after cardiovascular surgery,⁹⁸ but not in all studies⁹⁹), reduction in risk of all-cause mortality, reduction in symptomatic ventricular ectopy, and reduction in depression (depression is associated with increased mortality after myocardial infarction).¹⁰⁰ Although some data show benefits for atrial fibrillation,¹⁰¹ a placebo-controlled study found no value of fish oil.¹⁰²

In addition, data on patients after myocardial infarction have not shown benefit, likely because present therapy is already so good.¹⁰³ The higher-risk patients may be the ones who benefit the most.¹⁰⁴ Concerns also exist about the toxins in some of the supplements, including dioxins, polychlorinated biphenyls, polybrominated diphenyl ethers, and chlorinated pesticides.¹⁰⁵

Omega-3 fatty acids are available in various forms, not only fish oil.¹⁰⁶ Certain plant oils can be metabolized into omega-3 fatty acids, including flaxseed oil, which also has other potential benefits,¹⁰⁷ including those on mood. Because omega-3 fatty acids can improve mood, they may also have an autonomic affect that can decrease the sensation of arrhythmias or decrease arrhythmias altogether.

For dosing omega-3 fatty acids, educate the patient to read labels. If you are recommending 1000 mg of omega-3 fatty acids, the user needs to look at the amount of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) per serving size. If the label notes 300 mg

of EPA and 200 mg of DHA per two capsules (serving size), the patient would need to take four capsules daily to obtain 1000 mg of omega-3 fatty acids.

Vitamins

A long-standing case of sick sinus syndrome was reported to resolve with supplementation of 800 units per day of vitamin D.¹⁰⁸ However, it was not clear that vitamin D was the cause of this change.

Data indicate that vitamin C given postoperatively to patients at risk for atrial fibrillation and to patients who undergo coronary artery bypass graft surgery may lead to a marked reduction in atrial fibrillation¹⁰⁹⁻¹¹³; however, these data have not been confirmed. Although the underlying mechanism is unknown, vitamin C appears to have antiarrhythmic properties and can prevent atrial fibrillation, at least in some patients. The mechanism may be by clearance of free radicals or by an antiinflammatory effect.

Botanicals

Many of the original antiarrhythmic drugs were derived from herbal therapy: quinidine (a stereoisomer of quinine from cinchona bark), lidocaine, amiodarone (from khellin, derived from the herb *Ammi visnaga*), and digoxin (from foxglove) are a few.^{114,114a-c} Data suggest that several other herbal preparations may have antiarrhythmic effects.

Ciwujia or Siberian ginseng (*Acanthopanax senticosus* harms), which is used for athletic performance and weight loss, may have antiarrhythmic effects. Ciwujia was studied in isolated rat hearts with transient coronary occlusion.¹¹⁵ Ciwujia extract reduced reperfusion-induced ventricular fibrillation and ventricular tachycardia. It also reduced the number of cells with abnormal action potential configurations. Ciwujia may reduce the incidence of malignant arrhythmias.¹¹⁵ Siberian ginseng can cause an apparent increase in digoxin levels.¹¹⁶ Whether this finding represents a false serum elevation, whether ginseng converts to digoxin in vivo, or whether ginseng alters the metabolism of digoxin is unclear.

Angelica and *Ginkgo biloba* may have a protective influence during myocardial ischemia and reperfusion.¹¹⁷ In a rat model, the incidence of ventricular premature beats and the total incidence of arrhythmia were greatly reduced.¹¹⁸

Licorice root has been shown to have an antiarrhythmic property.¹¹⁹

Zhi gan cao (prepared licorice) injection can antagonize arrhythmias induced by chloroform, catecholamines, aconitine, strophanthin-K, and barium chloride. Licorice root may slow the heart rate, prolong PR and QT intervals, and antagonize the positive chronotropic response induced by catecholamines. Another component of licorice, sodium 18 beta-glycyrrhetinate, strongly counteracts arrhythmia induced by chloroform, lengthens the appearance time of arrhythmia induced by CaCl₂, slightly retards the heart rate of rats and rabbits, and partly antagonizes the acceleration effect of isoproterenol on rabbit hearts. The clinical significance of these experimental findings is unclear.¹²⁰

Various herbs are now considered potentially useful by some practitioners to treat ventricular and supraventricular arrhythmias. Motherwort contains butenolide, glycosides (stachydrine), and alkaloids. A dose between 4 and 5 g of motherwort can decrease palpitations, presumably by a mild beta-blocking effect, although the exact mechanism that motherwort exerts on the heart to decrease ectopic beats is unclear. No randomized controlled trial has been performed using motherwort.

