[Chapter 31. Food Allergy and Intolerance](#)

CHAPTER 29

Asthma

John D. Mark, MD

Pathophysiology

Asthma is a common chronic respiratory disorder characterized by episodes of airway obstruction and reversibility. Asthma affects more than 25 million persons in the United States, of which approximately 18 million are adults.¹ Asthma is known to be a complex inflammatory process caused by many factors including genetic predisposition, environmental exposures, viral infections, and other host factors such as lack of breastfeeding, second-hand smoke exposure, and prenatal stress.² The symptoms of asthma are usually recurrent episodes of wheezing, dry cough, chest tightness, and breathlessness. This chronic inflammation leads to bronchial hyperresponsiveness to various stimuli and results in the clinical manifestations and severity of asthma as well as subsequent responses to treatment.

Research into the immunological basis of asthma has shown that in susceptible individuals, chronic inflammation of the airways occurs and is characterized by infiltration of mast cells, eosinophils, and T-helper cell type 2 (Th2) CD4⁺ T-lymphocytes. Eosinophils are recruited via a chemical gradient due to the release of chemotactic agents, such as interleukin (IL)-5, and induce epithelial damage. This Th2 response within the lung then triggers an aberrant injury-repair mechanism that may lead to airway remodeling.³ Finally, Th2 cells induce the production of allergic antibody immunoglobulin E (IgE), ultimately resulting in the clinical manifestation of allergy and asthma.

Risk Factors and Triggers

Investigators believe that asthma often begins in childhood and may

result from an interaction of several factors ([Fig. 29.1](#)). Studies of case-controls and genomic linkages have identified 10 genomic regions and more than 100 genes associated with allergy and asthma. There are consistently replicated regions on the long arms of chromosomes 2, 5, 6, 12, and 13. This wide heterogeneity illustrates that the basis of asthma is both genetic predisposition and gene-by-environmental interactions.⁴ Thus the natural course of asthma varies considerably according to asthma phenotype and various environmental influences.

Asthma symptoms can be triggered by a variety of exposures ([Table 29.1](#)). Infections with viruses, such as respiratory syncytial virus and rhinovirus, have been thought to be triggers not only because they cause airway swelling and obstruction, but also because they influence cellular responses of the immune system increasing, thereby increasing susceptibility to asthma. The lung microbiome may also play a significant role in both the etiology of asthma and in asthma control. Certain viral and bacterial infections may alter the asthma phenotype. Recent studies have shown that bacterial colonization of the airways in neonates with *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* are associated with an increased risk of pneumonia and bronchiolitis in early childhood independent of current asthma.⁵ Once microbes become established in the lungs, a balance to maintain homeostasis may occur. Any imbalance in the microbial community may cause airway disease, such as asthma. Establishment of the lung microbiome is not static but dynamic and may affect the relationship between the microbiota and lung-specific immunity.⁶

Other key factors associated with poor asthma control include overestimation of asthma control by patients and physicians, improper technique in using inhaled medications, and nonadherence to therapies (particularly controller medications). These factors may lead to increased exacerbations, more hospitalizations, and higher mortality rates.⁷ Understanding current asthma guidelines, measuring lung function, and monitoring medication use, in addition to improving adherence and education, may improve asthma control ([Fig. 29.2](#)).

Integrative Therapy

Lifestyle

Environment

Reducing exposure to environmental triggers, such as dust mites and cockroaches, to which many patients with asthma are sensitive is important. House dust mites, which are microscopic insects that live off dead skin cell flakes, are all around us despite being too small to see. The mites and their waste products can be allergenic. To limit exposure to dust mites, particularly in the bedroom where they are most common, one should (1) enclose pillows and mattresses in airtight polyurethane covers or use fiberfill products instead of down or foam pillows, (2) remove carpeting (hardwood or linoleum floor is better) and curtains, (3) wash sheets and stuffed toys (for pediatric patients) in hot water every week, and (4) clean bedrooms frequently with a vacuum that has a high-efficiency particulate air (HEPA) filter. Cockroaches and their feces are also a recognized trigger for asthma, so cleanliness is important to decrease their presence. In addition, it helps to wash floors and counters frequently to eliminate cockroach debris. Other important control measures include eliminating exposure to tobacco smoke and removing pets from the home.

FIG. 29.1 Asthma severity may change with environment, activities, and other factors. When the patient is well, monitoring and treatment are still needed to maintain control.

TABLE 29.1**Triggers of Asthma Symptoms**

- Allergens, such as house dust mites, pets, and pollens
- Colds and viral infections
- Exercise
- Gastroesophageal reflux disease (stomach acid flowing back up the esophagus)
- Medications and foods
- Emotional anxiety
- Air pollutants, such as tobacco smoke, wood smoke, chemicals, and ozone
- Occupational exposure to allergens, vapors, dust, gases, and fumes
- Strong odors and sprays, such as perfumes, household cleaners, cooking fumes, paints, and varnishes

Nutrition

Diet therapy or nutritional advice is the most common “alternative” therapy prescribed by nonallopathic physicians for patients with asthma. In theory, diet can modulate intestinal flora (gut microbiome), affect immune maturation, and interact with underlying genetic dispositions in the development and even the origin of asthma. Nutrition, including the type of foods (saturated fats, amount of fiber), may influence the gut microbiome; studies have shown that having fewer bacterial species, such as *Lactobacilli*, *Bacteroidetes*, and *Bifidobacteria*, in addition to having more coliform bacteria, such as a *Clostridia* and *Enterococci*, may lead to allergic sensitization.⁸ Clinicians have long thought that eliminating certain “allergenic” foods and decreasing exposure to foods, such as dairy products (believed to be associated with increased mucus production), will help improve chronic asthma symptoms and their severity; however, studies have not supported this theory.⁹ Avoidance of certain foods or food types is a common practice. Food-induced asthma is rare; however, many patients feel that certain foods can trigger asthma exacerbations, so an elimination diet may be used.¹⁰ The easiest way to

conduct an elimination diet is to pick a food to which the patient appears to be sensitive, such as nuts or eggs, and then eliminate it from the diet for 2 weeks. At the end of 2 weeks, gently reintroduce the food into the diet. If a significant change occurs, such as bloating or headaches, the patient may indeed be sensitive to that particular food (see [Chapter 86](#)). Epidemiological studies have indicated that dietary habits influence lung function, with populations with a higher intake of polyunsaturated fatty acids (omega-6 fatty acids) shown to have a higher prevalence of asthma, eczema, and allergic rhinitis, and those with increased intake of omega-3 fatty acids to have a lower prevalence of atopy and asthma.¹¹ The use of the Mediterranean diet, which includes high consumption of fruits, vegetables, olive oil, whole grains, regular fish intake (with decrease in meat), has been posited to have utility in both preventing and treating asthma.^{12,13}

The following are the nutritional recommendations for patients with asthma:

1. Eliminate potential allergens:
 - a. Any food associated with a history of intolerance (gastrointestinal disturbance or eczema)
 - b. Sulfites (especially in dried fruits)
 - c. Food additives (aspartame, benzoates, and yellow dye no. 5)
 - d. Dairy products (for a trial period, as mentioned previously)
2. Increase intake of fruits and vegetables because they are rich in antioxidants, levels of which have been shown to be low in patients with chronic lung problems such as asthma.
3. Increase intake of omega-3 fatty acids by eating cold-water fish (e.g., sardines, herring, and salmon) and reduce intake of omega-6 fatty acids by eliminating vegetable oils and instead using olive oil (see [Chapter 88](#)).

If intake of dairy products is decreased or eliminated (especially in children), a calcium supplement should be considered.

Exercise

Although exercise can induce symptoms in patients with asthma, numerous studies have shown that asthma can be better controlled in patients who exercise regularly. No study has yet reported the superiority of one type of exercise over another. Investigators have long assumed that swimming may be beneficial as the environment is moister

and cold, dry air may exacerbate asthma symptoms. However, studies have not supported this concept. Instead, any type of exercise performed on a regular basis that does not increase symptoms should be encouraged. In addition, studies have reported that swimming in highly chlorinated pools or indoor pools with possible mold exposure may exacerbate asthma symptoms.¹⁴ A recent Cochrane review concluded that the overall quality of studies regarding water-based exercise and asthma was low but did observe clear differences between water-based exercise and comparator treatments.¹⁵ The older the patient, the greater the efficacy of exercise regimens in managing asthma. This effect may, in part, be attributable to improved self-image and overall health associated with regular exercise in adults.

STEPWISE APPROACH FOR MANAGING ASTHMA LONG TERM

The stepwise approach tailors the selection of medication to the level of asthma severity or asthma control. The stepwise approach is meant to help, not replace, the clinical decisionmaking needed to meet individual patient needs.

	STEP 1	STEP 2	STEP 3	STEP 4	STEP 5	STEP 6	
At each step: Patient education, environmental control, and management of comorbidities							
0-4 years of age	Intermittent asthma		Persistent asthma: daily medication				
	SABA* as needed		Consult with asthma specialist if step 3 care or higher is required. Consider consultation at step 2.				
	Preferred treatment†	SABA* as needed	Low-dose ICS*	Medium-dose ICS*	Medium-dose ICS* + Either LABA* or montelukast	High-dose ICS* + Either LABA* or montelukast	High-dose ICS* + Either LABA* or montelukast + Oral corticosteroids
	Alternative treatment‡		Cromolyn or montelukast				
	if clear benefit is not observed in 4-6 weeks, and medication technique and adherence are satisfactory, consider adjusting therapy or alternate diagnosis.						
Quick-relief medication	+ SABA* as needed for symptoms. Intensity of treatment depends on severity of symptoms. + With rare respiratory symptoms: SABA every 4-6 hours up to 24 hours (longer with physician consult). Consider short course of oral systemic corticosteroids if asthma exacerbation is severe or patient has history of severe exacerbations. + Caution: frequent use of SABA may indicate the need to step up treatment.						
5-11 years of age	Intermittent asthma		Persistent asthma: daily medication				
	SABA* as needed		Consult with asthma specialist if step 4 care or higher is required. Consider consultation at step 3.				
	Preferred treatment†	SABA* as needed	Low-dose ICS*	Low-dose ICS* + Either LABA*, LTRA* or theophylline§	Medium-dose ICS* + LABA*	High-dose ICS* + LABA*	High-dose ICS* + LABA* + Oral corticosteroids
	Alternative treatment‡		Cromolyn, LTRA* or theophylline§	OR medium-dose ICS	Medium-dose ICS* + Either LTRA* or theophylline§	High-dose ICS* + Either LTRA* or theophylline§	High-dose ICS* + Either LTRA* or theophylline§ + Oral corticosteroids
	Consider subcutaneous allergen immunotherapy for patients who have persistent, allergic asthma.**						
Quick-relief medication	+ SABA* as needed for symptoms. The intensity of treatment depends on severity of symptoms: up to 3 treatments every 20 minutes as needed. Short course of oral systemic corticosteroids may be needed. + Caution: Increasing use of SABA or use >2 days/week for symptom relief (not to prevent EIB†) generally indicates inadequate control and the need to step up treatment.						
≥12 years of age	Intermittent asthma		Persistent asthma: daily medication				
	SABA* as needed		Consult with asthma specialist if step 4 care or higher is required. Consider consultation at step 3.				
	Preferred treatment†	SABA* as needed	Low-dose ICS*	Low-dose ICS* + LABA* OR medium-dose ICS*	Medium-dose ICS* + LABA*	High-dose ICS* + LABA*	High-dose ICS* + LABA* + oral corticosteroids§§ AND consider omalizumab for patients who have allergies††
	Alternative treatment‡		Cromolyn, LTRA* or theophylline§	Low-dose ICS* + Either LTRA* theophylline§ or zileuton ††	Medium-dose ICS* + Either LTRA* theophylline§ or zileuton ††		High-dose ICS* + LABA* AND consider omalizumab for patients who have allergies††
	Consider subcutaneous allergen immunotherapy for patients who have persistent, allergic asthma.**						
Quick-relief medication	+ SABA* as needed for symptoms. The intensity of treatment depends on severity of symptoms: up to 3 treatments every 20 minutes as needed. Short course of oral systemic corticosteroids may be needed. + Caution: Use of >2 days/week for symptom relief (not to prevent EIB†) generally indicates inadequate control and the need to step up treatment.						

* Abbreviations: EIB, exercise-induced bronchoospasm; ICS, inhaled corticosteroid; LABA, inhaled long-acting beta₂-agonist; LTRA, leukotriene receptor antagonist, inhaled short-acting beta₂-agonist.
 † Treatment options are listed in alphabetical order, if more than one.
 ‡ If alternative treatment is used and response is inadequate, discontinue and use preferred treatment before stepping up.
 § Theophylline is a less desirable alternative because of the need to monitor serum concentration levels.
 ** Based on evidence for dust mites, animal dander, and pollen; evidence is weak or lacking for molds and cockroaches. Evidence is strongest for immunotherapy with single allergens. The role of allergy in asthma is greater in children than in adults.
 †† Clinicians who administer immunotherapy or omalizumab should be prepared to treat anaphylaxis that may occur.
 ‡‡ Zileuton is less desirable because of limited studies as adjunctive therapy and the need to monitor liver function.
 §§ Before oral corticosteroids are introduced, a trial of high-dose ICS + LABA + either LTRA, theophylline, or zileuton, may be considered, although this approach has not been studied in clinical trials.

FIG. 29.2 Stepwise Approach for the Long-Term Management of Asthma. (From the Department of Health and Human Services: Guidelines (from the National

Mind-Body Therapy

Breathing Exercises

Breathing exercises and breathing retraining have been used in the management of asthma (Buteyko, yoga, physical therapy). One specific form of breathing therapy, known as the Buteyko breathing technique, has been posited to have benefit in treating asthma by decreasing respiratory rate and allowing the carbon dioxide concentration in the lungs and blood to rise, thus resulting in bronchodilation. This technique dates back to 1952, when Dr. Buteyko theorized that “hidden” hyperventilation caused asthma symptoms. In vitro studies have indicated low alveolar carbon dioxide pressures may result in bronchoconstriction and greater airway resistance. Results of other studies suggest that the Buteyko breathing technique may be beneficial in treating asthma but were limited by small samples sizes. A study measuring end-tidal carbon dioxide (ETCO₂) found no correlation between ETCO₂ and breath-holding time, with the investigators postulating that the Buteyko breathing technique may help by improving the biomechanics of breathing.¹⁶ A systematic review concluded that “no reliable conclusions can currently be drawn concerning the use of breathing exercises for asthma in clinical practice.”¹⁷ A larger randomized controlled trial reported that the use of the Buteyko technique for 6 months was associated with improved asthma control, and those using Buteyko had an additional benefit of reduced inhaled corticosteroid use¹⁸ (see [Chapter 92](#)).

Yoga

Yoga embodies many of the previously discussed therapies for improving the health of patients with asthma. Yoga has a cardiovascular component because it is a form of exercise. This mind-body method involves using regulated breathing exercises (pranayama), with relaxation and meditation also included in many yoga practices. One study reported that yoga reduced airway hyperresponsiveness and improved some aspects of quality of life.¹⁹ In a separate study of 132

adults with mild asthma who were randomized into a yoga group and a control group, the yoga group had significantly improved lung function after 8 weeks. Both groups continued their regular pharmacological treatments.²⁰ Although promising, a recent review of yoga and asthma studies including 14 randomized controlled trials with 824 patients reported that yoga was associated with improvements in asthma control, quality of life, peak expiratory flow rates, and the ratio of forced expiratory volume in 1 second compared to psychological interventions. However, the authors concluded that no effect was robust enough against all potential sources of bias and could not be used as a routine intervention but may be considered as an ancillary or alternative therapy for asthma.²¹

Biochemical

Botanicals

The use of botanicals is one of the oldest and most widely used therapeutic approaches in asthma care worldwide. Although the amount of knowledge and information regarding herbal or botanical treatment of asthma is large, a significant portion is not based on well-designed or well-performed clinical studies.²² There have been several systematic reviews that continue to show the lack of high quality randomized controlled studies using botanicals in the treatment of asthma.^{23,24} The use of herbal remedies is reportedly associated with lower adherence to conventional medications, particularly inhaled corticosteroids.²⁵ Many of the botanicals used for the treatment of asthma are similar to pharmaceuticals in terms of chemical properties. Further, many are used traditionally, and tradition varies by culture.

Boswellia (*Boswellia serrata*)

Boswellia (also known as salai guggal or Indian frankincense) is a botanical used frequently in Ayurvedic medicine and traditionally used for inflammatory disorders, such as asthma and arthritis. Boswellic acid, the major constituent of *Boswellia*, is thought to inhibit 5-lipoxygenase and leukotriene synthesis, and this may be the mechanism for its antiinflammatory properties. *Boswellia* may enhance the effectiveness of conventional leukotriene modifier medications (see later). A small placebo-controlled study in adults reported that subjects taking *Boswellia* had fewer asthma exacerbations and improved lung function.²⁶

Dosage

A common dosage recommendation is 300 mg three times / day.

Precautions

Few precautions have been reported other than occasional gastrointestinal effects, such as epigastric pain, heartburn, nausea, and diarrhea.

Coleus (*Coleus forskohlii*)

Coleus is a fairly uncommon botanical in the United States but has a long history of use for respiratory and asthma problems in India in the Ayurvedic medicine tradition. A member of the mint family, *Coleus forskohlii* grows wild on the mountain slopes of Nepal, India, and Thailand. Traditionally, coleus was used for numerous purposes including treatment of rashes, asthma, bronchitis, insomnia, epilepsy, and angina. Coleus is thought to act much like theophylline and has been studied as an effective bronchodilator. Coleus has been shown to increase intracellular cyclic adenosine monophosphate levels and stabilize cells that release histamine, although its clinical value is still to be determined. One study showed that an inhaled dose of forskolin powder from an inhaler device increased lung function by improving forced expiratory volume in 1 second (FEV₁) in patients with asthma.²⁷ However, another study compared the efficacy of oral forskolin versus inhaled beclomethasone for mild or moderate persistent adult asthma and found no statistically significant difference between the forskolin and beclomethasone treatment groups in any lung function parameter at baseline or after treatment.²⁸

Dosage

A common dosage recommendation for coleus is 50 mg two or three times / day of an extract standardized to contain 18% forskolin or a 10-mg dose using an inhaler device.

Precautions

No precautions have been reported; however, coleus should be used

with caution in patients receiving antihypertensive (beta blocker) or anticoagulant therapy. Pregnant women should not take coleus or any derivative.

Ma Huang (*Ephedra sinica*)

Ma huang, also known as Chinese ephedra and Chinese joint fir, has been commonly used as an asthma remedy in China for thousands of years. The pharmaceutical ephedrine (derived from *Ephedra sinica*) was used in asthma therapy until the advent of more specific beta-agonist medications. Ma huang may be part of many combinations of other botanicals, including licorice and other antiinflammatory agents. Botanicals and supplements containing ephedra alkaloids have now appeared in many preparations for losing weight and increasing energy.

Precautions

Ephedra is not recommended for use in the treatment of asthma due to warnings from the U.S. Food and Drug Administration (FDA) and reports of serious side effects, particularly when used in combination with caffeine and other stimulants, such as bitter orange.

Ma huang botanicals and combination products have serious potential for side effects. Deaths associated with the use of ma huang have been reported. Central nervous system problems, such as nausea, vomiting, sweating, and nervousness, in addition to palpitations, tachycardia, hypertension, anxiety, and myocardial infarction, have been reported.²⁹

Complications, including death, have been reported when ma huang is taken at high doses or with caffeine-containing products. Deaths have been reported with just one use of ma huang.

Licorice (*Glycyrrhiza glabra*)

Licorice, also known as liquorice, sweet wood, and sweet root, has been used as a cough remedy and asthma treatment. The active ingredient is glycyrrhizin, also known as glycyrrhizic acid. The effect of licorice in treating asthma derives antiinflammatory effects and the enhancement of endogenous steroids. Licorice is also thought to be an expectorant, aiding in the expulsion of mucus from the bronchial passages, and a demulcent, which can be soothing to irritated airways and bronchioles.

Dosage

Licorice is available in several forms such as dried root, which can be used as an infusion or decoction. The dried root dose is usually 1.0 to 5.0 g three times per day. If a licorice tincture is used (1:5 strength is common), the dose is 2 to 5 mL three times a day. Finally, the standardized extract (containing 20% glycyrrhizic acid) dose is 250 to 300 mg three times a day.

Precautions

The side effects of licorice are minimal if less than 10 mg of glycyrrhizic acid is taken daily and prolonged use is avoided. Long-term use, however, can cause headache, hypertension, dizziness, edema, and other signs of aldosteronism (through the binding of mineralocorticoids). Licorice may also cause low serum potassium and should be avoided in patients taking cardiac glycosides, blood pressure medications, corticosteroids, diuretics, or monoamine oxidase inhibitors. A deglycyrrhized licorice (DGL) is available, but its effectiveness has not been well studied and may not be as effective as other products containing glycyrrhizin.

Pycnogenol

Pycnogenol (a proprietary mixture of water-soluble bioflavonoids extracted from French maritime pine) has been used for its antiinflammatory properties in conditions such as asthma. Pycnogenol is a blend of several bioflavonoids, including catechin, epicatechin, taxifolin, oligomeric procyanidins, and phenolic fruit acids such as ferulic acid and caffeic acid. This preparation is thought to exert its effect by blocking leukotrienes and other cytokines that increase inflammation and cause asthma symptoms. A study in children with asthma reported that Pycnogenol improved pulmonary function and reduced the need for rescue medications.³⁰ In a more recent study of 76 adults using Pycnogenol in addition to inhaled corticosteroids (ICS) or ICS alone, the Pycnogenol group had better control of signs and symptoms of allergic asthma and a reduced need for medications, predominantly a reduction in the strength of ICS required.³¹

Dosage

Pycnogenol is supplied in 30-, 50-, and 100-mg tablets. The usual dosage is 30 to 100 mg/day for maintenance therapy. The manufacturer recommends 1 mg/kg/day.

Precautions

No serious side effects have been reported; however, Pycnogenol is recommended to be taken with or after meals because it has an astringent taste. Minor side effects, including gastrointestinal discomfort, headache, nausea, and dizziness, have been reported, which resolve when the botanical is discontinued.

Herbal Mixtures

Japanese combination herbs and remedies (Kampo), such as Saiboku-to, blend black cumin, chamomile, cinnamon, cloves, rosemary, sage, spearmint, and thyme into a botanical combination that reduces asthma symptoms. This combination is thought to be effective due to antiinflammatory properties of blocking 5-lipoxygenase and inhibiting platelet-activating factor (PAF).³² PAF is produced by several inflammatory cells, including eosinophils, and is thought to cause airway hyperreactivity, microvascular leaks, increased airway secretions, and epithelial permeability. Other trials using traditional Chinese medicine herb mixtures have reported potential utility in improving asthma control. These mixtures include ASHMI (a traditional herbal mixture) and Ding Chuan Tang, with both shown to improve asthma control and airway reactivity.^{33,34} However, a Cochrane review of 27 studies using various herbal treatments (1925 subjects) found that the studies varied considerably and noted small sample sizes along with poor reporting quality and a wide variety of treatment regimens. Although the studies did provide some insight into the long-term efficacy and harm profiles of these various treatments, no recommendation for their standard use in the treatment of asthma could be made.³⁵

Dosage

Combination herbal preparations are usually prepared as a tea and taken two to four times/day, depending on the particular mixture and

brand used.

Precautions

No side effects have been reported with these combination therapies.

Supplements

Vitamin and Mineral Overview

In addition to botanical and herbal preparations, vitamins and minerals are frequently used for the long-term treatment of asthma. As with most of the treatments mentioned thus far, few studies support the use of supplements despite their use historically for the treatment of asthma and chronic respiratory symptoms.

Vitamin C

Vitamin C has been extensively studied in asthma; however, results have been mixed. It has been proposed that vitamin C may be protective because it is involved in the metabolism of histamine, prostaglandins, and cysteinyl leukotrienes, which all have been associated with exercise-induced bronchoconstriction (EIB). A recent meta-analysis concluded that vitamin C slowed decreases in lung function compared to control treatment in a subset of patients.³⁶ Another review of studies for using vitamin C for both asthma and exercise-induced bronchoconstriction analyzed 11 trials with over 400 subjects (only one study involved children). The authors concluded, by rating the quality of the studies, that there was no significant difference between vitamin C and placebo.³⁷

Dosage

The recommended dose of vitamin C is 250 to 500 mg once or twice a day.

Vitamin D

As with vitamin C, numerous studies have examined vitamin D levels and their correlation with asthma. Recent studies have demonstrated important roles of vitamin D outside of bone health, particularly in asthma and immune function. Because all cells in the body have vitamin

D receptors, vitamin D may play an integral part in immune function and affect Th1 and Th2 cytokines, which play a role in the development of atopy and asthma.³⁸ Vitamin D deficiency has been linked to asthma in children and shown to be correlated with severity of symptoms, increased exacerbations, and need for asthma medications.³⁹ In a survey of 616 children, serum vitamin D levels were associated with airway reactivity, hospitalizations, and the use of antiinflammatory drugs.⁴⁰ However, a study in adults (n = 207) with persistent asthma and vitamin D deficiency did not show a benefit in the prevention of asthma exacerbation when vitamin D was added to inhaled steroids.⁴¹ Lower vitamin D levels have also been shown to be inversely associated with recent upper respiratory tract infections, which are a common trigger of acute asthma.⁴² Taking supplemental vitamin D for the prevention of upper respiratory tract infections may help decrease asthma exacerbations.

Dosage

The recommended dose for vitamin D depends on patient age and the presence of vitamin D deficiency. For bone health, the recommended dose of vitamin D is 400 IU per day for children under the age of 1 year and 600 IU per day for those above the age of 1 year. However, many practitioners use doses up to 4000 IU per day with monitoring of serum levels of 25-hydroxyvitamin D (25[OH]D).

Precautions

The safe vitamin D dosing range is unknown; however, an excess of vitamin D may cause abnormally high serum levels of calcium that may damage bones, soft tissues, and kidneys.

Vitamin E

Vitamin E refers to eight tocopherols with variable antioxidant properties that are present in foods in differing amounts. Of these, α -tocopherol has been reported to have beneficial effects on lung function and wheezing in asthma. However, dietary supplementation with α -tocopherol reportedly has no effect on FEV1, asthma symptoms, or bronchodilator use in adults with mild-to-moderate asthma.⁴⁴ In epidemiological studies, intake of vitamin E by diet or supplementation has been associated with fewer

pulmonary problems, with poorly controlled asthma shown to be associated with low vitamin E levels.⁴⁵

Dosage

The recommended dose of vitamin E is 400 units/day of mixed tocopherols.

Precautions

The risk of all-cause mortality may be increased with prolonged use of doses greater than 400 units daily.

Magnesium

The role of magnesium in decreasing bronchospasm has been evaluated by both the conventional medical and the complementary and alternative medicine communities. Intravenous magnesium is now commonly used for serious asthma symptoms (status asthmaticus). The use of oral magnesium has also been studied. In adults, magnesium was shown to decrease symptoms but not to improve pulmonary function in one study and to have no benefit in another.⁴⁶ In a more recent study of 55 adults taking 340 mg of magnesium a day for 6 months, objective measurements of lung function, including bronchial reactivity to methacholine and peak flow measurements, improved in addition to subjective measures of asthma control and quality of life.⁴⁷

Dosage

The recommended dose of magnesium is 200 to 400 mg/day. Magnesium gluconate and magnesium glycinate are the forms least likely to cause diarrhea.

Precautions

Oral preparations of magnesium may cause diarrhea.

Selenium

Selenium is a potent antioxidant used in the treatment of many

inflammatory conditions, including asthma. Selenium is incorporated into glutathione peroxidase, which may protect cells against oxidative stress. Studies have reported that increased selenium levels are associated with a reduction in the prevalence of asthma.⁴⁸ The results of studies using selenium supplementation have been inconsistent regarding the control or treatment of chronic asthma. This inconsistency may result from the complex relationship between selenium and asthma, as selenium can augment the oxidative stress that accompanies asthma but also exert significant effects on various immune responses.⁴⁹

Dosage

The recommended dose of selenium is 100 to 200 mcg/day.

Precautions

When selenium is consumed in amounts exceeding 400 mcg/day, symptoms of toxicity may appear including nausea, vomiting, abdominal pain, fatigue, irritability, and weight loss.

Fish Oil

The use of antiinflammatory medications is now standard in the asthma treatment. If patient diets could be altered to decrease the propensity for the development of inflammatory precursors, conditions such as asthma would be less problematic. The inclusion of adequate amounts of dietary omega-3 essential fatty may limit leukotriene synthesis by blocking arachidonic acid metabolism. Because omega-3 fatty acids have the potential to resolve inflammation, omega-3 fatty acid intake is hypothesized to improve asthma by reducing.⁵⁰ A rich source of omega-3 fatty acid is fish oils. As eating cold-water oily fish (mackerel, sardines, herring, salmon, and cod) is not common in most Western diets, the use of fish oil capsules has become increasingly standard. Epidemiological studies have shown diets high in cold-water oily fish to significantly reduce the risk of asthma and improve pulmonary function. The vegetarian sources of omega-3 fatty acids (flaxseed oil, canola oil, and soy oil) are used even less in most diets, so the study of fish oil in asthma has been primarily investigated.

In one prospective study, dietary supplementation of omega-3 fatty acids in infants at high risk of developing asthma was associated with a

small reduction in wheezing episodes in the first 18 months; however, this association was no longer present by age 5.^{51,52}

Dosage

One 500-mg capsule of fish oil is taken two to three times/day. Benefit may not be evident for several months.

Pharmaceuticals

Bronchodilators

Bronchodilators have long been used to help alleviate bronchospasm and difficulty with breathing associated with asthma “attacks.”

Bronchodilators belong to several different classes. Commonly used beta agonists include albuterol, salmeterol, and formoterol. Levalbuterol is similar to albuterol and has been purported to have fewer cardiovascular side effects. The methylxanthines (theophylline and aminophylline) are used as second- or third-line drugs because they have more significant side effects, and their use requires serum level monitoring.

Dosage

- Albuterol: two to four puffs of a metered-dose inhaler (MDI) one to three times/day, as needed, or via nebulizer (unit dose) every 4–6 hours as needed
- Levalbuterol: one inhalation vial (three strengths) per nebulizer three times/day or two puffs one to three times/day by MDI as needed
- Salmeterol or formoterol (long-acting beta-agonist): one actuation of a dry powder inhaler (DPI) twice a day
- Methylxanthines (theophylline): dosage dependent on age and weight

Precautions

Beta agonists may cause rapid or irregular heartbeat, insomnia, and nervousness. Anticholinergic medications have few side effects, except for occasional dry mouth or headache. The theophylline-type medications may cause tremor, shakiness, nausea, and vomiting.

Overdose of methylxanthines can cause serious problems, such as seizures and cardiac arrhythmias.

Antiinflammatory Medications

Antiinflammatory medications are considered the most important components of the pharmacological approach to asthma care. Several categories of these medications are available, usually listed as steroidal and nonsteroidal. The steroidal MDIs and DPIs include fluticasone, beclomethasone, mometasone, ciclesonide, and budesonide. Newer proprietary preparations that have been shown to reduce the need for higher doses of the steroidal preparations include combinations of an inhaled steroid (fluticasone, budesonide, or mometasone) with a long-acting bronchodilator (salmeterol or formoterol). Oral preparations, such as prednisone, prednisolone, and methylprednisolone, are also available. Nonsteroidal medications include the leukotriene inhibitors montelukast and zafirlukast. These medications act by blocking certain pathways involved in airway inflammation once exposure (allergic, irritant, infectious, emotional, or exercise) has occurred. The oral steroids are considered the most potent agents and have the greatest potential for significant side effects.

Dosage

The dosage of leukotriene inhibitors differs according to the specific type used. The dosage of montelukast, for example, is 10 mg/day for adults and 5 mg/day for children (chewable tablets). For a child younger than 5 years, 4 mg/day is recommended (not to be used in children younger than 12 months).

Dosages for steroidal inhalers are usually two puffs (or one actuation of the DPI) twice/day. Oral steroids are usually taken at 1 to 2 mg/kg or 20 to 40 mg/day (adults) for varying amounts of time. A short “burst” of treatment may be prescribed for 3 to 5 days in total.

Precautions

Nonsteroidal medications have few side effects. Leukotriene inhibitors may cause headache or mood changes. Liver function should be monitored as some nonsteroidal medications may cause hepatic

dysfunction. The steroidal medications, particularly oral preparations, may cause decreased height velocity (in children), immune suppression, hypertension, cataracts, and hirsutism (if taken long-term or at high dose). The inhaled forms have less common side effects and have been studied long-term in children⁵³; however, they may cause hoarseness, cough, and oral candidiasis unless a spacer is used or thorough mouth rinsing is practiced. Combination medications (corticosteroids plus a long-acting beta agonist such as fluticasone and salmeterol) have a black box warning given by the FDA due to the possibility that some patients may have worsening of symptoms when using these types of medications, including increased asthma exacerbations and even death.

The newer antiinflammatory steroidal inhalers, used alone or in combination with a long-acting bronchodilator, constitute the most innovative and effective pharmacological approach to chronic asthma care.

Biomechanical Approaches

Massage

Massage therapy is an ancient treatment, dating back to the second century in China. It was referred to as the *art of rubbing* and was common until pharmaceuticals began to be heavily used instead, starting in the 1950s. Massage now commonly consists of using variable pressure, tension, and vibration on various parts of the body. Few studies have investigated the efficacy of massage, with studies performed before the 1990s limited by sampling issues, lack of controls, sample size, and inappropriate use of statistical analysis.^{54,55} However, improvements in pulmonary function have been reported after massage in children with asthma.⁵⁶ A more recent open parallel-group, randomized controlled trial study of 60 children with asthma (30 in each group) was conducted using 20 minutes of massage by parents at bedtime for 5 weeks. The massage group was found to have significant improvements in lung function (FEV1 and FEV1/FVC). The study also demonstrated good compliance by the parents in performing massage, with many continuing to use massage after the study was completed.⁵⁷

Dosage

The time and duration of massage therapy for the average patient with asthma are not known. The study that reported improvement in asthma symptoms used once-a-day massage for 30 days. Massage can be performed by a family member or friend who has been taught massage techniques or by a massage therapist.

Osteopathy

Osteopathy is another system of medical care that embraces the body as a whole and in which structure and function are closely interrelated. One main premise is that because osteopathy emphasizes that all body systems, including the musculoskeletal system, operate in unison, a disturbance in one system can alter functions of other systems. The main categories of osteopathic manipulative treatment (OMT; e.g., craniosacral, strain-counterstrain, and myofascial) involve more than 100 different individual treatments. OMT has been used for the treatment of both chronic and acute symptoms of asthma. OMT has demonstrated utility in increasing vital capacity and rib cage mobility, improving diaphragmatic function, clearing airway secretions, and improving autoimmune function. Studies of the efficacy of OMT in treating asthma have been small with poor methodology.⁵⁸ A study of 140 pediatric asthma subjects, where 90 subjects received OMT (specifics not provided) and 50 subjects received a sham (light touch) therapy reported a significant improvement in peak flow in the OMT group.⁵⁹ A study of the effectiveness of osteopathic manipulative treatment in pediatric asthma has been posted through the European Institute for Evidence Based Osteopathic Medicine on [ClinicalTrials.gov](https://clinicaltrials.gov) (NIH).⁶⁰

Dosage

The findings of an osteopathic practitioner determine the most appropriate form of OMT. Again, the form chosen may affect any part of the body depending on physical examination. Often, helping the patient use various parts of the chest in breathing may help.

Chiropractic

Chiropractic, the third largest regulated health care profession in North America, has been involved in health care for conditions such as asthma since the late 1800s. The theory of chiropractic care is based on the idea that the properly adjusted body, particularly the spine, is essential for health, with influence on life force and good health attained through the use of spinal manipulation therapy for the removal of subluxations.⁶¹

Although studies on chiropractic treatments in asthma have reported overall improvements in lung capacity, quality of life, and respiratory symptoms, a meta-analysis of these studies, including three randomized controlled trials, concluded that there was insufficient evidence to support the routine use of chiropractic adjustments in the treatment of asthma.⁶²

Dosage

The dosage of chiropractic care depends on the practitioner.

Precautions

Reported complications of chiropractic manual treatments have been documented, but none were found in relation to the treatment of asthma. Chiropractic care often involves repeated use of radiographs, thus making frequent radiation exposure an issue for some patients.

Mind-Body Therapy

Mind-body therapies have been used in the treatment of asthma in various ways. They are at times referred to as *cognitive-behavioral therapies* and encompass several approaches. No single therapy has been shown to be superior over another; however, some therapies appear to be more acceptable to individual patients. Discussing several types of therapy with patients and their families will enhance the success of mind-body interventions. Research in this area started in the early 1960s, and approaches have included relaxation therapy, breathing exercises, biofeedback, and hypnosis, and guided imagery.

The theory behind the use of these therapies is the inflammatory process can be modulated by the autonomic nervous system through emotions. Numerous studies in both children and adults have shown higher levels of anxiety and, at times, panic when asthma symptoms are perceived. In addition to anxiety, stress has been shown to influence the

immune response and may promote a higher sympathetic activity, augment IgE production, cause a shift from a Th1 to a Th2 allergic-type response, and promote airway inflammation without overt symptoms.⁶⁴ Stress has also been shown to enhance airway inflammation in asthma by modulating immune cell function through neural and hormonal pathways.^{65,66,67}

Hypnosis and Guided Imagery

Hypnosis has been used for achieving relaxation, relieving pain, helping with physical discomfort (even chronic pain), and altering moods. Hypnosis is multidimensional and helps patients develop a heightened focus on an idea or image. The process may be brief or may involve complex instructions depending on the subject, the goal, and the therapist. Hypnosis has been shown to be effective in patients whose asthma is mild and those whose symptoms have an emotional component. Studies on hypnosis have reported decreases in symptoms and medication use, as well as improvements in pulmonary function, in “motivated” patients.⁶⁸

Guided imagery involves a form of self-hypnosis in which the patient uses an image of her or his own creation after an initial relaxation period to help reduce asthma symptoms. This method is particularly effective in children with an active and vibrant imagination. Children can often be taught this technique in less than half an hour, with improvements in asthma symptoms observed after a few practice sessions. Guided imagery starts with initial relaxation (using diaphragmatic breathing, known as “belly breathing”) and then progresses to an imagery session. The subject develops an image and then focuses on taking control or command of the perceived airway or lung problem by using this image. An example is moving from a closet to the outdoors, where the child is able to breathe again. This emotion-mediated format enables disclosure and subsequent reframing for the child and allows independence from the chronic illness (see [Chapters 95](#) and [97](#)).

Dosage

As with relaxation, these therapies have the greatest effect if used often, and particularly if used when asthma symptoms are initially mild. This approach prepares the patient for dealing with worse symptoms during an attack.

Disclosure and Journaling

Much like the findings in rheumatoid arthritis, there is evidence to suggest that just having the patient with asthma discuss their symptoms may decrease the severity and frequency of the asthma. Journaling, in which one writes about asthma in a journal three to five times a week for 20 to 30 minutes, has been shown to reduce both symptoms and medication use. In one study, patients wrote in their journals about a stressful event that they had not discussed with others or that had been unresolved, while the control group just about daily events only.⁶⁹ The investigators reported a 13% improvement in lung function, as measured by the FEV₁, in patients who wrote about a stressful experience compared with the control group. In a more recent study, adults aged 18 to 80 years with asthma (n = 154) were instructed to use several integrative medicine interventions consisting of nutritional manipulation, yoga techniques, and journaling. The treatment group showed significant improvement in several areas of the Asthma Quality of Life Questionnaire⁷⁰ (see [Chapter 98](#)).

Other Therapies to Consider

The most appropriate placement of bioenergetic modalities, including traditional Chinese medicine (TCM), healing touch and prayer, and homeopathy, in the stepwise approach to asthma care is challenging. These modalities are suitable for all treatment plans, from the most mild to the most severe cases of asthma. These methods should be used in conjunction with the previously discussed therapies if patients have moderate or severe symptoms and are considered the appropriate first-line treatments in interested patients with mild or intermittent asthma.

Traditional Chinese Medicine

TCM has been practiced for several thousands of years and takes many forms. The basis of TCM is the understanding of the connections between the body, mind, and spirit in health and disease. The belief in an unseen vital energy that affects patient health and the flow of energy or qi (chi) through the appropriate channels is the basis of this practice. Practitioners can affect energy flow or intensity by manipulating balance through the use of acupuncture, Chinese herbs, diet, and physical therapy. TCM can successfully treat many medical conditions.

Acupuncture and other forms of TCM are thought to be beneficial in the treatment of asthma. Clinical observations indicate acupuncture and individually mixed Chinese herbs are effective, although clinical trials have not supported these observations. The National Institutes of Health 1997 Consensus Development Conference on Acupuncture recommended acupuncture for many conditions, including asthma.⁷¹ A study of children with asthma (n = 26 in both the acupuncture and control groups) using asthma diaries as the primary outcome reported a significant reduction in asthma symptoms, in addition to a reduced need for beta-agonist and inhaled steroid use, after 10 weeks of acupuncture treatments. However, no differences were observed between the groups at 8 months after the completion of acupuncture.⁷² In another small study, 52 asthmatic children were randomly selected to receive 10 laser sessions (3 sessions/week) on traditional Chinese acupoints. A significant reduction in asthma symptoms, improvement in lung function (FEV1), and subsequent reduction in the use of inhaled steroids was observed with the use of acupuncture, indicating improved asthma control.⁷³ In a recent review of acupuncture in children, a total of 32 articles were assessed for eligibility, resulting in seven studies (n = 410) being included. The authors concluded that the efficacy of acupuncture was unclear and larger randomized controlled studies are required.⁷⁴

Dosage

The dosage of acupuncture is practitioner-dependent, and the effects of TCM usually take several treatments to appear.

Precautions

Adverse side effects of acupuncture are rare but have been reported, including pneumothoraces.

Homeopathy

Homeopathy is considered an energy medicine because it is not based on the usual physical laws found in science, but rather on the premise that the use of “remedies” that would cause the same symptoms (principle of like cure) and are very dilute (the more dilute, the more potent; law of dilution) represents the most powerful treatments. Practitioners believe that dilution in water actually imparts healing energy, and this energy,

combined with the patient's vital force or energy, is used in healing.

A recent prospective, observational, longitudinal study of individualized homeopathic medicines used adjunctively in 30 children with asthma reported statistically significant improvements in the severity and frequency of nocturnal asthma attacks or awakenings, the use of inhalers and oral corticosteroids, and PFT parameters at 3 and 6 months.⁷⁶ A review of homeopathy in the treatment of respiratory allergies and asthma evaluated evidence from controlled trials considered to be of high quality. The authors concluded that homeopathy may be helpful in combination with conventional therapies in the treatment of respiratory allergies and asthma.⁷⁷ A review of studies of homeopathy in treating asthma (6 trials with a total of 556 subjects were included) concluded there is currently insufficient evidence to reliably assess the potential utility of homeopathy in treating asthma.⁷⁸

Homeopathic remedies depend on the particular patient's symptom pattern and should be individually assessed by an experienced homeopath to select the correct constitutional remedy. Some of the most commonly used homeopathic remedies are as follows:

- *Arsenicum album*: used for asthma with restlessness and anxiety
- *Ipecac*: used for chest constriction and cough
- *Pulsatilla*: used for chest pressure and air hunger
- *Sambucus*: used for asthma symptoms that awaken one during the night

Dosage

Dosage depends on the individual and on the guidance of the practitioner (see [Chapter 115](#)).

Precautions

Homeopathy is thought to be safe, owing to the extreme dilution, and the treatments are inexpensive.

Prevention Prescription

- Eliminate potential allergens and triggers in the environment.
- Increase fruit and vegetable intake, along with that of omega-3-rich fats, which are found in cold-water fish, nuts, greens, and ground

flaxseed.

- Follow an exercise regimen, and consider other types of activities that incorporate both exercise and meditation, such as yoga and martial arts.
- Take controller medications, such as inhaled steroids and leukotriene-modifier medication, routinely until asthma is no longer persistent and medications can be safely decreased or discontinued.
- Consider adding a multivitamin with antioxidants (vitamins C, D and E, B-complex, selenium) to the diet.
- Botanicals may be helpful in controlling and decreasing asthma symptoms but are best taken under the guidance of a health care provider with experience in using them.
- Mind-body therapies, such as relaxation, visualization, and self-hypnosis, may decrease asthma exacerbations and reduce the need for asthma medications.
- Stress reduction in the home, work place, and school may prevent or decrease asthma symptoms and airway inflammation.