Think of motherwort as the “beta blocker” of the botanicals.

Khella (*Ammi visnaga*) has significant antiarrhythmic effects. In the 1950s, a compound known as khella was derived from the *Ammi visnaga* plant and used to treat angina resulting from coronary heart disease, with significant improvement in those patients. Khella has also been used over the years by naturopaths to decrease palpitations. Khella is the original substance from which a very potent antiarrhythmic drug, amiodarone, was derived.¹²¹⁻¹²³

Hawthorn berry has been used to treat atrial fibrillation and may also have an effect on other rhythm disturbances.¹¹⁶ Hawthorn contains hyperoside (vitexin, rhamnose), rutin, and oligomeric procyanidins. A dose of 160–900 mg of the water ethanol extract is recommended. Exactly how this herb works is unknown, but it may act on the sodium-potassium adenosine triphosphatase pump similar to digoxin. More likely, hawthorn acts as a phosphodiesterase inhibitor. Hawthorn may reduce the risk of sudden death and help treat patients in heart failure, and may have other benefits.^{124,125}

Rhodiola may have had some antiarrhythmic effects in a rat model in which arrhythmias were induced by epinephrine and calcium chloride.¹²⁶

Rhodiola can increase the ventricular fibrillation threshold,¹²⁷ and although this effect may be beneficial, the meaning is uncertain. The antiarrhythmic effect of rhodiola may result from activation of the opioid system and stimulation of kappa-opioid receptors.¹²⁸

Data suggest that garlic, agrimony, celery, ginger, berberine, corkwort, *Stephania tetandra* root, astragalus, *Fissistigma glaucescens*, xin bao, bu xin, yu zhu, and mai dong, among others, are antiarrhythmic under various experimental conditions and for various arrhythmias. At the present time, however, the data are not definitive enough to recommend treatment with any of these herbal therapies for a specific arrhythmia.

Pharmaceuticals

The standard first-line drug therapy approach for benign PVCs, PACs, and episodes of atrial fibrillation is often a beta-adrenergic blocking drug. This class of drug alters the autonomic nervous system tone on the heart, although the effectiveness of this approach is unclear. Good data suggest that it is not effective whatsoever. Further, side effects are common when using these therapies for ectopic beats.

For atrial fibrillation, various antiarrhythmic drugs are available.¹²⁹ Their use depends on the underlying heart disease, link to the episodes, age of the patient, severity of symptoms, and the difficulty in maintaining sinus rhythm (see [Table 28.3](#))

For ventricular ectopy and PVCs, if beta-blockers do not work, various antiarrhythmic drugs can be used including, for normal hearts without any evidence of ischemic heart disease, class IC antiarrhythmic drugs such as propafenone and flecainide.^{6,7} One concern about these antiarrhythmic drugs, like any antiarrhythmic drug, is they can triple the mortality rate if underlying heart disease is present. The use of these drugs is never completely safe, and they can have other so-called proarrhythmic effects.²⁻⁹

Numerous other antiarrhythmic drugs can be used, but each one of them has significant side effects. The use of these drugs is discouraged for benign ventricular ectopy unless the patient is severely symptomatic.

Although antiarrhythmic drugs can suppress arrhythmias, the important issues of proarrhythmia and side effects must be considered. All antiarrhythmic drugs have the potential to increase ectopy or induce, or aggravate, monomorphic ventricular tachycardia, torsades de pointes, ventricular fibrillation, conduction disturbances, or bradycardia. This is known as proarrhythmia.²⁻⁹ The use of antiarrhythmic drugs should be

reserved for clinicians who are expert in their use.

The risk of proarrhythmias from medication is greatest in those who need the most protection, specifically those patients with depressed left ventricular function with an ejection fraction less than 30%.