Therapeutic Review

The following is a summary of therapeutic options for treating asthma. If a patient is having persistent symptoms (daily wheezing, shortness of breath, difficulty sleeping, or difficulty exercising) or severe symptoms (even if intermittent), it is best to prescribe more aggressive therapy, such as beta-agonists or antiinflammatory medications, as controller medications. For patients with mild to moderate or intermittent symptoms, this stepwise approach may be considered.

Lifestyle

- As with many chronic illnesses, asthma prevention is considered the best approach. Unfortunately, changing a patient's lifestyle, including their environment, is challenging. Due to cultural and regional differences in the United States, patient populations differ in how they approach chronic illness and the way they use medical care.

Environmental

- Reducing exposure to asthma triggers can be therapeutic in itself.

House dust mite reduction, frequent cleaning, use of HEPA filters, avoidance of secondhand smoke, and removal of all pets from the home will help decrease airway “irritability.” 

Nutrition

- Asthma symptoms often diminish following elimination of allergenic-type foods, such as dairy products (at least for a trial period); shellfish; and foods with nitrites, sulfites, added food coloring, and artificial sweeteners. Patients should consider increasing intake of organic fruits and vegetables for their antioxidant contribution, as well as foods rich in omega-3 fatty acids while decreasing those containing omega-6 fatty acids (vegetable oils). 

Supplements

- Magnesium: 200 to 400 mg/day 
- Fish oil: 1 g (eicosapentaenoic acid plus docosahexaenoic acid) twice daily 
- Vitamin D: 400 units for children younger than 4 years of age and 600 units daily for adults 
- Vitamin C: 250 mg twice daily 
- Vitamin E: 400 units a day or less of mixed tocopherols 

Mind-Body Therapy

- These techniques can be beneficial in the treatment of asthma, and breathing and relaxation are excellent places to start. 
- Guided imagery and hypnosis therapies are readily available in most communities and also help decrease symptoms, medication use, and physician or urgent care visits. Usually, these methods should be used regularly (once or twice daily) until familiar to the patient. They can then be used as needed for asthma symptoms. 
- Journaling is also recommended, and patients should spend at least 20 minutes writing about their asthma or other stressors in their lives three times per week. 

- Cognitive therapies should not be used in place of medications, particularly if symptoms are moderate or severe. If the patient is using a peak flow meter, these therapies can be used while peak flow values are in a safe range.

Exercise

- Exercise not only has benefits in managing asthma (three to five periods of exercise lasting a minimum of 20 minutes per week), but also improves self-esteem, weight loss, and cardiovascular health. Exercise should be used with caution in patients with exercise-induced asthma. 

Botanicals

- Coleus: 50 mg three times/day 
- Kampo (also known as Kanpo) is a mixture of Japanese herbs found in powder form, such as Easy-Breather Tea (Yama's Herbs, New York): 3 rounded teaspoons in warm water two to three times/day 
- Pycnogenol: 30 to 100 mg/day or 10 mg/kg/day, taken two to three times/day 

Pharmaceuticals

- For patients with mild to moderate symptoms that are persistent, starting with pharmaceutical agents with antiinflammatory properties, such as fluticasone two puffs of a 110 metered-dose inhaler (110 mcg/inhalation) twice daily, or budesonide one actuation twice daily, will improve symptoms in the majority of patients while the other interventions mentioned previously can be started. For acute symptoms, albuterol two puffs twice daily or levalbuterol two puffs twice daily should be considered. These medications should be considered first-line therapy for patients with persistent or severe symptoms. 
- Other medications, such as leukotriene modifiers (montelukast 10 mg daily), may also be considered. 

Biomechanical Approaches

- As adjuncts to other modalities and depending on patient preference, massage, osteopathic manipulative treatment, and chiropractic therapies may be very beneficial. All three have different approaches and regimens. Finding a practitioner familiar with treating patients with asthma is the key. 

Key Web Resources

Prevent Asthma Attacks. This website has links to many asthma education and asthma resources, including the American Lung Association.	http://www.aasthma.org/asthma-resources
Allergy and Asthma Network. This nonprofit patient education and advocacy organization provides consumer-friendly information about asthma and allergies.	http://www.aanasa.org/
Guidelines for the Diagnosis and Management of Asthma. The National Institutes of Health, through the National Heart, Lung, and Blood Institute, has published evidence-based guidelines for the treatment of asthma, including several interactive sections on patient and family education and environmental control.	http://www.nlm.nih.gov/ebnl/00-prog/asthma/asthma-guidelines/
Allergy Solutions, Inc. This company sells products for patients with allergies and asthma, including NEPA Ebino, and pillow and mattress covers.	http://www.allergysolutions.com/efact.asp

CHAPTER 30

The Allergic Patient

Randy J. Horwitz, MD, PhD

Allergic diseases are a ubiquitous part of modern life. Nearly 18 million people suffer from allergic rhinitis. If we add in drug allergies, food allergies, and allergic asthma, over 20% of U.S. citizens—approximately 50 million people—are estimated to suffer from an allergic condition, and they annually spend \$8 billion on prescription drugs for treatment of allergic symptoms.¹ A nationwide survey found that more than half (54%) of all U.S. citizens test positive to one or more allergens.² Although acute and chronic allergic diseases may not rank as a leading cause of mortality in the general population, they do constitute a leading cause of work and school absenteeism, generating a significant social and economic burden.

The incidence of allergies (and asthma) is increasing at a dramatic rate.³ Although both genetic and environmental factors are implicated in this rise, the rapidity of the increase favors environmental contributors—either directly or via epigenetic mechanisms. This hypothesis warrants a more careful consideration of modifiable factors that may alter allergic reactivity—factors which are ideally suited to an integrative approach.

This chapter considers general integrative approaches to the patient with atopy or environmental allergies, whether seasonal or perennial. Separate chapters in this volume deal with some of the more prominent allergic and allergy-related conditions, including asthma (see [Chapter 29](#)), atopic dermatitis (see [Chapter 72](#)), and food allergies (see [Chapter 31](#)). Some commonalities link these seemingly disparate disorders, however, and knowledge of these common principles may be helpful in devising treatment recommendations for patients with allergies.

Pathophysiology

The wide range of allergic conditions observed in the clinical setting and described in the literature may lead one to believe that a seemingly infinite number of discrete mechanisms are responsible for allergic symptoms. Despite the diversity in end-organ effects, however, much of the underlying pathophysiology in allergic diseases is remarkably similar. In addition, such knowledge enables the physician to recognize, and even anticipate, adverse reactions. For example, knowing that some patients with an anaphylactic reaction or an asthma exacerbation may experience a late-phase allergic response compels the physician to continue intensive therapy until the reaction has completely subsided.

The term allergy, in common usage, connotes a variety of reactions that range from mildly debilitating to life threatening. Patients are notorious for classifying *any* untoward adverse reaction as an “allergy,” a practice that is often promulgated by the harried health care staff and unwieldy electronic health records. In conventional medicine, however, we recognize that the term “allergy” specifically describes a precise cascade of biochemical reactions that, in genetically predisposed (or atopic) individuals, may result in certain physical symptoms, such as rhinorrhea, sneezing, wheezing, bronchoconstriction, and even life-threatening vasodilation and hypotension (anaphylaxis).

Underlying this reactivity is a phenotypic predilection toward activation of type 2 helper T cell (Th2) reactivity (and suppression of Th1 reactivity) in atopic individuals. The classification of helper T cells into these two categories is based upon the types of cytokines they produce following stimulation ([Table 30.1](#)). Th1-type cytokines tend to produce inflammatory responses that are responsible for killing intracellular parasites and for perpetuating autoimmune responses. Interferon gamma (IFN- γ) is a key Th1 cytokine. The Th2-type cytokines are implicated in allergic diseases and include interleukins 4, 5, and 13, which are associated with the promotion of IgE and eosinophilic responses in atopy, and interleukin-10, which exerts more of an antiinflammatory activity. In a healthy individual, we expect a balance of Th1 and Th2 responses, depending upon the provocative pathogen. In those with atopy or asthma, we typically see an overexuberant Th2 profile.

Much research has been focused upon modification of this Th2 phenotype, either in the prenatal period or in early childhood. If successful, such an intervention would likely reduce the prevalence of allergic diseases, or at least mitigate some of the more harmful sequelae of allergic reactions. Researchers have examined prenatal and postnatal infection exposure, early and late food introduction, and even household

pet exposures as predictors of atopy in later life. Unfortunately, despite several provocative studies, there is no recognized intervention that will accomplish this goal. In many cases, studies have actually prompted a complete reversal of conventional and accepted recommendations, as was the case with peanut avoidance in the prevention of peanut allergies.⁴ Lacking clear-cut allergy prevention guidelines, we are forced, at present, to temper and modify the allergic response in atopic individuals.

The pathophysiology of the allergic reaction has been well described. There are at least four classically defined mechanisms of pathophysiology as defined by Gell and Coombs; however, most allergic reactions involve more than one type of mechanism. For the purposes of this chapter, we will focus upon the IgE-mediated type 1 reaction, which is responsible for the more common clinical allergic conditions, including allergic rhinitis and allergic asthma.

The type I reaction, or the classic IgE allergic hypersensitivity reaction, is a two-step process by which a genetically susceptible (i.e., atopic) individual initially becomes allergic to a substance via a process known as *sensitization* (Fig. 30.1).

TABLE 30.1

Type 1 Helper T cell (Th1) versus Type 2 Helper T cell (Th2) Phenotypes

	Th1 cells	Th2 cells
Proposed function	Cell-mediated immunity & inflammation; intracellular pathogens; autoimmunity	Allergy/asthma; extracellular parasites; antibody-mediated immunity
Cytokines elaborated	IL-2: development of regulatory T cells and expansion of T cell repertoire IFN-g: activates macrophages, enhances IgG production and Th1 cell production	IL-4: enhances IgE production; inhibits Th1 responses IL-5: promotes eosinophil survival IL-10: inhibits antigen presenting cell function IL-13: enhances IgE and mucus production
Association with medical conditions	Autoimmune diseases Some viral infections Some bacterial infections	Allergic diseases Asthma Some parasitic infections
Differentiation from Th0 cells triggered by	IL-12	IL-4

IFN-g, interferon gamma; *Ig*, immunoglobulin; *IL*, interleukin.

During the initial stage of sensitization, the individual develops significant amounts of immunoglobulin E (IgE) antibodies against an inhaled, ingested, or injected substance, such as pollen. Long-lived memory B cells, which are capable of producing more of this specific IgE antibody immediately when stimulated, appear in the circulation, largely

through the action of Th2 cytokines. The newly formed IgE antibody binds either to circulating blood basophils or to mast cells located in the mucosal layers of the skin, the gastrointestinal tract, and the respiratory system. Millions of IgE molecules of different specificities (directed against different allergens) are present on the surface of each mast cell and basophil, with their concentration often determined by the degree of exposure. This explains why many people suffer seasonal allergy symptoms. An individual is considered sensitized only after sufficient levels of IgE antibodies directed against a specific substance have been produced and are bound to the surfaces of these cells. The process of sensitization does not produce any of the symptoms that we equate with allergic disease—in fact, a person is usually unaware of these initial molecular and cellular changes; not until reexposure to the allergen do allergic symptoms manifest.

Immunoglobulin E (IgE) acts as a bridge that cross-links a specific antigen on the surface of mast cells and basophils to release mediators that foster inflammatory activity.

The second step in the allergic process is the *reactivity* phase. This occurs when a sensitized person is reexposed to the allergen, which now acts as a bridge, cross-linking specific IgE molecules on the surface of each basophil or mast cell. This bridging phenomenon induces changes within the cell, typically through the action of complex protein kinase cascades. Ultimately, this cross-linking process leads to degranulation of the mast cell or basophil, a process that releases both preformed mediators (e.g., histamine, serine proteases, and proteoglycans) and newly synthesized compounds (e.g., eicosanoids and cytokines). The activities of these mediators of allergic inflammation are readily observable in a patient experiencing an allergic reaction. Histamine dilates blood vessels and thus causes localized edema in tissues such as the skin and mucosal membranes, as well generalized urticaria. Cytokines can chemotactically attract diverse cells to the “site of attack,” as is the case in an asthma exacerbation, when Th2 cells and eosinophils infiltrate and populate the lungs. In an allergic exacerbation, clinical symptoms vary from negligible rhinorrhea to sudden death (severe anaphylaxis) depending on the degree of exposure and the sensitivity of the person exposed to the allergen. Most cases lie somewhere between these extremes. Although the cellular and molecular events for all

immediate hypersensitivity reactions are similar, differences in target organ responses ultimately dictate the clinical patterns of disease activity once a reaction has been induced.

FIG. 30.1 Allergic Sensitization and Reactivity (Degranulation).

The process of sensitization and degranulation in mast cells begins with production of antigen-specific immunoglobulin E (*IgE*) in genetically predisposed individuals. Initial binding of specific *IgE* to the naive mast cell surface “primes” the cell for activity. Subsequent binding of a specific allergen to the mast cell triggers complex intracellular biochemical events, leading to degranulation and subsequent mediator release.

Allergic reactions also produce an inflammatory reaction; indeed, one of the most important research findings from the past few decades is the recognition that most of the pathophysiological processes of diverse allergic reactions have a common inflammatory pathway. Elucidation of this pathway has resulted in more precise, targeted therapies with which to control allergic inflammation. In the past, treatment with systemic corticosteroids was the only antiinflammatory intervention available. Although remarkably effective, these steroids provide relief at the expense of severe, long-term adverse effects, including osteoporosis, myopathy, and even psychiatric disturbances. The development of inhaled corticosteroids has mitigated some of these effects; however, these therapies still have adverse consequences. Fortunately, the identification of biochemical intermediates and enzymes in the inflammatory cascade has reduced the need for such powerful and nonspecific drugs and led to targeted therapies for interrupting the allergic inflammatory cascade, or at least controlling the allergic symptoms, until the triggered reaction eventually attenuates on its own.

TABLE 30.2**Antiallergy Activities of Select Compounds**

Class	Examples	Activity	Notes
Antihistamines	Loratadine Cetirizine Diphenhydramine	Block H1 receptors on target tissues	Works best prophylactically; may be sedating
Bioflavonoids	Quercetin Fisetin Cyanidin	Thymolase and cell degeneration inhibition	Works best prophylactically; poor absorption
Supplements	Magnesium Vitamin C	Unclear; may relax bronchial smooth muscle (Mg) or reduce oxidative stress (vit C)	Vitamin C is good preservative; magnesium primarily used acutely
Herbals	Stinging nettle Baccharis	Antioxidant development of histamine activity; inhibition of NF- κ B	Antihistamine activity; blocks NF- κ B
Natural oils	Fish oil	Reduces leukotriene production in arachidonic acid cascade	Use correlates with increases in omega-3 content of cell membranes
TCM	ASTM (Aerianthema Herbal Medicine Formula)	Reduces number and severity of asthma flares in people and animal models	Novel anti-inflammatory mechanisms as yet undefined

NF- κ B, nuclear factor- κ B.

Although analogues for specific pharmacological activities exist in the conventional and integrative therapeutic realms, it is the overall approach to treatment that more clearly differentiates the two approaches to care. Whereas a conventional physician tends to treat each disease state (and symptom) separately and specifically, an integrative practitioner may additionally consider measures to diminish an atopic predisposition. These additional therapies are described in this chapter and in the chapters on specific allergic diseases ([Table 30.2](#)).

Integrative Therapy

Nutrition

Specialized Allergen Avoidance Diets

The avoidance of specific foods or food additives that are found to be responsible for gastrointestinal or anaphylactic allergic reactions, such as peanuts in sensitive individuals, is an obvious and effective intervention. Such elimination diets are useful for both true food allergies and even for food sensitivities (see [Chapter 86](#)). However, food avoidance is also useful when one is attempting to control less severe, nongastrointestinal allergies. For example, patients who are troubled by recurrent sinus infections or mild to moderate refractory asthma symptoms often benefit from certain dietary modifications. Usually, these avoidance diets are specific to an individual, but some common classes of foods have been popularly linked to allergic exacerbations, such as dairy products, wheat, and even animal proteins. These foods seem to be associated with a worsening of allergic symptoms in many patients, although published clinical data in this area are scant. It is important to remember that

despite a shared diagnosis, allergic diseases are remarkably heterogeneous between individuals, so typically, one size does not “fit all.”

A handful of small studies refute the association between milk and mucus production or allergic symptoms,⁵ but biologically plausible hypotheses support such an association.⁶ For example, certain types of milk (from specific breeds of cow) contain a protein called β -CM-7, which has been shown to stimulate mucus glands in the human digestive tract.⁷ As these same glands are found in the upper and lower respiratory tract, milk proteins may increase phlegm production. In any case, a brief trial (4–6 weeks) of dairy avoidance is helpful to discern such an association in selected individuals and is widely used.

Omega-3 Fatty Acids

Alterations in the dietary intake of fats are known to affect the fatty acid composition of cell membranes.^{8,9} This fact is especially pertinent to inflammatory conditions because catabolism of cell membrane–derived fats is an initial step in inflammatory mediator production through the arachidonic acid cascade. Omega-3 supplementation decreases the ratio of omega-6 to omega-3 fatty acids in the inflammatory cell lipid membrane, thus creating less substrate for mediator production.^{8,9} This process, in turn, decreases the production of many potent bioactive compounds (e.g., leukotrienes) that are intimately involved in allergic inflammation. The level of inhibition of leukotriene production by dietary modification rivals that of pharmacological agents, such as zileuton¹⁰ (see [Chapter 88](#)). Clinical trials of fish and plant omega-3 acid supplementation in the treatment of asthma and allergic diseases have been inconsistent, likely owing to the heterogeneity of the disease and huge variation in the form and dosage of fats. Despite this, a significant proportion of subjects respond favorably, making increased dietary omega-3 intake (or a trial of omega-3 supplementation) a useful clinical intervention.¹¹

Several published studies have used doses of 3.2 g eicosapentaenoic acid (EPA) and 2.2 g docosahexaenoic acid (DHA) daily as a supplement to a standard diet.⁸ In one clinical trial, 26 patients with asthma were placed on defined diets of varying omega-3 to omega-6 content.¹² More than 40% of subjects showed marked improvement in airway hyperresponsiveness when they consumed a diet with an elevated omega-3 content. These responders to dietary interventions could be

readily identified through analysis of the leukotriene composition of their urine, a measure that predicted which patients were likely to improve with dietary intervention.¹² Interestingly, a similar evaluation of urinary leukotrienes was used in the development of leukotriene inhibitors (e.g., montelukast), and a differential responsiveness was observed among subjects.¹³ In practice, a trial of fish oil at this dose is useful in assessing responsiveness. Decreases to 1500–2000 mg EPA daily are then possible, with monitoring of clinical parameters.

Dietary Antioxidants

The association between dietary antioxidant intake and the allergic response has been the subject of much study over many years. Because oxidation reactions are commonplace among inflammatory processes (allergies included), the hope was that antioxidants would either prevent the development of allergic disease or mitigate the severity of the reactions. Many positive and negative reports exist in the literature, fairly equally divided, thus precluding definitive and global conclusions. Some findings are worthy of mention, however, particularly a few examining vitamin C and selenium intake.

A food frequency questionnaire was used to examine 4500 school-aged children in Korea and found that children with elevated vitamin C consumption had fewer allergic rhinitis symptoms.¹⁴ A case-control study, also using a food frequency questionnaire, found that apple consumption and dietary selenium intake were negatively associated with asthma prevalence in a 1500-person cohort.¹⁵ Interestingly, selenium functions as a cofactor for glutathione peroxidase, which helps prevent peroxidation of cell membranes by consuming free peroxide in the cell. In one report, children with asthma had significantly lower red blood cell glutathione peroxidase activity than that of a healthy control group.¹⁶ Finally, patients with asthma have higher amounts of oxidized glutathione in their airways, a finding perhaps indicating that patients with asthma are subject to greater oxidative stress.¹⁷

Studies examining whole food consumption, as opposed to individual antioxidant supplements, found that higher intakes of cooked vegetables, tomatoes, and fruits in children were protective factors for symptoms of shortness of breath and wheeze during a 12-month observation period.¹⁸ Consumption of citrus fruits, in particular, had a protective role for these symptoms, which may be related to vitamin C intake. In the same study, consumption of bread, butter, and margarine were all associated with an increased risk of shortness of breath and wheezing.¹⁸ These findings are

not universally accepted, however, because data in the literature are conflicting.

Finally, no conclusive consensus evidence indicates that antenatal supplementation of any vitamin or mineral during pregnancy will reduce the probability of atopy or asthma later in life for children.^{19,20} By definition, these studies are difficult to perform, and the number of confounding variables is extremely high.

Supplements

Many supplements are commonly used for the treatment of allergic rhinitis and asthma. The most promising of these are the flavonoids, which are plant pigments that give fruits and vegetables their brilliant colors. The benefits of these compounds have been demonstrated in both *in vitro* and animal studies, with human studies just beginning. Unfortunately, it is very difficult to absorb orally administered flavonoids owing to their unique chemistry. The addition of several compounds to flavonoid formulations (e.g., bromelain, vitamin C) are aimed at increasing systemic absorption. Some flavonoids have already been adopted by the pharmaceutical industry and are available as prescription medications. An example of this is cromolyn, which is commercially sold under the trademark of Intal. There are other over-the-counter products that are also promising, including quercetin, fisetin, and Pycnogenol. As this group has shown remarkable *in vitro* activity against allergic inflammation, it is worth considering each in some detail.

Quercetin

Quercetin is a bioflavonoid obtained from diverse sources, including apples, buckwheat, onions, and citrus fruits. Most data supporting the role of quercetin in attenuating allergic reactivity have been obtained from *in vitro* studies, as well as from animal models of allergic disease. *In vitro* studies have shown that quercetin stabilizes the membranes of mast cells and reduces the release of preformed histamine.^{21,22} In animal models, quercetin is able to suppress anaphylactic responses in sensitized rats,²³ and it inhibits asthmatic inflammation in guinea pigs and rats.²⁴

Quercetin must be used as a preventative—taken before allergen exposure. Thus the activity of quercetin is similar to that of cromolyn, a drug that is often prescribed for allergy and asthma prophylaxis (see later). Quercetin also inhibits the production of enzymes responsible for manufacturing the potent leukotrienes.²⁵ Practitioners usually

recommend that quercetin be used regularly during an individual's entire allergy season, or year-round for those with perennial allergies.

Quercetin is similar to cromolyn in its mechanism of action. Both are basophil and mast cell stabilizers.

Dosage

The dose of quercetin is usually 400–600 mg of a coated tablet one to three times daily between meals (adjust dose for clinical response). Quercetin is not soluble in water, however, so it is a poorly absorbed nutrient. Bromelain, a protein-digesting enzyme extracted from pineapples, increases the absorption of quercetin, as does vitamin C. Therefore quercetin is typically sold blended with one or both additives.

Precautions

None are reported.

Pycnogenol

Pycnogenol is a proprietary antioxidant–bioflavonoid mixed extract isolated from the bark of the maritime pine (*Pinus pinaster*). Pycnogenol has a variety of biological activities, ranging from blood pressure reduction to mitigation of elevated blood glucose. In terms of allergic diseases, it has been shown to be efficacious in a murine model of airway inflammation,²⁶ as well as in a clinical trial of children with asthma.²⁷ In this study, Pycnogenol improved asthma symptoms and pulmonary function and decreased rescue inhaler use. In addition, there was a significant reduction of urinary leukotriene production in the treated group.²⁷ More recent studies have explored the use of Pycnogenol in people with allergic rhinitis.²⁸ When taken well in advance of the “allergy season,” Pycnogenol improved both nasal and ocular symptoms with no significant adverse events.

Dosage

Pycnogenol is available from many sources; however, as a proprietary preparation, all products bearing the name “Pycnogenol” come from

one common source ([Fig. 30.2](#)). The recommended dose used in asthma studies is 1 mg/lb body weight in two divided doses. For allergic rhinitis, the recommended dose is 100 mg given once per day, which may be at the low end. As with many of these interventions, I tend to use the higher dose, gauge response, then try a dose reduction while observing clinical response.

Precautions

None are reported. Pycnogenol can be added to existing allergy / asthma regimens.

Fisetin

Fisetin is another bioflavonoid compound that is very active against allergic inflammation, at least in *in vitro* and in animal models. It is found primarily in strawberries, but also in apples, persimmons, and onions. Fisetin has gained some attention in the scientific community due to its memory-enhancing capabilities in rodents.²⁹ However, bioavailability is the biggest issue with fisetin, as with other flavonoids. Most studies of fisetin involving memory enhancement or asthma were performing using intravenous or intraperitoneal formulations. However, several studies used oral preparations.²⁹ A biological mechanism for the action of fisetin in attenuating allergic inflammation has been proposed, and it is more complex than that of other bioflavonoids. This compound appears to potently inhibit nuclear factor-kappaB (NF- κ B)—a transcription factor, or on-off switch, responsible for the expression of many inflammatory genes (e.g., IL-1, IL-2, IL-6, IL-8, tumor necrosis factor, adhesins, major histocompatibility class I, inducible nitric oxide synthase, and COX-2).³⁰ Accordingly, fisetin may produce antiinflammatory effects in many reactions that transcend allergic disease. In animal models, fisetin potently inhibited asthma flares in sensitized animals following exposure to allergens. The antiinflammatory effect of fisetin rivaled corticosteroids.³⁰

FIG. 30.2 Pycnogenol is a proprietary antioxidant-bioflavonoid mixed extract isolated from the bark of the maritime pine (*Pinus pinaster*).

Dosage

Typical oral doses for animals ranged from 5–25 mg/kg, and intraperitoneal doses were 0.3–3 mg/kg, in the presence of a chemical carrier (DMSO). Commercial doses for humans are at the lower end of this range and typically are 100–200 mg daily for the oral compound.

Precautions

None are reported. Fisetin can be added to existing allergy/asthma regimens.

Magnesium

Magnesium is a standard of care in the emergency treatment of acute asthma exacerbations, and it is usually administered as an intravenous solution, but occasionally in a nebulized form (the jury is still out as to the comparative efficacies of the two routes).³¹ Magnesium has been

shown to improve forced expiratory volume in 1 second (FEV₁) and reduce ICU admissions in that setting.³² Inverse associations have also been reported between intracellular (RBC) magnesium levels and asthma severity.³³ Despite this association, little convincing literature supports a role for long-term magnesium replenishment in the care of mild to moderate asthma. Some published reports note an improvement in asthma symptoms in subjects with higher magnesium intake,³⁴ while others link dietary magnesium intake with an increased risk of asthma and wheezing in children.³⁵ A recent 6-month study of magnesium supplementation (340 mg daily) in adults with mild-to-moderate asthma produced improvements in bronchial hyperreactivity, peak flow measures, and quality of life indices, without significant effects on other markers of asthma control nor inflammatory markers.³⁶

Dosage

Magnesium glycinate seems to be less irritating to the gastrointestinal system. The typical dose is 400–500 mg daily.

Precautions

Side effects are primarily gastrointestinal. At standard doses, magnesium can produce laxative effects, which are readily reversible with dose reduction.

Some forms of magnesium supplementation have prominent laxative effects. The clinician should be wary of prescribing magnesium citrate, oxide, or hydroxide in a patient for whom diarrhea is a problem. Start with 250 mg daily and build up to 400–500 mg daily.

Other Botanicals

Butterbur (*Petasites Hybridus*)

Butterbur has traditionally been used to treat migraine headaches but also asthma and bronchitis because it is thought to reduce mucus production. A study of 132 people with seasonal rhinitis (hay fever) found that an extract of butterbur was as effective as cetirizine (Zyrtec), a commonly prescribed, mildly sedating antihistamine, and had fewer side effects (especially less sedating). The study lasted only 2 weeks and

required four to five doses of the herb daily.³⁷ More recently, the mechanisms of butterbur action were more carefully delineated in a mouse model of asthma.³⁸ In this study, butterbur was shown to inhibit leukotriene activity and reduce allergic airway inflammation and bronchial hyperreactivity by specifically inhibiting allergic cytokine formation (including interleukins 4 and 5). An open trial of butterbur in the treatment of asthma in adults reported decreased beta agonist use, but it was a poorly designed study.³⁹

Dosage

Petasites extracts are typically standardized to contain a minimum of 7.5 mg of petasin and isopetasin. The adult dosage ranges from 50 to 100 mg twice daily for the treatment of migraine headaches. A high-quality, standardized product prepared in Germany is Petadolex. It is prepared using a carbon dioxide extraction, and its content of pyrrolizidine alkaloids is lower than the limits of detection (the German government requires content to be less than 1 mg daily by dosage). In the previously cited rhinitis study, participants took one butterbur extract tablet (standardized to 8.0 mg of total petasin per tablet) four times daily. The 50-mg Petadolex tablet is standardized to contain 7.5 mg petasins and may also be used up to four times daily in adults.

Precautions

The main concern in using butterbur is finding a preparation that is free of harmful pyrrolizidine alkaloids. These compounds are capable of causing toxic reactions in humans—primarily venoocclusive liver disease.

Stinging Nettle (*Urtica Dioica*)

Stinging nettle has a long history of use as an antiallergy preparation, and it is also used in the treatment of prostatic hypertrophy. The “stinging” hairs and leaves of this plant contain histamine, serotonin, acetylcholine, and 5-hydroxytryptamine, compounds that typically are the *cause* of allergic symptoms. Some investigators attribute the antihistaminic properties of ingested nettles to an autocoid or feedback

inhibition of histamine and histamine-related compounds. Studies have revealed that nettle extract also inhibits the release of tryptase, a mast cell mediator of allergic inflammation, as well as other proinflammatory mediators, such as cyclooxygenase-1 (COX-1), COX-2, and prostaglandin D₂ synthase (PGDS).⁴⁰ A more important activity, however, may be the inhibitory effect of nettle on the transcription of inflammatory genes. Nettle extracts have been shown to inhibit the activity of NF-κB—the transcriptional activator (described previously), which functions as an on-off switch for inflammatory genes.⁴¹

Clinically, few trials have been conducted. In one randomized double-blind study, 57% of patients rated nettles to be effective in relieving allergic rhinitis symptoms and 48% reported that nettles equaled or surpassed previously used allergy medications in effectiveness.⁴²

Dosage

The typical dosage is 300 to 350 mg of a freeze-dried extract used one to three times daily, as needed.

Precautions

Rare allergic reactions and possible gastrointestinal upset have been reported.

Pharmaceuticals

Cromolyn

Cromolyn is a prime example of a drug whose active ingredient was isolated from a botanical source with a historical record of effectiveness. Isolated from an extract of the khella plant (*Ammi visnaga*), cromolyn has demonstrated potent mast cell–stabilizing activity in vitro. When used prophylactically in advance of allergenic exposure, cromolyn can markedly reduce the rate and degree of mast cell degranulation and thus allergic symptoms. Cromolyn is available by prescription in a nebulized form for inhalation (Intal), as a liquid for oral use in gastrointestinal allergic conditions (Gastrocrom), and without a prescription as a nasal preparation for allergic rhinitis (NasalCrom). Unfortunately, it is no longer available as a metered-dose inhaler in the United States. Nebulized cromolyn is useful in treating children with asthma and was a

mainstay of asthma antiinflammatory medications prior to the development of inhaled corticosteroids.

Dosage

For the treatment of allergic rhinitis, the dosage is one spray of nasal spray (NasalCrom) into each nostril three to four times/day until the condition improves and then one spray in each nostril every 8 to 12 hours. This preparation can also be used prophylactically approximately 20–30 minutes before allergen exposure (e.g., exposure to a cat). For asthma, one ampule (20 mg) is used by nebulizer three to four times daily.

Precautions

Cromolyn is quite safe, and adverse reactions are extremely rare.

Antihistamines

Antihistamines bind to the H₁ histamine receptor and inhibit allergic reactions at the level of the target organs; that is, they do not prevent the initiation of the classic allergic response but can inhibit (or at least reduce) the effects of histamine, a key biochemical mediator of allergy. Many different chemical classes of antihistamines are available, but most clinicians prefer the first- and second-generation pharmaceutical agents.

First-generation antihistamines are safe, over-the-counter preparations that are effective in reducing allergic symptoms, but at the expense of significant central nervous system effects. First-generation compounds tend to be highly lipophilic and readily cross the blood–brain barrier thus causing mild-to-marked sedation. In addition, anticholinergic effects, such as urinary retention, may prevent the use of these drugs in patients with prostatic hypertrophy or urinary hesitancy from other causes. Because of the longer history of use of first-generation antihistamine products, many practitioners recommend them in certain higher-risk circumstances, such as in pregnancy. Examples of first-generation compounds are diphenhydramine (Benadryl), clemastine (Tavist), and chlorpheniramine (Chlor-Trimeton).

Second-generation antihistamines typically have fewer anticholinergic and antimuscarinic side effects than first-generation agents and appear to be equally effective. The mechanism of action is similar for first- and

second-generation drugs, although more research has focused on the presumptive antiinflammatory activity of the second-generation compounds. For example, desloratadine downregulates various inflammatory mediators, including the generation and release of IL-4 and IL-13 by human basophils.⁴³ Examples of second-generation antihistamines include cetirizine (Zyrtec), loratadine (Claritin), and fexofenadine (Allegra).

Although many advertisements have been devoted to identifying specific and superior uses for differing brands of antihistamines (e.g., better efficacy in treating urticaria or rhinitis), much of this information represents marketing efforts because large head-to-head published comparisons of drugs for specific allergic conditions are lacking.

Finally, topical antihistamines are available as nasal sprays. Although systemic absorption is less than with oral preparations, similar adverse effects can occur. Bitter taste limits use in many patients. Examples of topical antihistamines include azelastine (Astepro) and olopatadine (Patanase).

Dosage

The standard dose of antihistamine varies with the particular compound. Follow the label directions.

Precautions

Patients should not operate heavy machinery or automobiles while they are taking even mildly sedating antihistamines, including cetirizine (a second-generation compound). A study conducted in 2000 compared driving coordination in subjects administered standard doses of a first-generation antihistamine (diphenhydramine) with subjects given alcohol, fexofenadine, or a placebo. Remarkably, diphenhydramine had a greater impact on driving performance than alcohol.⁴⁴ In addition, urinary retention, confusion, dizziness, drowsiness, dryness of mouth, or convulsions (seizures) may be more likely to occur in older adults who take the older antihistamines.

Prolonged use of medicines with anticholinergic side effects has been associated with a higher risk for memory loss due to the inhibitory effect of acetylcholine.⁴⁵

Nasal Corticosteroids

Topical (nasal) corticosteroids are relative newcomers to the allergic rhinitis pharmacopeia. They are regarded as first-line therapy for moderate to severe rhinitis symptoms, especially nasal congestion, for which they seem to outperform antihistamines.⁴⁶ A brief period (perhaps weeks) often elapses before maximal effects are appreciated. These drugs function as topical antiinflammatory agents and reduce allergic inflammation locally in the nasal mucosa and sinus passages. Many of the newer preparations are regarded as safe because they exhibit first-pass metabolism and thereby lessen the possibility of systemic absorption and long-term adverse effects. As of 2013, two formulations are available as over-the-counter products: Flonase (fluticasone) and Nasacort (triamcinolone). More are expected to follow.

Dosage

The dosage varies with each preparation. Typically, one spray in each nostril daily is sufficient for maintenance. Occasionally, this dose is doubled for short periods (i.e., during peak allergy weeks).

Precautions

Common side effects include epistaxis (up to 10%). Concern also exists about growth rate declines in prepubescent children; however, this observation has been noted in very few reports. Higher rates of posterior subcapsular cataracts have also been reported. Concerns about systemic absorption of these steroid compounds and the long-term effects remain, although several studies have demonstrated only mild adrenal inhibition.

I have observed cases of septal perforation as a result of improper spraying of corticosteroids in the nares. Advise patients to aim the “nozzle” of the canister or bottle away from the nasal septum (i.e., toward the outside of the nostril). Use of the opposite hand for each nostril will naturally aim the mist away from the septum.

Immunotherapy

Allergic desensitization is an effective adjunct to drug therapy in selected

patients. It is generally reserved for those individuals who show no response to other therapies or for whom life-threatening reactions can occur with unpredictable frequency (e.g., insect sting anaphylaxis). Immunotherapy in the United States historically consisted of the subcutaneous administration of gradually increasing amounts of allergic material given at regular intervals (“allergy shots”). The mechanism by which the injections diminish allergenic sensitivity is not completely clear; however, their effectiveness has been demonstrated in cases of allergic rhinitis and for some types of asthma as well. This therapy is believed by some to be a last resort because the potential for an adverse reaction is always present and the reaction itself can be life threatening. From 1985 to 1993 in the United States, 52.3 million administrations of immunotherapy resulted in 35 deaths. These numbers equate to a mortality incidence of less than 1 per million, which is quite low but still unacceptable for patients treated for a nonlife-threatening condition such as allergic rhinitis.⁴⁷ Moderate to severe systemic reactions are fairly common and warrant close patient supervision immediately after the administration of a desensitization injection.

Sublingual Immunotherapy

A newer immunotherapy modality that is rapidly gaining acceptance in the United States is sublingual immunotherapy (SLIT). Popularized in Europe years ago, when subcutaneous immunotherapy was deemed too dangerous for regular use, sublingual immunotherapy is similar to the subcutaneous route except that the allergen extract is provided as drops that the patient self-administers under the tongue (sublingually) on a daily basis. Many subspecialists decried this newer therapy as it opened the treatment of allergic diseases to nonallergists. However, it is gaining acceptance among younger practitioners and medical consumers alike. The sublingual route has been shown to be efficacious in numerous studies, and it is considered very safe, with few mild reactions reported and no deaths.⁴⁸ SLIT therapy is usually initiated with a full dose (or a very short dose escalation schedule), with the first dose given under medical supervision. Dosing continues once daily and is self-administered by the patient at home.

Over the past several years in the United States, there has been “off-label” use of regular injectable liquid allergen extracts for sublingual immunotherapy, but this is somewhat controversial.

SLIT therapy can be used for foods as well as for aeroallergens. The efficacy of this method depends upon appropriate allergen testing and

careful extract dosing. Although considered very safe, as with any active immunotherapy, there is still a risk of anaphylaxis.

Dosage

In 2014, the FDA approved three commercially available SLIT products: Oralair, a once-daily sublingual tablet that contains a mixture of freeze-dried extracts from the pollens of five grasses; Grastek, a single-species Timothy grass pollen sublingual tablet; and Ragwitek, a short ragweed pollen sublingual tablet. These products are designed to be initiated a few months before the start of the grass (or ragweed) pollen season and are continued throughout the season.

Mind-Body Therapy

Numerous studies have documented the value of mind-body approaches to many allergic conditions. Classic studies from the late 1960s demonstrated that many patients with moderate to severe asthma exhibit severe symptoms when they are exposed to saline mists that they believed were potent allergens. Even more remarkable was their prompt recovery with use of a saline inhaler that they believed to be a beta agonist.^{49,50} Even standard skin test reactions that produce classic wheal-and-flare reactions to subcutaneously introduced allergens can be modulated by mind-body techniques. In one study, patients with dust mite sensitivity who were skin tested after viewing a humorous video demonstrated lower wheal-and-flare reactivity to dust mite allergen than did patients viewing a control video (weather documentary).⁵¹ Finally, a randomized controlled trial examined the effectiveness of the addition of self-hypnosis to a pharmacological regimen for allergic rhinitis. Allergic symptoms in 79 patients with “hay fever” showed significant improvement over the course of two pollen seasons compared with those in control groups⁵² (see [Chapter 95](#)).

Traditional Chinese Medicine

Until recently, relatively few controlled studies have examined the role of acupuncture or Chinese herbs as part of a traditional Chinese medicine (TCM) approach to allergies. Now, however, owing to several ground-

breaking studies from the Mount Sinai Hospital in New York, this is perhaps the most exciting area for future innovation. Researchers there purified and dissected several ancient Chinese herbal formulations for both asthma and food allergies and uncovered some remarkable results.

An herbal preparation, tested in an animal model of asthma, was shown to be as effective an antiinflammatory agent as corticosteroids, but through a novel mechanism and with potentially fewer adverse effects.⁵³ Through a series of carefully designed experiments, the group was able to test the compound, which they call ASHMI (Antiasthma Herbal Medicine Intervention), on 90 adults with mild–moderate asthma.⁵⁴ They compared their formulation to daily prednisone over a 4-week period and determined that the TCM herbal compound was safe, well tolerated, and as effective as the corticosteroid at improving peak flow, FEV1, symptoms, and reducing the need for bronchodilators. However, ASHMI did not affect serum cortisol levels or cause weight gain, relative to the corticosteroid. This herbal blend is expected to enter the marketplace soon.

A similar research initiative by the same workers led to the discovery of a Chinese formula that was completely protective in an animal model of peanut allergy.⁵⁵ The therapy also proved to be long lasting. This finding is remarkable because few, if any, therapies exist for this potentially fatal condition.

A human study demonstrated the superiority of a regimen of acupuncture plus Chinese herbs (versus placebo) in the treatment of seasonal allergic rhinitis.⁵⁶ The study assessed rhinitis symptoms with several validated scales, which showed significant improvements in quality of life and symptom control in patients who received a standard regimen of acupuncture along with a standardized herbal decoction. The therapy was found to be well tolerated and safe in this study population. Finally, a recent meta-analysis evaluated the efficacy of traditional Chinese herbal medicine for the treatment of persistent allergic rhinitis. The list of acceptable studies was pared down to seven, involving a total of 533 patients. Although nasal symptom scores were significantly reduced with herbal medicine, no other outcomes (i.e., objective measures) were affected.⁵⁷

Prevention Prescription

- Use environmental modification, including reduction of dust mite allergen: encase mattress and pillows, remove carpeting if possible,

and replace curtains with shades or blinds

- Remove allergenic pets from the home, or at least from the bedroom
- Consider buying a high-efficiency particulate air (HEPA) filter
- Plan activities to avoid exposure to early morning peak pollen counts
- Resist the temptation to open the windows; use the air conditioner and change furnace filters often
- Follow an antiinflammatory diet. Avoid processed foods, partially hydrogenated oils, white sugar, and flour. Replace vegetable oils with olive or canola oil for cooking. Avoid excessive amounts of saturated fat
- Consider a 4-week elimination diet to see if it impacts symptoms. Start by eliminating dairy or wheat

Therapeutic Review

The following is a summary of general therapeutic options for allergies (e.g., allergic rhinitis). If a patient presents with severe respiratory or anaphylactic symptoms, stabilizing pulmonary function or allergen exposure risk with potent conventional therapies is prudent before introducing supplements or botanical preparations. For the patient with mild to moderate allergy symptoms, however, this stepladder approach is appropriate.

Remove Environmental Triggers From the Home

- With perennial allergens (e.g., dust mites), tell the patient to wash bedclothes weekly in hot water, encase mattresses and pillows in mite-impermeable covers, and remove carpeting from rooms (especially bedrooms). Regular vacuuming of carpeted areas (by someone without allergies) is also suggested. 
- Pet-sensitive individuals are a special case. The ideal solution, removal of the pet from the household, is typically not an option with pet lovers. In this case, removing pet access to the bedroom is helpful. Regular washing of the pet may or may not be of benefit 
- A high-efficiency particulate air (HEPA) filter is useful for light, floating allergens, such as cat allergens; it is less effective with dog

allergens. 

Avoid Peak Pollen Exposure Outdoors

- Outdoor pollens are ubiquitous; avoidance is nearly impossible. Pollen-sensitive patients can avoid significant exposure by limiting outdoor activities between 5 and 10 a.m. and on dry, windy days when airborne pollen levels are highest. 

Nutrition

- Decrease dairy (milk protein) and total protein intake. Plant proteins may be preferable. 
- Consume fats rich in omega-3 found in cold-water fish, nuts, greens, and ground flaxseed. Consider the addition of pharmaceutical-grade (distilled) fish oil capsule or liquid supplements. 
- Increase water intake dramatically to maintain adequate hydration. 
- Increase intake of natural bioflavonoids and antioxidants by eating more organic fruits (especially brightly-colored berries) and vegetables. 

Mind-Body Therapy

- Clinical hypnosis may markedly attenuate allergic reactivity. 
- Consider a trial of homeopathy, which is particularly helpful in individuals with multiple chemical or drug sensitivities. This form of therapy is safe for adults and children. 

Traditional Chinese Medicine

- Acupuncture therapy with or without Chinese herbal therapy can be used for allergic rhinitis. Most studies used artificially standardized regimens; individualized therapy may be more efficacious. 
- Chinese herbal therapy and acupuncture can be helpful for asthma control, especially the latest compounds from Mt Sinai School of Medicine (ASHMI; Antiasthma Herbal Medicine Intervention). 

Supplements

- Pycnogenol: 100 mg twice daily 
- Fisetin: 100 mg once or twice per day 
- Quercetin: 400–600 mg one to three times daily 
- Magnesium glycinate: 400 mg daily 
- Vitamin C: 250 mg twice daily 

Botanicals

- Freeze-dried stinging nettles: 300–500 mg one to three times / day 
- Butterbur (Petadolex): 50–100 mg twice daily 

Pharmaceuticals

- Cromolyn sodium: nasal spray, one spray / nostril three to four times daily; nebulizer, 20 mg (one ampule) two to four times daily 
- Second-generation antihistamines (oral) 
 - Loratadine: 10 mg daily
 - Fexofenadine (Allegra): 180 mg daily or 60 mg twice daily
 - Cetirizine (Zyrtec): 5–10 mg daily
- Nasal antihistamines 
 - Azelastine (Astepro), olopatadine (Patanase): one to two sprays / nostril twice daily
- Nasal corticosteroids (may be added if other natural and pharmacological interventions fail or if nasal congestion or recurrent sinusitis is a prominent problem) 
 - Fluticasone nasal (Flonase): 1–2 sprays / nostril daily
 - Triamcinolone (Nasacort): 1–2 sprays / nostril daily
 - Budesonide nasal (Rhinocort): 1–2 sprays / nostril daily

Immunotherapy

- This is typically reserved for those patients with more severe or refractory symptoms, life-threatening allergic reactivity, or coexisting conditions (e.g., asthma, sinusitis). 

- Consider sublingual immunotherapy (SLIT) before subcutaneous immunotherapy.

CHAPTER 31

Food Allergy and Intolerance

Alan R. Gaby, MD

Food allergy is well recognized in clinical medicine as a cause of acute attacks of asthma, urticaria, and angioedema and as a contributing factor in some cases of eczema and rhinitis. These types of allergic reactions are called immediate or type 1 hypersensitivity reactions and are mediated by immunoglobulin E (IgE). The diagnosis and treatment of type 1 hypersensitivity reactions is well covered in standard medical texts, and a detailed discussion of this type of allergy is beyond the scope of this chapter.

Another type of food reaction, often referred to as “hidden” or “masked” food allergy, was described as early as the 1930s^{1,2} and 1940s,^{3,4} and has been described in the medical literature hundreds of times since then.⁵ Hereinafter, unless otherwise specified, the term “food allergy” in this chapter will refer to hidden food allergy. Many integrative-medicine practitioners, including the author of this chapter, have observed that food allergies are a common cause of, or triggering factor for, a wide range of physical and mental disorders and that working with food allergies is an essential component of the practice of medicine. According to one estimate, as much as 60% of the population suffers from undetected food allergies.⁶ Symptoms and disorders that have been reported to have a significant food allergy component are listed in [Table 31.1](#).

Hidden food allergies appear to be a common cause of, or triggering factor for, a wide range of physical and mental disorders.

Many doctors are not convinced that food allergy is a common problem, and some doubt that it even exists. Skeptics emphasize that many of the conditions said to be related to food allergy fluctuate in

severity and have a significant psychological component. Consequently, it may be difficult to distinguish a true food reaction from a conditioned (psychogenic) response or a spontaneous exacerbation of symptoms. Moreover, there is no generally accepted mechanism to explain how foods could cause such a wide range of seemingly unrelated symptoms and conditions.

Proponents of the food allergy-disease connection point out that hidden food allergies are often overlooked because they are difficult to identify. Unlike type 1 hypersensitivity reactions, which usually trigger immediate symptoms and are therefore relatively easy to identify, hidden food reactions are often delayed for hours or even days. Moreover, hidden food reactions do not necessarily occur every time the offending food is consumed, but may depend on factors such as coingestion of other allergens, the method of cooking or processing of food, coexisting stressors, and hormonal cycles. Identifying a cause-effect relationship between ingestion of specific foods and the development of symptoms is further complicated by the tendency of people to become addicted to the foods to which they are allergic and to experience transient relief after ingesting foods that are later demonstrated to be the cause of their chronic symptoms. Thus patients are often unaware that they have food allergies, and medical histories and diet diaries are frequently of little or no value for identifying specific allergens.

Nomenclature

It has been argued that food-induced symptoms should not be called allergic reactions unless an immune-mediated mechanism can be demonstrated and that in the absence of such demonstration, terms such as intolerance or sensitivity would be more appropriate. However, the more we learn about physiology, the more apparent it becomes how blurred the lines are between the immune system and various other bodily systems (such as the endocrine, nervous, and cardiovascular systems). Some mediators of food-induced symptoms (e.g., platelet activation) could reasonably be considered to be within the domain of any of these systems, including the immune system.^{7,8}

In the primary care setting, it is often difficult or impossible to identify the mechanisms underlying food-induced symptoms. Moreover, it is not clinically useful to attempt to delineate these mechanisms in many cases (although there are some important exceptions, as discussed in the

section on differentiating food allergy from other food reactions). Notwithstanding concerns about its scientific accuracy, use of the term “allergy” has some advantages. In particular, it helps patients understand that food reactions can involve a wide array of different tissues and organs, and that in many instances even very small doses of an offending agent can evoke symptoms. For these reasons, the author tends to refer to food reactions as allergies unless a nonimmune-mediated mechanism is suspected (as in, for example, gastrointestinal reactions to fermentable carbohydrates or pseudoallergic reactions to food-derived salicylates or histamine).

Pathophysiology

Why an Epidemic of Food Allergies?

When the author was in elementary school in the 1950s, virtually none of the children had attention deficit-hyperactivity disorder (ADHD). Today, ADHD is very common and appears to be related in many cases to food allergy. In addition, the frequency of anaphylactic reactions to peanuts and other foods has been increasing in recent years.⁹

TABLE 31.1

Symptoms and Conditions That May Be Caused or Exacerbated by Food Allergy

Cardiovascular
Angina
Arrhythmias
Hypertension
Thrombophlebitis

Dermatological
Acne vulgaris
Dermatitis herpetiformis
Eczema
Pruritus
Purpura
Status ulcers
Urticaria

Ear, Nose, and Throat
Hearing loss
Hoarseness
Meniere's disease
Nasal polyps
Nosebleeds (epistaxis)
Olfactory dysfunction
Otitis externa
Otitis media
Sinusitis
Sore throat
Taste disorders
Vasomotor rhinitis
Vertigo

Gastrointestinal
Abdominal pain
Constipation
Crohn's disease
Diarrhea
Eosinophilic esophagitis
Gallbladder disease
Gastritis
Gastroesophageal reflux disease
Irritable bowel syndrome
Nonulcer dyspepsia
Pancreatitis
Peptic ulcer
Proctitis
Pruritus ani
Rectal bleeding
Ulcerative colitis
Vomiting

Neurological
Ataxia
Epilepsy
Migraine
Multiple sclerosis
Restless legs syndrome
Tension-type headache

Ophthalmological
Conjunctivitis
Uveitis

Pediatric
Colic
Enuresis
Growing pains

Psychiatric
Anxiety
Attention deficit-hyperactivity disorder
Autism
Bipolar disorder
Depression
Dysthymia
Panic attacks
Schizophrenia

Pulmonary
Asthma
Chronic obstructive pulmonary disease
Cough

Renal
Glomerulonephritis
Nephrotic syndrome

Rheumatological
Juvenile rheumatoid arthritis
Psoriatic arthritis
Rheumatoid arthritis
Systemic lupus erythematosus
Vasculitis

Urological
Dysuria
Urethritis
Urinary frequency
Urinary tract infections

Miscellaneous
Aphthous ulcers
Candidiasis (<i>Candida</i> -related complex)
Edema
Fatigue
Food cravings
Halitosis
Insomnia
Obesity
Recurrent infections
Teeth grinding (bruxism)
Thrombocytopenia
Vaginitis

While one can only speculate on the reasons for the increased prevalence of allergies, possible culprits include alterations in immune function induced by environmental pollutants¹⁰ and vaccinations, multiple antigenic exposures from the 2700 additives in our food supply, and genetic engineering of foods.^{11,12} In particular, hybridization techniques have been used since the 1950s to produce new strains of wheat to increase crop yield.¹³ Genetic modification has introduced new

immunogenic proteins into modern wheat, which may explain, in part, the apparent increases in the prevalence of celiac disease and nonceliac gluten sensitivity in recent decades.

It has been suggested that immunoglobulin G (IgG) is involved in at least some food reactions^{14,15}; however, that possibility has not been well studied. The results of one study suggested that the innate immune system (for example, Toll-like receptor 2) plays a role in the pathogenesis of nonceliac gluten sensitivity, whereas the adaptive immune system does not seem to be involved.¹⁶ In contrast, both the innate and adaptive immune systems appear to contribute to type 1 hypersensitivity reactions. Whether the innate immune system plays a role in hidden allergy to food proteins other than gluten has not been investigated. Aside from these preliminary clues, the molecular mechanisms underlying hidden food allergy are poorly understood.

Specific Adaption

Another way of looking at the pathophysiology of food allergy is through the conceptual framework elucidated by Theron Randolph regarding the adaptation of patients to foods to which they are sensitive.¹⁷ Randolph, a pioneer in the field of hidden food allergy, referred to this process as specific adaptation (SA), which he considered to be analogous to, though distinct from, the general adaptation syndrome (GAS) response to stress, as described by Hans Selye. A schematic representation of these types of adaptation is presented in [Fig. 31.1](#).

Stage 1 of SA (which corresponds to the alarm stage of the GAS) is the preadaptive/nonadapted stage. In this stage, repeated exposure of a susceptible individual to an allergenic food results in progressively increasing sensitivity to the food, although symptoms are typically absent or mild at this point. Stage 2 of SA corresponds to the adaptation/resistance stage of the GAS. Initially, the patient is relatively symptom free (stage 2a, addicted/adapted), but may have adapted to the allergenic food by becoming addicted to it. He/she may have learned subconsciously to consume the food at regular intervals to avoid withdrawal symptoms. With continued exposure, the patient progresses to stage 2b (addicted/maladapted), in which ingestion of the food causes various physical and mental symptoms. However, the patient remains addicted and is usually unaware that the food is causing problems. It is at this stage that patients typically consult a health care practitioner.

Stage 3 of SA (postadaptive/nonadapted) corresponds to the exhaustion stage of the GAS. In this stage, exposure to the food, even in low doses, produces acute symptoms. Some patients approach stage 3, but few actually reach it.

Patients who are in stage 2b can be reverted to a nonadapted stage 1 by means of an elimination diet, after which exposure to the allergenic food results in a rapid and exaggerated reaction. Thus an elimination diet followed by individual food challenges can be used diagnostically to demonstrate the etiology of patient symptoms.

Research Validation

This section reviews several clinical trials that demonstrate the role of food allergy in the etiology of common clinical conditions. These studies were chosen for review either because the findings were confirmed by double-blind, placebo-controlled food challenges or because the observed improvements were substantially greater than those obtainable with conventional medical approaches.

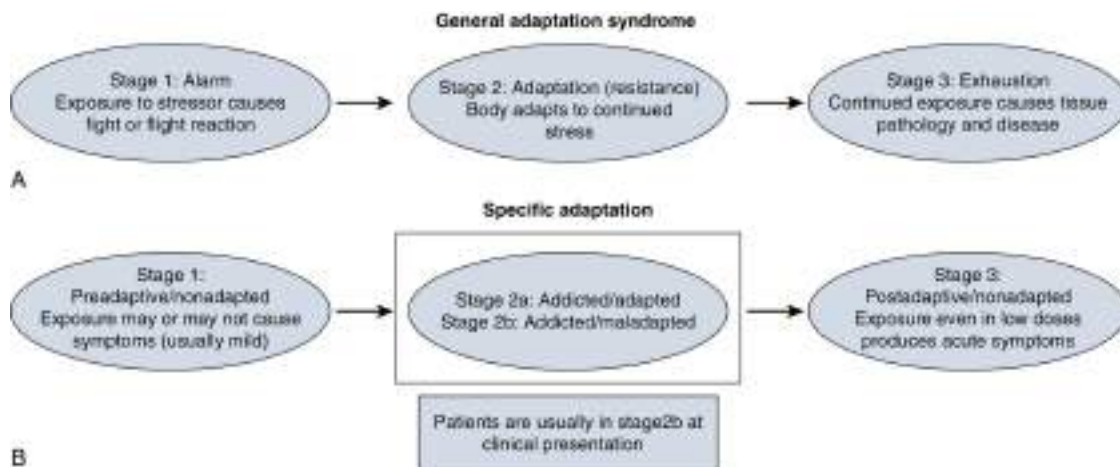

FIG. 31.1 Stages in the development of hidden food allergy (specific adaptation) as contrasted with the general adaptation syndrome.

Migraine

Sixty patients with chronic, frequent migraines (mean duration of illness, 18.5 years) consumed an elimination diet for 5 days consisting only of

two low-risk foods (usually lamb and pears) and bottled spring water. Migraines disappeared within 5 days in most cases. Each patient then tested one to three common foods per day, with evaluation of symptoms and acute pulse changes (which are thought by some investigators to indicate allergic reactions). Foods that most frequently caused reactions were wheat (78%); orange (65%); egg (45%); tea and coffee (40% each); chocolate and milk (37% each); beef (35%); corn, cane sugar, and yeast (33% each); mushrooms (30%); and peas (28%). When an average of 10 (range, 1–30) foods were avoided, all patients improved. The number of headaches in the treated group fell from 402 per month to 6 per month, with 85% of patients becoming headache free.¹⁸

Rheumatoid Arthritis

Fifty-three patients with rheumatoid arthritis were randomly assigned to a diet that excluded common allergens or to their usual diet (control group). After 1 week, the patients on the exclusion diet began reintroducing one food at a time, and any foods that produced symptoms were removed from the diet. After a total of 6 weeks, the diet group had significant improvements in subjective and objective measures of disease activity compared with the control group.¹⁹ Long-term follow-up of 100 rheumatoid arthritis patients who underwent diet therapy at the same clinic revealed that one-third remained well on diet alone (without any medication) for up to 7.5 years after starting treatment.²⁰

Irritable Bowel Syndrome

Twenty-one patients with irritable bowel syndrome followed a strict elimination diet consisting of a single meat, a single fruit, and distilled or spring water for 1 week. Symptoms disappeared in 14 patients (67%). Subsequently, individual food challenges identified the following symptom-evoking foods: wheat (64% of patients), corn (36%), dairy products and coffee (29% each), tea (21%), and citrus fruits (14%). Jejunal biopsies were normal in all patients who reacted to wheat, indicating the absence of celiac disease. Six patients underwent double-blind food challenges; in each case, the food reaction was confirmed.²¹

Nonceliac Gluten Sensitivity

Sixty-one adults without celiac disease or type 1 hypersensitivity to

wheat (i.e., negative wheat-specific IgE test) who believed that gluten was the cause of their intestinal and extraintestinal symptoms were randomly assigned to receive, in double-blind fashion, 4.4 g per day of gluten or placebo (rice starch) in capsules for 1 week. After a 1-week washout period on a gluten-free diet, each participant was crossed over to the other treatment for an additional week. Compared with placebo, gluten significantly increased overall symptoms ($p < .04$). Abdominal bloating ($p = .04$), abdominal pain ($p < .05$), foggy mind ($p < .02$), depression ($p = .02$), and aphthous stomatitis ($p < .03$) were significantly more severe with gluten than with placebo. These results confirm that gluten can trigger both intestinal and extraintestinal symptoms in nonceliac patients with self-reported gluten sensitivity.²²

Diagnosis

Medical History

Food allergy should be considered in the differential diagnosis of all of the symptoms and conditions listed in [Table 31.1](#). The likelihood that a patient has food allergies appears to increase in proportion to the number of symptoms and conditions the patient has that could be due to food allergy. In addition, the index of suspicion should be increased in patients who have a childhood history of colic, recurrent ear infections, sore throats, runny nose, “growing pains,” asthma, eczema, or “getting sick all the time,” and in those with a family history of allergy. On questioning, patients may report that they feel worse after eating and better when they fast. However, many patients with food allergies also have reactive hypoglycemia, which generally has the opposite pattern with respect to meals (i.e., better after eating, worse when fasting). When patients have both reactive hypoglycemia and food allergies, it may be difficult to draw diagnostic conclusions from the symptom pattern in relation to meals. As previously noted, patients may be unaware that they have food allergies, and dietary histories and diet/symptom diaries are frequently of little or no diagnostic value.

Many patients with chronic illnesses are unaware that they have food allergies, and diet histories are often of little or no value for identifying symptom-evoking foods.

Physical Examination

Physical signs of allergy (food or inhalant) may include pallor of the nasal mucosa, general pallor, “allergic shiners” (edematous dark circles under the eyes), generalized edema, Dennie’s lines (horizontal creases across the lower eyelids), and ecchymoses. Signs seen primarily in allergic children include the “allergic salute” (wiping or rubbing the nose with an upward movement of the hand) and an “allergic crease” (a single horizontal crease across the lower portion of the nose from repeated allergic saluting).

Other Diagnostic Tests

Conventional skin-prick tests, scratch tests, and blood tests for food-specific IgE antibodies are of value for identifying IgE-mediated type 1 hypersensitivity reactions, but these tests have repeatedly been found to be unreliable for diagnosing hidden food allergies.

IgG4 Antibody Testing

Blood tests that measure food-specific IgG4 antibodies are also commercially available; however, the reliability of these tests is in doubt for a number of reasons. First, some commercial laboratories have reported widely divergent results when sent split samples of the same blood. Second, various microorganisms and other contaminants may be present in the food samples from which the test antigens are prepared. Therefore, the presence of antibodies to a food extract may, in some cases, indicate nothing more than previous exposure to common bacteria and fungi. Third, some allergic reactions are not due to native food proteins but to polypeptides produced during the process of digestion or to glycosylation products produced during cooking. Those antigens would not be among the ones measured by blood tests. Fourth, while there is evidence that antibodies within the IgG4 fraction act as symptom-evoking antibodies, the IgG4 fraction also appears to contain blocking antibodies, which may prevent allergic reactions.²³

Consequently, the theoretical basis for measuring IgG4 antibodies as a diagnostic test for food allergies is open to question. Fifth, as previously noted, some food reactions are not mediated by antibodies and would therefore not be identifiable by antibody testing. The author is not aware of any published research that addresses the incidence of false-positive and false-negative results from IgG antibody tests. However, clinical

experience suggests that the frequency of incorrect test results (i.e., those that conflict with the results of elimination and rechallenge) is unacceptably high, with one study reporting that IgG blood testing was of no value for identifying specific food sensitivities in children with attention deficit-hyperactivity disorder.²⁴

ALCAT Testing

Another blood test, known as antigen leukocyte antibody test (ALCAT), measures platelet aggregation and morphological changes in white blood cells after whole blood is mixed with various food extracts. In one study, the incidence of false-positive results using this test was 24.3% and the incidence of false-negatives was 30.9%,²⁵ suggesting that this test is unreliable for diagnosing food allergies. In addition, when split samples of the same blood were sent under different names to a laboratory that performs the ALCAT test, only 34% of the tests performed showed the same results.²⁶

Food Extract Testing

Provocative testing is used by some practitioners to diagnose food allergies. This procedure involves intradermal or sublingual administration of various dilutions of food extracts. A similar procedure is used to “neutralize” or desensitize allergies. Although the efficacy of food extract injection therapy has been demonstrated in a double-blind study,²⁷ others have failed to find a beneficial effect.²⁸ Accordingly, provocative testing and neutralization remain controversial techniques.

Integrative Therapy

Elimination Diet

Hidden food allergies can usually be “unmasked” by means of an elimination diet, followed by individual food challenges.²⁹ After a patient has been on a hypoallergenic diet for a period of time (usually 2–3 weeks), chronic symptoms often disappear or improve and the body reverts from a state of “waterlogged” allergy-addiction to one of increased alertness and sensitivity. In this hypersensitive state, ingestion of an offending food results in a rapid and exaggerated reaction, allowing the patient to identify previously unsuspected allergens.

In most cases, hidden food allergies can be identified by means of an elimination diet, followed by individual food challenges.

The author has prescribed elimination diets for more than 2000 patients. The diet used in the vast majority of cases is described in detail in [Appendix A](#), Allergy Elimination Diet (available online at ExpertConsult.com) and is a modification of an elimination diet developed by William Crook.¹⁸ It excludes all foods that contain refined sugar, wheat, dairy products, corn, eggs, citrus fruits, coffee, tea, alcohol, and food additives other than vitamins. Patients also exclude any foods to which they know or strongly suspect they are allergic (even foods that are normally allowed on the diet) and any foods they eat three or more times a week. The reason that frequently eaten foods are eliminated is that individuals with an allergic constitution may develop hidden allergies to foods they eat frequently (even foods that are not common allergens). Patients who find it too difficult to eliminate otherwise permitted foods that they have been eating frequently may consume those foods on a rotating basis (i.e., no more than every 4 days) during the elimination phase.

Alternatives to refined sugar (such as honey, maple syrup, and barley syrup) are permitted or prohibited on an individual basis depending on whether the patient is suspected to be sensitive to simple sugars. Tap water is excluded if the patient is thought to be highly sensitive. When tap water is excluded, the patient is advised to use spring or distilled water bottled in glass or hard (nonleaching) plastic containers.

This method of selecting which foods to avoid seems to be reasonably effective at excluding the most common allergens, as well as most other foods to which a particular patient is likely to be sensitive. Allergenic foods that are not initially excluded can frequently be detected by the patient during the elimination phase (after the body has become hyperalert from excluding the major allergens), particularly if those foods are being consumed on a rotating basis. Foods that clearly evoke symptoms during the elimination phase are removed from the diet.

A marked diuresis is common during the early part of the elimination diet, as chronic allergic edema begins to resolve. Approximately 25% of patients experience “withdrawal” symptoms within a few days of starting the diet. Withdrawal symptoms may include fatigue, irritability, headaches, malaise, and increased hunger. These symptoms typically resolve after 1–3 days, and the patient begins to feel better than before starting the diet. In most cases, withdrawal symptoms are not severe and

do not require treatment. If symptoms are too uncomfortable, patients may obtain relief by taking buffered vitamin C (sodium ascorbate or calcium ascorbate) at a dose of 1000 mg up to four times per day. Withdrawal symptoms may also be ameliorated by taking alkali salts (such as sodium bicarbonate and potassium bicarbonate in a 2:1, 1:1, or 1:2 ratio) at a dose of 1/4 to 1/2 teaspoon dissolved in 6–8 ounces of water three to four times per day, as needed.

Clear symptomatic improvement is usually evident after 10–21 days on the elimination diet, although some patients improve more quickly. In a small proportion of patients, improvement is not seen until the fourth week on the diet.

Editor's Note

The author offers his recommendations on how to do an elimination diet in [Appendix A](#) (available online at ExpertConsult.com). Also see [Chapter 86](#) for further discussion and recommendations.

Individual Food Challenges

Patients are typically advised to continue the elimination diet for 3 weeks, after which they undergo individual food challenges. Food challenges may be started sooner if the patient has experienced marked improvement for at least 5 days and has been on the diet for at least 10 days. Patients who have not improved after 3 weeks are encouraged to continue the elimination diet for an additional week. If no improvement is seen after 4 weeks, patients are given the option of returning to a healthful diet or undergoing individual food challenges. Occasionally, patients who have not shown clear improvement on the elimination diet discover from individual challenges that specific foods exacerbate their symptoms.

Methods of testing individual foods are described in [Appendix A](#). Allergic reactions to foods typically occur within 10 minutes to 12 hours of ingestion, although the onset of joint pain may be delayed by as much as 48 hours. Typically, one new food is tested per day. However, if the patient's chief complaint is arthritis, new foods are tested every second day. Challenge foods that evoke symptoms are removed from the diet, and the patient waits until the symptoms have largely disappeared before testing the next food. Foods that do not trigger symptoms are also

removed from the diet for the remainder of the testing period, but they may be consumed again after the individual food challenges have been completed. If the patient is uncertain whether or not a food has triggered symptoms, that food should be retested 4–5 days later. Occasionally, it is not clear whether a reaction is due to the most recently tested food or to a delayed reaction to a previously tested food. In that case, both foods should be retested at a later time.

Some patients feel so much better on the elimination diet that they choose not to undergo the individual food challenges. This can lead to confusion regarding which foods truly need to be avoided because waiting too long (such as more than 6 weeks) before undergoing food challenges may decrease a person's reactivity to allergenic foods and therefore decrease the probability that challenges with these foods would provoke symptoms. However, as long as the patient is consuming a balanced diet that contains adequate amounts of all macronutrients and micronutrients, there does not appear to be any harm in continuing the elimination diet indefinitely.

Alternative Elimination Diet

In cases where multiple food allergies are suspected, patients can be placed on a highly restrictive diet (usually lamb, pears, and spring water) for 5 days, followed by individual food challenges (up to three different foods per day). The advantage of this approach is that it may result in rapid clearing of symptoms and it allows for rapid retesting of foods. However, such an approach requires a highly motivated patient.

Elimination-and-Rechallenge Diets in Clinical Practice

Some patients are able to undertake the elimination-and-rechallenge program successfully by simply reading the information provided in [Appendix A](#) (available online at ExpertConsult.com).

More often, patients find the prospect of markedly changing their diet to be overwhelming. This reaction to being shown the elimination diet is due, in part, to a lack of familiarity with alternative foods and, in part, to their knowledge (conscious or unconscious) that they are addicted to substances such as sugar, wheat, dairy products, coffee, or alcohol.

To enhance compliance, I informed patients that the elimination diet is a diagnostic test of finite duration; that withdrawal symptoms are

transient; and that identifying hidden allergens may allow the patient to regain control of his or her health. The staff nutritionist spent as much time as necessary to teach patients the specifics of the program (usually 30–60 minutes), and patients were encouraged to phone the office if they had questions or problems. About 80%–90% of patients who were taught the elimination diet completed it successfully; of those, more than two-thirds experienced significant clinical improvement. In many cases, identification and avoidance of allergenic foods resolved chronic issues that had failed to respond to any other treatment.

Differentiating Food Allergy From Other Food Reactions

Some food reactions are mediated by the immune system, others are nonimmune mediated, and in others the mechanism is uncertain. The various mechanisms underlying food reactions are summarized in [Chapter 86](#). As previously mentioned, in many cases it is both difficult and not clinically useful to determine whether a food reaction is a true allergy or whether it occurs through a nonimmune-mediated mechanism. However, there are some important exceptions.

Pseudoallergy

Pseudoallergic reactions are hypersensitivity reactions to food additives or to compounds that occur naturally in foods.³⁰ Examples of pseudoallergens include salicylates, histamine, sulfites, benzoates, and tartrazine (FD&C Yellow #5). Pseudoallergic reactions appear to involve direct (as opposed to antibody-mediated) activation of mast cells or a pharmacological effect (as in the case of histamine intolerance).

Distinguishing pseudoallergy from allergy has two advantages. First, identifying a pseudoallergen as an etiological factor may help the patient devise a more focused and effective diet. For example, if the pattern of food reactions suggests sensitivity to salicylates or histamine, the patient can be directed to information on how to follow a low-salicylate or low-histamine diet. Second, pseudoallergic reactions are often dose dependent in contrast to allergic reactions, which may occur even with low-level exposures. Awareness of this dose–response relationship may allow for a less restrictive diet.

Reactions to Fermentable Carbohydrates

Some patients with irritable bowel syndrome (IBS) are intolerant to one or more types of fermentable, poorly absorbed carbohydrates, which can cause symptoms by exerting an osmotic effect in the gastrointestinal tract.³¹ These carbohydrates are collectively called FODMAPs, which is an acronym for fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (see [Chapter 90](#)). FODMAPs include fructose, lactose, sorbitol, fructans (fructooligosaccharides, inulin), and galactooligosaccharides. Several studies have demonstrated that consumption of a low-FODMAPs diet improves symptoms in patients with IBS.³²⁻³⁵ Fructans are present in relatively high concentrations in gluten grains, and some IBS patients who are intolerant to fructans erroneously attribute their gastrointestinal symptoms to gluten sensitivity.³⁶

FODMAPs intolerance should be considered in patients whose food-induced symptoms are limited to the gastrointestinal tract. As with pseudoallergy, identifying FODMAPs as etiological agents may lead to a more effective diet plan, and awareness that the reactions are dose dependent may allow for a less restrictive diet.

Celiac Disease versus Nonceliac Gluten Sensitivity

As previously mentioned, many patients who experience gluten-induced intestinal or systemic symptoms do not have celiac disease. To provide appropriate dietary recommendations and follow-up, it is important to distinguish celiac disease from nonceliac gluten sensitivity. In people with celiac disease, strict avoidance of gluten is essential because ingestion of even small amounts may increase the risk of developing intestinal lymphoma, nutrient deficiencies, and other complications. In contrast, patients with nonceliac gluten sensitivity may experience symptoms if they eat gluten, but they do not appear to be at increased risk for serious complications.

In patients who react to gluten, it is important to distinguish between celiac disease and nonceliac gluten sensitivity.

Some of the differences in clinical presentation and laboratory findings

between celiac disease and nonceliac gluten sensitivity are listed in [Table 31.2](#). Awareness of these differences may help the clinician determine whether a small-bowel biopsy or genetic and serological testing for celiac disease is necessary.

Precautions With Elimination Diets

As previously noted, exaggerated reactions may occur when individual foods are reintroduced after the patient has been on an elimination diet for a few weeks. While life-threatening or severe anaphylactic reactions to food challenges are uncommon, they have been known to occur, particularly in patients with a history of severe asthma or severe atopic dermatitis.^{17,37,38} In addition, some patients with atopic dermatitis who had not previously experienced acute problems from ingesting cow's milk became sensitized to cow's milk after its removal from the diet. Symptoms such as urticaria, dyspnea, vomiting, cough, or rhinoconjunctivitis have occurred in such patients after a cow's milk challenge, even if they had been avoiding cow's milk for years.³⁹

Patients considered at risk for severe reactions should either not undergo diet therapy or should have food challenges performed under the guidance of an experienced practitioner in a hospital or other properly equipped setting. Patients considered at risk for moderately severe reactions who are conducting individual food challenges at home should have epinephrine and other rescue medication close at hand.

Individuals who abuse alcohol are at risk of developing delirium tremens when they withdraw from alcohol. These individuals should not attempt an elimination diet until they have completed an alcohol detoxification program. It would be prudent to observe similar precautions with people who abuse cocaine, narcotics, or other drugs.

TABLE 31.2

Prevalence of Various Clinical and Laboratory Findings in Patients With Celiac Disease (CD) and Nonceliac Gluten Sensitivity (NCGS)

Clinical or Laboratory Finding	CD	NCGS
Constipation	7%	51%
Diarrhea with weight loss or steatorrhea	67%	25%
Severe vitamin D deficiency (serum 25[OH]D < 10 ng/ml)	30%	0.8%
Iron-deficiency anemia	20%	2.4%
Presence of two or more nutritional deficiencies (vitamin D, iron, vitamin B ₁₂ , zinc)	20%	0.8%

Serology (tTG [IgA/IgG], DGP, EMA) ^{26,48-51}	Usually positive, relatively high sensitivity and specificity	Usually negative
HLA type DQ2 and/or DQ8	Nearly 100% (negative test makes it very unlikely that a person has celiac disease)	Approximately 30%–40% of the general population
Intestinal permeability ¹⁶	Tends to be increased	Tends to be normal or decreased

DGP, deaminated gliadin peptide antibodies; *EMA*, antiendomysium IgA antibodies; *HLA*, human leukocyte antigen; *tTG IgA/IgG*, tissue transglutaminase IgA/IgG antibodies.

Modified from Kabbani TA, Vanga RR, Leffler DA, et al. Celiac disease or non-celiac gluten sensitivity? An approach to clinical differential diagnosis. *Am J Gastroenterol*. 2014;109:741-746.

Some patients with food allergies, particularly those with multiple allergies, may develop a fear of eating, which can lead to malnutrition. The practitioner should assess the nutritional adequacy of these patients' diets and should provide dietary and psychological counseling when necessary.

Patients with food allergies should receive appropriate counseling to ensure that their diet is nutritionally adequate.

After Testing

The information provided in this paragraph relates to hidden food allergies and does not apply to type 1 (immediate) hypersensitivity reactions. Most foods become progressively less reactive the longer they are avoided, although a small percentage of food allergies are permanent (i.e., the food provokes symptoms even after many years of avoidance). Adults should avoid allergenic foods for at least 6–12 months before attempting to reintroduce them into their diet. Some children are able to resume eating allergenic foods after as little as 3 months. Previous allergens that are successfully reintroduced should, in most cases, be consumed no more than once every 3–4 days. More frequent consumption of these foods may eventually cause the allergy to return.

Highly allergic patients may fare best if they follow a rotary diversified diet in which no food is eaten more often than every 4 days. Some practitioners recommend rotating food groups (e.g., legumes every other day) in addition to rotating specific foods (e.g., soy on day 2, lentils on day 4). While most of the patients the author has worked with did not need to follow a strict rotation diet, it would be prudent for all individuals with allergies not to eat the same foods every day.

Patients who need to avoid common foods should receive appropriate counseling to ensure that their diet is balanced and not nutritionally

deficient.

“Allergic to Everything”

Some patients react to so many foods that they find it difficult to consume a nutritionally adequate diet. In these patients, symptom-evoking foods may be tolerated to some extent if they are consumed as part of a 4- or 5-day rotation diet. However, patients with multiple allergies represent a major challenge, and their clinical outcomes are often less than satisfactory. Many such patients also have multiple chemical sensitivities and inhalant allergies. Avoiding such exposures as much as possible and administering desensitization therapy for foods, inhalants, and other substances may be worthwhile. Comprehensive treatment of patients with multiple sensitivities is beyond the scope of this chapter and may require referral to a physician trained in environmental medicine. Many such physicians are members of the American Academy of Environmental Medicine. Information about this organization is available below under Key Web Resources.⁴⁰

Other Treatments

Total Allergic Load

Patients with food allergies often improve when their total allergic load is decreased by identifying and avoiding inhalant and chemical allergens and by undergoing desensitization therapy when appropriate. Similarly, sensitivity to inhalants and chemicals may decrease when patients begin avoiding allergenic foods.

Nutritional Supplements

Specific nutritional supplements may be of benefit for the prevention and treatment of certain conditions that are often caused or triggered by food allergy. For example, magnesium⁴¹ and riboflavin⁴² often reduce the frequency of migraine episodes, and omega-6 fatty acids have been found to be of benefit for patients with eczema.⁴³ However, there is no clear evidence that nutritional supplements reduce allergic reactivity per se.

Anti-Candida Program

In the author's experience, an anti-*Candida* program, consisting of dietary

modifications and prescription of herbal antifungal agents, sometimes decreases allergic reactivity in patients who have clinical evidence of a syndrome that has been called chronic candidiasis, *Candida*-related complex, or *Candida* hypersensitivity syndrome. Although other practitioners have reported similar observations, the existence of this syndrome remains controversial. An anti-*Candida* program may work by decreasing intestinal inflammation and permeability, thereby decreasing the absorption of allergenic macromolecules. The evaluation and management of chronic candidiasis is described elsewhere.^{44,45}

Prevention Prescription

- Encourage breastfeeding: In observational studies, atopic dermatitis developed less frequently in children who had been breastfed than in those who had been formula fed.^{46,47} Whether breastfeeding would prevent other conditions associated with food allergy is not known.
- Consider introducing eggs and peanuts between 4 and 11 months of age. Early introduction of peanuts and eggs has been associated with less IgE allergy to these foods later in life.^{47a}
- Avoid unnecessary chemical exposures: In some patients, food allergies develop or become worse after exposure to toxic or allergenic chemicals, presumably as a result of stress on, or injury to, the immune system.
- Follow a rotary diversified diet: People with an allergic constitution tend to become allergic to foods they consume frequently. Including a wide range of foods in the diet and not eating the same foods every day may reduce the risk of developing hidden food allergies.

Therapeutic Review

Testing

- Conduct a thorough medical history and physical examination to assess the likelihood that the patient has food allergies.
- When appropriate, prescribe and supervise an elimination diet followed by individual food challenges. 

Nutrition

- Work with the patient to devise a nutritionally adequate, diverse diet that avoids the symptom-evoking foods identified during the testing period. 

Nutritional Supplements

- Various nutritional supplements may be useful for specific conditions that have a food allergy component (e.g., magnesium for the prevention of migraines or asthma attacks, probiotics for the treatment of irritable bowel syndrome, and fatty acids for the treatment of eczema). While there is no clear evidence that nutritional supplements can prevent food-allergic reactions per se, an individualized program of hypoallergenic nutritional supplements may improve clinical outcomes in allergic patients. 

Lifestyle

- Integrative approaches such as avoiding stress and engaging in regular physical exercise may improve the overall health of allergic patients, although there is no clear evidence that these lifestyle factors decrease allergic reactivity per se.

Appendix A. Allergy Elimination Diet

The elimination diet described in the following is from Gaby AR, *Nutritional Medicine*, a modification of a diet recommended by William Crook, M.D., a pioneer in the evaluation and management of hidden food allergy.¹ The purpose of this diet is to identify hidden food allergens that may be causing some or all of your symptoms. During the elimination period, all common allergens are completely eliminated from the diet for 2–3 weeks. After your symptoms improve, foods are added back one at a time to determine which foods have been causing symptoms.

Foods You Must Avoid

Dairy products: Milk, cheese, butter, yogurt, sour cream, cottage cheese, whey, casein, sodium caseinate, calcium caseinate, and any food containing these.

Wheat: Most breads, spaghetti, noodles, pasta, most flour, baked goods, durum semolina, farina, and many gravies. Although this diet prohibits wheat, it is not a gluten-free diet. Oats, barley, and rye are allowed.

Corn: Whole corn and foods made with corn (such as corn chips, tortillas, popcorn, and breads and other baked goods that list corn as an ingredient). Also avoid products that contain corn oil, vegetable oil from an unspecified source, corn syrup, corn sweetener, dextrose, and glucose.

Eggs: Whites and yolks, and any product that contains eggs.

Citrus fruits: Oranges, grapefruits, lemons, limes, tangerines, and foods that contain citrus fruits.

Coffee, tea, and alcohol: Avoid both caffeinated and decaffeinated coffee, as well as standard (such as Lipton) tea and decaffeinated tea. Herb teas are allowed, except those that contain citrus.

Refined sugars: Avoid table sugar and any foods that contain sugar, such as candy, soft drinks, pies, cake, cookies, chocolate, sweetened apple sauce, etc. Other names for sugar include sucrose, high-fructose corn syrup, corn syrup, corn sweetener, fructose, cane juice, glucose, dextrose, maltose, maltodextrin, and levulose. These must all be avoided. Some patients (depending on their suspected sensitivity to refined sugar) will be allowed 1–3 teaspoons per day of pure, unprocessed honey, maple syrup, or barley malt syrup. This will be decided on an individual basis. Patients restricted from all sugars should not eat dried fruit. Those who are not restricted from all sugars may eat unsulfured (organically grown) dried fruits sparingly. Because little is known about alternative sweeteners such as stevia, they should not be used during the elimination phase.

Honey, maple syrup, or barley syrup (1–3 teaspoons per day)
Allowed Not allowed

Food additives: Avoid artificial colors, flavors, preservatives, texturing agents, artificial sweeteners, etc. Most diet sodas and other dietetic foods contain artificial ingredients and must be avoided. Grapes, prunes, and raisins that are not organically grown may contain sulfites and should be avoided.

Any other food you eat three times a week or more: Any food you are

now eating three times a week or more should be avoided and tested later.

Known allergens: Avoid any food you know you are allergic to, even if it is allowed on this diet.

Tap water (including cooking water): Tap water is eliminated in cases where more extreme sensitivity is suspected. If tap water is not allowed, use spring or distilled water bottled in glass or hard plastic. Water bottled in soft (collapsible) plastic containers tends to leach plastic into the water. Bottles with the numbers 3 or 7 are likely to leach phthalates. Choose bottles and containers that are free of bisphenol A (BPA). Some water filtration systems do not take out all potential allergens. Take your water with you, including to work and to restaurants.

Tap water Allowed Not allowed

Read Labels

Hidden allergens are frequently found in packaged foods. “Flour” usually means wheat; “vegetable oil” may mean corn oil; and casein and whey are dairy products. Make sure your vitamins are free of wheat, corn, sugar, citrus, yeast, and artificial colorings.

Foods You May Eat

Cereals: Hot: oatmeal, oat bran, cream of rye, Arrowhead Mills Rice and Shine. Dry: Barbara’s or Erewhon’s puffed rice, Barbara’s Brown Rice Crisps Cereal. Diluted apple juice with apple slices and nuts go well on cereal. You may use soy milk that has no corn oil or sugar added (such as some Eden Soy and Rice Dream products). Most of these foods are available in health food stores and some grocery stores.

Grains and flour products: Flours: soy, rice, potato, buckwheat, and bean flours. Breads: rice, 100% rye, spelt, or millet bread (as long as they do not contain dairy, eggs, sugar, or wheat). Cooked whole grains: oats, millet, barley, buckwheat groats (kasha), brown rice, brown rice pasta, rice macaroni, spelt (flour and pasta), amaranth, and quinoa. Other: 100% rice cakes (such as Quaker), rice crackers, rye crackers, Orgran Buckwheat Gluten-free Crispbread, flax crackers (from Foods Alive), Blue Dragon Spring Roll Wrappers, Oriental noodles (such as 100% buckwheat Soba noodles from Eden), and Ka-Me Bean Threads. Most of these products are available at health food stores and can be ordered

from any grocery store that carries Arrowhead Mills, Bob's Red Mill, Shilo Farms, or Ancient Harvests.

Legumes: Soybeans, tofu, lentils, peas, chickpeas, navy beans, kidney beans, black beans, string beans, and others. Dried beans should be soaked overnight. Pour off the water and rinse before cooking. Canned beans often contain added sugar or other potential allergens. Some cooked beans packaged in glass jars (generally sold at health food stores) contain no sugar. You may also use bean dips (like hummus) that do not contain sugar, lemon, or additives. Canned soups such as split pea, lentil, and turkey/vegetable (without additives) may also be used. Companies that make acceptable products include Amy's, Kettle Cuisine, and Imagine Natural Creations.

Vegetables and fruits: Use a wide variety. All vegetables except corn and all fruits except citrus are permitted.

Proteins: This includes beef, lamb, pork, chicken, turkey, and fish. Lamb rarely causes allergic reactions and can be used by most people who have multiple sensitivities. Grain/bean casseroles may be used as an alternative to animal foods (see vegetarian cookbooks for recipes). Shrimp and most canned or packaged shellfish (such as lobster, crab, and oysters) may contain sulfites and should be avoided. Canned tuna, salmon, and other canned fish are allowed.

Nuts and seeds: Nuts may be eaten raw or roasted (without sugar). To prevent rancidity, nuts and seeds should be kept in an airtight container in the refrigerator. You may also use nut butters (such as peanut butter, almond butter, cashew butter, walnut butter, sesame butter, hemp seed butter, and sesame tahini). Companies that make acceptable products include Full Circle, Arrowhead Mills, and Natalie's. Nut butters go well on celery sticks and crackers. In recipes, freshly ground flaxseed can be used instead of egg. One tablespoon of ground flaxseed with a 1/3 cup of water will bind in recipes as well as one egg, but additional leavening may be needed depending on the recipe.

Oils and fats: Sunflower, safflower, olive, sesame, peanut, flaxseed, canola, and soy oils may be used. Do not use corn oil or "vegetable oil" from an unspecified source (which is usually corn oil). Soy, sunflower, and safflower margarines are acceptable from an allergy standpoint, but most margarines contain trans fatty acids (which may promote heart disease) and are therefore not recommended. Vegetable spreads and bean spreads (such as hummus) may be used instead of butter or margarine. Ripe avocado can also be spread on sandwiches in place of mayonnaise.

Snacks: Any permitted food can be eaten as a snack any time of day. Acceptable snacks include Danielle Veggie Chips and Gorge Delight's Just Fruit Bars. Other good snacks include celery, carrot sticks, and other vegetables; fruit (no citrus); and unsalted fresh nuts and seeds.

Beverages: Acceptable drinks include spring water in glass bottles or hard plastic, herb teas (no lemon or orange), noncitrus fruit juices without sugar or additives (dilute 50:50 with water), and soy or rice milk without corn oil (such as Eden Soy Plain or Rice Dream Original). Cafix, Inka, and Kafree Roma may be used as coffee substitutes. Tap water contains chlorine, fluoride, and other potentially allergenic chemicals. In some cases, spring water in glass or hard plastic bottles is the only water allowed. This would include water used for cooking. If tap water is eliminated, it should be reintroduced as if it were a test food. Restrictions on the type of water permitted will be made on a case by case basis.