Risk-to-Benefit Ratio

The goal of therapy for any arrhythmia is to eliminate symptoms or prevent a potentially serious outcome, primarily a life-threatening arrhythmia and sudden death. These goals must be balanced against the risks associated with antiarrhythmic therapy, including proarrhythmia and the side effects of individual drugs.

No study has shown that ventricular ectopy suppression in any group of patients with asymptomatic arrhythmia improves survival. The only reason to treat is to suppress symptoms from arrhythmias as long as treatment does not worsen arrhythmias and the prognosis.

Ablation Therapy

Another potential treatment that is nonpharmacological is ablation therapy. Occasionally, ablation therapy can be used to remove focal triggers for rhythm disturbances in the atrium or ventricles for eliminating PACs and PVCs.

Occasionally, a patient with ventricular bigeminy does not perfuse with the PVC and therefore has an underlying rapid ventricular rate without adequate perfusion, especially during the PVC. Such a patient can develop tachycardia-mediated cardiomyopathy, and heart failure will ensue. This problem can be eliminated by treating the PVC. Ablation therapy is also used to treat various supraventricular tachyarrhythmias. In fact, atrial fibrillation, especially when paroxysmal, can be treated by ablating focal ectopic beats that often originate from the pulmonary veins.

Conclusion

Arrhythmia management is complex and multifaceted. Treatment depends on the arrhythmia, its implications, the symptoms, and the effect on the patient. Patients with serious rhythm disturbances must be

referred to a specialist, especially if the arrhythmias are potentially life threatening. If not, an approach to improve outcomes should involve change in lifestyle and exercise. Following these dietary recommendations may be useful. If this is not enough, mind-body effects can be substantial. Consider meditation. Acupuncture can have beneficial effects as well. Several herbal preparations may influence the presence of an arrhythmia; however, care must be taken because some supplements, such as ma huang, can worsen an arrhythmia or even create a new, life-threatening one.

Prevention Prescription

- Avoid arrhythmia triggers if identified and definable (e.g., excess caffeine intake).
- Encourage regular aerobic exercise as long as it does not trigger arrhythmias.
- Urge risk factor reduction to prevent the development of structural heart disease (treatment of hypercholesterolemia, hypertension, smoking, or excess ethanol intake).
- Moderate balanced caloric intake and maintenance of appropriate weight.
- Prevent stress. Incorporate meditation, yoga, and bioenergy techniques.
- Maintain a regular sleep-wake cycle with at least 7–8 hours of sleep nightly.
- Encourage two to three servings of fish a week and, if unable, consider supplementing with 1–2 g of fish oil.
- Avoid the use of drugs or supplements that stimulate or mimic the effect of catecholamines (e.g., over-the-counter decongestants, ephedra [ma huang], and caffeine).

Therapeutic Review

The treatment of arrhythmias cannot be easily standardized and does not fit into any clearly defined algorithmic pathway. The reason for this is the diverse presentations of arrhythmias, the complexity of management, the great span of problems ranging from completely

benign to clearly life threatening, the lack of randomized controlled clinical data in some instances, the difficulty in diagnosing problems, and the overlap with many other syndromes. Despite these caveats, some rational common sense recommendations can be set forth to manage patients who have suspected cardiac arrhythmias.

For Patients With Palpitations

- Diagnosis is crucial, and arrhythmias can range from sinus rhythm through various types of ectopy to supraventricular or ventricular tachycardia.
- If no arrhythmia is documented, consider anxiety or panic attacks and treat accordingly.
- Encourage stress reduction techniques such as meditation and yoga.

For Patients With Symptomatic Ectopy or Premature Ventricular Contractions

Lifestyle

- Determine the severity of the symptoms and their relation to the arrhythmia. Assess underlying conditions.
- Determine the risk to the patient.
- For proven benign ectopy, discuss the risks of drug therapy and suggest alternatives first.

Nutrition

- Eliminate dietary or other apparent triggers (caffeine, alcohol, trans-fatty foods, blood glucose fluctuations).

Mind-Body Therapy

- Promote mind-body interventions such as meditation, yoga, Reiki, or qi gong.
- Counsel the patient about the benign nature of the condition. Patients who understand will be able to tolerate the arrhythmia better.