Thickeners: Rice, oat, millet, barley, soy, or amaranth flours; arrowroot powder; agar flakes; and kudzu powder may be used as thickeners.

Spices and condiments: Acceptable items include salt (in moderation), pepper, herbal spices (without preservatives, citrus, or sugar), garlic, ginger, onions, catsup and mustard without sugar (such as catsup from Muir Glen and mustard from Full Circle), Bragg Liquid Aminos (as a replacement for soy sauces that contain wheat or additives), and vitamin C crystals in water (as a substitute for lemon juice).

Miscellaneous foods: Sugar-free spaghetti sauce (such as Amy's) and fruit jellies without sugar or citrus (such as Suzanne's fruit spreads).

General Suggestions

Do not restrict calories. Start with a good breakfast, eat frequently throughout the day, and consume at least four glasses of water per day. If you do not eat enough, you may experience symptoms of low blood sugar, such as fatigue, irritability, headache, and rapid weight loss. Eat a wide variety of foods. Do not rely on just a few foods because you may become allergic to foods you eat every day. To ensure adequate fiber intake, eat beans, permitted whole grains, whole fruits and vegetables, homemade vegetable soup, nuts, and seeds. Be sure to chew thoroughly in order to enhance digestion.

Plan Meals

Plan your meals for the entire week. Take some time before starting the

diet in order to develop meal plans and stock the kitchen with adequate amounts of permitted foods. For ideas, look through cookbooks that specialize in hypoallergenic diets. Most meals can be modified easily to meet the requirements of the diet without changing the meal plan for the rest of your family. When you go to the health food store, ask for assistance in locating appropriate breads, crackers, cereals, soups, etc. Some people find it useful to prepare additional foods on the weekend, which helps to cut down on thinking and preparation time during the week. If you need further assistance or ideas, talk with your diet counselor at the office.

People With Limited Access to a Health Food Store

Searching for hypoallergenic foods on one of the Internet sites listed below can be helpful. Perform the search as an “advanced search,” with as many limitations as the site allows, such as wheat free, corn free, dairy free, casein free, and no added sugar. This type of search eliminates many of the unacceptable products, but you will still need to read the ingredients of products that interest you. You can buy directly from websites such as Glutenfreemail.com, Allergygrocer.com, and Shoporganic.com, or special order foods through your local grocery.

Dining Out

Do not hesitate to ask questions or make requests. For example, you could ask for fish topped with slivered almonds and cooked without added seasoning, butter, or lemon. Get baked potato with a slice of onion on top. Order steak or lamb chops with fresh vegetables also prepared without added seasonings (with the exception of garlic and plain herbs). Make sure the salad bar does not use sulfites as a preservative and bring your own dressing (oil and cider vinegar with chopped nuts/seeds and fresh herbs). Carry pure water, snacks, and seasonings, etc. wherever you go to supplement your meals or to have something on hand if you get hungry.

Withdrawal Symptoms

Approximately one in four patients develop mild “withdrawal” symptoms within a few days after starting the diet. Withdrawal

symptoms may include fatigue, irritability, headaches, malaise, or increased hunger. These symptoms generally disappear within 2–5 days and are usually followed by an improvement in your original symptoms. If withdrawal symptoms are too uncomfortable, take buffered vitamin C (sodium ascorbate or calcium ascorbate) at a dose of 1000 mg in tablet/capsule form or a 1/4 teaspoon of the crystals up to four times per day. Your doctor may also prescribe alkali salts (a mixture of sodium bicarbonate and potassium bicarbonate, taken as needed at a dose of 1/4 to 1/2 teaspoon dissolved in 6–8 ounces of water up to 3–4 times per day). In most cases, withdrawal symptoms are not severe and do not require treatment. When starting the elimination diet, it is best to discontinue all of the foods abruptly (“cold turkey”) rather than easing into the diet slowly.

Testing Individual Foods

It usually takes 2–3 weeks for symptoms to improve enough to allow you to retest foods. However, you may begin retesting sooner if you have been feeling a lot better for at least 5 days and have been on the diet for at least 10 days. If you have been on the diet for 4 weeks and feel no better, contact the office for further instructions. Most patients do improve. Some feel so much better on the diet that they decide not to test the foods. This could be a mistake. If you wait too long to retest, your allergies may “settle down” and you will not be able to provoke symptoms by food testing. As a result, you will not know which foods you are allergic to. If reintroducing certain foods causes a recurrence of symptoms, you are probably allergic to those foods.

Food Sources for Testing

Test pure sources of the various foods. For example, do not use pizza to test cheese because pizza also contains wheat and possibly corn oil. Do not use bread to test wheat because bread often contains other potential allergens. It is best to use organic foods for testing so as not to risk interference from pesticides, hormones, or other additives that may be present in some foods.

Testing Procedure

Test one new food each day. If your main symptom is arthritic pain, test

one new food every other day. Allergic reactions to test foods usually occur within 10 minutes to 12 hours after ingestion. However, joint pains may be delayed by as much as 48 hours. Eat a relatively large amount of each test food. For example, on the day you test milk, consume a large glass at breakfast along with any of the other foods on the “permitted” list. If, after one serving, your original symptoms come back, or if you develop a headache, bloating, nausea, dizziness, or fatigue, do not eat that food again and place it on your “allergic” list. If no symptoms occur, eat the food again for lunch and dinner and watch for reactions. Even if the food is well tolerated, do not add it back into your diet until you have finished testing all of the foods. If you do experience a reaction, wait until your symptoms have improved before testing the next food. In some instances, it may not be clear whether the symptoms you are experiencing are due to the most recently eaten food or to a delayed reaction to a previously eaten food. If you are uncertain whether you have reacted to a particular food, remove it from your diet and retest it 4–5 days later. You do not have to test foods you never eat. Do not test foods you already know cause symptoms. Foods may be tested in any order. Begin testing on a day you are feeling well. Keep a daily journal that records individual food challenges and symptoms.

Dairy tests: Test milk and cheese on separate days. You may wish to test several cheeses on different days since some people are allergic to certain cheeses but not to others. It is usually not necessary to test yogurt, cottage cheese, or butter separately.

Wheat test: Use Wheatena (with no milk or sugar) or another pure wheat cereal. You may add soy or rice milk.

Corn test: Use fresh ears of corn or frozen corn (without sauces or preservatives).

Egg test: Test the whites and yolks on separate days using hard-boiled eggs.

Citrus test: Test oranges, grapefruits, lemons, and limes individually on separate days. Lemon and lime can be squeezed into water. For oranges and grapefruits, use whole, fresh fruit.

Tap water and frequently eaten foods: Test tap water if you have eliminated it. Also test the foods you have eliminated because they were being eaten frequently.

Optional tests: If any of the items below are not now a part of your diet or if you are committed to eliminating them from your diet, there is no need to test them. However, if you have been consuming any of these items regularly, it is a good idea to test them and find out how they affect

you. Reactions to these foods and beverages may be severe in some cases. They should be tested only on days that you can afford to feel bad.

Coffee and tea: Test on separate days. Do not add milk, nondairy creamer, or sugar; however, an acceptable soy or rice milk may be added. If you use decaffeinated coffee, test it separately. Coffee, tea, decaffeinated coffee, and decaffeinated tea are separate tests.

Sugar: Put 4 teaspoons of cane sugar in a drink or on cereal, or mix it with another food.

Chocolate: Use 1–2 tablespoons of pure baker’s chocolate or Hershey’s cocoa powder.

Food additives: Buy a set of McCormick or French’s food dyes and colors. Put 1/2 teaspoon of each color in a glass. Add one teaspoon of the mixture to a glass of water and drink. If you wish, you may test each color separately.

Alcohol: Beer, wine, and hard liquor may require testing on different days because the reactions to each may be different. Have 2 drinks per test day, but only if you can afford not to feel well that day and possibly the next day.

After the Testing

After the testing is finished, please return to the office for a follow-up visit. Bring your journal with you in order to review your experiences with the doctor.

Suggestions For Self-Help

Rotation Diet

If you have an allergic constitution and eat the same foods every day, you may eventually become allergic to those foods. After you have discovered which foods you can eat safely, make an attempt to rotate your diet. A 4-day schedule is necessary for some highly allergic people, but most people can tolerate foods more frequently than every 4 days. You may eventually be able to tolerate allergenic foods after you have avoided them for 6–12 months. However, if you continue to eat these foods more frequently than every fourth day, the allergy may return.

Consume a wide variety of foods, not just a few favorites. If you are rotating foods, be sure to avoid all forms of the food when you are on an “off ” day. For example, if you are rotating corn, avoid corn chips, corn

oil, corn sweeteners, etc. except on the days you are eating corn and corn products. It is not necessary to do strict food rotation during the elimination and retesting periods.

Watch for other allergic reactions. If you have an allergic constitution, you may be allergic to foods other than those you have eliminated and tested on this diet. Pay attention to what you are eating and review recent meals if you develop symptoms. You can then eliminate that food for 2 weeks and test it again to see if it triggers the same symptoms.

Insulin Resistance and the Metabolic Syndrome

Edward (Lev) Linkner, MD, and Corene Humphreys, ND

Defining Metabolic Syndrome

The terms “syndrome of insulin resistance (IR)” and “the metabolic syndrome” were coined in the 1980s by Gerald Reaven, MD, an endocrinologist at Stanford Medical School in California. Other names used to describe the condition include syndrome X, prediabetes, dysmetabolic syndrome, and cardiometabolic syndrome.¹

Metabolic syndrome is associated with a constellation of risk factors for atherosclerosis and type 2 diabetes mellitus (DM) including²:

- Elevated fasting glucose
- Elevated triglycerides
- Reduced high-density lipoprotein (HDL) cholesterol
- Hypertension
- Central obesity

The presence of three or more of these risk factors defines the metabolic syndrome. Following a joint scientific statement by several major organizations, a set of defined cut off values were determined for all components, with the exception of waist circumference ([Table 32.1](#)).³ According to the National Cholesterol Education Program Adult Treatment Panel III, a waist circumference of more than 40 inches (101 cm) in men and more than 35 inches (89 cm) in women is a defining criteria for metabolic syndrome.⁴ These values apply to Western cultures only. For information regarding other ethnic groups, readers should refer to the 2010 article by Lear et al.⁵ that outlines existing and proposed waist circumference and waist-to-hip ratios.

Additional abnormalities posited to define the metabolic syndrome

include endothelial dysfunction, and procoagulant and proinflammatory states.⁶

IR is the most common clinical finding associated with metabolic syndrome and is thought by many investigators to represent the predominant mechanism underlying the pathogenesis of this condition. IR is defined as decreased cellular sensitivity to insulin and varies according to cell type, organ, and particular metabolic pathway.¹ Research suggests that IR is associated with an inflammatory state and the activation of inflammatory pathways sustains IR and ultimately leads to the development of metabolic syndrome.⁷

Prevalence

The incidence of metabolic syndrome has reached epidemic proportions, with nearly 35% of all U.S. adults and 50% of those aged 60 years and older estimated to have metabolic syndrome in a 2015 report. Data from the National Health and Nutrition Examination Survey (NHANES) 2003 to 2012 reported a prevalence of metabolic syndrome of 33% (95% confidence interval [CI], 32.5% to 33.5%), with a significantly higher prevalence in women compared with men (35.6% vs 30.3% respectively; $P < 0.001$). When stratified according to ethnicity, the highest prevalence of metabolic syndrome is observed among Hispanics (35.4%; CI, 34.2% to 36.6%), followed by nonHispanic whites (33.4%; 95% CI, 32.6% to 34.2%) and blacks (32.7%; 95% CI, 31.5% to 33.9%). Overall, an increasing prevalence with advancing age has been reported for all ethnic groups. The prevalence of metabolic syndrome was reported as 18.3% among individuals aged 20 to 39 years and to be significantly higher at 46.7% among individuals aged 60 years or older.⁸

The increased prevalence of IR, metabolic syndrome, and type 2 DM is thought to be attributable to the global rise in the prevalence of obesity. Visceral fat is now considered to be involved in a number of metabolic, endocrine, and immune functions, all of which have been shown to increase risk of cardiovascular disorders.¹¹ Metabolic syndrome is reportedly associated with a two-fold increased risk of cardiovascular disease (CVD) and a four-fold increased risk of type 2 DM compared to individuals without the condition⁴ ([Table 32.2](#)).

Pathophysiology

The etiology of IR and the metabolic syndrome is multifactorial and encompasses genetics, nutrient deficiencies, and metabolic defects in addition to lifestyle and environmental factors. The pathophysiology of the metabolic syndrome involves a complex cascade of events that occur intracellularly. Insulin is a major hormone whose action is required for proper tissue development, growth, and maintenance of glucose homeostasis.¹² Insulin also affects lipid metabolism by increasing hepatic and adipose lipid synthesis. IR is characterized by decreased responsiveness in the tissues to appropriate circulating levels of insulin and is considered the major contributor to the pathogenesis of metabolic syndrome (Fig. 32.1). Accordingly, IR in muscle tissues causes reduced glucose disposal from the bloodstream, and hepatic IR causes increased glucose production. Impairment of insulin secretion by pancreatic beta cells is a critical feature of the metabolic syndrome that leads to hyperglycemia due to defective insulin secretion and timing of the insulin response to glucose.¹³

TABLE 32.1
Criteria for the Clinical Diagnosis of the Metabolic Syndrome^{3,6}

Measure	Categorical Cut Points
Elevated waist circumference	Greater than 40 inches (102 cm) in men or greater than 35 inches (88 cm) in women
Elevated triglycerides (drug treatment for elevated triglycerides is an alternate indicator)	150 mg/dL or greater
Reduced HDL cholesterol (drug treatment for reduced HDL cholesterol is an alternate indicator)	Less than 40 mg/dL for males and less than 50 mg/dL for females
Elevated blood pressure (drug treatment for hypertension is an alternate indicator)	Systolic 130 mm Hg or greater and/or diastolic 85 mm Hg
Elevated fasting glucose (drug treatment for diabetes mellitus is an alternate indicator)	100 mg/dL or greater

HDL, high density lipoprotein.

Modified from Alberti KG, Eckel RH, Grundy SM, et al. Harmonizing the metabolic syndrome: a joint interim statement of the International Diabetes Federation Task Force on Epidemiology and Prevention; National Heart, Lung, and Blood Institute; American Heart Association; World Heart Federation; International Atherosclerosis Society; and International Association for the Study of Obesity. *Circulation*. 120(16):1640-1645, 2009 and Aguilar M, Bhuket T, Torres S, Liu B, Wong RJ. Prevalence of the metabolic syndrome in the United States, 2003-2012. *JAMA*. 313(19):1973-1974, 2015.

The key targets of insulin action are predominantly skeletal muscle (75%), followed by cardiac muscle, adipose tissue, and the liver. In the liver, insulin inhibits the production and release of glucose in healthy subjects by inhibiting gluconeogenesis and glycogenolysis. Defects in

glucose transport or in the hexokinase II pathway may represent the principle mechanism underlying the inhibition of muscle glycogen synthesis. *In vivo* studies using nuclear magnetic resonance spectroscopy have demonstrated defects in muscle glycogen synthesis are caused by a defect in muscle glucose itself.¹⁴ The glucose transporter 4 (GLUT4) is the major carrier of glucose into the cell. Stimuli, such as insulin and exercise, promote GLUT4 activity by embedding it into the cell membrane. Peroxisome proliferator–activator receptors (PPARs) are nuclear hormone receptor transcription factors that cause target genes to be expressed and play essential roles as regulators of insulin action¹³ (Fig. 32.2).

Previous definitions of IR generally considered the condition exclusively in terms of the negative effects on glucose metabolism. Such effects include hyperglycemia following a high carbohydrate meal and overstimulation of pancreatic beta cells to produce more insulin. Eventually, pancreatic beta cells become unable to produce sufficient insulin to maintain normal blood glucose levels. This inability of beta cells to produce sufficient insulin underlies the transition from IR to type 2 DM.¹⁵ It is important to emphasize that IR occurs at the cellular level despite pancreatic beta cell dysfunction (Fig. 32.3).

TABLE 32.2

Abnormalities Associated With Insulin Resistance^{9,10}

Some Degree of Glucose Intolerance

- Impaired fasting glucose
- Impaired glucose tolerance

Abnormal Uric Acid Metabolism

- ↑ Plasma uric acid concentration
- ↓ Renal uric acid clearance

Dyslipidemia

- ↑ Triglycerides
- ↓ High-density lipoprotein cholesterol
- ↓ Low-density lipoprotein particle diameter
- ↑ Postprandial lipemia

Hemodynamic Changes

- ↑ Sympathetic nervous system activity

- ↑ Renal sodium retention
- ↑ Blood pressure (50% of patients with hypertension have insulin resistance)

Hemostatic Changes

- ↑ Plasminogen activator inhibitor-1
- ↑ Fibrinogen

Endothelial Dysfunction

- ↑ Mononuclear cell adhesion
- ↑ Plasma concentration of cellular adhesion molecules
- ↑ Plasma concentration of asymmetric dimethyl arginine
- ↓ Endothelial-dependent vasodilatation

Reproductive

- Polycystic ovarian syndrome
- Low testosterone in men

Data from Corona G, Monami M, Rastrelli G, et al. Testosterone and metabolic syndrome: a meta-analysis study. *J Sex Med.* 2011;8:272-283 and Reaven G. Metabolic syndrome: pathophysiology and implications for management of cardiovascular disease. *Circulation.* 2002;106:286-288.

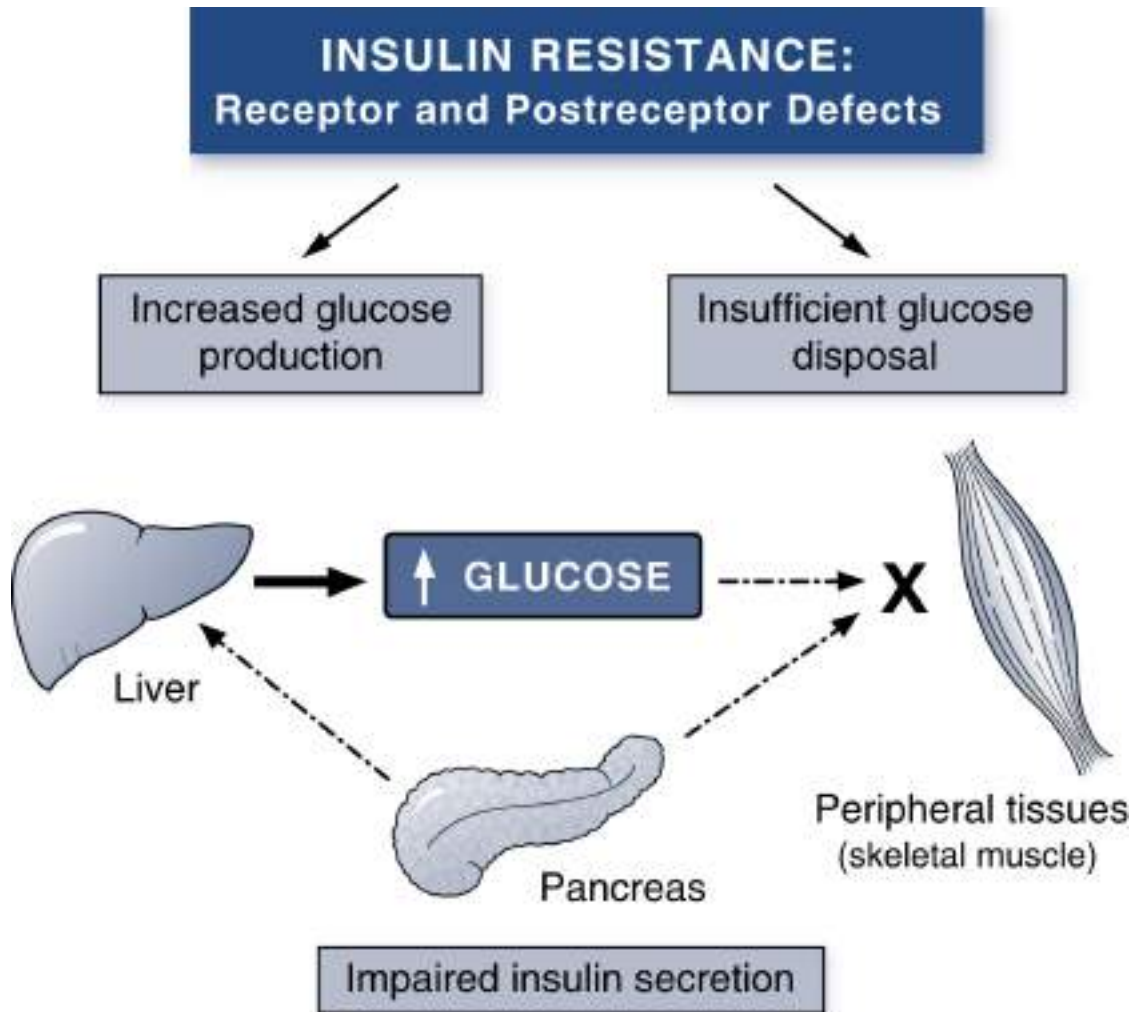

FIG. 32.1 Sites of the Three Major Pathogenic Defects That Lead to Type 2 Diabetes Mellitus.

Insulin resistance in muscle causes reduced glucose disposal from the bloodstream, and hepatic insulin resistance causes increased glucose production. Impairment of insulin secretion by pancreatic beta cells is a critical feature that leads to hyperglycemia when insulin secretion and the timing of the insulin response to glucose are defective.

FIG. 32.2 Insulin Signaling Pathways.

AMP, adenosine monophosphate; ATP, adenosine triphosphate; CLA, conjugated linoleic acid; cox, cyclooxygenase; glut, glutamine transporter; HDL, high-density lipoprotein cholesterol; LDL, low-density lipoprotein cholesterol; NF- κ B, a B cell-specific transcription factor; PPAR, peroxisome proliferator-activator receptor; TNF, tumor necrosis factor.

As further studies of the pathophysiology of IR have been reported, the traditional glucocentric view of IR has evolved to include the “lipocentric” concept. Scientists have discovered that abnormalities in fatty acid metabolism cause inappropriate build-up of fat in muscle tissue, the liver, and other organs. Lipotoxicity, associated with increased plasma free fatty acid levels, is a hallmark of IR. Subsequently, these lipids are associated with not only an abnormal accumulation but also increased fat oxidation with further damage to the cell.^{16,17}

IR may involve the insulin receptor itself. The insulin receptor belongs to the receptor tyrosine kinase family which also includes insulin-like growth factor-1 receptor (IGF-1R) and the insulin receptor-related receptor (IRR). Therefore impairment of insulin-stimulated glucose

uptake may also result from the upregulation of inhibitors of these signaling pathways. Furthermore, protein-tyrosine phosphatases (PTPases) may also have a role as negative regulators of the insulin-signaling cascade. A combination of the downregulation and upregulation of certain receptors may be a key element of IR pathophysiology.¹³

Chronic, low-grade inflammation has also been posited to have a central pathogenic role in IR. Research has shown that proinflammatory cytokines and acute-phase reactants are associated with many features of the metabolic syndrome. These inflammatory cytokines promote IR through site-specific serine phosphorylation of insulin substrates.¹⁶

Therefore, IR, predominantly in skeletal muscle, manifests as a reduction in insulin-stimulated glycogen synthesis resulting from decreased glucose transport. Once this occurs, lipid accumulates in many cells, most importantly in the liver and pancreas, causing oxidative stress and deleterious changes to cellular metabolism. These multiple defects in insulin signaling have been posited to underlie downstream impaired glucose metabolism in most tissues^{13,18} ([Table 32.3](#)). These pathways are summarized in [Fig. 32.4](#).

FIG. 32.3 Natural history of diabetes, depicting rising blood glucose levels with progressive beta cell dysfunction.

Impact of Environmental Toxins on Metabolic Syndrome and Type 2 Diabetes Mellitus New research points to the role of environmental toxins as etiological factors in the pathogenesis of IR and type 2 DM. The organic compound bisphenol A (BPA) has been found to have an association with IR and type 2 DM. BPA is used to make polycarbonate and epoxy resins and is primarily found in food and beverage containers. BPA has been used commercially since 1957, with more than 90% of U.S. residents estimated to have detectable levels in urine. Findings from the 2003–2008 NHANES report revealed an association between BPA and prediabetes, independent of traditional risk factors.¹⁹ Based on experimental studies, BPA appears to affect glucose metabolism through a number of pathways including insulin resistance, pancreatic beta cell dysfunction, adipogenesis, inflammation, and oxidative stress.¹⁹ Other

pollutants, such as air pollution²⁰ and traffic-related pollution,²¹ have also been implicated in IR and increased risk of mortality attributable to type 2 DM.

Persistent organic pollutants (POPs) may also play a role in the pathogenesis of the metabolic syndrome and type 2 DM. POPs are a class of compounds characterized by low water and high lipid solubility, an ability to persist in the environment, and a cause of biomagnification in the food chain. Pesticides, solvents, and foods from animals, such as seafood, are the main sources of POPs. Because POPs are lipophilic, these substances are highly resistant to degradation and have an estimated half-life of 7 to 10 years.⁴⁵ Some of the most common POPs found in humans include dioxins, polychlorinated biphenyls, dichlorodiphenyldichloroethylene, transnonachlor, hexachlorobenzene, and hexachlorocyclohexanes.⁴⁶ In the 1999–2002 NHANES report, higher concentrations of POPs (mainly pesticides and herbicides) were associated with an increased prevalence of type 2 DM. Subjects in the highest category (more than the 90th percentile) of exposure, as compared with the lowest category (less than the 25th percentile), had a 38-fold ($P < 0.001$) increased prevalence of type 2 DM. Obesity was not found to be a risk factor for type 2 DM in individuals with undetectable levels of persistent organic pollutants.⁴⁷ A year later, the same research group reported a positive correlation between POPs (in particular organochlorine pesticides) and the metabolic syndrome.⁴⁸ According to a *Lancet* editorial, the findings from the study by Lee et al. might imply that “virtually all of the risk of diabetes conferred by obesity is attributable to persistent organic pollutants, and that obesity is only a vehicle for such chemicals.”⁴⁶ In a 2013 review of the epidemiological evidence of an association between POPs and diabetes, Magliano et al.⁴⁵ concluded that there is an independent relationship between POPs exposure and diabetes in the general population as well as occupationally exposed and high-risk populations.

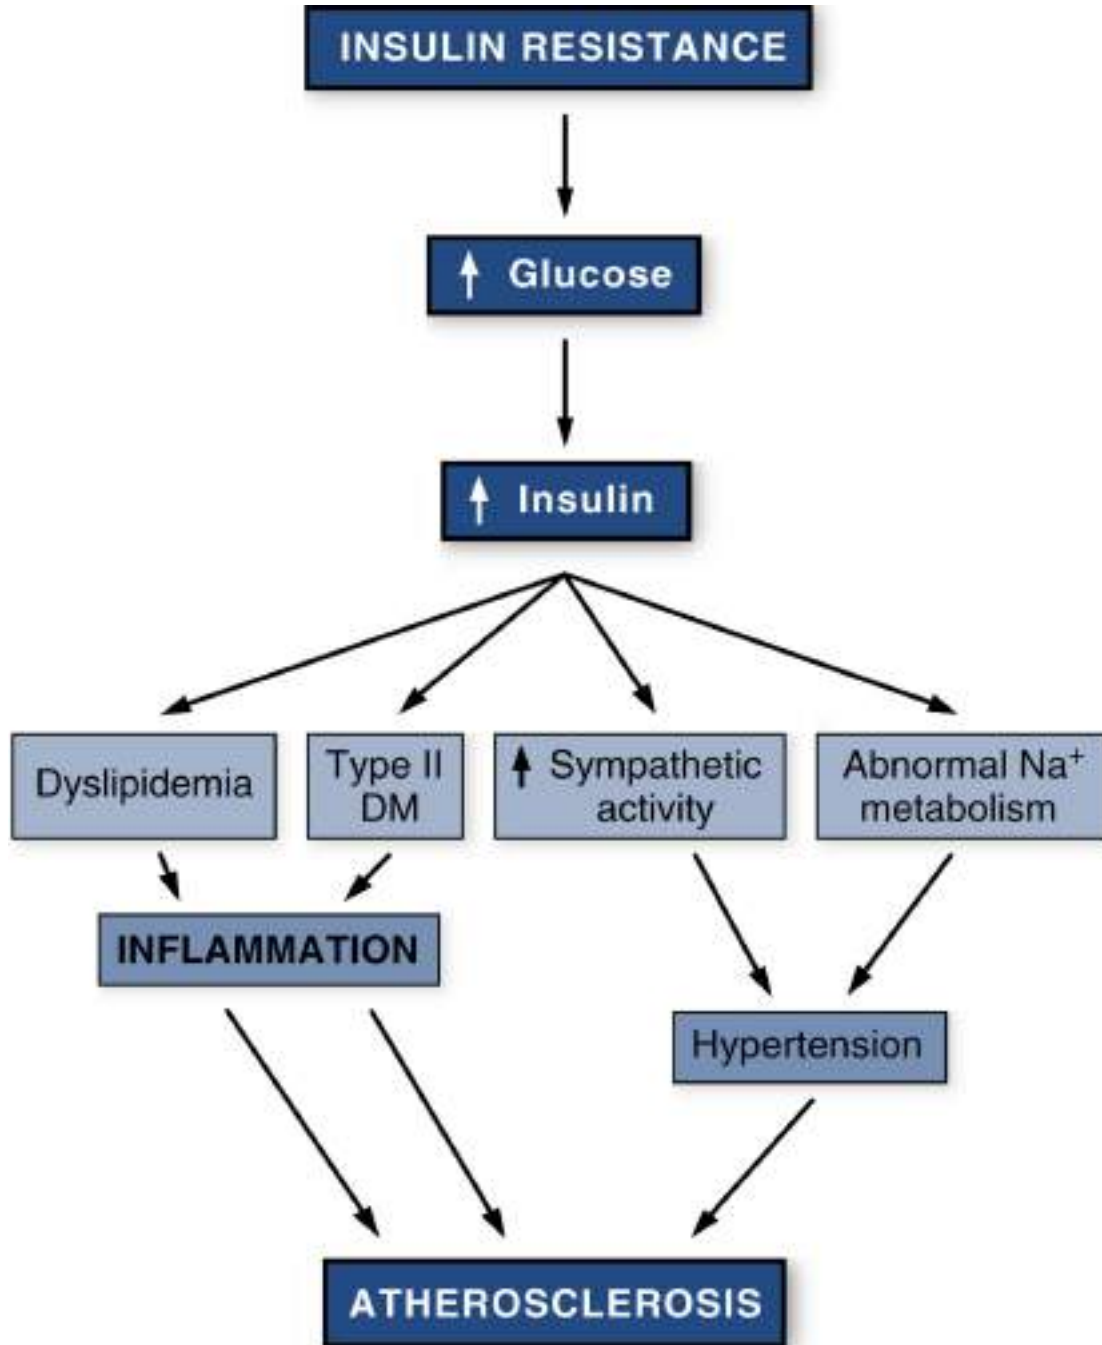

FIG. 32.4 Summary of Insulin Resistance and Its Effects.

DM, diabetes mellitus; Na⁺, sodium.

Inorganic arsenic is another environmental toxin that appears to be associated with the metabolic syndrome and type 2 DM. The primary sources of inorganic arsenic are contaminated drinking water due to naturally occurring arsenic in rocks and soils, and food.⁴⁹ Organic arsenic

is predominately derived from the ingestion of fish and shellfish, and is considered nontoxic as it is excreted unchanged in the urine. Results from the 2003–2004 NHANES cross-sectional study revealed a positive association between increasing levels of total urinary arsenic and type 2 DM. Subjects with type 2 DM had 26% higher total arsenic levels than subjects without DM. In the fully adjusted model comparing the 80th and 20th percentiles of total urine arsenic (16.5 vs 3.0 g/L), the odds ratio for type 2 DM was 3.58.⁵⁰ No association was observed between organic arsenic and type 2 DM. The investigators suggested that 8% of public water systems in the United States exceed the U.S. Environmental Protection Agency's standard of 10 mcg/L for drinking water.⁵⁰ Wang et al.⁵¹ also found an increased prevalence of metabolic syndrome in subjects with elevated hair arsenic levels. After adjustment for confounding variables, subjects with hair arsenic in the 2nd tertile (0.034 mcg/g) had a statistically significant increased risk of metabolic syndrome (odds ratio, 2.54; 95% CI, 1.20 to 5.39; $P < 0.015$). Inorganic arsenic is thought to increase the risk of type 2 DM by stimulating increased expression and secretion of high sensitivity C-reactive protein (hs-CRP), which in turn activates nuclear factor kappa-beta via the Rho-kinase pathway.⁵²

Metabolic syndrome is primarily an environmental phenotypic disorder (92%) rather than a genotypic disorder (8%).

Nonalcoholic Fatty Liver Disease

Nonalcoholic fatty liver disease (NAFLD) has been defined as the accumulation of fat in the liver (hepatic accumulation of greater than 5% of liver weight confirmed by magnetic resonance spectroscopy or liver biopsy) in the absence of other specific causes of liver infiltration, such as recent or significant alcohol ingestion, hepatic viral infections, or other causes of liver disease.^{53,54} NAFLD is now the most common chronic liver disease worldwide, affecting both adults and children with an estimated prevalence of 20% to 35% in the general population.⁵⁵

Traditionally NAFLD has been viewed as a histological continuum from pure fatty liver (steatosis) through nonalcoholic steatohepatitis (NASH) to liver fibrosis, potentially leading to liver cirrhosis associated with increased risk of hepatocellular carcinoma.⁵³ The histological progression of NAFLD begins with micro–macro vesicular steatosis,

which primarily affects the perivenular regions, and may extend to panacinar distribution. The diagnosis of NASH is informed by the presence of fatty infiltration accompanied by inflammation associated with one of three additional features on liver histology: hepatocyte ballooning; Mallory hyaline; or fibrosis.^{54,56} IR is considered the initial injury to the liver, which leads to increased uptake and synthesis of free fatty acids and impaired inhibition of adipose tissue lipolysis with resultant steatosis. Following initial fatty infiltration, the liver becomes increasingly vulnerable to multiple hits including gut-derived bacterial endotoxins, cytokine and adipokine imbalance, mitochondrial dysfunction, oxidative stress, lipid peroxidation, Kupffer cell activation, and hepatic stellate cell activation.⁵⁸ These multiple hits are proposed to stimulate hepatocyte injury and the progression from steatosis to NASH and ultimately fibrosis and cirrhosis (Fig. 32.5).⁵⁹

Single nucleotide polymorphisms (SNPs) appear to be associated with NASH but not simple steatosis. NASH confers an increased risk of cirrhosis and secondary malignancy, partly attributable to genetic predisposition.

Immunological events are believed to play a role in the development and progression of NASH, and to be associated with hepatic apoptosis and fibrogenic responses. Additionally, impaired regeneration of hepatic progenitor cells appears to be a unifying pathophysiological pathway for NASH, with resultant dysregulated adipokine production and fibrosis.⁵³ In recognizing simple steatosis and NASH as two discrete entities with different etiologies, clinicians can identify and more closely monitor patients at greatest risk of liver fibrosis and cirrhosis, and individualize therapeutic interventions.

The Interrelationship Between Nonalcoholic Fatty Liver Disease and IR

NAFLD is considered the hepatic manifestation of metabolic syndrome, as IR is currently considered the fundamental underlying pathogenetic mechanism underlying the development of hepatic steatosis.

Additionally, all key components of metabolic syndrome (abdominal obesity, impaired fasting glucose, dyslipidemia, and elevated blood pressure) have been identified as major risk factors for the development and progression of NAFLD.⁵⁵ Based on epidemiological studies, cardiovascular disease is the leading cause of death in NAFLD patients, followed by malignancy and liver disease, respectively. These findings

imply NAFLD is a strong risk factor for cardiovascular disease and cardiovascular-related mortality.^{61,62}

The prevalence of NAFLD is estimated to be 50% to 100% in obese and overweight patients, and 30% to 50% in patients with metabolic syndrome.⁵⁵ NAFLD combined with metabolic syndrome is reportedly correlated with greater severity of liver disease and increased likelihood of NASH, independent of age, sex, and body weight. Given the high prevalence of NAFLD, it has been proposed that NAFLD be incorporated into diagnostic criteria for the metabolic syndrome.⁵⁵

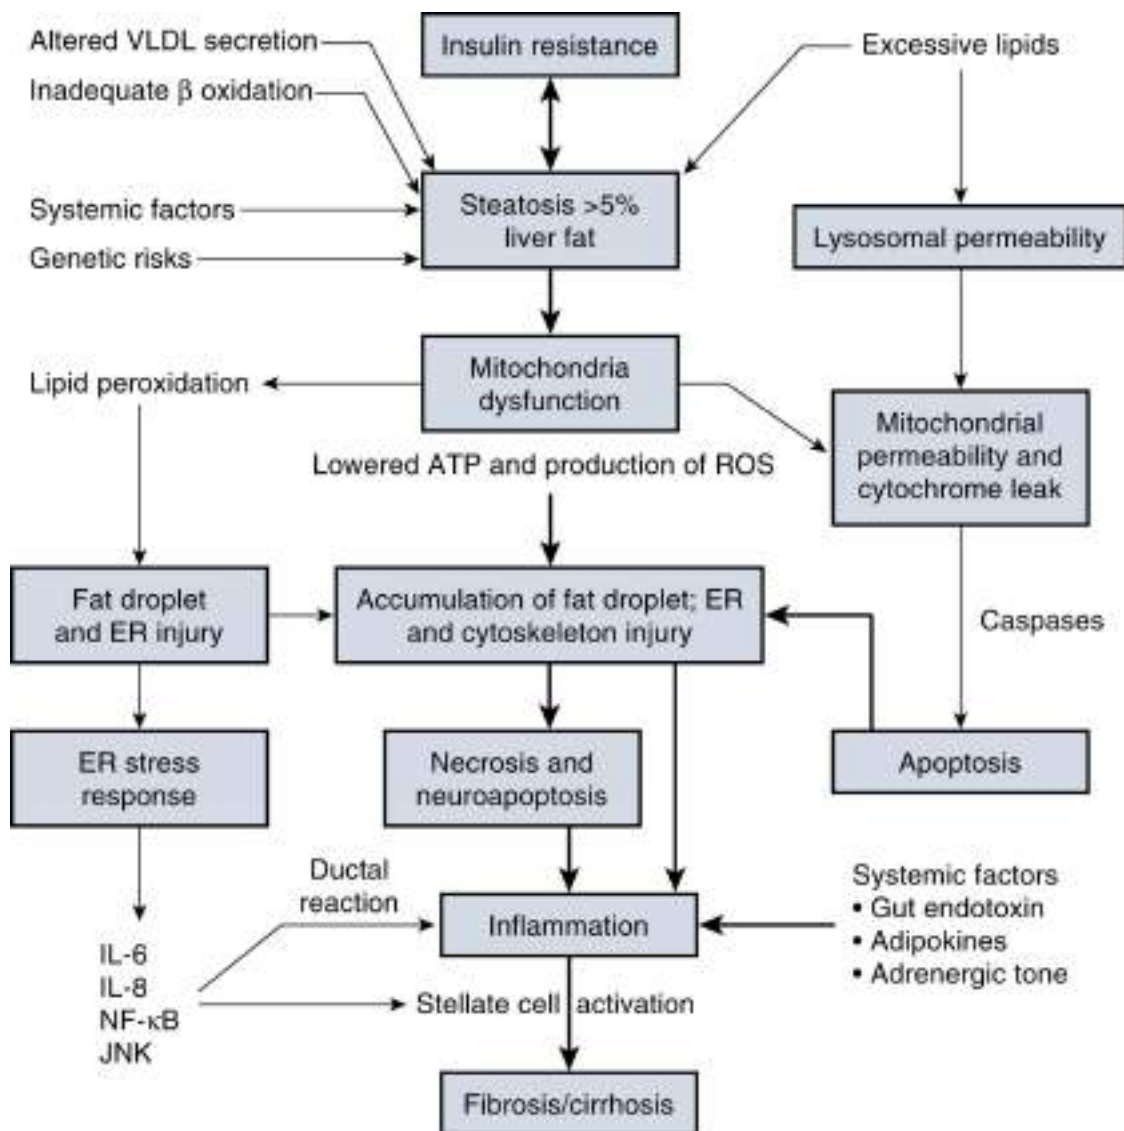

FIG. 32.5 Illustration of Molecular Events Involved in the Pathogenesis of Nonalcoholic Fatty Liver Disease.

ATP, adenosine triphosphate; ER, endoplasmic reticulum; IL, interleukin; JNK, c-Jun-N-terminal kinase; NF- κ B, nuclear factor kappa beta, a B cell-specific transcription factor; ROS, reactive oxygen species. (Reprinted with permission from Xiao J, Fai So K, Liong EC, Tipoe GL. Recent advances in the herbal treatment of non-alcoholic fatty liver disease. *J Tradit Complement Med.* 2013;3(2):88-94.)

In the hepatic IR state, fatty infiltration is characterized by an increase in free fatty acids (FFAs) from sources including diet, adipose tissue, and de novo lipogenesis. Persistently increased glucose and hyperinsulinemia stimulate de novo lipogenesis by upregulating a number of transcription factors, which increase the activity of lipogenic enzymes. Fructose and high-fructose corn syrup have been identified as sugars that stimulate lipogenesis more profoundly than glucose. Ordinarily, FFAs are transported to the mitochondria for beta-oxidation or undergo esterification for excretion in VLDL or storage as fat droplets. IR-induced upregulation of FFAs causes direct hepatotoxicity via a number of intracellular responses. Excess FFAs activate the endoplasmic reticulum stress response, cause leakage during mitochondrial beta-oxidation, and lipid peroxidation in mitochondria (primarily), microsomes, and peroxisomes leading to reduced intracellular antioxidant capacity and increased oxidative stress. These mechanisms promote cellular apoptosis, a self-protective cellular response and key pathogenic event in NAFLD. Prolonged and increased levels of reactive oxygen species generated from mitochondrial dysfunction ultimately lead to steatosis and hepatic fibrosis.⁵⁸

Diagnosis

Metabolic syndrome can be diagnosed using the criteria described in [Table 32.1](#). Outside a research laboratory, standard of practice for the diagnosis of the metabolic syndrome is to conduct a 2-hour glucose and insulin tolerance test (GITT), which can easily be ordered through any outpatient laboratory. The protocol is as follows: (1) 2 days of carbohydrate loading, (2) blood sampling for fasting glucose and insulin measurements, and (3) consumption of a 75-g glucose drink. Thereafter, blood specimens for glucose and insulin measurements are obtained (but not always necessarily) at half-hour intervals for the first hour, followed by a final specimen 2 hours later. In the majority of patients, fasting and 2-hour measurements are sufficient. Essentially, this protocol is the standard glucose tolerance test (GTT) with concomitant insulin testing. A

caveat of this approach is that clinicians should ensure the laboratory used is familiar with diagnostic procedures involving insulin, which is a very unstable hormone in vitro. False-negative diagnoses are possible if only a fasting insulin specimen is obtained. Regular drawing of blood specimens for the measurement of insulin is required to maintain test functionality. Clinicians are required to understand the effect of insulin on managing blood glucose levels following glucose consumption. Baseline fasting insulin levels should normally be less than 15 microunits/mL and less than 30 microunits/mL at 2 hours following consumption of a 75-g glucose load.

Although the 2-hour GITT is considered the most accurate and functional test, other methods for the diagnosis of the metabolic syndrome include the following:

- Triglyceride-to-HDL cholesterol ratio (TG:HDL-C)—a healthy ratio is less than 2.
- Glycosylated hemoglobin (HbA1c): values for patients with IR are between 5.7 and 6.4 as per the 2010 American Diabetes Association guidelines.⁶³
- Fasting insulin: When assessed in isolation, normal values should be less than 15 microunits/mL (140 pmol/L); however, a normal fasting insulin result does not rule out IR. Reference ranges are laboratory specific, so clinicians must check with the clinical laboratories for specific values. In addition, what is “normal” and what is “healthy” can be vastly different.

Other markers of importance include elevated hs-CRP, uric acid, small dense low-density cholesterol (sd LDL-C), and inflammatory markers such as IL-6 and IL-8, TNF-alpha, PAF-1, and adiponectin. Because NAFLD is hypothesized to represent the hepatic manifestation of IR, the measurement of gamma-glutamyl transpeptidase (GGT) levels should also be considered as this transaminase enzyme is the most sensitive in detecting liver toxicity.

For the majority of clinicians, the 2-hour GITT is the most valuable in terms of diagnosis and patient education, particularly for normal-weight individuals suspected to have metabolic syndrome and women with polycystic ovarian syndrome.

Integrative Therapy

Lifestyle intervention offers the greatest promise for the prevention and management of the metabolic syndrome.

Lifestyle Factors

Although the pathogenesis of IR is multifactorial, lifestyle factors are known to have a profound effect on blood glucose homeostasis. According to statistics reported in 2009, at least 92% of type 2 DM cases are related to lifestyle choices.⁶⁴ Lack of exercise, central adiposity, and a diet high in refined carbohydrates and saturated fats and low in fiber represent key lifestyle characteristics associated with IR and type 2 DM. Knowler et al.,⁶⁵ researchers in the Diabetes Prevention Program, compared lifestyle modification with diet and medication in more than 3000 patients with prediabetes. The investigators assigned patients to three groups who received one of the following: (1) metformin 850 mg twice daily, (2) a lifestyle modification program with goals of at least 7% weight loss, or (3) placebo. After 3 years of follow-up, the metformin group contained 31% fewer diabetics, and the lifestyle modification group contained 58% fewer subjects with diabetes compared with the placebo group. Exercise, weight loss, and a healthy diet are key lifestyle interventions for reducing IR and the risk of developing type 2 DM.⁷

Exercise

Regular exercise is a vital component of a holistic medical treatment plan and has been shown to reduce the incidence of IR by half.⁶⁶ Patients with IR and metabolic syndrome are recommended to partake in 30 to 60 minutes of moderate-intensity aerobic workouts (e.g., brisk walking) at least five times per week. Resistance training should also be encouraged up to twice weekly.⁷ Exercise offers a number of physiological and mental/emotional benefits. One physiological benefit is that exercise enhances GLUT4 transporter activity, which in turn facilitates glucose entry into cells while bypassing the need for insulin.⁶⁷ This effect has been demonstrated both in healthy individuals and those with IR or T2DM. Preliminary research also suggests that exercise has utility in improving the inflammatory state associated with IR by reducing levels of proinflammatory chemokines.⁶⁸ Yoga is another modality proven to help reduce oxidative stress in patients with type 2 DM. Yoga combined with standard care reportedly improves glycemic control and reduces body mass index.⁶⁹ Other benefits of regular workouts include increased

lean muscle mass and reduced body fat (see [Chapter 91](#)).

Weight Management

Excessive food consumption, particularly dietary fat and foods with a high glycemic index, is a key contributor to the pathogenesis of IR and metabolic syndrome.² Although the majority of patients with IR are overweight, a small subgroup of patients has a normal body mass index. These patients are termed *metabolically obese*, normal-weight individuals and share the same risks of developing type 2 DM and cardiovascular disease due to increased visceral fat.⁷⁰ Increased visceral fat is associated with increased release of free fatty acids and initiates a self-perpetuating cycle leading to the development of increased IR. Affected patients are said to be “bathed in cortisol” and have the appearance of Cushing syndrome. As previously mentioned, this type of fat affects other organs by causing dysfunction and increasing inflammation. Adipose cells are not, as previously believed, passive depots for energy but are rather hormonally active by secreting adipokines. Adipose cells have also been shown to secrete TNF-alpha, adiponectin, resistin, leptin, and other inflammatory mediators, all of which are involved in the promotion and exacerbation of IR. Hu et al.⁷¹ reported sedentary behaviors (particularly watching television) are associated with significantly elevated risks of visceral adiposity, irrespective of exercise levels. Studies have reported that even small percentages of weight loss (6 to 10%) can significantly improve IR and reduce the risk of developing type 2 DM by 58%.^{65,72} Weight reduction (coupled with exercise) has also been shown to improve histological disease activity in patients with NAFLD.⁵⁸

As little as 10% weight loss can reverse fatty infiltration of the liver.

The speed of chewing has also been shown to have an impact on diabetes risk. Fast eating is reported associated with a more than two-fold increased risk of type 2 DM compared with slower eating.⁷³ Eating quickly has also been positively associated with body mass index, increased body weight, and weight gain based in a nationwide survey of middle-aged women.⁷⁴

Nutrition

For patients with insulin resistance, the focus should be on diets rich in

whole grains rather than refined grains, fish and white meat instead of red meat, and plenty of fruits and vegetables along with nuts, legumes, and soy. In 2002, researchers from the Harvard School of Public Health published a set of nutritional guidelines known as the Alternative Healthy Eating Index (AHEI) with an emphasis on the foods listed previously. Results from the Whitehall II Prospective Cohort Study showed that adherence to the AHEI in a middle-aged population was associated with a reversal of the metabolic syndrome after 5 years (odds ratio 1.88; 95% CI, 1.04 to 3.41). This effect was more pronounced in subjects with central obesity and elevated serum triglycerides.⁷⁵

The Mediterranean and low glycemic index/load diets are considered the most effective nutritional regimens for the treatment of metabolic syndrome, insulin resistance, and NAFLD.

Mediterranean Diet

Much has been written about the Mediterranean diet, which is rich in vegetables, legumes, soy products, fish, and essential fatty acids. This type of diet is also low in refined carbohydrates and “junk foods,” as well as in red meat, which is rich in saturated fats.⁵⁵ The beneficial effects associated with adherence to the Mediterranean diet relate to the nutrient-dense properties of the foods (i.e., vitamins, minerals, phytochemicals, and fiber).⁵⁵ In a randomized trial, Esposito et al.⁷⁶ compared a Mediterranean diet with a standard diet in 180 patients with metabolic syndrome. After 2 years, only 40 out of 90 subjects on the Mediterranean diet still had features of metabolic syndrome compared with 78 out of 90 participants in the standard diet group. A recent paper by Salas-Salvadó et al.⁷⁷ also demonstrated a significant reduction in the incidence of type 2 DM with adherence to a Mediterranean diet. In this trial, nondiabetic subjects aged 55 to 80 years old were randomly assigned to either a low fat diet (control group), a Mediterranean diet supplemented with 1 L/week of free virgin olive oil, or a Mediterranean diet supplemented with 30 g/day of nuts. All diets were ad libitum. After 4 years, the incidence of type 2 DM was 18% in the control group, 10% in the Mediterranean plus olive oil group, and 11% in the Mediterranean plus nuts group. When pooling the Mediterranean diet groups, there was a 52% reduction in the incidence of type 2 DM when compared with the control group. Of particular interest was the fact that

the reduced incidence of type 2 DM occurred in the absence of any significant alterations in body weight or physical activity. Adherence to the Mediterranean diet has also been associated with reduced risk of metabolic syndrome in NAFLD patients⁵⁵ (see [Chapter 88](#)).

Low-Glycemic Index Foods

The glycemic-index is a system for classifying carbohydrate-containing foods based on glycemic response. Carbohydrates range from simple sugars to starches and can all be converted to glucose. The rate at which conversion occurs is determined by saccharide chain length, with longer chains constituting complex carbohydrates. The glycemic index value for carbohydrates can vary by more than fivefold, with starchy foods having a higher glycemic index than nonstarchy foods such as fruits, vegetables, and legumes. Diets that favor high-glycemic index foods are associated with increased 24-hour glucose and insulin levels in addition to higher levels of C-peptide and glycosylated hemoglobin. These effects have been demonstrated in both nondiabetic and diabetic individuals.⁷⁸

Research has shown that a combination of exercise and a low-glycemic index diet in obese subjects with prediabetes not only improves postprandial hyperinsulinemia but also reduces pancreatic beta cell stress. Conversely, exercise in combination with a high-glycemic index diet impairs beta and intestinal K cell function despite a similar reduction in weight loss. These findings emphasize the importance of diets rich in low-glycemic index foods that support beta cell preservation, a key factor in the prevention of type 2 DM⁷⁹ (see [Chapter 87](#)).

Fiber

Dietary fiber, either from whole foods or dietary supplements, is a vital component of the treatment plan for IR and metabolic syndrome. Fiber helps reduce blood pressure as well as total and LDL cholesterol levels, and it modifies inflammatory markers. When taken with meals, soluble fibers, such as psyllium, have been shown to improve postprandial glycemic index and increase insulin sensitivity. Psyllium appears to work by reducing glucose absorption from the intestine and increasing GLUT-4 protein expression in muscles. Regular consumption of dietary fiber also promotes weight reduction by enhancing satiety. Oats and barley are other examples of soluble fiber that have U.S. Food and Drug Administration (FDA)-approved health claims for reducing the risk of heart disease.⁴

Cooking Techniques

Cooking methods can also have an impact on biochemical markers associated with IR and metabolic syndrome. High-heat-treated foods typically found in the Western diet generate harmful compounds known as Maillard reaction products. These compounds have been found to reduce insulin sensitivity and increase plasma cholesterol and triglycerides.⁸⁰ Mild cooking techniques such as steaming, poaching, and stewing are recommended instead of roasting, barbecuing, broiling, or frying.

Therapeutic Foods

Blueberries are rich in phenolic compounds and anthocyanins and have been demonstrated to have certain health benefits, including improved cognition and reduced cardiovascular and cancer risk. Preliminary research suggests blueberries may also exhibit antidiabetic effects. In a double-blind, placebo-controlled randomized trial, consuming the equivalent of two cups of fresh blueberries a day improved IR in nondiabetic and obese insulin-resistant individuals.⁸¹ Consuming this quantity of blueberries has also been shown to reduce blood pressure, oxidized LDL cholesterol, and lipid peroxidation in patients with metabolic syndrome.⁸²

Apple cider vinegar (20 g diluted in 40 g of water) has been shown to reduce postprandial fluxes in glucose and insulin following a carbohydrate-rich meal. Acetic acid in vinegar acts similarly to medications such as acarbose and metformin by suppressing disaccharidase activity and increasing glucose-6-phosphate concentrations in skeletal muscle.⁸³ Other forms of vinegar, such as white vinegar in a vinaigrette sauce, can also be used to lower post-prandial glucose (20 to 28 g white vinegar mixed with 8 g olive oil).^{84,85} Another first step would be to promote the patient's own acid production by stopping unnecessary chronic usage of antacid medications if possible.

Foods and Substances to Avoid or Consume in Moderation

[Table 32.4](#) provides a list of foods and substances that should be avoided, given their direct or indirect role in affecting glucose and insulin metabolism.

Research has shown that low to moderate alcohol consumption (one to two standard drinks per day) increases insulin sensitivity and reduces insulin concentrations in nondiabetic postmenopausal women. However,

regular consumption in this cohort also increased levels of the steroidogenic hormones DHEA-S and estrone sulfate, which are possible risk factors for breast cancer.⁸⁶ Alcohol appears to have a U-shaped relationship with metabolic syndrome, with nondrinkers and heavy drinkers having a similar risk profile. This curious finding may be attributable to increased levels of HDL cholesterol observed in heavy drinkers.⁸⁷ As the potential risks may outweigh the benefits, teetotalers should not be encouraged to start drinking to reduce their risk of developing type 2 DM. Smoking should be avoided as it is a known health hazard and shown to be associated with an increased risk for type 2 DM.⁸⁸

Mind Body

Stress Management

Relaxation techniques are valuable in the treatment of IR because they promote stabilization of adrenal gland function. Stress management lowers both cortisol levels and blood pressure, increases DHEA, improves immunity, and reduces anxiety and depression. Patients are therefore less likely to abuse their bodies and tend to feel better about themselves following the use of relaxation techniques. A prescription with an individualized approach involving meditation, relaxation techniques, prayer, visualization, and other stress-reducing modalities is indicated in patients with IR or type 2 DM.⁹²

TABLE 32.4

Foods to Avoid in Patients With Insulin Resistance and the Metabolic Syndrome

Food/Substance Metabolic Effect	
Refined Starchy Foods	Instant rice, potatoes, white breads, pasta, cereals such as Rice Krispies and corn flakes, corn chips, and canned foods have a high glycemic index and are known to impair glucose metabolism and increase insulin secretion. ⁷⁸
Fast Foods	These foods are calorie rich, given their high sugar and fat content, and contribute to weight gain, insulin resistance, and hyperlipidemia. ²
Sugar Sweetened Beverages	Soft drinks, fruit drinks, iced tea, and energy and vitamin water drinks are often rich in fructose corn syrup and are associated with weight gain and an increased risk of IR and type 2 DM. ⁸⁹ Consuming one to two drinks/day is associated with a 26% increased risk of developing type 2 DM. ⁹⁰
Artificial Sweeteners	Artificial sweeteners, such as aspartame, saccharin, and sucralose, are associated with obesity and a twofold increased risk of type 2 DM. ⁹¹

DM, diabetes mellitus.

Stress management and exercise are key components of therapies for IR and type 2 DM.

Depression

The results of a 2009 study by Takeuchi et al.⁹³ indicate the metabolic syndrome may be a predictive factor for the development of depression but not anxiety. Multivariate analysis indicated that an increase in waist circumference was the main factor influencing the relationship between metabolic syndrome and new-onset depression. Skilton et al.³⁵ also found a positive association between depression (versus anxiety) and metabolic syndrome. In light of their research, the investigators posited screening for depression in patients with the metabolic syndrome.

Supplements

Numerous nutritional supplements have demonstrated a beneficial effect on glucose and insulin metabolism. Patients with IR and metabolic syndrome should include a multivitamin as a core component of their health regime. Certain nutrients, including antioxidants, may be required in therapeutic doses to ensure a physiological effect in the management of IR and metabolic syndrome.⁹⁴⁻⁹⁶ Supplementation with the following nutraceuticals should be guided by overall health and dietary habits along with laboratory parameters and current IR status.

Vitamin B6

A deficiency in vitamin B6 is associated with a decrease in several important enzymes that contribute to gluconeogenesis (the generation of glucose from nonsugar substrates).⁹⁷ In patients taking metformin for polycystic ovarian syndrome, vitamin B6 and folate have been shown to counteract increases in homocysteine levels.⁹⁸

Dosage

The recommended dose of vitamin B6 is 50 mg to 100 mg/day.⁹⁹

Precautions

None have been reported at the recommended dose. Higher doses

(>150 mg) may cause reversible neuropathy.

Folic Acid

The combination of IR and elevated plasma homocysteine levels is associated with cardiovascular risk. Research has shown that patients with this combination of risk factors also have altered or reduced folate levels, which are thought to lead to the progression of hypertension.¹⁰⁰ High dose supplementation with folic acid has been shown to protect against microvascular complications associated with metabolic syndrome¹⁰¹ and improve metabolic profiles in women with polycystic ovarian syndrome.¹⁰² Patients heterozygous or homozygous for the methylenetetrahydrofolate reductase single nucleotide polymorphism (MTHFR C677T) may benefit from supplementation with L-5-Methyltetrahydrofolate rather than folic acid.

Dosage

The recommended dose of folate is 500 mcg to 5 mg / day.⁹⁹⁻¹⁰²

Precautions

None have been reported. The administration of high doses of folic acid to patients with a concomitant vitamin B₁₂ deficiency may correct megaloblastic anemia but increase the risk of irreversible neurological damage.¹⁰³

Vitamin B₁₂

Research has demonstrated a negative correlation between B₁₂ status and body mass index.¹⁰⁴ In patients with metabolic syndrome, the administration of folate and vitamin B₁₂ reportedly decreases IR and improves endothelial function. Homocysteine levels have also been shown to improve with folate and vitamin B₁₂, affirming the beneficial effect of these treatments on cardiovascular disease risk factors.¹⁰⁵ Because metformin has been shown to impair vitamin B₁₂ status, practitioners should assess and monitor B₁₂ levels in patients receiving metformin.¹⁰⁶

Dosage

The recommended dose of vitamin B₁₂ is 500 mcg/day.¹⁰⁷

Precautions

None have been reported at the recommended dose.

Vitamin C

Individuals with metabolic syndrome have been found to have significantly lower levels of vitamin C compared to healthy individuals.^{108,109} A deficiency of vitamin C is thought to be associated with a greater resistance to fat mass loss.¹¹⁰ High doses of vitamin C have also been found to reverse the adverse effects of free fatty acids on vascular function.^{111,112}

Dosage

The recommended dose of vitamin C is 1000 to 2000 mg/day.¹¹³

Precautions

Take with food to reduce the risk of diarrhea.

Vitamin D

Supplemental (and dietary) vitamin D has been shown to reduce the development of metabolic syndrome.¹¹⁴ In a study of young adults, an inverse relationship between blood glucose, IR, and serum 25-hydroxy (OH) vitamin D was demonstrated.¹¹⁵ Other research has confirmed that serum 25(OH) D levels positively correlate with insulin sensitivity.^{116,117} Ford et al.¹¹⁸ also reported significant inverse relationships between serum vitamin D levels and abdominal obesity, elevated triglycerides, and hyperglycemia. Visceral fat reduces the absorption of vitamin D from the skin.

Dosage

The recommended dose of vitamin D is 300 to 2000 IU/day.^{119,120}

Dosing may also be guided by the season of the year and serum 25(OH)

D levels (the preferred range is 30 to 60 ng/mL or 75 to 150 nmol/L).¹²¹

Precautions

Monitor serum calcium levels in patients taking thiazide diuretics and vitamin D supplements, as this combination may cause hypercalcemia.¹²²

Vitamin E

Vitamin E supplementation has demonstrated hepatoprotective effects in patients diagnosed with NAFLD (including those with NASH when accompanied with pharmacological medications).^{58,123}

Dosage

The recommended dose is 400 IU per day (or 200 IU twice daily) of alpha tocopherol or 400 mg of mixed tocotrienols.¹²³⁻¹²⁵

Precautions

Exercise caution in patients taking anticoagulants, as chronic high dosing may affect blood clotting and induce symptoms of muscular weakness and fatigue (reported at doses of 720 mg alpha tocopherol per day).¹²⁶

Biotin

High-dose biotin is considered an important vitamin for preventing and treating IR and obesity.¹²⁷ When given in quantities 10 times greater than the physiological range, biotin directly activates an enzyme that mimics the action of nitric oxide. Biotin has also been shown to improve glycemic control by reducing excessive hepatic glucose output.¹²⁸

Dosage

The recommended dose of biotin is 3 mg three times a day.¹²⁷

Precautions

None have been reported.

Chromium

The trace element chromium is an important nutrient that helps prevent IR and dyslipidemia associated with obesity.¹²⁹ Chromium also appears to have important effects on skeletal muscle IR.¹²⁸ Chromium has been found to improve insulin sensitivity and increase glucose disposal in women with polycystic ovarian syndrome.¹³⁰

Dosage

The recommended dose of chromium is 200 to 1000 mcg / day.¹³⁰⁻¹³²

Precautions

Take chromium supplements half an hour before or 3 to 4 hours after thyroid or levothyroxine medications, as chromium may bind to these medications and reduce absorption.¹³³

Magnesium

Intracellular magnesium plays a vital role in regulating insulin action, insulin-mediated glucose uptake and vascular tone.¹³⁴ Higher intakes of magnesium are associated with increased insulin sensitivity and a reduced risk of developing metabolic syndrome.¹³⁵⁻¹³⁷ Conversely, low dietary intake of magnesium is associated with an increased risk of developing IR and type 2 DM.^{138,139}

Dosage

A dose of 100 mg / day is recommended to reduce the risk of developing type 2 DM.¹⁴⁰ A dose of 382 mg / day is required to improve metabolic profiles and blood pressure.^{134,141} Dosing can also be guided by assessing red blood cell magnesium levels.

Precautions

High-dose magnesium may cause gastric irritation and diarrhea.¹⁴²

Zinc

Recent research has reported an inverse relationship between serum zinc concentrations and insulin resistance.¹⁴³ The antioxidant capacity of zinc is thought to underlie its valuable effects on IR.¹⁴⁴ Two randomized controlled trials reported a reduction in fasting glucose and insulin in addition to other markers of IR in obese prepubescent children following zinc supplementation.^{145,146}

Dosage

The recommended dose of zinc is 20 mg/day.¹⁴⁶

Precautions

None reported at the recommended dose.

Alpha lipoic acid

Alpha lipoic acid (ALA) is a potent antioxidant that is considered important for the treatment of metabolic syndrome. The mechanisms by which ALA exerts its effects include protection against oxidative stress-induced IR, inhibition of hepatic gluconeogenesis, and increased peripheral glucose use.¹⁴⁷ ALA may also exert modest reductions in plasma nonesterified fatty acid concentrations.¹⁴⁸ When administered solely or in combination with the angiotensin receptor blocker irbesartan, ALA has been shown to improve endothelial function and reduce IL-6 and PAF-1 levels in subjects with metabolic syndrome.¹⁴⁹

Dosage

The recommended dose of ALA is 100 mg three times daily before each meal.¹⁴⁹

Precautions

None reported.

Coenzyme Q10

Coenzyme Q10 (CoQ10) is required for adenosine triphosphate (ATP) synthesis and is therefore important for the conversion of carbohydrates

to energy.¹⁵⁰ By enhancing the functioning of the mitochondrial enzyme glycerol-3-phosphate dehydrogenase, CoQ10 helps with glycemic control.¹²⁸ A study by Singh et al.¹⁵¹ reported reductions in systolic and diastolic blood pressure, fasting and 2-hour plasma insulin, and triglycerides with the use of CoQ10 supplementation. Markers of oxidation, such as lipid peroxides, malondialdehyde, and diene conjugates, were also lowered by CoQ10, indicating a decrease in oxidative stress. Many patients with IR and metabolic syndrome are treated with statin drugs, and these medications have been found to lower plasma and tissue levels of CoQ10.¹⁵²

Dosage

The recommended dose of CoQ10 is 120 mg/day (or 60 mg twice daily).¹⁵¹

Precautions

CoQ10 may decrease the anticoagulant effect of warfarin. Monitor clotting time regularly, particularly within the first 2 weeks of taking CoQ10.¹⁵³

Acetyl-L-Carnitine

The amino acid, carnitine, plays an important role in energy metabolism, largely through its effects on fatty acid oxidation. Carnitine deficiency has been associated with various conditions, including obesity and type 2 DM.¹⁵⁴ When fatty acids are unable to enter the cell, triglycerides accumulate in the cytosol; an important contributor to the pathogenesis of IR. The administration of acetyl-L-carnitine to patients with type 2 DM and to healthy persons have been shown to improve insulin-mediated glucose disposal.¹⁵⁵

Dosage

The recommended dose of carnitine is 1 to 2 g/day between meals.¹⁵⁶

Precautions

None have been documented at the dose recommended.¹⁵⁶

Omega-3 Fatty Acids

Long term supplementation with omega-3 fatty acids has been shown to improve postprandial lipoprotein metabolism by decreasing triglycerides and increasing HDL-cholesterol.² Omega-3 fatty acids have also demonstrated improvements in endothelial function and arterial stiffness, with an accompanying reduction of the proinflammatory cytokine, IL-6.¹⁵⁷

Dosage

The recommended dose is 1 g/day of eicosapentaenoic acid and docosahexaenoic acid (EPA and DHA). For patients with elevated triglycerides, the dose is 2 to 4 g/day of EPA and DHA.¹⁵⁷⁻¹⁵⁹

Precautions

None have been reported at the recommended dose.

Botanicals

Ginseng (*Panax ginseng*)

The herb *Panax ginseng* has numerous medicinal effects, including antiinflammatory and antioxidant properties, and has also been used in the treatment of type 2 DM. Ginseng is thought to control and prevent type 2 DM by increasing insulin sensitivity and enhancing insulin secretion.¹⁶⁰ Another proposed mechanism of action lies in the herb's ability to modulate glucose activity by increasing GLUT-4 transporter activity.¹⁶¹

Dosage

The recommended dose is 100 to 200 mg/day (standardized to contain 4% ginsenosides).^{162,163}

Precautions

Ginseng may decrease the effectiveness of warfarin.¹⁶⁴

Green Tea (*Camellia sinensis*)

Green tea supplementation has been shown to improve whole blood glutathione and plasma antioxidant capacity and reduce plasma iron in adults with metabolic syndrome.¹⁶⁵ Based on the research by Basu et al.,¹⁶⁶ supplemental green tea in patients with metabolic syndrome is thought to reduce serum amyloid alpha, an independent cardiovascular disease risk factor. Green tea may also maintain normal body composition by stimulating thermogenesis and enhancing fat oxidation.¹⁶⁷

Dosage

Green tea extract (270 mg to 460 mg/day of epigallocatechin gallate).¹⁶⁵⁻¹⁶⁷

Precautions

Green tea may decrease the effectiveness of warfarin.¹⁶⁸ Do not combine with ephedrine or other stimulants.¹⁶⁹

Milk Thistle (*Silybum marianum*)

Milk thistle is considered an important herb in the treatment of hepatic disorders and also appears to play a beneficial role in maintaining normal glucose and lipid metabolism. Liver dysfunction impairs the efficiency of postprandial hepatic glucose storage and is thought to trigger hyperinsulinemia due to reduced liver clearance of insulin.¹⁷⁰ Phase III clinical trials have determined silymarin (the active component of milk thistle) to be the best medication for NAFLD due to its effects in lowering aminotransferase levels and reducing steatosis severity, liver ballooning, and fibrosis. Milk thistle has also been shown to act as an insulin sensitizer in studies of patients with NAFLD.¹⁷¹

Dosage

Give 420 to 600 mg/day (standardized to contain 70%–80% silymarin).^{172,173}

Precautions

Exercise caution in patients taking drugs metabolized by cytochrome, the P-450 isoenzymes CYP3A4 and CYP2C9, because the silibinin content of milk thistle may inhibit these hepatic isoenzymes.¹⁷⁴

Pharmaceuticals

While lifestyle modification is the preferred approach to managing IR and metabolic syndrome, at times prescription drugs are necessary. The problem with such medications is that they do not correct underlying nutrient deficiencies. Medications often merely “treat” the results of the disease; that is, they reduce high serum lipid or glucose levels or high blood pressure but do not treat the overall patient. Although no FDA-approved prescription drugs exist for IR, many of the medications used for type 2 DM have studied as treatment of metabolic syndrome. Some of these medications may not specifically address IR or may have unhealthy side effects. For example, 3-hydroxy-3-methyl-glutaryl-coenzyme A (HMG-CoA) reductase inhibitors (statins) lower serum CoQ10, and metformin reduces folic acid and vitamin B₁₂ levels but may increase homocysteine levels. Statin administration is also associated with a dose-dependent increase in insulin resistance.¹⁷⁵ Of importance is the fact that pharmaceutical drugs do not correct diet and lifestyle issues.

Pharmaceuticals can be an appropriate complementary option when required. Following is a list of medications grouped according to their physiological action. There are a number of brands in each category, and many can be used in combination with each other. Even though these medications are usually used for type 2 DM, they are often prescribed for IR (although they may need to be prescribed “off-label”). It should be noted that medications approved for type 2 DM are the main medications being investigated for the treatment of NAFLD.⁵⁸

Oral Medications

Insulin Sensitizers

Biguanides (e.g., metformin) are the most commonly used front-line medications. These drugs work by reducing glucose output from the liver (most likely by decreasing gluconeogenesis).¹⁷⁶

Thiazolidinediones help improve body cell sensitivity to insulin by stimulating the nuclear receptor, peroxisome proliferator activated receptor (PPAR-gamma). These receptors are primarily found in fat cells

and, to a lesser extent, in liver and skeletal muscle.¹⁷⁶

Agents That Slow the Digestive/Absorptive Process

Alpha-glucosidase inhibitors help slow down the absorption of carbohydrate into the bloodstream following a meal, thereby reducing postprandial glucose peaks.¹⁷⁷

Medications That Increase Insulin Production and Decrease Glucose Production

Dipeptidyl peptidase-4 (DPP-4) inhibitors are a newer class of drugs that work by inhibiting the breakdown of incretin hormones glucagon-like peptide-1 and glucose dependent insulinotropic peptide. Increased levels of these hormones result in improved glucose-dependent insulin secretion, suppressed glucagon secretion, and reduced gastric emptying.¹⁷⁸

Sodium-Glucose Transporter-2 (SGLT-2) Inhibitors

These medications work by a novel insulin-independent mechanism by blocking the reabsorption of glucose in the proximal convoluted tubules of the kidneys, thereby resulting in increased glucosuria and weight loss (due to loss of 300 to 400 kcal/day).¹⁷⁹

Bile Acid Sequestrants

Colesevelam is a second-generation bile acid sequestrant and the only drug in this class that is approved for the treatment of hyperlipidemia and type 2 DM.¹⁸⁰ Bile acid sequestrants work by binding bile acid in the intestinal lumen, thus impeding bile acid reabsorption in the terminal ileum and increasing fecal bile-acid output.¹⁸¹ A small study reported the efficacy of colesevelam in improving impaired fasting glucose levels.¹⁸²

Surgery

The most dramatic, but at times successful, option for the treatment of type 2 DM is bariatric surgery. While the majority of studies have focused on bariatric surgery for type 2 DM,¹⁸³⁻¹⁸⁹ there is research to support the use of this procedure in obese patients. In a nonrandomized, prospective, controlled study, bariatric surgery proved to be more efficient than usual care in the prevention of type 2 DM in obese persons.

Subjects were divided into patients who underwent bariatric surgery (1658) and obese matched controls (1771). No participants had type 2 DM at baseline. After 15 years, type 2 DM developed in 392 participants in the control group compared with 110 in the bariatric surgery group, corresponding to incident rates of 28.4 cases per 1000 person-years and 6.8 cases per 1000 person-years, respectively (adjusted hazard ratio with bariatric surgery, 0.17; 95% CI, 0.13 to 0.21; $P < 0.001$).

Prevention Prescription

- Maintain a healthy body weight. People with an increase in visceral (truncal) fat are at higher risk.
- Exercise of 30 minutes/day is recommended on most days of the week for patients with appropriate weight and 60 minutes/day on most days of the week for those needing to lose weight.
- Manage stress and increase the relaxation (parasympathetic) response.
- Follow a low-glycemic load, Mediterranean-type diet.
- Take a high quality multivitamin that includes minerals and B-group vitamins.

Therapeutic Review

Laboratory Evaluation

- 2-hour glucose and insulin tolerance test to measure glucose and insulin levels after a glucose load.
- Serum lipid measurements (looking for increased triglyceride level, decrease in high-density lipoprotein cholesterol level, and normal or slightly increased low-density lipoprotein cholesterol level).
- Fasting glucose higher than 100 mg/dL.
- High-sensitivity C-reactive protein, a marker of inflammation, and gamma-glutamyltranspeptidase, a marker of liver toxicity.

Lifestyle

- Encourage an exercise routine that consists of moderate intensity workouts and resistance training. 

- Encourage goals to achieve appropriate weight. 
- Encourage the patient to stop using nicotine-containing products. 

Nutrition

- Low-carbohydrate, Mediterranean-type diet with a focus on low-glycemic index foods. 
- High-fiber diet including soluble fibers, such as psyllium, oats, and barley. 
- Decreased consumption of red meat and fried foods. 

Mind-Body Therapies

- Encourage lifestyle choices to reduce stress and anxiety. Recommend a relaxation technique tailored to the individual. 
- Note: The preceding recommendations highly outweigh those that follow for the treatment of IR and metabolic syndrome.

Supplements

- High-quality multivitamin with minerals and B-group vitamins. 
- Omega-3 fatty acids (eicosapentaenoic acid / docosahexaenoic acid) 1 to 4 g/day to reduce inflammation, blood pressure, and triglyceride levels. 
- Chromium picolinate: 200 to 1000 mcg/day. 
- Vitamin C: 1000 to 2000 mg/day. 
- Vitamin D: 300 to 2000 IU/day. 
- Alpha-lipoic acid: 100 to 300 mg/day. 
- Coenzyme Q10: 60 to 120 mg/day. 
- High risk individuals may need to consider additional supplementation as outlined in the body of the text.

Botanicals

- American ginseng: 100 to 200 mg/day. 

- Milk thistle: 420 to 600 mg / day. 

Pharmaceuticals

- Metformin: 500 to 2500 mg each morning or twice daily. 
- Pioglitazone: 15 to 45 mg / day.

CHAPTER 33

Diabetes Mellitus

Matthew Moher, MD

Type 2 diabetes mellitus represents a global epidemic that is predicted to intensify. The number of individuals with type 2 diabetes mellitus (DM) worldwide was 30 million in 1985, 171 million in 2000, and 220 million in 2009.¹ As of 2014, type 2 DM is estimated to affect 387 million individuals worldwide,² representing a worldwide prevalence of 8.3%. From 1990 to 2008, the prevalence of DM doubled, and had not declined by 2012.³ From 1998 to 2009, the prevalence of DM rose a staggering 230% in Canada alone and is predicted to continue rising. The CDC estimates 40% of Americans will develop DM in their lifetime.⁴

Type 2 DM is common in both the developed and developing worlds.^{5,6} The increasing prevalence of DM is attributed to rising obesity rates, sedentary lifestyles, aging populations, and improved survival of individuals with the disease.⁷

Type 2 DM is also associated with huge health care costs. In a special report from 2009 entitled, *An Economic Tsunami: the Cost of Diabetes in Canada*, the estimated cost of type 2 DM in 2010 was \$12.2 billion and projected to increase by a further \$4.7 billion by 2020.⁸

The silver lining is that type 2 DM is largely preventable, with epidemiological studies predicting primary prevention of diabetes in America could reduce the risk of all-cause and cardiovascular mortality by up to 9.0%.⁹

Pathophysiology

The pathophysiology of type 2 DM is complex and fundamentally consists of hyperglycemia, insulin resistance, and impaired insulin secretion⁴ (see [Fig. 33.1](#) for a general overview).

Carbohydrate intake and subsequent absorption of glucose into the

blood triggers insulin release from the beta cells of the pancreas. Insulin stimulates the uptake of glucose into cells via the GLUT-4 glucose transporter. Insulin resistance (IR) may ensue after chronic exposure to high serum glucose levels. Steroid administration and physical inactivity may also contribute.¹⁰ The development of type 2 DM is thought to be characterized by peripheral cells becoming unable to efficiently uptake glucose in response to insulin in combination with beta islet cell dysfunction and decreased insulin production.

Insulin functions in stimulating cellular glucose uptake, decreasing hepatic gluconeogenesis, and increasing adipose tissue triglyceride synthesis, glucagon regulation, and vascular tone. These important functions of insulin are all impaired in type 2 DM.

Diabetes is referred to as “starving amidst the feast.” IR refers to impaired glucose transport into muscle cells that accounts for the “starving” amidst the hyperglycemia “feast.” Additionally, cellular starvation feedback mechanisms exacerbate hyperglycemia by stimulating hepatic gluconeogenesis and fat breakdown.

IR also contributes to the production of free fatty acids and inflammatory cytokines. Inflammatory markers shown to be elevated in DM include C-reactive protein, IL-6, plasminogen activator inhibitor-1 (PAI-1), and tumor necrosis factor (TNF)-alpha, in addition to white cell count.¹¹⁻¹³

Adiponectin is an antiinflammatory cytokine that has been shown to reduce plasma levels of free fatty acids. High adiponectin is associated with improved lipid profiles, glycemic control, and reduced inflammation.¹⁴ DM has shown to be correlated with a reduction in adiponectin.¹⁵

Adiponectin is a hormonal protein produced by adipose tissue. Contrary to common sense, low levels (not high) of adiponectin are bad and result from a proinflammatory state. Adiponectin levels can be increased with exercise and weight loss.

While studies on type 2 DM pathophysiology have previously focused on IR, the role of the pancreas has become increasingly recognized. Beta islet cells are well known to produce insulin; however, these are not the only pancreatic islet cells. Alpha islet cells produce glucagon, considered a counterpart of insulin. The interaction between insulin and glucagon is usually very tightly regulated; however, increased glucagon further

exacerbates the hyperglycemic state in type 2 DM as a result of IR and impaired insulin secretion.¹⁶

Genetics also contribute to the pathogenesis of type 2 DM. Medical genomics is considered to be a field of active research with great potential. Genomic single-nucleotide polymorphisms (SNPs) have been shown to be associated with DM risk.¹⁷⁻²⁰ Genetic risk may also interact with environmental factors.

Inorganic arsenic exposure in drinking water increases risk of type 2 DM.²¹ Bisphenol A, used in hard plastics and resins, has also been linked to DM.²² Pesticide exposure, specifically organophosphates and chlorinated pesticides, may also be associated with increased risk.²³

Integrative Therapy

Lifestyle

Diabetes is largely preventable. The principles of preventative management apply a holistic therapeutic approach to patients with established DM.

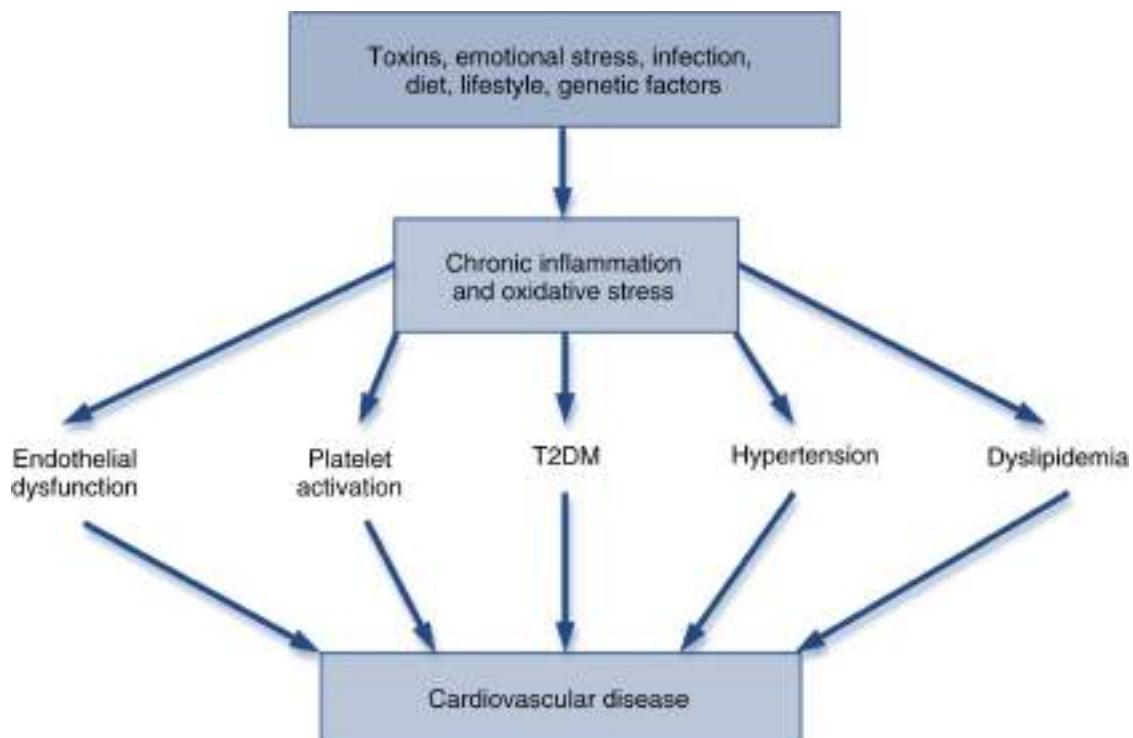

FIG. 33.1 Pathophysiology of type 2 diabetes mellitus and inflammatory disorders. T2DM, type 2 diabetes mellitus.

Four large epidemiological, long-term studies are widely cited in support of lifestyle intervention as the cornerstone of type 2 DM prevention.

In 2001, the Finnish Diabetes Prevention Study (DPS) investigated 522 middle-aged, overweight subjects with impaired glucose tolerance over 4–10 years. The lifestyle intervention consisted of counseling aimed at reducing weight, total intake of fat, and intake of saturated fat, and increasing intake of fiber and physical activity. Annual oral glucose tolerance testing indicated DM to be largely preventable in this cohort of high-risk individuals.²⁴

In 2002, the Diabetes Prevention Program (DPP) investigated 3234 overweight high-risk individuals with impaired glucose intolerance (mean age, 51 years) over a 3-year period. Similar lifestyle interventions to the Finnish study were found to be superior to metformin in terms of diabetic prevention.²⁵

The China Da Qing Diabetes Prevention Study, involving 577 high-risk individuals identified by a region-wide clinic screening process of >110,000 individuals, reported similar results over 6 years of lifestyle intervention.²⁶

More recently, the 2011 nationwide Zensharen Study for Prevention of Lifestyle Diseases involving 641 overweight Japanese middle-aged persons with impaired glucose tolerance reported lifestyle modifications regarding weight loss, diet scrutiny, and exercise were associated with a decreased risk of type 2 DM.²⁷

Smoking

Several studies, including meta-analyses, have shown smoking is a preventable risk factor for type 2 DM.^{28,29} Mechanisms underlying the association between smoking and type 2 DM include impaired insulin sensitivity, glucose tolerance, and the metabolic syndrome.

Exercise

Exercise is tantamount in both the prevention and management of type 2 DM. Large cohort studies over 15–20 years have reported decreased cardiovascular risk and all-cause mortality in diabetics who undertake

regular physical activity.³⁰⁻³² Both aerobic exercise and resistance training reduce HbA1c in patients with type 2 DM.³³

Studies indicate regular yoga can reduce HbA1c and fasting blood glucose levels. Hatha yoga is reported to have most evidence in reviews. In fact, Hatha yoga has shown to reduce HbA1c to the same effect as regular aerobic exercise.^{34,35}

Health care providers can support patients by encouraging 30 to 60 minutes of moderate-intensity aerobic activity on most days of the week. The American Heart Association, the American Diabetes Association, and the American College of Sports Medicine recommend at least 150 minutes of moderate-intensity aerobic activity per week for patients with diabetes³⁶ (see [Chapter 91](#), Writing an Exercise Prescription).

Nutrition

Nutrition, exercise, and lifestyle are the tripartite cornerstones of integrative diabetic management. Evidence supports the use of all three of these important modalities.

Nutrition therapy alone has been shown to improve glycemic control and lower HbA1c levels by 1%–2%.^{37,38} This powerful evidence comes from multidisciplinary efforts between general practitioners, registered dietitians, and educators to individualize diet plans with regular follow-up. Dietitians and diabetic nurse educators are valuable resources with clear benefit in DM management.³⁹⁻⁴¹

In general, diets incorporating the principles of food guides, such as the Healing Foods Pyramid ([Fig. 33.2](#)), are a good starting point for clinicians and patients. Education regarding glycemic index (GI) takes this approach a step further. Glycemic index refers to blood glucose spikes following the intake of certain foods. High GI foods, such as table sugar, have greater effects on blood glucose levels and generate wide swings in insulin levels, eventually contributing to IR. A large multicenter meta-analysis demonstrated that diets containing low GI foods can reduce HbA1c by 0.43%.⁴² GI tables are widely available online (<http://www.diabetes.ca/diabetes-and-you/healthy-living-resources/diet-nutrition/the-glycemic-index>).

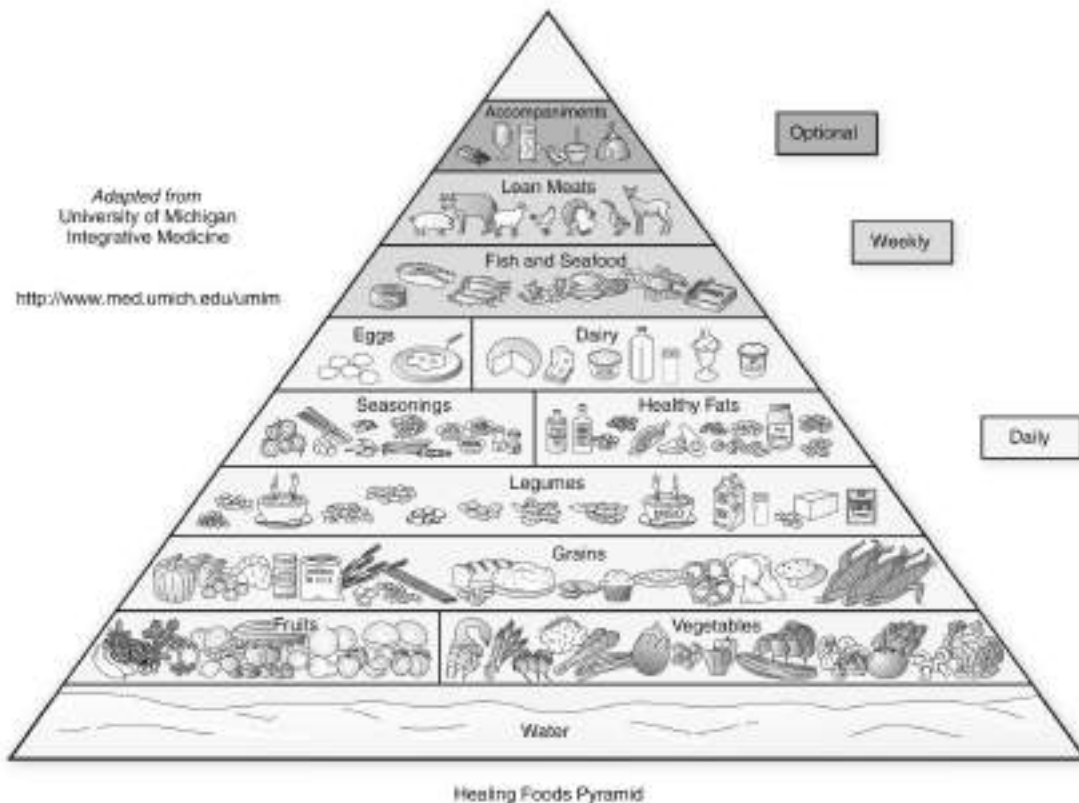

FIG. 33.2 University of Michigan integrative medicine health foods pyramid. (Reproduced from Regents of the University of Michigan. Developed by Monica Myklebust, MD, and Jenna Wunder, MPH, DR, 2008.)