Exercise

- Determine the relation to exercise, and consider a tailored exercise

program. 

Supplements and Botanicals

- Suggest omega-3 fatty acids: 2–3 g/day of eicosapentaenoic acid plus docosahexaenoic acid essential fatty acids 
- Magnesium supplementation: 300–1000 mg daily 
- Consider herbal approaches: motherwort, 4–5 g of dried above-ground parts daily 
- Consider carnitine: 3 g daily and then coenzyme Q10: 100–300 mg daily with a meal 

Pharmaceuticals

- Drug therapy: only if resistant to foregoing measures 
- Beta blockade (titrated upward): consider extended-release metoprolol (Toprol XL), 50, 100, or 200 mg daily; or atenolol, 50–100 mg daily 
- Calcium channel blockers (diltiazem or verapamil): 120–360 mg daily 
- Antiarrhythmic drugs: used as last resort (if no structural heart disease, flecainide, propafenone, sotalol are the first choices; then amiodarone, but only in resistant, highly symptomatic cases; risks may outweigh benefits) 

Ablation Therapy

- Suggest ablative therapy for motivated patients willing to take the excess risk (counsel patients that symptoms are benign) 

For Patients With Paroxysmal Atrial Fibrillation

Lifestyle and Risk Factors

- Correlate symptoms with the arrhythmia. Determine the presence of underlying conditions, including hyperthyroidism.
- Assess the risk to the patient and the need for rate control, anticoagulation, and maintenance of sinus rhythm (see [Table 28.3](#)).

Nutrition

- Determine triggers, if possible. If a relationship is determined, eliminate caffeine, alcohol, and any potentially offending drug. 
- If arrhythmia occurs at night, consider changes in diet (no large meals causing gastric distention). 

Exercise

- If arrhythmia is exercise related, consider an exercise program. 

Mind-Body Therapy

- Promote mind-body interventions such as relaxation techniques. 
- Counsel patients and educate them about the disease process.

Acupuncture

- Suggest acupuncture (not well tested but perhaps effective). 

Supplements and Botanicals

- Omega-3 fatty acids: 2–3 g of fish oil daily. 
- Magnesium supplementation: 300–1000 mg daily. 
- Coenzyme Q10: 100–300 mg daily with a meal. 
- Hawthorn berry: 160–900 mg daily. 
- Motherwort: 4–5 g daily. 

Pharmaceuticals

- Beta blockade (to control rhythm and rate): see earlier for dosage. 
- Calcium channel blockade (to control rate, diltiazem or verapamil): 120–360 mg daily. 
- Digoxin (little effect, but may help in combination with a beta blocker and is safe if used carefully at appropriate doses). 
- Antiarrhythmic drugs depend on the patient and the conditions. 
The risk-to-benefit ratio is complex and depends on other diagnosed conditions, symptoms, and antiarrhythmic drugs. Amiodarone is the

most effective drug but has the greatest risk of side effects. Propafenone and flecainide can triple the risk of death in patients with underlying heart disease and are contraindicated in patients with coronary disease or impaired ventricular function.

Ablation Therapy

- Ablation of the pulmonary veins or parts of the left atrium. 
- Ablation of the atrioventricular node with a pacemaker (patient remains in atrial fibrillation) not completely effective. 
- Ablation of other inciting arrhythmias.

NOACs for Nonvalvular Atrial Fibrillation

NOAC	Dosage	Benefits/Risks Compared to Warfarin
Dabigatran (Pradaxa)	Creatinine clearance (CrCl) ≥ 30 = 150 mg bid CrCl 15–30 = 75 mg bid	Less intracranial and fatal bleeds Higher rate of GI bleeds
Rivaroxaban (Xarelto)	20 mg/day with evening meal CrCl 30–50 requires close monitoring CrCl ≤ 30 : Avoid the use of NOACs	Less intracranial and fatal bleeds
Apixaban (Eliquis)	5 mg bid ↓dose to 2.5 mg bid if any two of the following: Age ≥ 80 Weight ≤ 60 kg Serum Cr ≥ 1.5 mg/dL	Less intracranial bleeds same GI bleeds. One study showed bleeding risk to be similar to ASA in those who were unsuitable for warfarin.