Another important concept is glycemic load (GL). GL is based on GI but also incorporates the quantity of carbohydrate in a typical serving size. For example, bananas have a low GI (52) but a high GL (10.5) due to high carbohydrate content by weight). Conversely, watermelon has a high GI (72) but low GL (3.6) (see [Chapter 87](#)).

Specific Foods

Fiber

Soluble dietary fibers, such as psyllium, oats, beans, and eggplant, have been shown to lower postprandial blood glucose.⁴³ Pulses, such as lentils, chickpeas, and beans, also lower blood glucose.⁴⁴ Soy, walnuts, and other nuts have demonstrated similar benefits.⁴⁵⁻⁴⁷ Almonds in particular have been shown to reduce both HbA1c and postprandial blood glucose levels in small trials.^{48,49} A growing body of research supports the beneficial effects of vegetarian and vegan diets for patients with type 2 DM.⁵⁰⁻⁵² In

addition to vegetable protein, whole grains are also rich in minerals and antioxidants. In a large prospective cohort study, fiber from whole grains improved glycemic control in patients with type 2 DM.⁵³

Alcohol

Light to moderate alcohol consumption may be beneficial in DM. Studies have shown decreased risk of type 2 DM and death due to CAD in established diabetics.⁵⁴ The majority of studies included in this review favored red wine, indicating the antioxidant effects of resveratrol to be a potential mechanism. Further, moderate alcohol consumption has been linked with higher adiponectin levels. Adiponectin, described previously, supports glucose homeostasis and improves insulin sensitivity.

The resveratrol and alcohol in red wine may raise adiponectin levels and maintain insulin sensitivity.

Dietary Fat

Diets higher in saturated versus polyunsaturated fats have been shown to be associated with increased HbA1c and IR in patients with type 2 DM.⁵⁵ The quality of fat is important. Research supports selective fat intake, favoring monounsaturated and polyunsaturated fats such as omega-3, which have been shown to prevent cardiovascular disease.

The Mediterranean diet captures the beneficial effects of macronutrient selectivity. A rigorous 4-year trial and subsequent 8-year follow-up comparing a low carbohydrate Mediterranean diet versus a low fat diet reported a reduction in HbA1c, decreased requirement for the initiation of diabetes medications, and an increase in cases of diabetes remission.^{56,57}

Other foods that may be of benefit include chia (*Salvia hispanica*), which is rich in alpha-linoleic acid, and onions (*Allium cepa*). Magnesium deficiency has been shown to be a risk factor for type 2 DM.⁵⁸ Magnesium is found in dark green leafy vegetables, nuts, whole grains, and coffee. Moderate caffeine intake in the form of coffee or green tea may decrease risk of type DM according to a systematic literature review and meta-analysis.⁵⁹

Mind-Body Therapy

Mindfulness

A plethora of literature is amassing in support of the health benefits of mindfulness, with 52 papers published in 2003, rising to 477 by 2012. Nearly 100 randomized controlled trials (RCTs) of mindfulness were published in 2014. Mindfulness has been shown to reduce stress, blood pressure, and even mitigate cardiovascular risk. A particularly interesting study involving PET scans of Buddhist monk brains during meditation provided concrete evidence that meditation can induce neurophysiological changes⁶⁰ (see [Chapter 100](#)).

Cognitive-Behavioral Therapy

Cognitive-behavioral therapy helps patients gain insight into the habits and patterns that affect their thoughts and actions and the ways in which these thoughts and actions affect their health and lives. A sizeable body of research has established the benefits of cognitive-behavioral therapy on glycemic control and self-care. In a systematic review of 25 trials in type 2 DM, 12 trials involving 522 patients used glycemic control as an outcome measure. In those trials, participants who received 6 to 16 group or individual counseling sessions had a 0.76% reduction in HbA1c levels compared to placebo.^{61,62}

Biofeedback

Biofeedback training can strengthen the mind-body connection by helping patients learn to control specific bodily functions, including muscle tension, skin temperature, sweating, breathing, heart rate, and even regional brain waves. In a published study, researchers randomized 39 patients with well-controlled type 2 DM to receive 10 weekly individual sessions of skin temperature and electromyograph biofeedback or 3 group education sessions. Biofeedback was associated with improved glycemic control and a decrease in HbA1c levels by 0.8%.⁶³ This finding may seem surprising; however, biofeedback trials have reported changes in plasma cortisol, peripheral vasoconstriction, and other markers of sympathetic nervous system activity.

Sleep Hygiene

Several studies have linked poor sleep hygiene with DM risk. Systematic

and meta-analyses of these studies have confirmed that too short, too long, or interrupted sleep compared to 8 hours of uninterrupted sleep significantly increases DM risk.⁶⁴

Herbalism

Herbalism is the most ancient practice of medicine, indeed as old as human beings. Even chimpanzees have been shown to use plant medicines for the treatment of certain gastrointestinal ailments.

As an example, metformin, a derivative of the French lilac, has been used to treat DM since the middle ages.

Personally, I advise consultation with professional herbalists, preferably registered under their respective regional guild, to ensure prescription quality. In general, I value tincture extracts more than capsules of ground material due to greater potency and bioavailability. For patients who prefer over-the-counter medications or are unable to afford a herbalist consultation, I would recommend the use of products that are standardized extracts.

[Table 33.1](#) includes a review of literature regarding commonly used plants and supplements. Below are plant medicines that have been trialed for at least 3 months (the lifespan of a RBC is 120 days) and demonstrated reductions in HbA1c levels of at least 0.5% in patients with type 2 DM.

Botanicals

Coccinia cordifolia

Coccinia cordifolia, or ivy gourd, is a perennial herb of the cucumber family. It is native to India but spreads easily and is now distributed worldwide. It is an important Ayurvedic diabetes medicine with additional choleric, laxative, antiinflammatory, and demulcent properties. The leaves appear to have insulinomimetic effects on lipoprotein lipase, glucose-6-phosphatase, and other glycolytic enzymes. A double-blind, placebo-controlled RCT of 60 diabetics aged 35–60 years was performed, with the treatment arm consisting of 1 g ivy gourd extract for 90 days. The results demonstrated significant decreases in fasting, postprandial blood glucose, and HbA1c levels compared to placebo.⁶⁵

Dosage

Dried leaves or extracts at doses equivalent to 15 g can be taken with meals.

Precautions

Ivy gourd is well-tolerated but may cause nausea, drowsiness, and headaches.

TABLE 33.1

Glycemic Effects and Cardiovascular Benefits of Different Treatments for Type 2 Diabetes Mellitus

Therapy	Effects	Cardiovascular Benefits
Arsenic exposure avoidance	Arsenic exposure increased risk by 358% in population studies	—
Emotional stress avoidance	Emotional stress increased risk by 60% to 236% in population studies	CV and all-cause mortality
Egg avoidance	Egg consumption increased risk by 50% in two population studies	CV disease
Coffee	Reduced risk by 40% in meta-analysis	Lipids, CV mortality
Leafy green vegetables	Reduced risk by 14% in meta-analysis	BP, lipids, all-cause mortality
Moderate alcohol consumption	Reduced risk by 50% in meta-analysis	Lipids, CV and all-cause mortality
Avoidance of sugar-sweetened beverages	Sugar-sweetened beverages increased risk by 26% in meta-analysis	—
Treatment of periodontal disease	Periodontal disease increased risk by 150% to 225% in population studies	MI and stroke risk
Lifestyle intervention	HbA1c decreased 0.3% in meta-analysis	BP, lipids
Regular exercise	HbA1c decreased 0.6% in meta-analysis	BP, lipids, CV and all-cause mortality
Low-glycemic diet	HbA1c decreased 0.5% in meta-analysis	Lipids, CV disease
Beans and pulses	HbA1c decreased 0.5% in meta-analysis	BP, lipids
Chia	—	BP, C-reactive protein
Cognitive-behavioral therapy	HbA1c decreased 0.78% in meta-analysis	—
Biofeedback	HbA1c decreased 0.8% in one trial	—
Treatment of vitamin D deficiency	May decrease type 2 DM risk	Endothelial function
Chromium	HbA1c decreased 0.6% in meta-analysis	—
Alpha-lipoic acid	Decreased diabetic neuropathy	? Liver, CV disease
Omega-3 fatty acids	—	Lipids, platelets, CV disease
Magnesium	HbA1c decreased 0.3% in meta-analysis Reduces type 2 DM risk 16%	Lipids, endothelial function
L-Carnitine	? Insulin sensitivity	Lipids, lipoprotein(a)
Benfotiamine	—	Endothelial function
Vitamin K ₂	? Stimulates beta cells	CV disease
Avoidance of selenium	Selenium may increase risk 55%	—
Avoidance of high-dose vitamin B ₆ , vitamin B ₁₂ , folate	These vitamins may increase nephropathy	Increased CV disease
Berberine	HbA1c decreased 0.9% in one trial	—

Cinnamon	HbA1c decreased 0.5% in one trial	—
Ginseng	Improved glucose parameters	—
Fenugreek	HbA1c decreased 1.4% in one trial	—
Ivy gourd	HbA1c decreased 0.6% in one trial	—
<i>Momordica charantia</i>	Improved glucose parameters in four trials	—
Prickly pear cactus stem	Improved glucose parameters in one trial	—
Pycnogenol	HbA1c decreased 0.8% in one trial	—
Metformin	HbA1c decreased 1.0%	CV and all-cause mortality
Sitagliptin	HbA1c decreased 1.25%	—
Sulfonylurea	HbA1c decreased 1.0%	May increase risk
Pioglitazone	HbA1c decreased 1.25%	—
Bariatric surgery	Curative in 78% of patients	? CV and all-cause mortality
Insulin	Dose-dependent	—

BP, blood pressure; CV, cardiovascular; DM, diabetes mellitus; HbA1c, glycosylated hemoglobin; MI, myocardial infarction.

Salacia Reticulate

Salacia reticulata, or kothala himbutu, was investigated in a double-blind, crossover RCT of an herbal tea containing kothala himbutu extract in 51 patients with controlled DM over 3 months. This study reported significantly lower HbA1c levels in the treatment arm.⁶⁶

Dosage

Three times daily before meals. In the previous trial, the tea was manufactured by Siddhalepa Ayurveda Hospitals, Ratmalana, Sri Lanka and prepared in accordance with a patented formula (international patent application no. PCT/IB00/00405).

Precautions

Side effects are dose-dependent and predominantly include gastrointestinal disturbances, such as gas, bloating, abdominal pain, and diarrhea.

Touchi (Soy)

Water-extracted touchi, a traditional Chinese food (soybean extract), has been shown to exert a strong inhibitory effect on rat intestinal alpha-glucosidase. Touchi was also investigated in a 3-month, double-blind, randomized trial of 36 diabetics. Treatment consisted of 0.3 g of touchi in the form of tea preprandially for 3 months and resulted in a reduction in HbA1c levels by 0.5% vs placebo.⁶⁷

Dosage

0.3 g in tea before meals.

Precautions

Well tolerated orally but may cause mild gastrointestinal upset.

Gynostemma Pentaphyllum

Gynostemma pentaphyllum is a Vietnamese herb used as a tea to treat DM. A double-blinded RCT of 24 drug-naïve patients with diabetes treated with 6 g tea daily for 12 weeks vs placebo reported a reduction in plasma glucose and a decrease in HbA1c levels of 2%.⁶⁸

Dosage

6 g in tea daily.

Precautions

Generally well tolerated but may cause nausea and diarrhea.

Marine Collagen Peptides (Gelatin)

Marine collagen peptides from fish hydrolysate, a traditional Chinese medicine, were investigated in an RCT of 100 patients with diabetes compared to a control group. This trial reported that administration of 13 g of marine collagen peptides for 3 months significantly lowered LDL, free fatty acids, and markers of inflammation, such as C-reactive protein and nitric oxide, in addition to reducing HbA1c levels and increasing adiponectin levels.⁶⁹

Dosage

13 g as a capsule daily.

Precautions

May cause an unpleasant taste, bloating, gas, or heaviness in the stomach.

Silymarin (Milk Thistle)

The antioxidant flavonoid silymarin, an extract of milk thistle (*Silybum marianum*), has demonstrated good results in several rigorous trials. As an adjunct to glibenclamide, silymarin was investigated at a dose of 200 g/day in 52 patients with diabetes for 120 days. This randomized, placebo-controlled, double-blinded trial reported reductions in HbA1c levels and body-mass index.^{70,71}

Dosage

200 g/day extract.

Precautions

Well tolerated but may have a laxative effect or cause gastrointestinal symptoms.

Citrullus Colocynthis

Citrullus colocynthis, also known as the schrad fruit, is a traditional medicine of Iran. A clinical trial investigating 25 patients with diabetes treated with 100 mg fruit capsules versus control reported significant reductions in plasma glucose and HbA1c levels.⁷²

Dosage

100 mg fruit capsules.

Precautions

High doses may cause irritation of the gastric mucosa resulting in bloody diarrhea and colitis. Nephrotoxicity has also been documented.

Cinnamon

Cinnamon is a culinary spice made from the bark of *Cinnamomum* sp. trees. The aqueous extract appears to improve insulin receptor function by multiple mechanisms in addition to increasing glycogen synthase activity. However, the results of clinical trials have been inconsistent, with the majority of trials being small and insufficiently powered. A

proportion of trials have reported the benefit of cinnamon in reducing HbA1c levels.⁷³ A trial compared *Cinnamomum aromaticum* (cassia cinnamon) 500 mg twice daily with usual care in 109 patients with type 2 DM for 90 days. This trial reported mean reductions in HbA1c levels of 0.83% in the cinnamon group and 0.37% in those receiving usual care, a difference that reached statistical significance.⁷⁴ A Cochrane meta-analysis of 10 RCTs did not demonstrate the efficacy of 2-g *Cinnamomum cassia* in reducing HbA1c levels.⁷⁵ However, a separate meta-analysis concluded that cinnamon can reduce plasma blood glucose levels.⁷⁶ More investigation is required regarding this.

Dosage

The optimal dose of cinnamon for the treatment of type 2 DM is unclear; however, 1- to 2-g doses are commonly prescribed (1 teaspoon of cinnamon is equivalent to 4.75 g). The majority of over-the-counter cinnamon preparations are a combination of cassia and Ceylon cinnamon.

Precautions

Stomatitis and perioral dermatitis have been reported with the use of cinnamon.

Fenugreek

Trigonella foenum graecum, or fenugreek, is a legume used extensively in India, North Africa, and the Mediterranean. The defatted seeds of fenugreek have been used to treat diabetes for centuries in Ayurvedic and other healing systems. A component of fenugreek, 4-hydroxyisoleucine, has been shown to increase pancreatic insulin secretion and inhibit glucosidase activity, with studies reporting effects on satiety, gastric emptying, and insulin receptor function. Fenugreek may also have lipid-lowering effects and several studies have posited hypoglycemic effects. In 42 patients with diabetes poorly controlled with sulfonylureas, 2.1 g fenugreek extract tid for 12 weeks reduced HbA1c and fasting blood glucose levels compared to placebo.⁷⁷

Dosage

Until further evidence provides clear guidance, practitioners may use crude powder or extracts at doses equivalent to 20 to 30 g of crude seeds. This dose can be titrated according to meal size and individual results.

Precautions

Fenugreek may cause gastrointestinal intolerance, with diarrhea, dyspepsia, abdominal distention, and flatulence.

Supplements

[Table 33.1](#) describes the glycemic effects and cardiovascular benefits of different treatments for type 2 DM.

Vitamin D

25(OH)D levels have been shown to be lower in type 2 DM and obesity. Studies have reported that vitamin D levels are associated with increased risk of type 2 DM, by virtue of insulin sensitivity and beta cell activity. However, while studies are supportive of the use of vitamin D supplementation in the management of type 2 diabetes, others remain inconclusive. A review of eight trials reported no glycemic benefit of vitamin D supplementation.⁷⁸

Chromium

This trace element has several effects on carbohydrate and lipid metabolism. A complex containing trivalent chromium has been shown to influence glucose tolerance. Evidence suggests that chromium acts to reduce tissue lipid content and that chromium responders are more likely to be more obese, more insulin resistant, and have poorer glycemic control regardless of baseline chromium status.⁷⁴ A meta-analysis of 41 trials evaluating the glycemic effects of various formulations identified 14 trials of chromium including patients with type 2 DM.⁷⁵ However, the evidence was determined to be difficult to interpret because of low study quality and differences in formulation and dose, with the best results reported by trials evaluating chromium picolinate or brewer's yeast at doses of at least 200 mcg daily. In these trials, a mean reduction in HbA1c

of 0.6% compared with placebo was reported.

Dosage

A dose of 200 to 1000 mcg daily is recommended.

Precautions

Chromium has no known side effects.

Alpha-Lipoic Acid

Also known as *thioctic acid*, alpha-lipoic acid (ALA) is a potent lipophilic antioxidant that is found in most eukaryotic cells. ALA also acts as a cofactor for several mitochondrial and cytosolic enzymes, with the right-sided enantiomer being the active form. In addition to its antioxidant activity, ALA can also regenerate other antioxidants via reduction reactions, including vitamins C and E, coenzyme Q10, and glutathione. ALA also chelates mercury, arsenic, iron, and other metals that act as free radicals. ALA is present in trace amounts in organ meats and some vegetables, but these amounts are negligible compared with usual therapeutic doses.

ALA has been used to treat several diseases in Europe and Japan since the 1950s. A large body of preclinical research supports the potential benefit of ALA in liver disorders, cardiovascular disease, cancer prevention, and neuropsychiatric disorders, and for heavy metal and general detoxification.

Good evidence indicates that ALA reduces painful diabetic neuropathy. First used parenterally, ALA in oral form has been shown to be effective in a multicenter trial involving 181 patients with type 2 DM who received varying doses for 5 weeks. All doses provided an overall reduction in symptoms of 50%, with the lowest dose (600 mg daily) causing the fewest side effects.⁷⁶ This finding may be related to reduced lipid peroxidation in neuronal cell membranes or improved endothelial function and microvascular blood flow.⁷⁷ ALA may also improve insulin sensitivity through enhanced GLUT4 translocation and glucose uptake in muscle and fat cells.⁷⁸ This last effect was observed by trials of intravenous ALA and has yet to be firmly established with the oral form; however, this study provides further support for the use of ALA in patients with type 2 DM.

The majority of published trials have used regular ALA (an R-S racemic mixture). R-Lipoic acid is marketed as a superior product because it is the endogenously produced form; however, there is a lack of evidence from clinical trials to support this claim. A sustained-release form of ALA is marketed as superior based on the short half-life of regular ALA; however, data to indicate whether peak or total levels are most important, and evidence of the safety and efficacy of this product are similarly lacking. At this time, regular ALA is the only recommended form.

Dosage

The most appropriate dose for neuropathy is 600 mg daily; however, a dose of 50 to 100 mg is sufficient for antioxidant purposes. Absorption is greatest on an empty stomach.

Precautions

The most common side effect of ALA is nausea; however, insomnia, fatigue, diarrhea, and rashes have also been reported.

Omega-3 Fatty Acids

Fish and other marine species are the main sources of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in the human diet. Alpha-linoleic acid is an omega-3 precursor found in walnuts, flax, and other grains. Although omega-3 fatty acids have no effect on glycemic control, these fats have antiinflammatory, antithrombotic, and antiarrhythmic effects that appear to prevent and treat cardiovascular disease. For this reason, omega-3 fatty acids offer important benefits to patients with type 2 DM.

A Cochrane systematic review of 23 trials involving 1075 patients who used omega-3 fatty acids at an average dose of 3.5 g daily reported improved lipid parameters and platelet function.⁷⁹ Small trials have reported improvements in endothelial function, with one study reporting significant improvements in impaired flow-mediated dilatation with the consumption of 2 g of omega-3 fatty acids.⁸⁰

Dosage

The majority of cardiovascular benefits of omega-3 fats occur at doses of 1000 mg (EPA and DHA) daily; however, higher doses are often used.

Precautions

Fishy repeats and mild gastrointestinal upset are the only side effects of omega-3 fatty acid supplementation. Although bleeding in aspirin or warfarin users is often cited as a reason for caution, the literature contains no specific reports of this effect.

Magnesium

Magnesium affects insulin secretion and action in addition to influencing lipid parameters and endothelial function. A systematic review identified nine trials that evaluated magnesium supplementation for 4 to 16 weeks in 370 patients with type 2 DM and noted improvements in fasting glucose and high-density lipoprotein cholesterol. In the five trials of sufficient duration to evaluate HbA1c, a nonsignificant reduction of 0.31% (95% CI, -0.81 to 0.19) was reported.⁸¹ A separate review of magnesium for the prevention of type 2 DM found seven cohort studies and reported an overall benefit, with an average daily dose of 100 mg decreasing the risk of type 2 DM by approximately 16%.⁸² The accuracy of routine tests in reflecting total magnesium body stores remains unclear.

Dosage

Usual starting doses are approximately 100 mg daily and can be increased as desired or to bowel tolerance. Magnesium is available as oral liquid or tablets, transdermal lotion, or Epsom salts, as well as in parenteral formulations.

Precautions

Gastrointestinal intolerance, mainly diarrhea, is the most common side effect. Chelated magnesium (magnesium glycinate) causes less diarrhea than do other forms of magnesium.

Antioxidants

Individuals who consume diets rich in antioxidants are at greatly reduced risk of type 2 DM; however, commonly-used antioxidant supplements do not appear to have the same preventive effect. In 8171 women who were followed for 9.2 years in the Women's Antioxidant Cardiovascular Study, only a mild benefit of vitamin C in the prevention of type 2 DM was indicated by a nonsignificant trend, whereas vitamin E increased the risk of type 2 DM and beta-carotene offered no benefit.⁸³ The Prevention of Progression of Arterial Disease and Diabetes (POPADAD) trial reported no significant benefit in 1276 Scottish adults administered a low-dose mixed antioxidant supplement or placebo for 8 years.⁸⁴

The benefits of antioxidant-rich foods are likely attributable to the dozens of phytochemicals they contain, components that are currently poorly understood. Although antioxidants and multivitamins are commonly prescribed by integrative practitioners as "insurance against deficiency," this practice may not be safe. High doses of vitamins have been shown to interfere with absorption and use of lesser-known but potentially more powerful antioxidants in food. High profile examples include tocopherols and carotenoids. Whole food supplements may be a reasonable alternative approach. In one study, an antioxidant supplement derived from pomegranate, green tea, and ascorbic acid improved lipid parameters and markers of oxidative stress in a placebo-controlled trial involving 114 patients with type 2 DM conducted in Turkey.⁸⁵

Vitamin E

Vitamin E is one of the most commonly used specific antioxidants; however, there is a lack of evidence to support its use in patients with type 2 DM. Negative results reported by large cardiovascular and cancer trials have been the subject of media reports, controversy, and debate among integrative medicine practitioners. Alpha-tocopherol supplementation did not decrease the risk of type 2 DM in the large Alpha-Tocopherol Beta-Carotene (ATBC) cancer trial,⁸⁶ and a separate small trial reported prooxidant effects shortly after ingestion of a single 1200-unit dose.⁸⁷

Although several tocopherols and tocotrienols have vitamin E-like activity, the majority of vitamin E supplements contain alpha-tocopherol only. Some investigators have posited that the negative results of vitamin E trials are attributable to decreased absorption of other, more potent molecules of this family whose absorption is inhibited by alpha-

tocopherol supplementation.⁸⁸ In fact, one study found no difference between the effects of alpha-and gamma-tocopherol on markers of oxidative stress and inflammation in patients with type 2 DM.⁸⁹ Other trials have reported that gamma-tocopherol increases blood pressure⁹⁰ and has no effect on platelet function.⁹¹

Greater benefit from alpha-tocopherol has been demonstrated among individuals who are homozygous for a haptoglobin gene variant that has been shown to increase oxidative stress and is present in 3% to 4% of the population. In an Israeli double-blind study involving 1434 people with type 2 DM who were homozygous for haptoglobin-2, alpha-tocopherol reduced the risk of a combined cardiovascular end point by more than 50%.⁹² This is an example of how genetics may improve future treatment outcomes in personalized medicine.

Vitamin E supplements containing mixed tocopherols and trienols are increasingly available; however, clear dosing guidelines for their use for type 2 DM have yet to be published. Vitamin E has no known side effects.

L-Carnitine

L-Carnitine shuttles fatty acids into mitochondria and has been proposed as a potential therapy for type 2 DM based on its potential effects on intracellular lipid accumulation. A pilot study found no improvements in glycemic control after 4 weeks of L-carnitine use in 12 patients with type 2 DM;⁹³ however, several trials have reported that L-carnitine improves lipid parameters and significantly reduces lipoprotein (a), an important independent inherited cardiac risk factor for which few effective therapies exist.⁹⁴

Dosage

The usual dose is 500 to 1000 mg three times daily.

Benfotiamine

Postprandial endothelial dysfunction has been proposed as a link between metabolic syndrome and atherosclerosis. This state is associated with oxidative stress, hyperglycemia, hypertriglyceridemia, and altered nitric oxide function, and been attributed to glucose-protein complexes in food, named advanced glycation end products (AGEs). These complexes

are formed at high temperatures and activate AGE-specific receptors, which stimulate monocytes and endothelial cells and ultimately promote inflammation.

Benfotiamine is a synthetic analogue of thiamine with significantly greater bioavailability. Benfotiamine activates transketolase, an enzyme that helps clear AGEs, thus improving postprandial endothelial function. In a pilot study, 350 mg of benfotiamine after meals completely eliminated vascular measures of postprandial endothelial dysfunction in 13 patients with type 2 DM.⁹⁵

This important finding has not been replicated since it was reported in 2006; however, there is a substantial clinical need for corroborating evidence. Several trials have indicated that benfotiamine improves diabetic neuropathy,^{96,97} an unsurprising finding considering the neurological symptoms observed in cases of thiamine deficiency. While one trial reported no improvement in markers of diabetic nephropathy,⁹⁸ a separate trial reported improvements in microalbuminuria.⁹⁹

Dosage

The 350-mg dose used in the pilot study is higher than found in most formulations.

Precautions

While early evidence is very promising, it is probably premature to recommend the widespread use of synthetic thiamine analogues because long-term safety data are not available.

Vitamin K

This fat-soluble vitamin exists as phylloquinone (K1) in plants, menaquinone (K2) in animals, and a fermented soybean product known as *natto*. Vitamin K2 is considered more biologically active and is a cofactor for the carboxylation of proteins. Vitamin K2 is involved in the production of osteocalcin, which strengthens bones by forming a protein scaffold. Vitamin K2 is also involved in the production of matrix Gla protein, which prevents vascular calcification by repairing smooth muscle and endothelium. Vitamin K2 is receiving growing attention as a target for the treatment of diverse disorders in addition to its established role in coagulation factors biosynthesis.

Early studies indicate that vitamin K2 stimulates beta cell proliferation and enhances insulin sensitivity. Vitamin K deficiency, as suggested by low levels of carboxylated osteocalcin, is also associated with an increased risk of type 2 DM.¹⁰⁰ Recommending vitamin K2 for glycemic control is premature; however, its endothelial and cardiovascular benefits make it an appealing addition to an integrative type 2 treatment plan.

Dosage

The starting dose of vitamin K2 is typically 100 mcg daily; however, higher doses have been commonly used.

Precautions

Patients taking warfarin require close monitoring and dose adjustment after starting vitamin K2; however, vitamin K2 ultimately reduces the fluctuations in international normalized ratio observed in vitamin K2-deficient patients.¹⁰¹ Vitamin K has no other known side effects.

Risks of Specific Supplements

Although evidence indicates selenium has insulin-like actions and may delay microvascular complications, integrative practitioners should be aware of the association between selenium and the risk of type 2 DM. In the Nutritional Prevention of Cancer trial, 1202 individuals with localized melanoma were randomized to receive selenium or placebo for cancer prevention. After a mean follow-up duration of 7.7 years, selenium users developed type 2 DM more often (hazard risk, 1.55; 95% CI, 1.03 to 2.33), with the greatest risk observed in individuals with the highest baseline selenium levels (hazard risk, 2.70; 95% CI, 1.30 to 5.61).¹⁰² Selenium supplementation should only be considered in patients with low baseline selenium levels. The maximum daily dose is 200 mcg. The mechanisms underlying the difference in effects of inorganic and organic forms of selenium on the risk of type 2 DM risk have yet to be elucidated.

Practitioners should exercise caution when using B vitamins in patients with nephropathy. In the Canadian Diabetic Intervention with Vitamins to Improve Nephropathy (DIVINE) trial, 238 patients with type 1 DM or type 2 DM were administered a tablet containing folic acid 2.5 mg, vitamin B₆ 25 mg, and vitamin B₁₂ 1 mg daily or placebo for

approximately 3 years for the treatment of elevated homocysteine levels. Although the treatment group had lower plasma homocysteine levels, worse kidney function and a higher incidence of cardiovascular events were observed in this group.¹⁰³ The investigators postulated that this finding may be attributable to increased cell proliferation induced by folic acid, increased methylation from folic acid and vitamin B₁₂, or nitric oxide-related mechanisms. Earlier reports noted poorer cardiovascular outcomes associated with B vitamins, indicating further studies are required to clarify this issue.

Pharmaceuticals

The standard approach to treating type 2 DM is focused on improving glycemic control, as reflected by serum levels of HbA1c. This approach is based on the assumption that all reductions in HbA1c are of equal benefit, regardless of how they are achieved. However, more recent evidence contradicts this assumption.

Recent systematic reviews clearly indicate that different drugs have different effects on real-world clinical measures of morbidity and mortality, independent of their ability to lower blood glucose. Growing recognition of this important gap in our understanding of type 2 DM treatment has created confusion for patients and caregivers. Bridging this gap will be crucial for providing more effective integrative treatment in the future.

Metformin

Metformin is a biguanide that is structurally similar to guanidines that were originally discovered in extracts of *Galega officinalis* (French lilac). Metformin has been in use since the 1950s, thus making it one of the oldest, and perhaps most effective, oral hypoglycemic drugs. Although its exact mechanism of action is unclear, metformin improves insulin sensitivity and reduces hepatic gluconeogenesis.

Metformin is the only diabetes medication shown to reduce cardiovascular mortality (OR, 0.74; 95% CI, 0.62 to 0.89) in systematic reviews,¹⁰⁴ and as such should be considered first-line treatment for diabetes.

Dosage

The typical dose range is 500 to 1000 mg twice daily.

Precautions

Other than mild occasional nausea and diarrhea, the only drawback of metformin use is impaired vitamin B₁₂ absorption in the terminal ileum, which may lead to vitamin B₁₂ deficiency.¹⁰⁵ Metformin may also cause lactic acidosis in patients with renal insufficiency or alcoholism.

Sulfonylureas

Sulfonylureas increase insulin secretion by pancreatic beta cells by binding to membrane channels. Sulfonylureas drugs have also been used for several decades but do not appear to improve cardiovascular outcomes. The use of sulfonylureas is limited by their potential to cause weight gain and association with more frequent hypoglycemic episodes, which can lead to arrhythmias and cardiac ischemia.¹⁰⁶ A systematic review found that glyburide was almost twice as likely as other sulfonylureas to cause hypoglycemia; however, cardiovascular outcomes were identical for all drugs in this class.¹⁰⁷ Patients using sulfonylureas and metformin in combination are reportedly at greater risk of cardiovascular mortality than patients using metformin alone.¹⁰⁸

Dosage

The usual dose of glyburide is 2.5 to 10 mg twice daily.

Precautions

Glyburide may cause hypoglycemia and weight gain.

Thiazolidinedione

Thiazolidinediones increase insulin sensitivity by activating peroxisome proliferator-activated receptor gamma, a nuclear receptor with salutary effects on fatty acid balance, adipocyte differentiation, adiponectin, and other factors involved in glucose and lipid metabolism. The use of rosiglitazone has decreased dramatically since it was found to increase the risk of heart attacks by more than 40% in patients with type 2 DM, possibly because of drug-related increases in LDL or congestive heart failure. Pioglitazone (Actos) is the only drug in this class currently

licensed for the treatment of type 2 DM. The impact of pioglitazone on cardiovascular outcomes remains unclear; however, a systematic review did find that it improves glycemic control with a mean reduction in HbA1c levels of 0.58%.

Dosage

The dose of pioglitazone is 15 to 30 mg once daily.

Precautions

The average weight gain associated with the use of pioglitazone is 7 lb, and mild edema is commonly noted. A further issue with long-term pioglitazone use is osteoporosis, with a meta-analysis of 10 trials involving 13,715 participants demonstrating fracture risk is more than doubled with the use of pioglitazone (OR, 2.23; 95% CI, 1.65 to 3.01).¹⁰⁹ Pioglitazone may increase cardiovascular risk.

Incretins

Incretins are hormones produced in the small intestine during a meal that enter the vasculature and trigger insulin release by pancreatic beta cells. The two incretins are glucagon-like peptide (GLP-1) and gastric inhibitory peptide (GIP). A newer class of drugs that inhibit dipeptidyl peptidase-4 (DPP-4), an enzyme that degrades GLP-1 and GIP, have demonstrated efficacy in increasing insulin and decreasing glucagon levels.

Sitagliptin

Sitagliptin (*Januvia*) is a dipeptidyl peptidase-4 inhibitor.

Dosage

The recommended dose of sitagliptin is 100 mg once daily.

Precautions

The only side effects noted in trials are nasopharyngitis and headache; however, the long-term safety of sitagliptin remains unclear because

DPP-4 degrades dozens of other enzymes and sitagliptin has not been evaluated in long-term trials. The impact of sitagliptin on cardiovascular events and mortality remains unclear; however, meta-analyses indicate that the use of sitagliptin is associated with HbA1c reductions by 0.7%.¹¹⁰

Exenatide and Liraglutide

Exenatide (Byetta) and Liraglutide (Victoza) are GLP-1 analogues. In comparison trials with insulin and other oral hypoglycemic, exenatide and liraglutide have been shown to reduce HbA1c by approximately 1.0% without causing hypoglycemia or weight gain.¹¹¹ Liraglutide has also been approved for weight loss.

Dosage

The dose of exenatide is 5 mcg twice daily for 1 month and increased to 10 mcg twice daily as required. A once-weekly injection is available as a 2 mg weekly subcutaneous dose. The dose of liraglutide is 0.6 mg subcutaneous injection daily for 1 week and then increased to 1.2 mg daily.

Precautions

Reported side effects include diarrhea, nausea, and vomiting. Cases of pancreatitis have been reported. Data regarding cardiovascular outcomes are not currently available.

Insulin, sulfonylureas, and thiazolidinedione all cause weight gain. Metformin, incretins, and sodium-glucose cotransporter 2 inhibitors are weight neutral or can help with weight loss.

Sodium-Glucose Cotransporter 2 Inhibitors

This new class of medicines inhibits the reabsorption of glucose in the kidney, thereby encouraging the excretion of glucose via the urine. Sodium-glucose cotransporter 2 inhibitors have been found to reduce HbA1c levels by 0.5 to 0.8% and result in mild weight loss.⁷⁹

Dosage

- Dapagliflozin (*Farxiga*); 5–10 mg by mouth every morning.
- Canagliflozin (*Invokana*); 100–300 mg before breakfast.
- Empagliflozin (*Jardiance*); 10–25 mg by mouth every morning.

Precautions

Sodium-glucose cotransporter 2 inhibitors may increase the risk of lower urinary tract infections and should be avoided in patients with a GFR < 45.

Insulin

Although insulin administration can be lifesaving, insulin is a proinflammatory hormone. Every effort should be made to optimize glycemic control; however, it is probably best to use the lowest possible doses of exogenous insulin to achieve this goal. Insulin-dependent patients with type 2 DM can often greatly reduce their dose requirements by following an integrative treatment protocol, as described in this chapter.

One important mechanism underlying the risk of type 2 DM is stimulation of insulin-like growth factor-1 (IGF-1) and other growth hormones. IGF-1 levels predict cancer risk, with the first indication that insulin users may be at increased risk of cancer published in 1967.¹¹² For reasons that are unclear, patients with type 2 DM are at a 20% increased risk of breast cancer¹¹³ and a 30% increased risk of colon cancer.¹¹⁴ Research indicates glargine, a long-acting insulin analogue, may be more carcinogenic due to greater stimulation of IGF-1 compared to other types of insulin. The hope is that the International Study of Insulin and Cancer, funded by Sanofi-Aventis (the makers of glargine), will clarify this issue. Many insulin protocols, regimens, and analogues are available; however, their use is beyond the scope of this chapter. Practitioners should be aware that, although these regimens may allow patients to take their insulin in a more convenient or practical manner, there is a lack of evidence demonstrating any approach is superior to another. Short-acting insulin analogues are commonly used; however, meta-analyses indicate these therapies do not provide any advantage over regular human insulin.¹¹⁵ Similarly, there is no evidence to suggest the long-acting insulin analogues, glargine and detemir, are superior to regular insulin.¹¹⁶ Continuous infusion pumps represent a newer technology that

may be superior; however, their benefit has been demonstrated only among patients with type 1 DM.¹¹⁷

Other Drugs That Improve Outcomes

Angiotensin-Converting Enzyme Inhibitors

ACE inhibitors have been shown to have efficacy in preventing and treating type 2 diabetes. Accordingly, the integration between seemingly disparate physiological systems may have a powerful impact on health and disease. The precise mechanisms underlying the effect of the renin-angiotensin system on glucose metabolism remain unclear; however, multiple lines of evidence exist. Angiotensin II is known to mediate vasoconstriction and hypoperfusion of skeletal muscle and pancreatic islets. Angiotensin II also appears to affect insulin signaling and glucose transport by mechanisms that have yet to be elucidated. In a systematic review of 13 trials involving 93,451 patients with hypertension, the use of ACE inhibitors reduced the risk of incident type 2 DM by an impressive 26%.¹¹⁸ A number of ACE inhibitors are available, with ramipril being the most widely studied at a recommended dose of 2.5 to 10 mg once daily.

Statins

Statins are universally recommended for patients with type 2 DM; however, their effectiveness in treating type 2 DM is increasingly complicated. As a drug class, 3-hydroxy-3-methyl-glutaryl-coenzyme A (HMG-CoA) reductase inhibitors are known to improve lipid parameters. However, the clear cardiovascular benefits of statins are more strongly associated with antiinflammatory effects. The absolute risk reduction observed with statins is compelling in people who have already had a cardiovascular event; however, the effectiveness of statins is limited in patients who have not. Patients with type 2 DM fall somewhere in between these two patient populations, with the higher baseline vascular risk among patients with diabetes making statin therapy more appropriate.¹¹⁹

Red yeast rice is a natural source of several statin compounds and may represent a reasonable alternative for patients who are unable to tolerate or do not wish to use a statin drug.

Unfortunately, recent evidence indicates some statins increase the risk of type 2 DM. In a meta-analysis of 13 trials involving 91,140 adults, the overall increase in type 2 DM risk was 9% (95% CI, 1.02 to 1.17).¹²⁰

Subgroup analysis revealed that different statins have very different effects. Simvastatin, atorvastatin, and rosuvastatin increased the risk of type 2 DM, whereas pravastatin reduced the risk.¹²¹ This finding indicates pravastatin may be a more appropriate choice in patients with type 2 DM until this issue has been resolved. The recommended dose of pravastatin for the treatment of type 2 diabetes is 20 to 80 mg once daily.

Bariatric Surgery

Various surgical procedures can induce weight loss by resecting, tightening, shrinking, or bypassing the stomach and upper digestive tract. These forms of so-called bariatric surgery lead to profound weight loss and may be the most important advance in the treatment of type 2 DM in decades. Although surgery is not the most philosophically appealing solution to the worldwide epidemic of type 2 DM and other metabolic diseases related to obesity, it is increasingly recognized by governments and insurers worldwide.

In a review of 103 clinical trial treatment arms involving 3188 patients with type 2 DM, 78% had complete resolution of clinical and laboratory manifestations of diabetes postoperatively, with significant improvements observed in 87% of patients with a reported average weight loss of 38.5 kg.¹²² Long-term reductions in all-cause morbidity and mortality are increasingly reported.

Short-term complications include gastric dumping syndrome, hernias, wound infections, and pneumonia. The most important long-term consideration following bariatric surgery is nutrient malabsorption.

Deficiencies of vitamins A, C, D, K, and B₁₂, and folate, iron, selenium, calcium, zinc, and copper should be expected following bariatric surgery.¹²³ All patients who have undergone bariatric surgery should take a daily multivitamin and multimineral supplement. Anemia, hyperparathyroidism, and peripheral neuropathy are common postoperatively. Patients who report vague symptoms following bariatric surgery should be evaluated for nutrient deficiency and reminded of the importance of supplementation.

Prevention Prescription

- Reduce stress.
- Obtain 6 to 8 hours of restful sleep per night.

- Eat a low-glycemic Mediterranean diet that includes whole grains, vegetable protein, vegetables, and some fruit, coffee, and moderate alcohol.
- Practice daily exercise, aerobic or resistance.
- Manage weight and treat obesity.
- Avoid air pollution by maintaining a safe distance from high-traffic roads at work and home.
- Practice a form of mindfulness or meditation.
- Treat prediabetes with aggressive lifestyle intervention and consider metformin 500 to 1000 mg twice daily.

Therapeutic Review

Lifestyle

- Consider referral to a comprehensive lifestyle program if available.

Exercise

- Encourage daily aerobic or resistance exercise.

Diet

- Low-glycemic diet and moderate carbohydrate reduction.
- Avoidance of sugar-sweetened beverages and juices.
- Consumption of more lentils, beans, pulses and soy, chia and other whole grains, onions and green leafy vegetables, almonds, walnuts, and other nuts.
- Moderate coffee and wine consumption.

Mind-Body Therapy

- Ask about and treat disordered sleep, stress, anxiety, and depression.
- Discuss stress reduction options and facilitate the chosen modality.

Supplements

- Alpha-lipoic acid: 50 to 100 mg daily. 
- Chromium: 200 to 1000 mcg daily. 
- Benfotiamine: 350 mg with meals. 
- Omega-3 fatty acids: 1 to 4 g daily. 
- L-Carnitine: 500 to 1000 mg three times daily. 
- Magnesium: 200 to 500 mg daily. 
- Vitamin K: 100 mcg daily (caution with warfarin). 

Botanicals

- Cinnamon: 1 to 5 g ground bark with meals or equivalent extract. 
- Fenugreek (*Trigonella foenum-graecum*): 30 g seed powder or equivalent extract with meals. 
- Touchi, water extract (soy) 0.3 g in tea daily. 
- Marine collagen peptides: 13 g daily. 
- Silymarin: 200 g daily. 
- Ivy gourd (*Coccoloba indica*): 15 g powdered dried leaves or equivalent extract. 
- *Salacia reticulata* (kothala himbutu): premanufactured tea daily. 
- *Gynostemma pentaphyllum*: 6 g in tea daily. 

Pharmaceuticals

- Metformin: 500 to 1000 mg twice daily. 
- Add other drug classes as required to achieve optimal glycosylated hemoglobin levels.

Surgery

- Bariatric surgery for morbidly obese patients.

CHAPTER 34

Hypothyroidism

Leslie Mendoza Temple, MD, ABOIM, and Pooja Saigal, MD

Pathophysiology

Normal Thyroid Physiology

Thyrotropin-releasing hormone (TRH) from the hypothalamus increases release of thyroid-stimulating hormone (TSH) from the anterior pituitary gland. TSH stimulates the thyroid gland to release the prohormone thyroxine (T4) alongside the active metabolite triiodothyronine (T3); this yields 20% of the body's available T3. Thyroid hormone transporters transport circulating T4 into cells of various peripheral organs, where type 1 deiodinase (D1) and type 2 deiodinase (D2) catalyze intracellular conversion of T4 to T3; this yields the remaining 80% of the body's available T3. T4 and T3 suppress both TRH and TSH secretion via negative feedback. Type 3 deiodinase (D3) clears T4 and T3 by catalyzing the conversion of T4 to reverse T3 (rT3) and T3 to T2. In a single day, the human body generally produces T4:T3 in a ratio of 5:2; however, the half-life of T4 is much longer than that of T3, so the physiological serum ratio of T4:T3 in the human body is 14:1.^{1,2} In a healthy individual, thyroid hormones, enzymes, and nutritional cofactors (to be described in this chapter) will influence and are influenced by other members of the endocrine system, notably the hypothalamus, pituitary, adrenal glands, ovaries, and testes.

Pathophysiology of Hypothyroidism

Hypothyroidism is the insufficient synthesis of thyroid hormone necessary for metabolic processes throughout the body. Worldwide, iodine deficiency is the most common cause of **primary hypothyroidism**.

In iodine-sufficient countries, autoimmune destruction of the gland (Hashimoto disease) is the leading cause of primary hypothyroidism. The second leading cause is iatrogenic, including surgery, radioactive iodine, medications (e.g., lithium, amiodarone), overconsumption of goitrogens, and external beam radiation. Primary hypothyroidism accounts for approximately 95% of cases compared with less than 5% from secondary and tertiary types. One must evaluate and treat for other causes of hypothyroid-like symptoms that can trigger body stress, including adrenal insufficiency, hypogonadism, anemia, anxiety, depression, toxic exposures, and food sensitivities or allergies.

Secondary hypothyroidism results from decreased TSH secretion from pituitary tumors (adenomas most common), pituitary surgery, or other pituitary diseases, such as Sheehan syndrome. **Tertiary hypothyroidism** results in decreased TRH secretion because of infiltrative processes in the brain such as sarcoidosis, infection, or congenital defect. TSH levels may vary from low, normal, or even slightly elevated values, whereas the free T4 (FT4) level remains low. Generally, serum TSH concentrations are low in patients with pituitary disease and normal or high in those with hypothalamic disease. Clinical correlation and magnetic resonance imaging (MRI) of the hypothalamus and pituitary are necessary for proper diagnosis. **Transient hypothyroidism** may occur after abrupt withdrawal of long-term thyroid hormone therapy or from silent or subacute thyroiditis. **Resistance to thyroid hormone (RTH)** is a rare autosomal dominant inherited syndrome of decreased end-organ sensitivity to thyroid hormone.

Subclinical Hypothyroidism

In subclinical hypothyroidism (SCH), TSH is elevated but FT4 is in the normal range. The thyroid gland is stimulated to work harder but is still keeping up with the body's metabolic needs. The prevalence of SCH is variable, with 8% of women and 3% of men affected, increasing to 15%–18% in women aged more than 60 years.³ In addition, 2%–5% of patients with SCH progress to overt hypothyroidism per year.⁴

In SCH, the clinical decision to prescribe thyroid hormone is based mainly on the presence of symptoms and lab results. If a patient is symptomatic, checking thyroid peroxidase antibodies (TPO Ab) and thyroglobulin antibodies (Tg Ab) may help identify an autoimmune cause (Hashimoto disease) and the risk for progression to overt hypothyroidism. If antibodies are positive and the patient is

symptomatic, then treatment with low-dose thyroid hormone may be indicated. If the patient has symptoms, yet has negative antibodies and no other possible causes, a low dose of thyroid hormone may still be warranted for several months' trial.

Subclinical hypothyroidism is when the TSH is elevated but FT4 is normal. Do not consider treating unless the patient is symptomatic, has underlying heart disease, or the TSH is >10 mIU/L.

Possible consequences of untreated SCH are coronary atherosclerosis, elevated low-density lipoproteins (LDLs), and progression to overt hypothyroidism.⁵ Statin-induced myopathy may be associated with mild thyroid insufficiency, so thyroid hormone may be useful for high-risk cardiovascular patients starting statin medication, particularly if the TSH is elevated.^{6,7}

The risks for cardiac arrhythmias (atrial fibrillation) and osteoporosis must be weighed against the benefits of receiving thyroid hormone therapy,⁴ but clinical monitoring of pulse rate and symptoms of hyperthyroidism (e.g., anxiety, insomnia, palpitations, diarrhea, weight loss, irritability), as well as periodic bone density testing in appropriate patients, would likely reduce these risks.

Other abnormal laboratory findings in hypothyroidism may include increased creatine phosphokinase, elevated cholesterol and triglycerides, and normocytic or macrocytic anemia.

Clinical Presentation

Common symptoms of hypothyroidism can include fatigue, dry skin, cold intolerance, hair loss, concentration problems, constipation, weight gain, carpal tunnel symptoms, dyspnea, hoarseness, and menorrhagia. Physical signs are manifested by obesity, dry, coarse skin; brittle nails; cool extremities; thinning of the lateral eyebrows and hair; myxedema; delayed tendon reflexes; and diminished hearing.⁸ In addition to the physical findings described, basal metabolic rate may be estimated using axillary temperature measurements and assessment of Achilles tendon reflexes (ATRs). A series of morning basal body temperatures less than 97.4°F and delayed ATRs may enhance the clinical diagnosis.⁹

Laboratory Studies

The laboratory evaluation of hypothyroidism remains a controversial topic in the medical community. Minimal evaluation should include TSH, FT4, and TPO Ab. Some clinicians monitor free T3 (FT3) and rT3 levels, which will be discussed later in the chapter. Additional testing may include measuring nutritional cofactors and related hormone pathways, e.g., urinary iodine levels and adrenal gland function, although these tests are not commonly performed in conventional endocrinology with respect to hypothyroidism.

Timing of Blood Collection

In individuals with intact endogenous thyroid function, circadian fluctuation yields the highest TSH secretion between 10 p.m. and 4 a.m. and lowest secretion between 10 a.m. and 6 p.m.; T3 levels peak at 3 a.m.^{1,10} However, in patients receiving oral thyroid hormone replacement therapy, serum TSH is lowest about 14 hours after ingestion, FT4 peaks 4–6 hours after ingestion, and FT3 serum peaks 2–4 hours after ingestion. Though these fluctuations may be blunted by endogenous hormone production, it is prudent to check thyroid function tests several hours after thyroid hormone replacement therapy is dosed to capture peak FT4 and FT3 levels and to rule out suprathreshold dosing regimens.¹ Thus if thyroid hormone replacement therapy is taken at night, then thyroid function tests should be drawn in the morning, preferably prior to caffeine consumption. Alternatively, if thyroid hormone replacement therapy is taken in the morning, then thyroid function tests should be drawn in the afternoon. In general, testing at a consistent time of day is best for serial comparisons.

Optimal Lab Values and Treatment Targets

Every individual has an endogenously set TSH concentration that corresponds to their optimal thyroid function. The normal TSH reference range proposed by the American Association of Clinical Endocrinologists (AACE) and the American Thyroid Association (ATA) is wide, ranging from 0.4 to 4.0 mIU/L. Some investigators suggest lowering the upper limit of serum TSH reference range to 2.5 mIU/L. This narrower TSH reference range may be appropriate when TSH is utilized as a target for therapeutic purposes in overt hypothyroidism, though it may lead to overdiagnosis when TSH is utilized for initial diagnostic purposes.^{1,4,11,12}

The ideal TSH range is controversial. Consider using the broader range of 0.4–4.0 mIU/L for diagnosis and an upper limit of 2.5 mIU/L to guide replacement therapy.

In patients with subclinical hypothyroidism, AACE and ATA guidelines suggest levothyroxine (LT4) supplementation when TSH is greater than 10 because of an increased risk for heart failure (HF) and cardiovascular mortality. They also state that LT4 supplementation may be considered when TSH is greater than the laboratory upper limit but less than 10 if patients have symptoms suggestive of hypothyroidism, positive TPO Abs, evidence of atherosclerotic cardiovascular disease (ASCVD), HF, or associated risk factors for these diseases^{1,2,13}

AACE and ATA guidelines recommend treatment for SCH or hypothyroidism if TSH is greater than 2.5 in all females during the preconceptional period or if TSH is greater than trimester-specific reference ranges during pregnancy (0.1–2.5 mIU/L in the first trimester, 0.2–3.0 mIU/L in the second trimester, and 0.3–3.0 mIU/L in the third trimester).^{1,2,13}

TSH normalization is usually the goal of thyroid hormone replacement therapy, with improvement of the patient's symptoms being paramount. However, it should be noted that overtreatment with thyroid hormone to achieve subnormal TSH levels is not advised because TSH levels of less than 0.1 are associated with increased risk for osteoporosis and atrial fibrillation. FT4 and FT3 may also be tested and should achieve levels within normal laboratory reference ranges during therapy. Unfortunately, FT3 levels are difficult to interpret because the target reference range, yielding normal physiological function, is uncertain and performance of T3 assays is limited.¹

An algorithm summarizing diagnosis of hypothyroidism and indications for therapy is shown in Figs. [34.1](#) and [34.2](#).

Environmental Toxins and Endocrine Disruptors

Multiple factors such as a low-salt/low seafood diet; high goitrogen consumption; exposure to chlorine, bromine, fluoride, mercury, perchlorate, and certain medications; and heavy metal toxicity can negatively influence the iodination steps necessary for thyroid hormone production.¹⁴ Functional laboratory testing can further elucidate toxic environmental exposures, including heavy metal testing, food sensitivities, and chemical residues that may interfere with thyroid

hormone production. Testing and treatment for these conditions vary and may require further training for the clinician or referral to an experienced clinician.

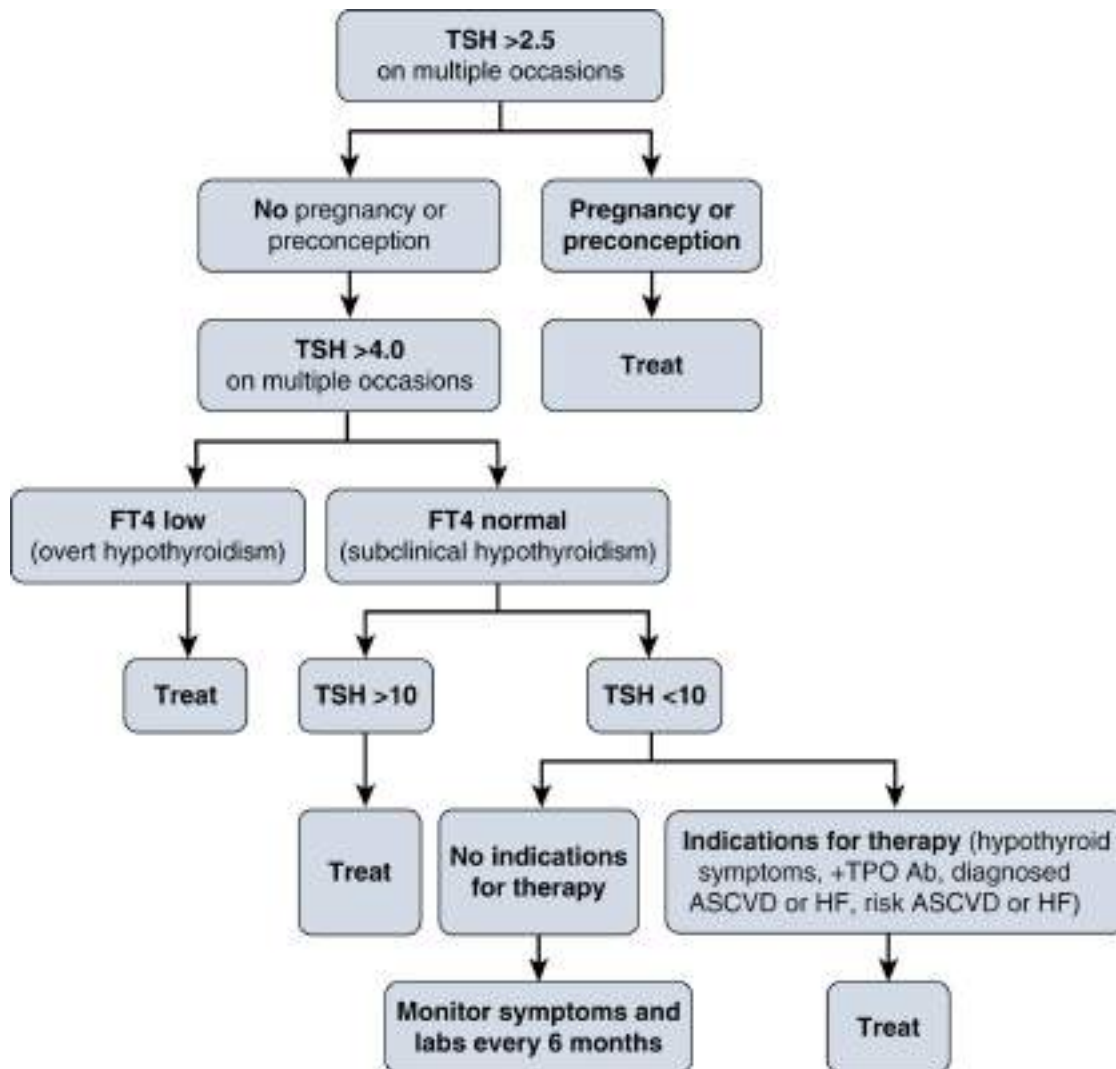

FIG. 34.1 Indications for thyroid hormone replacement therapy. (Adapted from Garber JR, Cobin RH, Gharib H, et al. Clinical practice guidelines for hypothyroidism in adults: cosponsored by the American Association of Clinical Endocrinologists and the American Thyroid Association. *Endocr Pract* . 2012;18(6):988-1028.)

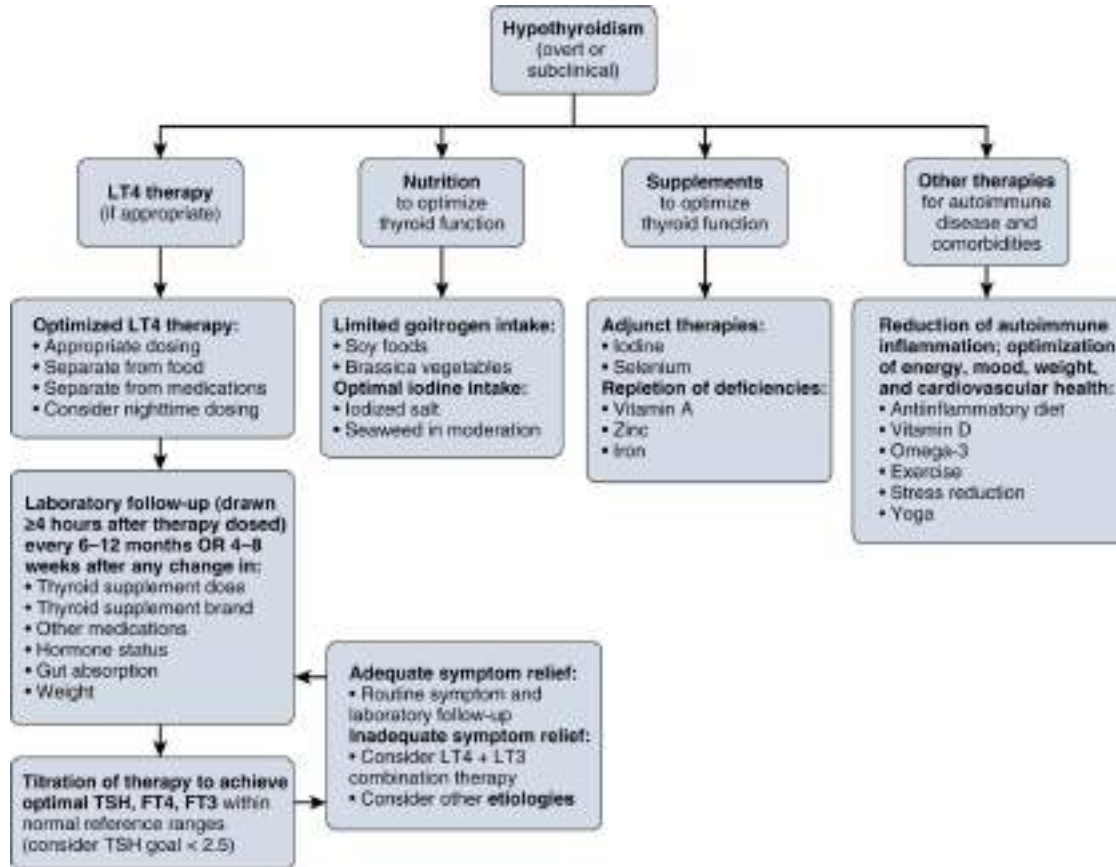

FIG. 34.2 Hypothyroidism Treatment Algorithm.

Integrative Therapy (Fig. 34.3)

Tenets of an integrative, functional medicine approach for improving thyroid health:¹⁴

- Reduce chronic stress from physical, emotional, nutritional, and environmental sources that can promote a dysfunctional immune system, particularly in patients with positive antithyroid antibodies.
- Provide nutrients that are needed for adequate T4 manufacture, proper T4 to T3 conversion, and optimal T3-binding activity to intracellular receptors.
- Exercise and follow a heart-healthy nutrition program to increase energy and maintain weight (or at least stop gaining weight).
- Use appropriate testing, monitoring, and medications to treat

hypothyroidism.

Exercise

Along with a heart-healthy, antiinflammatory nutrition plan, exercise is absolutely critical for hypothyroid patients to maintain healthy weight (or stop gaining weight), elevate mood, modify cardiac risk, and increase bone density, especially in the face of a decreased metabolic rate (see [Chapter 91](#)).

Nutrition

Diet

Optimization of endogenous thyroid function is important to compensate for inadequacies of exogenous LT4 therapy. In the setting of autoimmune hypothyroidism, it is prudent to pursue an antiinflammatory diet to reduce autoimmune inflammation and optimize cardiovascular health (see [Chapter 88](#)). At present, studies are lacking to determine the efficacy of an antiinflammatory dietary pattern on the course of hypothyroidism. Studies thus far have demonstrated that specific elimination diets, such as a gluten-free diet or lactose-free diet, do not change the natural history of autoimmune hypothyroidism, even in individuals with known sensitivities to specific dietary components. However, a 1-month elimination–rechallenge trial of these diets may be safe and helpful in ameliorating gastrointestinal symptoms and possibly others in the hypothyroid individual.^{1,15,16}

Brassica Vegetables

Patients should avoid eating abnormally high levels of Brassica vegetables (e.g., cabbage, turnips, Brussels sprouts, rutabagas, broccoli, cauliflower, bok choy). Millet, peaches, peanuts, pine nuts, strawberries, spinach, and cassava root have small levels of goitrogens as well. These foods are rich in dietary sulfhydryl and thiocyanate compounds that can adversely impact the iodination of thyroglobulin if consumed in high amounts, thus inhibiting the uptake of iodine by the thyroid gland.¹⁷ An observational study of 37 healthy subjects looked at a high daily soybean intake of 30 grams or more over 1–3 months. The subjects had within normal range increases in TSH levels and more hypothyroid-like symptoms that normalized 1 month after soybean cessation.¹⁸ There has

been a case report of an 88-year-old woman who was in a coma because of severe myxedema, which was a result of consuming 2–3 pounds of raw bok choy daily for several months.¹⁹ When eaten raw, Brassica vegetables release the enzyme myrosinase, which accelerates the hydrolysis of glucosinolates. Cooking mostly deactivates the myrosinase in these vegetables.²⁰ When eating a reasonable amount of soy and Brassica vegetables, steaming or cooking these foods briefly may help reduce their goitrogenic effect while preserving their nutrient content.^{21,22}

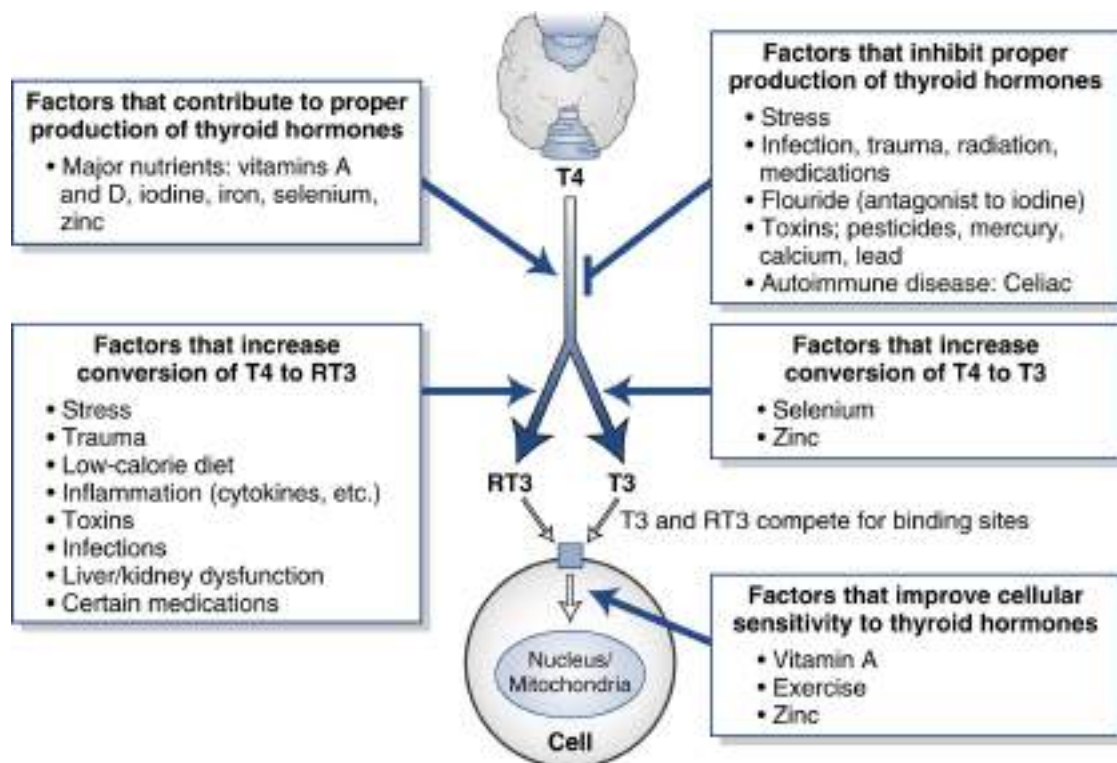

FIG. 34.3 Factors that affect thyroid functions. (Reprinted with permission from Brand JS, Jones DS. Clinical approaches to hormonal and neuroendocrine imbalances. In: Jones DS, ed. *Textbook of functional medicine*. Gig Harbor WA: The Institute for Functional Medicine; 2006:593-604.)

Steaming or cooking Brassica vegetables and soy briefly may help reduce the goitrogenic effect of myrosinase while preserving their nutrient content.

Soy

The overall evidence suggests that soy, particularly the isoflavone genistein, does not significantly alter thyroid function in iodine-replete, euthyroid patients. In vitro and in vivo studies account for a majority of the evidence for soy's goitrogenic effects.^{23,24} In infants fed noniodine-fortified, soy-based formula, goitrogenic effects were seen, but the problem was easily solved with iodine repletion.²⁵ Soy isoflavones can aggravate hypothyroidism in iodine-deficient adults as well. Isoflavones are iodinated by thyroid peroxidase, which may be the mechanism for their competitive interference with thyroid hormone production.^{26,27} Adequate supplementation of at least 150 mcg of iodine and 200 mcg of selenium may counteract this risk.

TABLE 34.1
Iodine Content of Selected Foods

Food	Content (mcg)
Salt, iodized, 1 teaspoon	400
Bread made with iodate dough conditioner and continuous mix process, 1 slice	142
Bread, made with regular process, 1 slice (most widely available)	35
Haddock, 3 oz	104-145
Shrimp, 3 oz	21-37
Egg, 1	18-26
Cottage cheese 2%, ½ cup	26-71
Cheddar cheese, 1 oz	5-23
Ground beef, 3 oz	8

Adapted from U.S. Department of Agriculture. *Composition of foods, USDA Handbook No. 8 Series*. Agricultural Research Service. Washington, DC; 1976-1986.

For adults on thyroid hormone replacement therapy who enjoy eating soy often or take daily soy supplements, the dosage of thyroid hormone may require more frequent surveillance and higher dosing. Ideally, soy foods and thyroid medication should be taken several hours apart.²⁸

Supplements

Several minerals and trace elements are essential for proper thyroid function and metabolism. The clinician and patient should be wary of supplements marketed as thyroid supports given the risk for adulteration with T4 and T3 products.²⁹ The clinician should monitor hormone levels closely for patients on nutritional supplementation

(whether adulterated or clean) because this can potentially reduce pharmaceutical thyroid hormone needs. Should the clinician recommend nutritional supplements, only manufacturers with regularly maintained certifications for Food and Drug Administration (FDA)–required current good manufacturing practices (cGMPs) should be recommended.

Iodine: Too much or too little can cause hypothyroidism; too much iodine given too quickly in a hypothyroid patient can also cause hyperthyroidism. Iodine supplementation with kelp or iodine tablets may be recommended but only for short term after urine testing for iodine deficiency.

Iodine Deficiency

Underconsumption of iodine deprives the thyroid gland of manufacturing active thyroid hormones through the organification of iodine. Repleting with iodine is the treatment of choice for iodine deficiency, achieved with varying success in areas of the world by the iodination of refined salt. Iodine lost from salt is estimated to be 20% from production site to table, with another 20% lost during cooking.³⁰ Thus iodine should also come from sources such as fresh ocean fish, seaweed, and unrefined sea salt (Tables 34.1 and 34.2). Short-term iodine repletion with supplements is discussed in the following section for appropriate patients. A minimum of 150 mcg of iodine should be consumed on a daily basis (200 mcg for pregnant women and 290 mcg for lactating women).³¹

TABLE 34.2
Commonly Used Seaweed Preparations

Type of Seaweed	Common Use	Amount to Meet Minimum Iodine Dose of 150 mcg/day	Amount to Meet Maximum Iodine Dose of 1100 mcg/day
Nori	Sushi wrapper, rice balls	9 g/day	69 g/day
Wakame	Miso soup	2 g/day	17 g/day
Dulse	Seaweed chips, soups, sauces	2 g/day	15 g/day
Kelp/Kombu	Hot pot dishes, soups	9 mg/day	710 mg/day

Minimum and maximum daily iodine amounts are based on U.S./Japanese source values.

Adapted with permission: Teas J, Pine S, Critchley A, et al. Variability of iodine content in common commercially available seaweeds. *Thyroid*. 2004;14(10):839.

Iodine Testing

If a patient is suspected to have iodine deficiency because of dietary restrictions (e.g., seafood avoidance, low salt consumption), iron deficiency, medication use, or heavy metal toxicity, iodine testing may be useful. Since public health programs to iodize salt have occurred worldwide, it may be assumed that most individuals are iodine replete in targeted countries. However, cases of iodine deficiency have been identified in the United States, a country that has largely eradicated iodine deficiency. The **24-hour urine iodine test** (unprovoked) is the standard test for checking iodine status, although it is a cumbersome test for the patient.³²

Some clinicians use the **iodine loading test**, a provoked measure of body iodine stores. The test consists of consuming 50 mg of an iodine/iodide combination followed by a 24-hour urine collection. A normal iodine loading test results if 90% or more iodine was excreted in the urine. If the test resulted in a 75% excretion rate, this would imply that the body needs more iodine.^{33,34} If an iodine deficiency is noted from this test, some clinicians have used kelp tablets or iodine/iodide replacement (Lugol solution or Iodoral). Iodine supplementation should be recommended for short term only with iodine sources coming from food thereafter.

The **iodine skin patch test** is unreliable and should not be used in isolation for determining iodine status. The test consists of painting a 3 × 3 inch square of iodine tincture on the inner forearm or abdomen at bedtime. A normal body iodine level is supposedly diagnosed if the orange color of the patch takes longer than 24 hours to disappear. If the patch disappears in 10 hours or less, it implies a significant iodine deficiency. However, the iodine skin patch test fails to consider the differences in an individual's skin moisture, ambient temperature, and atmospheric pressure, all of which may affect iodine evaporation rate and patch color intensity in the skin.

The 24-hour unprovoked urine iodine test is the standard test for checking iodine status, although a spot urine iodine test may still be useful and easier for the patient to perform.

Iodine Excess

The tolerable upper intake level (UL) for adults is 1100 mcg/day (1.1

mg/day).³⁵ The UL is the highest level of daily intake that is likely to pose no risk for adverse health effects to almost all individuals in the general population. Chronic overexposure to iodine reduces organic binding of iodine by the thyroid gland. A daily iodine intake of 10 times (>1500 mcg/day) the minimum daily adult requirement may cause iodine goiter in some people, especially in individuals with underlying thyroid abnormalities such as Hashimoto disease.³⁶⁻³⁹

Difficulty arises in determining the cumulative daily dose of iodine one is exposed to in food (i.e., kelp, seafood, food preservatives) and iodine-containing substances (i.e., medications, contaminated drinking water, topical antiseptics) over time.

Some practitioners believe in using iodine doses well above the tolerable UL to overcome measured deficiencies for hypothyroidism and even other conditions such as breast cancer.^{40,41} The evidence based on this practice needs larger studies to address concerns with potential iodine excess from supplementation or overzealous consumption of iodine-rich foods such as seaweed.

Hence, iodine supplementation should be maintained at a safe level. Levels that are more than adequate (median urinary iodine excretion, 200–299 mcg/L) or excessive (median urinary iodine excretion, >300 mcg/L) may be unsafe, especially for susceptible persons with autoimmune thyroid diseases or iodine deficiency, where iodine repletion should be cautious and for short term with follow-up testing.⁴²

Patients who are closely monitored with documented iodine deficiency should receive dietary or medical iodine replacement even if the dose exceeds the UL. The UL is not meant to be applied to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.³⁵ The best dosage and duration of oral iodine replacement varies with the individual patient. A dosing regimen is suggested in the following section.

The clinician must use caution in recommending high doses of iodine in a person with a low iodine state as this can temporarily trigger an iodine-induced hyperthyroidism (Jod-Basedow phenomenon) or an iodine-induced hypothyroidism state (Wolff-Chaikoff effect). Patients should be counseled to report side effects that are consistent with either a worsened hypothyroid state or conversely, a hyperthyroid state when taking iodine supplements or kelp tablets.

Daily Dosage: Dietary Iodine for the General Population

- Adult men: 150–1100 mcg
- Adult women: 150–1100 mcg
- Pregnant women: 220–1100 mcg
- Lactating women: 290–1100 mcg^{31,35}
- Iodized salt equivalent: up to 2.75 teaspoons per day (based on 400 mcg of iodine per 1 teaspoon). Caution: not for individuals on low-sodium diets.

Daily Dosage: Iodine Tablets or Drops for Documented Iodine Deficiency

- For documented iodine–deficient adults through a 24-hour urinary iodine test, monitor closely for iodine toxicity if prescribing oral iodine/iodide and use it for short term only. Iodine should then be replaced by food sources, and substances that deplete iodine stores should be avoided when possible. See [Table 34.1](#) for selected foods high in iodine.
- **Lugol solution:** Two drops contain 5 mg iodine and 7.5 mg iodide as potassium iodide. Sig: Two drops po daily for 1–3 months, then retest.
- **Iodoral tablet:** Each 12.5 mg tablet contains a combination of 5 mg iodine and 7.5 mg iodide as potassium iodide.⁴³
- **Sig:** ½–1 tablet po daily for 1–3 months, then retest.

Precautions

Monitor for signs of iodine toxicity: brassy taste in the mouth, increased salivation, gastrointestinal upset, and acne. Chlorophyll tablets may ease the metallic taste side effect.³⁴

TABLE 34.3
Selenium Content of Selected Foods

Food	Content (mcg)
Brazil nuts, unblanched, dried, 1 oz (6–8 nuts)	543
Halibut, Atlantic, or Pacific, ½ filet (159 g weight)	88
Pearled barley, raw, 1 cup	75

Wheat flour, whole grain, 1 cup	74
Lobster, 3 oz	62
Sardines, Atlantic 3 oz	45
Couscous, 1 cup	43

Adapted from U.S. Department of Agriculture, Agricultural Research Service. *USDA National Nutrient Database for Standard Reference, Release 23. Nutrient Data Laboratory*. Available at: <http://www.ars.usda.gov/ba/bhnrc/ndl>. Accessed 2010.

Selenium

Selenium is an essential trace element required for the deiodination of T4 to active T3 hormone.^{40,41} At least 55 mcg per day of selenium is recommended for adults. Eating 4 raw brazil nuts per day provides approximately 300 mcg of selenium, which is within the tolerable UL. [Table 34.3](#) shows high selenium containing foods.⁴⁴ Selenium supplementation may help normalize suboptimal T4 and T3 levels.⁴⁵

A meta-analysis of 9 trials found evidence that selenium supplementation was associated with a significant decrease in TPO-antibody titers at 6 and 12 months. Thyroglobulin antibody titers decreased at 12 months. Selenium supplementation was also associated with improvement in mood or well-being compared with placebo. In other meta-analyses, however, the evidence has been mixed on whether selenium has positive or null effects on thyroid function or quality of life.⁴⁶⁻⁴⁹

Daily Dosage: Selenium

- Adult men: 55–400 mcg
- Adult women: 55–400 mcg
- Pregnant women: 60–400 mcg
- Lactating women: 70–400 mcg^{28,35}

Precautions

The UL for adults is 400 mcg per day based on the risk for selenosis.^{50,51} Excessive intake of selenium (selenosis) can cause discoloration of the skin, deformation and loss of nails, reversible baldness, excessive tooth decay and discoloration, garlic breath odor, weakness, lack of mental alertness, and listlessness.⁵²

Vitamin A

Vitamin A is a fat-soluble vitamin obtained directly from animal sources (preformed vitamin A known as retinol) or synthesized from beta-carotene from plant sources. Beta-carotene is a provitamin A precursor that is converted to retinol in the gut. In persons with vitamin A and iodine deficiency from malnutrition, hypothyroidism risk can be reduced with vitamin A supplementation.⁵³ Vitamin A is involved in T4 manufacture and for intracellular receptor formation for T3.⁵⁴ In the United States, vitamin A deficiency is most often associated with excess alcohol intake and strict dietary restrictions. Vegetarians who avoid dairy and eggs should be able to meet their vitamin A requirements through beta-carotene by eating at least 5 servings of fruits and vegetables daily. At least 3–6 mg of beta-carotene daily (equivalent to 833–1667 IU of vitamin A) may maintain blood levels in the range associated with a lower risk for chronic diseases. The highest yielding sources of carotenoids are carrots, cantaloupes, sweet potatoes, and spinach. Most Americans consume enough retinol in milk, margarine, eggs, meat, liver, and fortified ready-to-eat cereals.⁵⁵

Daily Dosage: Vitamin A (preformed, Retinol)

- 1 mcg retinol = 3.33 IU vitamin A (on a label) = 12 mg beta-carotene (from food)
- Adult men: 900–3000 mcg (\approx 3000–10,000 IU) preformed vitamin A
- Adult women: 700–3000 mcg (\approx 2300–10,000 IU) preformed vitamin A
- Pregnant women: 770–3000 mcg (\approx 2500–10,000 IU) preformed vitamin A
- Lactating women: 1300–3000 mcg (\approx 4300–10,000 IU) preformed vitamin A.^{28,35}

Precautions

Too much preformed vitamin A can lead to toxic symptoms, namely birth defects, liver abnormalities, reduced bone mineral density, and central nervous system disorders. There is no published UL for carotenoids.³⁵

Zinc

Abnormal zinc metabolism has been linked to hypothyroidism.^{56,57} Zinc participates in more than 300 enzymatic reactions, along with multiple functions in transport, immunity, metabolism, and cell structure. Zinc is involved in the conversion of T4 to T3 through the deiodinase enzyme and helps synthesize retinol-binding protein, which transports vitamin A to body tissues. Zinc is an important factor in T3 binding to intracellular receptors in the body. Severe zinc deficiency often accompanies vitamin A deficiency in malnutrition or severe dietary restriction. For most Americans, a majority of zinc in the diet comes from meat, fish, poultry, fortified breakfast cereals, dairy, oysters, liver, dry beans, ginger, soy, and nuts. Good protein intake correlates with zinc intake.⁵⁸ The UL for zinc is 40 mg/day for adults.³⁵

In a randomized, double-blind, controlled trial, 68 female hypothyroid patients were randomized to one of four treatment groups receiving 30 mg zinc gluconate and 200 mcg selenium as high-selenium yeast, zinc-placebo, selenium-placebo, or placebo-placebo for 12 weeks. Mean serum FT3 levels rose significantly in the zinc-selenium and zinc-placebo groups ($p < .05$). Mean serum FT4 increased and TSH dropped significantly ($p < .05$) in the zinc-selenium group. Total T3 (TT3) and total T4 (TT4) decreased significantly in the selenium-placebo group ($p < .05$). Mean FT3:FT4 ratio increased significantly in the zinc-placebo group ($p < .05$). Hence, the clinician should choose to optimize these and other micronutrients before adjusting thyroid medication doses if a deficiency is suspected.⁵⁹

Daily Dosage: Zinc

- Adult men: 11–40 mg
- Adult women: 8–40 mg
- Pregnant women: 11–40 mg
- Lactating women: 12–40 mg^{31,35}

Precautions

Doses greater than 40 mg/day can lead to copper deficiency and gastrointestinal irritation.

Iron

Iron deficiency impairs thyroid hormone synthesis by reducing the

activity of thyroid peroxidase. In a deficient state, iron supplementation may improve the efficacy of iodine supplementation.⁶⁰ A trial conducted in an iodine-sufficient area in China demonstrated that nonpregnant and pregnant women in their first trimester who had iron deficiency experienced a dramatically increased risk for mild or severe hypothyroidism.⁶¹ Animal sources provide the most potent iron content, with liver, seafood, organ meats, and poultry in descending order of potency. Vegetarian sources of iron are most potent in dried beans, iron-fortified cereal/bread, blackstrap molasses, spinach, peas, and dried apricots. Concomitant intake of vitamin C-rich food or as a supplement enhances the gastrointestinal absorption of iron. Lab evaluation should include serum ferritin which reflects the body's iron storage pool and is the carrier protein for iron.⁵⁸ The UL for iron is 45 mg/day for adults.³⁵

Daily Dosage: Iron

- Adult men and postmenopausal women: 8–45 mg/day
- Adult premenopausal women: 18–45 mg/day
- Pregnant women: 27–45 mg/day
- Lactating women: 9–45 mg/day^{31,35}

Precautions

Long-term overdose of iron can create an abnormal accumulation in the liver. Hemochromatosis may occur, causing tissue damage. Iron overload can also favor oxidation of LDL cholesterol and the generation of free radicals, which may also damage body tissues.⁵⁸

Omega-3

Omega-3 fatty acids alter signal transduction via changes in cell membrane lipid composition; furthermore, they modulate gene transcription. Through these mechanisms, omega-3 fatty acids may alter TSH receptor activity, signal transduction, and thyroid hormone synthesis and release; omega-3 fatty acids may also affect thyroid follicular cell proliferation and differentiation. Studies are lacking to determine effects of omega-3 supplementation, plasma concentration, or erythrocyte cell membrane concentration on onset and progression of autoimmune hypothyroidism. One study did show less severe symptoms of hypothyroidism, more rapid response to LT4 therapy, significantly

lower TSH, and significantly higher FT4 and FT3 in individuals with higher plasma free fatty acid concentrations compared with those with lower concentrations. A follow-up study demonstrated that administration of omega-3 fatty acids in the form of purified eicosapentaenoic acid (EPA) prevented hypothyroidism based on laboratory and histopathological parameters in rats that were given 1-methyl-2-imidazolethiol to induce hypothyroidism.⁶² Further research in human subjects is necessary, but data are promising and warrant consideration of dietary or supplemental omega-3 fatty acids in individuals with autoimmune hypothyroidism. Furthermore, omega-3 fatty acids may also be considered for cardiovascular benefits given the correlation between hypothyroidism and cardiovascular morbidity.

Daily Dosage: Omega-3

Adults: 1000 mg/day

Vitamin D

The vitamin D receptor and vitamin D activating enzyme are expressed by immune cells; vitamin D is thus able to regulate inflammatory cytokine production and inflammatory cell proliferation in a pattern that enhances innate immunity and inhibits autoimmune inflammation. Vitamin D deficiency plays a known role in the onset and progression of several autoimmune diseases. Some studies have shown higher incidence of vitamin D deficiency in individuals with autoimmune hypothyroidism and those with TPO antibodies; however, data are mixed, and several studies do not control for confounders. Furthermore, effects of vitamin D deficiency may be more pronounced in certain subgroups of individuals with specific vitamin D receptor polymorphisms. Efficacy of vitamin D supplementation in preventing onset or progression of autoimmune hypothyroidism has not yet been studied in humans, though rat models are promising. Given the potential role of vitamin D in autoimmune hypothyroidism and the many other known benefits of vitamin D optimization, it is prudent to ensure that vitamin D levels are at goal in individuals with autoimmune hypothyroidism and in those with TPO antibodies.^{63,64}

Daily Dosage: Vitamin D

Adults: 400–4000 IU/day titrated to achieve serum 25(OH)D level of 30–50 ng/mL⁶⁵

Probiotics

Hypothyroidism slows gut motility and therefore leads to symptoms of constipation, bloating, and flatulence. Furthermore, small intestinal bacterial overgrowth is also more prevalent in individuals with hypothyroidism. Probiotic therapy and antibiotic decontamination may be considered to treat alterations in gut flora, as this has been found to reduce the aforementioned gastrointestinal symptoms. Such therapies have not been found to change thyroid function based on measurement of TSH and thyroid hormone levels, though this has not been adequately studied^{66,67} (see [Chapter 105](#)).

Botanicals

Seaweed

Seaweed is a rich source of naturally occurring iodine and is a good source for meeting daily iodine requirements. It may aggravate thyroid conditions if too much is ingested, which is seen in Asian populations that regularly consume seaweed.

Seaweed iodine content varies by many factors, posing a challenge in terms of determining safe consumption levels. The part of seaweed used, cooking method, genus, geographic location, climate, and stage of growth, all play a role in seaweed's iodine content. Iodine content is lowest in certain genus of seaweed such as nori and dulse. Iodine is also lowest in seaweed harvested and dried on the beach or free-floating in bunches. Iodine level can be reduced by boiling seaweed for 15 minutes and discarding the water. Iodine content is highest if the seaweed is harvested from young plants, stored in water- and air-tight containers, and eaten roasted rather than boiled.⁶⁸ Exercise caution in patients on blood thinners taking bladderwrack, an edible brown kelp, which may have some anticoagulant activity.⁶⁹ Depending on local pollution levels, edible seaweeds may contain heavy metals such as arsenic and cadmium. Hence, selection of high-quality kelp and seaweed from reputable harvesters is ideal to reduce the risk for toxic ingestion.⁷⁰ [Table 34.2](#)

outlines commonly used seaweed preparations and iodine content based on US and Japanese source values.⁶⁸ There has been recent concern about nuclear fallout affecting seaweed harvested in Japan after the Fukushima Daiichi nuclear disaster in March 2011. Measurements of radioactive isotopes in water, bottom sediment, and marine organisms returned to pre-Fukushima background levels by 2–2.5 years after the disaster. Thus it appears safe to purchase seaweed harvested during or after 2014.⁷¹⁻⁷⁴

Guggulu (*Commiphora mukul*)

Some animal studies have shown that the Ayurvedic herb guggulu, a gum resin of the *Commiphora mukul* tree, may stimulate thyroid function. It seems to increase T3 synthesis by increasing conversion of T4 to T3.⁷⁵⁻⁷⁷ Asian studies have shown that guggulu may also improve the hyperlipidemia that often accompanies hypothyroidism.⁷⁸

However, a double-blind, randomized control trial in the United States showed that hyperlipidemic patients on a standard Western diet who took a standardized dose of guggulu experienced a rise in LDL cholesterol levels compared with placebo. TSH levels were not significantly different after treatment with guggulu.⁷⁹

It is important to consider the differences in medical traditions of Ayurvedic, Western medicine, and diet with respect to these differing results. More research is necessary to study the effects of guggulu in the context of a holistic Ayurvedic treatment plan versus its incorporation as a single ingredient in a conventional Western medicine regimen. Take great care in recommending Asian-source Ayurvedic herbs because some brands commonly found in the United States were found to have significant levels of lead, mercury, and arsenic.⁸⁰

Pharmaceuticals

Approach to Thyroid Hormone Replacement Therapy (E-Table 34.4)

The goals of thyroid hormone replacement therapy include resolution of clinical signs and symptoms of hypothyroidism, normalization of labs, and avoidance of iatrogenic hyperthyroidism. Treatment based on symptoms alone is not accurate; symptoms lack sensitivity and specificity given the indolent nature of hypothyroidism and many other conditions that may cause similar symptoms. Monitoring of laboratory tests is therefore necessary with titration of therapy to achieve

therapeutic ranges as discussed previously.¹

The conventional therapy for thyroid hormone replacement in hypothyroidism remains LT4 alone.⁸¹ The initial LT4 dose should be weight-based (1.6 mcg/kg/day); alternatively, the initial dose should be 50 mcg/day in patients older than 50 years or those with known cardiovascular disease. The half-life of LT4 is 7 days; thus, thyroid function testing should be pursued when steady-state concentrations are achieved about 4–8 weeks after initiation of therapy. Thyroid function testing should also be reassessed 4–8 weeks after adjustment in therapy as well as after treatment of malabsorptive disorders, significant changes in weight, or change in hormonal status (e.g., pregnancy, menopause, exogenous hormone therapy).¹

The brand of LT4 therapy prescribed is an important consideration. As of 2007, the FDA requires all LT4 preparations to maintain doses within 95%–105% of stated potency. Given this permissible degree of variation, studies have shown lack of bioequivalence between similar doses of different LT4 formulations.^{82,83} Patients should therefore be advised to maintain therapy on one specific brand name or one specific generic formulation. For patients who are given generic therapy, patients and providers must both be aware of the potential for pharmacies to switch from one generic formulation to another, which requires repeat dose titration.¹

Preparation of levothyroxine sodium is now also a consideration. LT4 is conventionally available as a solid tablet. However, gelatin capsules for LT4 supplementation have recently become available under the brand name Tirosint; these capsules contain levothyroxine sodium as a liquid dissolved in glycerin and water. The gelatin capsule formulation excludes dyes and excipients (fillers), therefore conferring a lower risk for allergic reactions compared with standard LT4 tablets. If allergic reaction is a concern and cost prohibits switching to the gelatin capsule formulation, the practitioner may alternatively consider achieving the therapeutic dose by utilizing whole and half tabs of the 50 mcg solid tablet formulation, which does not contain dyes (though it still contains excipients). The gelatin capsule formulation may also have better absorption than standard solid tabs in individuals with reduced stomach acid or when taken alongside espresso coffee, though definitive studies are lacking. If malabsorption is a concern and cost prohibits switching to the gelatin capsule formulation, the practitioner may alternatively consider increasing the dose of the solid tablet formulation. Both approaches require follow-up thyroid function tests in 4–8 weeks.¹

E-Table 34.4

Adult Thyroid Hormone Dosage Recommendations

Thyroid Hormone	Generic (Trade Name)	Starting Oral Dose	Average Daily Dose and Titration
Synthetic T4 alone	T4 levothyroxine (Synthroid, Unithroid, Levothy, Tirosint) Note: Stick with one formulation (generic or brand name) throughout the course of treatment because of dose variability. Branded name thyroid medication is generally preferred to avoid subtle dose fluctuations in generics which are variable enough to cause worsening of symptoms.	100 mcg daily* or 25–50 mcg daily in elderly or sensitive patients	200–300 mcg daily* Titrate every 6 weeks until symptoms improved and TFTs normalize. Follow TFTs every 6 months or sooner if symptoms arise.*
Synthetic T4 + T3 separate tablets or compounded together by a sterile compounding pharmacy	T4 levothyroxine + T3 liothyronine (Cytosol)	100 mcg T4 + 3 mcg T3 twice daily** or 25–50 mcg T4 + 3 mcg T3 daily in elderly or sensitive patients	Titrate T4 as previous. Titrate T3 by 5–12.5 mcg/day every 1–2 weeks to a maximum of 100 mcg/day; sustained release T3 may be more effective ⁹⁴
T4 and T3 desiccated porcine thyroid gland	Armour, Nature-Throid or Westhroid 1 grain = 60 mcg = 36 mcg T4 + 9 mcg T3	Start with 1/4–1/2 grain = 15–30 mcg daily Consider BID dosing	60–120 mcg (1–2 grain) daily Titrate by 15 mcg (1/4 grain) per every 2–4 weeks*

T4, levothyroxine; T3, liothyronine; TFTs, thyroid function tests (TSH, free T4, free T3).

For converting synthetic T4 and T3 to desiccated porcine thyroid, the clinician is referred to the website <http://thyroid.about.com/library/drugs/blconversionchart.htm>.

- Lexi-Comp Online⁹⁴
- Blanchard⁹² Henneman⁹³
- Gaby⁹, Armour Thyroid website⁹⁵

Optimal time for LT4 ingestion is controversial. Temporal relation to food and medication should be considered. LT4 absorption in the gut is inhibited by food, fiber, soy, espresso coffee, and several medications (e.g., ferrous sulfate, calcium carbonate, bile acid sequestrants, sucralfate, phosphate binders, aluminum-containing antacids). Thus, LT4 should be ingested on an empty stomach and separated from medications.¹ Time of day is also a consideration. Two small studies revealed statistically significant improvements in hourly measurements of thyroid function tests when LT4 was dosed in the evening instead of the morning. Circadian variation in all thyroid hormones was preserved; however, there was no significant difference in subjective symptoms between the two groups.^{84,85} Thus evening administration of LT4 may be considered, but advantages are unclear. All in all, timing of LT4 dosage should be tailored around individual patient preferences with ingestion in the morning at least 1 hour before food or ingestion at night at least 3 hours after food; LT4 should be separated from other medications and supplements by at least 4 hours.¹

Patients should be reminded to store LT4 per the instructions on the product insert at 68°F–77°F, protected from light and moisture.¹³

Timing of LT4 dosage should be tailored around individual patient preferences. To optimize absorption, LT4 may be ingested in the

morning at least 1 hour before food or at night at least 3 hours after food; LT4 should be separated from other medications and supplements by at least 4 hours.¹

Excessive Thyroid Hormone Dose Requirements

Oral LT4 therapy is largely absorbed in the ileum. Celiac disease, *Helicobacter pylori* gastritis, atrophic gastritis, inflammatory bowel disease, lactose intolerance, intestinal giardiasis, and other malabsorptive disorders should be considered in patients who require unexpectedly high doses of LT4 (i.e., doses greater than 2 mcg/kg per day). These conditions are associated with poor LT4 absorption, and celiac disease and autoimmune atrophic gastritis are more prevalent in individuals with autoimmune thyroid disease. Appropriate treatment of the diagnosed malabsorptive disorder tends to cause a reduction in LT4 dose requirements because of improved absorption in the gut, although such treatment (including gluten- or lactose-free diet) may not change the natural history of the hypothyroidism itself. Therefore when appropriate therapy is initiated for a malabsorptive disorder, thyroid function tests should be monitored and the LT4 dose should be adjusted accordingly. Of note, in patients with lactose intolerance, a lactose-free LT4 preparation should be considered.^{1,5,16}

Inadequate Response to Thyroid Hormone Replacement Therapy

Several studies have shown that LT4 supplementation may achieve normal TSH levels without achieving normal FT3 levels or resolution of hypothyroid symptoms. As previously mentioned, it must be kept in mind that the physiologically optimal FT3 range is uncertain and that the differential diagnosis for hypothyroid symptoms is broad. That being said, several etiologies have been proposed for low FT3 levels and persistent hypothyroid symptoms despite normal TSH.

Adequate thyroid hormone production and symptom resolution requires an intact hypothalamic pituitary thyroid axis. This includes intact hypothalamic production of TRH and pituitary production of TSH. This also includes intact thyroid gland production of T4 and 20% of the body's T3; this endogenous thyroid function is particularly important to compensate for inadequacies of exogenous LT4 therapy, which may not yield adequate FT3 levels or replicate circadian thyroid hormone patterns. Finally, this axis also includes intact peripheral conversion of T4

to produce the remaining 80% of the body's T3.

Perturbations at any level of the hypothalamic pituitary thyroid axis may lead to inadequate FT3 levels and persistent hypothyroid symptoms. At the level of the central nervous system, it has been proposed that LT4 therapy inhibits the hypothalamic release of TRH and pituitary release of TSH via negative feedback, therefore suppressing any remaining endogenous thyroid function. At the level of the thyroid gland, it is known that athyreotic individuals do not have any endogenous production of T4 or T3 to compensate for inadequacies of LT4 therapy. At the level of peripheral organs, T4 transporter mutations may compromise T4 movement into cells, thus preventing peripheral conversion of T4 into T3. Finally, at the level of thyroid hormone clearance, it has been proposed that LT4 therapy upregulates D3, which clears T4 and T3 by catalyzing conversion of T4 to rT3 and T3 to T2. Unfortunately, assays to measure transporter function, intracellular T4, and deiodinase function are not yet available.¹

Some clinicians check the rT3 level, which is believed to be metabolically inactive. Elevated rT3 levels may improve with resolution of the underlying trauma, stress, infection, or malnutritive factors that promoted its formation. In addition to elevated rT3 levels, sick individuals may also have a low-normal TSH, low T4, and low T3. This euthyroid-sick syndrome is thought to be a compensatory mechanism to prevent excessive tissue catabolism during severe illness, unlike the abovementioned pathological perturbations. Many mechanisms contribute, including ectopic T3 production with negative feedback, central hypothyroidism with low TSH production, reduced thyroid hormone-binding proteins, and increased D3 activity. Adding zinc and selenium to nutritional supplementation or in the diet may help improve a high rT3 level.^{48,86} In a study of athyreotic patients versus euthyroid controls, the average FT3 to FT4 ratio was 0.32 in those with normal thyroid function.⁸⁷ Setting a treatment target for thyroid hormone replacement based on FT3 to FT4 ratio is not well-established but may provide partial guidance in dosing and overall treatment.

In complex cases, the clinician should consider RTH syndrome, which is characterized by low FT4 to FT3 ratios, low rT3, constipation, growth retardation, and skeletal dysplasia, with referral to an endocrinologist.⁸⁸

In general, thyroid function should not be assessed, and thyroid replacement therapy should not be initiated during severe illness unless thyroid dysfunction is highly suspected.¹

LT4 + LT3 Combination Thyroid Hormone Replacement Therapy

The use of combination LT4 plus liothyronine (LT3) therapy instead of LT4 alone has been controversial.⁸⁹⁻⁹³ Thus far, data are limited and inconclusive on efficacy and safety of combination therapy. Existing studies have utilized a variety of dosing regimens that do not closely replicate physiological T4:T3 ratios. Furthermore, they have not sufficiently studied specific population subgroups, such as athyreotic individuals. Finally, symptomatic relief has been noted in only a few studies and might be attributed, at least in part, to placebo effect in patients who seek combination therapy.²

In patients who achieve normal TSH levels without achieving resolution of hypothyroid symptoms, combination therapy may be considered. The ATA and European Thyroid Association (ETA) guidelines recommend that “LT4 and LT3 combination therapy might be considered as an experimental approach in compliant LT4-treated hypothyroid patients who have persistent complaints despite serum TSH values in the reference range, provided they have previously been given support to deal with the chronic nature of their disease and associated autoimmune diseases have been ruled out.” It should be noted that combination therapy is not appropriate in pregnancy, during which exclusive T4 supplementation is crucial for fetal brain development.²

Combination therapy regimens should attempt to replicate human physiology, including a T4:T3 ratio of 14:1 and a circadian peak T3 level at 3 a.m. Combination therapy should also account for pharmacokinetics of LT4 and LT3; the half-life of LT4 is 7 days, whereas that of LT3 is much shorter at 1 day; FT4 peaks 4–6 hours after LT4 ingestion and FT3 peaks 2–4 hours after LT3 ingestion. Thus, in accordance with ETA guidelines, if combination LT4 and LT3 therapy is initiated, the total LT4 plus LT3 dose should be equal to the weight-based starting dose that one would use for isolated LT4 therapy, as described previously (1.6 mcg/kg per day or 50 mcg/day if age is more than 50 years or known cardiovascular disease). The T4:T3 dose ratio should be between 13:1 and 20:1. The LT4 dose should be given once daily; the LT3 dose should be divided into two doses daily (bedtime and morning). If available formulations result in unequal doses when the total LT3 dose is divided, the larger of the two doses should be given at bedtime.^{1,2}

To achieve the abovementioned therapeutic regimen, combination therapy is best given as isolated LT4 alongside isolated LT3, each of which can be titrated separately to achieve laboratory endpoints. Isolated

LT3 is commercially available as a generic formulation and as a brand name formulation (Cytomel). Combination therapy can also be achieved with use of reliable compounding pharmacies. Proponents of combination therapy have also promoted use of sustained release combination products or desiccated porcine thyroid (e.g., Armour [Forest Pharmaceuticals], Nature-Thyroid [RLC Labs], WP Thyroid [RLC Labs]) containing natural T3 and T4 plus other iodinated compounds.^{9,92,93} It should be noted that available synthetic and natural preformulated combination preparations do not provide the aforementioned physiological ratios of T4 and T3. For example, the concentration of T4:T3 in desiccated porcine thyroid is 4.2:1, which yields supraphysiological levels of T3 when ingested by humans.^{1,2}

During combination therapy, there is a concern for transient thyrotoxicosis 2–4 hours after the LT3-containing supplement is ingested. Therefore it is prudent to check thyroid function first thing in the morning (after ingestion of the nighttime LT3 dose and prior to ingestion of the morning LT3 dose) to ensure that FT4 and FT3 levels are never outside of laboratory reference ranges, even at their peak. TSH should always be maintained within normal range.

Patients should be counseled about the paucity of conclusive data regarding safety, symptomatic relief, and physiological benefit from combination therapy. They should be counseled about short-term and long-term risks for suprathreshold thyroid supplementation; they should also be instructed to monitor for symptoms of hyperthyroidism during combination therapy. Finally, patients should be informed that if they do not experience relief of hypothyroid symptoms, or if they do experience hyperthyroid symptoms during the trial of combination therapy, then LT4 monotherapy should be resumed.²

A trial of combination LT4 plus LT3 therapy may be considered in LT4-compliant patients who achieve normal TSH levels without resolution of hypothyroid symptoms. TSH, FT4, and FT3 should always be maintained within normal reference ranges. Other conditions that may contribute to hypothyroid symptoms should be ruled out.

Thyroid (T4) Hormone Dosage

Most patients should be treated with LT4 alone. The dose should be

weight based (1.6 mcg/kg per day); alternatively, the initial dose should be 50 mcg/day in patients older than 50 years or those with known cardiovascular disease.

Gel formulations (*Tirosint*) may be better absorbed and tolerated in sensitive patients as it is void of dyes and fillers.

Combination Therapy (T4 + T3) Dosage

Porcine thyroid hormone (e.g., Armour, Nature-Throid, Westhroid) is an older medication used in hypothyroidism.

Desiccated porcine thyroid contains approximately 80% T4 and 20% T3 (4:1 ratio), as well as other iodinated compounds, diiodotyrosine (T2) and monoiodotyrosine (T1), which may play a role in providing additional relief of symptoms.^{94,95} Given the short half-life of T3, the total daily dose may be divided into two doses daily (bedtime and morning).

Ideally, the clinician would use T4 (levothyroxine) daily with the addition of T3 (*Cytomel*) dosed twice daily at a ratio of 10–14:1 (T4:T3). So if the patient is on 110 mcg total thyroid, they would be dosed 100 mcg of T4 at night and 5 mg of T3 in morning and 5 mg T3 at night.

Precautions

Vegetarians, vegans, and patients who avoid pork because of allergies, religious, or other reasons should be informed of the source of this hormone. Close monitoring of symptoms and thyroid function tests are very important when caring for patients who are taking porcine thyroid replacement; tests should ideally be drawn several hours after ingestion of therapy with the goal of keeping TSH, FT4, and FT3 within normal reference ranges. The T4:T3 ratio in these preparations is 4.2:1 compared with the physiological serum ratio of 14:1; patients should be counseled about the potential risks associated with supraphysiological levels of T3. Recommended thyroid hormone dosages are shown in [E-Table 34.4](#).

1 grain (60 mg) desiccated porcine thyroid = 100 mcg T4 and 25 mcg T3.

Therapies to Consider

Traditional Chinese Medicine

In the traditional Chinese medicine (TCM) system, the diagnosis and treatment of individuals with a conventional medicine diagnosis of hypothyroidism depends on the history, tongue, and pulse diagnosis. Hypothyroidism is generally considered to be a deficiency of spleen and/or kidney “yang” energy, especially if characterized by cold sensation, lack of appetite, fatigue, and weight gain. Weight gain is the evidence of “dampness,” which is a complication of spleen or kidney yang deficiency. The spleen and kidney are considered too weak to transform excess dampness, causing accumulation of fat and swelling. It is important to appreciate that these findings are classic and may not adequately describe an individual’s complete Chinese medicine diagnosis.⁹⁶

Herbal treatment in hypothyroidism aims to strengthen qi and yang deficiency. Qi and yang tonics may include codonopsis, astragalus, epimedium, curculigo, cinnamon bark, and cuscuta, to name a few.⁹⁷

TCM therapies include acupuncture, herbs, moxibustion, nutrition, massage, and movement. The therapeutic effect of these therapies on hypothyroidism may result from promotion of T4 deiodination with production of more active T3.⁹⁸⁻¹⁰¹ Research in this area is necessary to more fully understand TCM’s mechanisms of action in the treatment of thyroid disease.

Stress Reduction

Stress is known to contribute to centrally driven hypoactivation of peripheral glands; furthermore, it is known to contribute to primary gland dysfunction in the setting of autoimmune disease.¹⁰² However, several studies have failed to find an association between psychosocial stress and onset of autoimmune hypothyroidism or emergence of TPO antibodies. Although stress was not found to cause hypothyroidism, hypothyroidism was found to cause stress. This is because of the secondary depressive symptoms, fatigue, and the diagnosis of a chronic disease. Practitioners should screen patients with hypothyroidism for psychological symptoms; moreover, they should provide education about expected symptoms and the natural history of hypothyroidism. Despite current lack of evidence, stress reduction may be advised to optimize hypothalamic–pituitary–thyroid axis function and to help

address comorbid psychological symptoms¹⁰³⁻¹⁰⁵ (see [Chapter 94](#)).

Yoga

One study has demonstrated increased thyroid gland release of thyroid hormones after Yoga therapy in euthyroid men.¹⁰⁶ Another study demonstrated improvement in quality of life scores across physical, psychological, and social parameters after Yoga therapy in hypothyroid women.¹⁰⁷ Both studies involved 1-hour daily Yoga sessions for one month, including specific asanas (stretches and poses) and pranayama (breath practice). Each study included a pose that imparted pressure onto the thyroid gland, including sarvāṅgāsana (shoulder stand, as demonstrated in [Fig. 34.4](#)) and jalandhara bandha (sitting position with chin tucked into throat, as demonstrated in [Fig. 34.5](#)), respectively. Of note, contraindications to such poses include spinal osteoarthritis, cervical disk disease, neck injury, hypertension, glaucoma, stroke, and vertebrobasilar syndrome. Inversion poses like the shoulder stand should be avoided in women while menstruating and after the first trimester of pregnancy in accordance with yogic texts.¹⁰⁸⁻¹⁰⁹

The aforementioned poses may stimulate thyroid gland function via increased perfusion because of the locked position of the chin. Other potential mechanisms for the benefits of yoga may include rebalancing of neurotransmitters, shifting towards parasympathetic state, and promotion of mastery over the mind, body, and emotional self. Further research is needed to identify which specific yogic practices are most efficacious for hypothyroid symptoms and which subpopulations may benefit most. Autonomic balance promoted by yoga may also address the increased sympathetic tone and cardiovascular risk associated with hypothyroidism, though this area also requires future research.¹¹⁰⁻¹¹¹ It is reasonable for practitioners to recommend a trial of yoga therapy to those patients who are interested in this.

FIG. 34.4 Sarvāṅgāsana (shoulder stand).

FIG. 34.5 Jalandhara bandha (sitting position with chin tucked into throat).

Prevention Prescription

- Consume a diet with adequate amounts of iodine, selenium, iron, vitamin A, vitamin D, and zinc.
- Do not consume excessive amounts of iodine for long periods of time.
- Avoid substances that block thyroid hormone synthesis, such as chlorine, bromine, perchlorate, mercury, certain medications, and radiation to the head and neck area when possible

Therapeutic Review

Following is a summary of therapeutic options for hypothyroidism.

Exercise

- Maintain a regular aerobic and weight-bearing exercise routine. 

Nutrition

- Separate and avoid excessive amounts of goitrogenic foods and substances which may interfere with thyroid activity. 

Vegetables from the *Brassica* family (cabbage, turnips, Brussels sprouts, rutabagas, broccoli, cauliflower, bok choy); millet, peaches, peanuts, pine nuts, strawberries, spinach, and cassava root. Cook vegetables briefly to reduce goitrogenic substances.

Medications/Toxins: lithium, thionamides, amiodarone, interferon- α , interleukin (IL)-2, cholestyramine, perchlorate, expectorants, aluminum hydroxide, raloxifene; heavy metals, fluoride, bromine

Topical antiseptics (betadine), radiocontrast dyes

- Eat a heart-healthy, antiinflammatory diet to maintain proper body weight and reduce cardiovascular risk. 

Vitamins and Minerals (Preferably Consumed in Food)

- Iodine*: 150–1100 mcg/day 
- Iron: 8–45 mg/day 
- Selenium: 55–400 mcg/day 
- Vitamin A**: 2300–10,000 IU/day 
- Zinc: 8–40 mg/day 
- Vitamin D: 1000–2000 IU/day 

Botanicals

- Seaweed: total iodine content should not exceed 1100 mcg/day for the general population unless on targeted megadose therapy. See [Table 34.2](#) for assistance in determining allowable grams/day depending on the variety of seaweed. 
- Guggulu: consider using in the context of an  Ayurvedic treatment regimen and not as an isolated treatment for hypothyroidism or hyperlipidemia. Take care to avoid heavy metal toxicity in certain Asian-sourced formulations. 

Pharmaceuticals

- Levothyroxine alone (T4): gold standard of therapy 
- Synthetic combination T3 + T4: consider if T4 alone fails to control symptoms adequately; may use compounded formulations 
- Desiccated porcine thyroid: consider if synthetic or compounded T3 + T4 fails to control symptoms adequately or based on patient preference/physician experience

Traditional Chinese Medicine (TCM)

- Qi and yang tonics: includes codonopsis, astragalus, epimedium, curculigo, cinnamon bark, and cuscuta. A TCM practitioner with a strong background and certification in Chinese herbal medicine should prescribe these combinations. 

Yoga

- Advise yoga therapy with emphasis on thyroid-enhancing poses like

the shoulder stand (Sarvāngāsana) or jalandhara bandha poses if the patient has no contraindications. 

Yoga practice may still be helpful even without challenging poses like the shoulder stand for the purposes of stress reduction, meditation, enhanced flexibility, and strength.

CHAPTER 35

Polycystic Ovarian Syndrome

Melinda Ring, MD

Polycystic ovarian syndrome (PCOS) is the most common female endocrine disorder, affecting 10% of women of reproductive age, yet it is frequently overlooked.^{1,2} PCOS affects young women and is associated with oligoovulation (which leads to oligomenorrhea in more than 75% of affected patients), infertility, acne, and hirsutism. It also has notable metabolic sequelae, including an elevated risk of diabetes and cardiovascular disease, and attention to these factors is important.³ The heterogeneous nature of PCOS and the diversity of presentations requires a symptom-based approach to treatment because PCOS manifests differently depending on many interacting factors, including environmental exposures, genetics, and lifestyle ([Fig. 35.1](#)). This chapter discusses the pathophysiology and integrative approaches to treatment of women with PCOS.

Pathophysiology

When PCOS was first described (as Stein-Leventhal syndrome) in the 1930s, the presence of cysts in the ovaries was believed to be a defining factor in the origin of the syndrome.⁴ Since then, research has shown that, in fact, cysts are only one potential expression of what begins as a disorder of the endocrine system. On pelvic ultrasound, 90% of women with biochemical features of PCOS will have characteristic changes; however, 20% to 30% of women without hormonal disturbance due to PCOS will have similar ultrasound features.⁵ Our current understanding, albeit incomplete, is the phenotypic expression of PCOS results from primary hormone imbalances. The three prevalent theories for the pathogenesis of PCOS are as follows:

1. Hypothalamic–pituitary dysfunction results in gonadotropin-releasing

hormone and luteinizing hormone dysfunction, which then has downstream effects on ovarian hormone production.

2. A primary ovarian defect (with or without an adrenal defect) in steroidogenesis results in hyperandrogenism.

3. A metabolic disorder characterized by peripheral insulin resistance exerts adverse effects on the hypothalamus, pituitary, ovaries, and, possibly, the adrenal gland.

A number of variables, including genetic factors and lifestyle choices, contribute to the wide range of manifested symptoms of PCOS and make the diagnosis challenging unless clinicians are aware of PCOS as a potential cause. A typically chronic time course assists in diagnosis, with symptoms often developing in adolescence and advancing over time. However, this pattern may be disrupted by lifestyle factors, including weight loss impacting on frequency of ovulation, and contraceptive hormones masking symptoms, thereby complicating the diagnosis.⁶

Criteria for PCOS have been debated among leading organizations since 1990. The differences in criteria reflect the controversy over the origin of the syndrome, as well as its heterogeneous manifestations ([Table 35.1](#)).^{7,8a} However, current diagnostic criteria have unifying trends. All require the presence of at least one of the stigmata of ovarian disease; a history of anovulation or the finding of classic polycystic ovaries on ultrasound. All three criteria are consistent in terms of the inclusion of hyperandrogenism, determined by either clinical (hirsutism or acne) or laboratory findings. Finally, all guidelines require exclusion of hormonal disorders that may mimic PCOS. Although insulin resistance has been noted consistently among women with PCOS, it is not included in any of the current diagnostic criteria.

Based on current data, evaluation for PCOS should include a search for both primary markers and secondary dysfunction. History and physical examination should focus on symptoms and signs, such as oligomenorrhea, acne, hirsutism, and central obesity, as well as searching for manifestations of other confounding diseases. Laboratory tests should include androgen levels (dehydroepiandrosterone [DHEA] sulfate and total and free testosterone measured by equilibrium dialysis) and tests to rule out alternative diagnoses as warranted (e.g., congenital adrenal hyperplasia, androgen-secreting tumors, Cushing syndrome, 21-hydroxylase-deficient nonclassic adrenal hyperplasia, androgenic or anabolic drug use or abuse, syndromes of severe insulin resistance, thyroid dysfunction, or hyperprolactinemia). Laboratory testing for antimüllerian hormone is a newer diagnostic tool that, in combination

with measurement of luteinizing hormone levels, has been shown to have high sensitivity and specificity for the diagnosis of PCOS. Polycystic ovaries contain an increased amount of antral follicles, which produce antimüllerian hormone.^{8b}

The ratio of total testosterone to dihydrotestosterone (TT/DHT) has demonstrated potential as a new biomarker for an adverse metabolic phenotype in PCOS patients. A study of 275 premenopausal PCOS patients and 35 BMI-matched, healthy controls found a correlation between a high TT/DHT ratio and various adverse hormonal, lipid, and glucose metabolism parameters in patients with PCOS.^{8c}

The presence of metabolic syndrome and cardiovascular risk should also be evaluated in patients suspected to have PCOS (e.g., insulin resistance measurement by oral glucose tolerance tests, including glucose and insulin levels, and measurement of lipids and inflammatory markers such as C-reactive protein and fibrinogen). Pelvic ultrasound also has utility in supporting the diagnosis of PCOS.

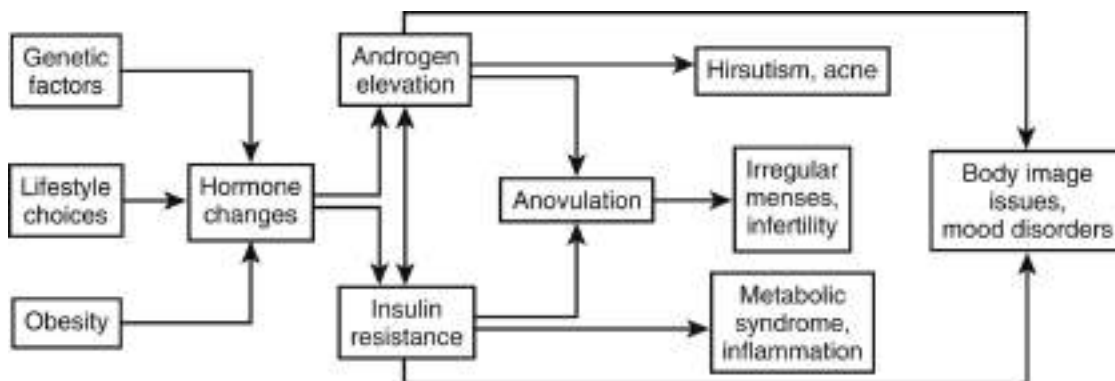

FIG. 35.1 Proposed relationships leading to phenotypic expression of polycystic ovarian syndrome.

TABLE 35.1

Differing Criteria for Polycystic Ovarian Syndrome Among Organizations

Organization	Criteria	Ovarian Dysfunction	Ovarian Morphology	Hyperandrogenism
National Institutes of Health (1990)	Both of the following and exclusion of related disorders	Oligo-ovulation (less than six ovulations per year)		Clinical or biochemical (not specific)
Rotterdam Group (2002)	Any two of three of the following and exclusion of related disorders	Oligo-ovulation (non-specific)	Polycystic ovaries (≥ 12 follicles 2 to 9 mm, or ovarian volume >10 mL)	Clinical or biochemical (free testosterone or free testosterone index)
Androgen Excess Society (2006)	Hyperandrogenism is critical, with addition of at least one ovarian marker and exclusion of related disorders	Oligo-ovulation and/or polycystic ovaries	Oligo-ovulation and/or polycystic ovaries	Clinical or biochemical (free testosterone)

A thorough clinical assessment is critical both to confirm the diagnosis and to identify risk factors for long-term health maintenance. This information helps clinicians prioritize integrative approaches when creating a management plan by elucidating the primary metabolic targets. Treatment plans should take into equal consideration each woman's unique concerns, such as weight management, acne, hair loss, or infertility.

Integrative Therapy

A holistic approach to PCOS addresses the impact of the syndrome on patient mental state and sense of self in addition to immediate symptoms and risk management.

Lifestyle

Weight Management

Weight management plays a central role in the expression of symptoms and long-term consequences of PCOS. A reported 50% to 70% of women with PCOS are obese and should be informed that even 5% to 10% loss of body mass is associated with significant improvements in clinical metabolic and hormonal markers.⁹⁻¹¹ Guiding women in this arena can be challenging because insulin resistance may inherently make weight loss more difficult, and women are often frustrated by repeated failed attempts to lose weight. Current evidence suggests that the approaches described in the next sections may be most successful.

Physical Activity

Exercise is an important lifestyle approach in PCOS, with diverse benefits including improved insulin sensitivity and preservation of lean body mass. A significant relationship exists between PCOS and inappropriate diet and low physical activity.¹¹ A 2010 systematic review of exercise therapy in PCOS identified eight studies (five randomized controlled and three cohort) involving moderate intensity physical activity (aerobic and/or resistance) for 12 to 24 weeks.¹² The most consistent reported

improvements included improved ovulation, reduced insulin resistance (9% to 30%), and weight loss (4.5% to 10%). Because the optimal exercise regimen for PCOS has yet to be defined, current recommendations for interval training and full-body exercise should be used (see [Chapter 91](#)).

A study published in *Human Reproduction* compared the effects of exercise versus a low-calorie diet in 40 women with PCOS.¹³ The exercise group had higher ovulation rates, better insulin sensitivity, and greater reduction in waist measurements despite less absolute weight loss.

Nutrition

Macronutrients

Although caloric restriction is clearly required for weight loss, to date only a few, small studies have examined the impact of macronutrient composition in PCOS. Several studies ranging from 1 to 6 months that compared a high-protein and low-carbohydrate diet with a high-carbohydrate and low-protein diet have reported no significant differences in weight loss, circulating androgens, glucose metabolism, or leptin levels.^{14,15} Conversely, two pilot studies reported that low-carbohydrate diets were associated with improved depression scores and self-esteem ratings, in addition to lower fasting insulin levels and lower rates of acute insulin response to glucose.^{16,17} None of these studies took into account the glycemic index of carbohydrates or the source of protein (animal versus plant based), which may be important factors in insulin resistance and hormone regulation. In 2010, the first study examining the impact of glycemic index in overweight and obese premenopausal women with PCOS (n = 96) randomized women to either an ad libitum low-glycemic index diet or a macronutrient-matched healthy diet and followed the women for 12 months or until they achieved a 7% weight loss. The attrition rate was high in both groups (49%). Of the women who completed the study, those on the low-glycemic index diet demonstrated greater improvements in insulin resistance (p = 0.03), menstrual cyclicity (95% compared with 63%; p = 0.03), and serum fibrinogen concentrations (p < 0.05).

A randomized controlled clinical trial of 48 women diagnosed with PCOS found that following the DASH (Dietary Approaches to Stop Hypertension) diet for 8 weeks led to a significant reduction in serum insulin, triglycerides, and very-low-density lipoprotein cholesterol levels, and significant increases in plasma total antioxidant capacity (TAC) and total glutathione (GSH). The diet in this study consisted of 52%

carbohydrates, 18% proteins, and 30% total fats.^{17a} At this point, no firm recommendations can be given regarding macronutrient content, although trends indicate women may do best on a low-carbohydrate diet with inclusion of low-glycemic index, high-fiber carbohydrates (see [Chapter 87](#)).

Soy

Soy intake in PCOS is a controversial topic. Soy is a plant food and complete protein, meaning that it has all the required amino acids. Soy is also low in fat and contains essential fatty acids, numerous vitamins, minerals, and fiber. Foods containing soy include soy milk and cheese, tofu, tempeh, miso, soy sauce, and edamame. Soy contains phytoestrogens, which has led to debate regarding the benefits versus risks of soy consumption in PCOS.

Currently, very few studies have evaluated soy intake in patients with PCOS. One study reported favorable results regarding the utility of soy in improving cholesterol among patients with PCOS.¹⁸ In this study, 12 obese women with PCOS and high insulin and high cholesterol levels consumed 36 g of soy each day for 6 months. The results demonstrated reduced low-density lipoprotein cholesterol levels following the consumption of soy. However, the investigators noted no effect on weight loss, hormones, or menstrual cycle. Conversely, many animal studies have demonstrated that soy intake can negatively affect fertility. A review of seven soy intervention studies performed in women using 32 to 200 mg/day of isoflavones demonstrated increased menstrual cycle length.¹⁹ Current evidence does not imply that soy prevents ovulation; however, soy may delay ovulation.

Further studies of soy consumption in polycystic ovarian syndrome (PCOS) are required. Women with PCOS who struggle with infertility, consume few calories, or eat a poor diet may wish to consider avoiding or limiting the consumption of soy products. Otherwise, moderate to low intake of soy (once a day or several times a week) can be part of a healthy diet for women with PCOS.

Omega-3 Fatty Acids

Inflammation has been identified in patients with PCOS, whether as a

consequence or a contributing factor remains unclear.^{20,21} In comparison with control subjects, patients with PCOS have decreased fibrinolytic activity, higher levels of plasminogen activator inhibitor-1, and increased C-reactive protein levels (in both obese and nonobese women), all of which are markers of inflammation.^{25,26} These findings indicate interventions to reduce cardiovascular risk should be more aggressive in women with PCOS who have increased C-reactive protein levels. Including omega-3 fatty acids may have utility in managing the inflammatory component of PCOS in addition to supporting cardiovascular health (see [Chapter 88](#)). The lignans in flaxseeds may provide additional benefit through promoting estrogen elimination.

Supplements

Inositol Family

Investigations into the cause of insulin resistance in PCOS led some researchers to investigate whether derangements in insulin signal transduction could be overcome by oral administration of *D-chiro*-inositol (DCI), a mediator of insulin action that is naturally formed in the human body from the metabolism of pinitol and myoinositol (commonly known as *inositol*) in the diet. In several early studies, evidence favored a benefit of DCI in improved insulin sensitivity, triglyceride, and testosterone levels, in addition to improving blood pressure, ovulation, and weight loss.^{22,23} In a separate study, 44 obese women with PCOS were randomly assigned to receive placebo or DCI (1200 mg once a day) for 8 weeks. Supplementation with DCI resulted in an improvement in insulin resistance ($p = 0.07$), a 55% reduction in the mean serum free testosterone concentration ($p = 0.006$), and an increase in ovulation from 27% to 86% compared with placebo ($p < 0.001$). The more readily commercially available *D*-pinitol (*D-chiro* (+)-*O*-methyl inositol) has been shown to raise DCI serum levels; however, results of clinical end points, such as impact on insulin sensitivity, have been mixed.^{24,25} In an important study of this nutrient in diabetic patients, 600 mg of pinitol twice per day for 3 months lowered blood glucose levels by 19.3%, lowered average glucose levels by 12.4%, and significantly improved insulin resistance.²⁹ In another study, 25 women received inositol for 6 months. Twenty-two of the 25 (88%) had a single spontaneous menstrual cycle during treatment, of whom 18 (72%) maintained a normal ovulatory activity. Ten pregnancies (40% of patients) occurred during this study.

Dosage

DCI: 600 mg daily in patients weighing less than 60 kg (130 lb) or 1200 mg daily in patients weighing more than 60 kg. Pinitol: 600 mg twice daily.

Precautions

No interactions with herbs and supplements are known. There is concern that high consumption of inositol may exacerbate bipolar disorder.

Chromium

Chromium is an essential trace mineral that enhances the action of insulin. Although supplementation with chromium has been shown in studies to improve blood glucose control in type 2 diabetes mellitus, little research has focused specifically on patients with PCOS.²⁶ A pilot study of six women with PCOS concluded that 1000 mcg per day of chromium for as little as 2 months improved insulin sensitivity by an average of 38% (statistically significant) and decreased baseline insulin by 22% (not statistically significant).²⁷

Dosage

Chromium picolinate: 600 to 1000 mcg in divided doses daily. Picolinate, a byproduct of the amino acid tryptophan, is combined to support absorption of chromium. Dietary sources include Brewer's yeast, liver, mushrooms, wheat germ, oysters, and some fresh fruits.

Precautions

The adequate daily intake of chromium for women ranges from 20 to 45 mcg depending on age. Laboratory animals have tolerated 350 times this dose without adverse effects, although there is concern regarding mutagenicity with prolonged use. In humans, short-term use of chromium at 1000 mcg daily is safe; however, these doses are not recommended in pregnancy or renal insufficiency. Prolonged use should be avoided due to concerns regarding adverse effects.

Vitamin D

Vitamin D plays a role in insulin resistance and egg follicle maturation and development. In a small trial of 13 women with PCOS and vitamin D deficiency, normal menstrual cycles resumed within 2 months of vitamin D repletion with calcium therapy in seven of the nine women who had irregular menstrual cycles.²⁸ Two women subsequently had established pregnancies. The authors of the study posited that abnormalities in calcium balance may be responsible, in part, for arrested follicular development in women with PCOS and may contribute to the pathogenesis of PCOS. Vitamin D also plays a key role in glucose regulation, notably in decreasing insulin resistance,^{29,30} and low levels of vitamin D have been negatively correlated with the incidence of type 1 and type 2 diabetes.

Dosage

Vitamin D₃: 2000 units daily. Higher doses may be prescribed based on serum 25-OH vitamin D levels. Overweight individuals have a greater risk of vitamin D deficiency because the bioavailability of vitamin D, a fat-soluble vitamin, may be reduced in fat tissue.

Precautions

Vitamin D is well tolerated. Gastrointestinal side effects are most commonly reported.

N-Acetylcysteine

Many studies of *N*-acetylcysteine (NAC) have reported benefit in diabetes, with several demonstrating benefit in PCOS. NAC has multiple actions, including increasing levels of glutathione (an antioxidant), lowering inflammatory markers such as tumor necrosis factor-alpha, and improving insulin sensitivity.^{31,32} A study in clomiphene-resistant patients demonstrated improved ovulatory rates (49.3% vs. 1.3%) and pregnancy rates (21% vs. 0%).³³ A prospective randomized placebo-controlled study of 60 women with PCOS aged 25–35 years undergoing intracytoplasmic sperm injection (ICSI) found that NAC improved oocyte and embryo quality. This study also compared the effects of NAC and metformin on oocyte quality, with the results indicating NAC

represents an alternative to metformin for women with PCOS undergoing ICSI.³³

Dosage

Give 1200 to 1800 mg/day in divided doses.

Precautions

NAC is well tolerated, with occasional reports of nausea.

Selenium

Selenium is an essential micronutrient involved in antioxidant reactions, such as catalyzed by glutathione peroxidase. Studies have suggested selenium also possesses insulin-like actions, and has a potential role in fat and carbohydrate metabolism. A recent randomized, double-blind, placebo-controlled study of 70 women aged 18–40 years with PCOS found that selenium supplementation led to significantly decreased levels of serum insulin (–29 vs. 9 pmol/L), serum triglycerides (–0.14 vs. 0.11 mmol/L) and VLDL-C concentrations (–0.03 vs. 0.02 mmol/L) compared with placebo.^{33a} Researchers from this study hypothesized these effects were attributable to inhibition of COX2 expression and inflammatory cytokines, including TNF-alpha and IL-1. Further studies are required to assess the potential benefits and toxicities associated with long-term selenium intake.

Dosage

Give 200 microgram per day for 8 weeks.

Precautions

No side effects were reported by any PCOS study participants who were taking selenium supplementation. While one study demonstrated selenium intake up to 200 mcg/d for up to 16 weeks is safe for patients over 18 years of age, other studies have reported adverse side effects of hair loss and dermatitis.

Botanicals

Cinnamomum cassia

Cinnamomum cassia (not *Cinnamomum zeyanicum* or *Cinnamomum verum*) has been studied in vitro and in humans for its effects in lowering glucose levels in patients with diabetes.³⁴⁻³⁶ A pilot study published in the July 2007 issue of *Fertility and Sterility* reported that 1/4 to 1/2 teaspoon of cinnamon powder reduced insulin resistance in 15 women with PCOS.

Dosage

The dose is 1 to 6 g powdered cinnamon (1/4 to 1 teaspoon) or 200 to 300 mg cassia extract.

Precautions

Cinnamon is well tolerated. Gastrointestinal side effects are most common.

Licorice

Licorice root and glycyrrhetic acid have antiandrogen effects that may support treatment goals in PCOS. Licorice root as part of a traditional Chinese medicine formula has also been associated with reduced serum testosterone and ovulation induction in women with PCOS.^{37,38} Additionally, licorice is synergistic with spironolactone, with its effects on potassium loss, hypertension, and fluid retention counteracting the opposing actions of spironolactone. A study of 32 hirsute women with PCOS administered 100 mg of spironolactone per day, with half also receiving 3.5 g/day of a licorice root extract standardized to 7.6% glycyrrhetic acid for 2 months.³⁹ Licorice use was associated with amelioration of orthostatic symptoms, polyuria, and systolic blood pressure drops, particularly during the first 2 weeks of treatment.

Dosage

Glycyrrhiza glabra: 500 mg standardized to 6% to 15% glycyrrhizin (approximately 3.0 to 8.0 g of crude plant material).

Precautions

Few adverse events have been reported at lower doses or normal consumption levels. A no-observed effects level has been proposed as purified glycyrrhizin, 2 mg/kg/day. The acceptable daily intake for glycyrrhizin is recommended as 0.2 mg/kg/day. Toxicity from excessive licorice ingestion is well established, including hypokalemia, hypertension, and fluid retention. Licorice is contraindicated in pregnancy.

Chaste Tree Berry (*Vitex Agnus-castus*)

Vitex is one of the most popular botanicals for PCOS, although data from well-conducted studies are not available. *Vitex* is believed to shift the estrogen–progesterone balance in favor of progesterone through increased luteinizing hormone levels and mild inhibition of follicle-stimulating hormone secretion. *Vitex* also reduces prolactin secretion, which may inhibit fertility when elevated. A small study involving women with fertility disorders examined pregnancy rates following the administration of a chaste berry–containing herbal blend versus placebo twice daily for 3 months.⁴⁰ Women with secondary amenorrhea or luteal insufficiency in the active treatment group achieved pregnancy twice as often as in the group receiving placebo. However, the total number of patients conceiving was small (15 women).

Two other publications explored the benefits of a *Vitex*-containing blend on progesterone levels, basal body temperature, menstrual cycle length, pregnancy rate, and side effect profile.^{41,42} Both were double-blind, placebo-controlled trials of a proprietary nutritional supplement containing chaste berry, green tea, L-arginine, and vitamins and minerals. The treatment group (n = 53) demonstrated increased mean midluteal progesterone levels, particularly among women with very low pretreatment levels. Cycle length and luteal basal body temperatures improved significantly. After 3 months, 14 women in the treatment group were pregnant (26%) compared with 4 of the 40 women in the placebo group (10%; p = 0.01). The results of these studies are difficult to extrapolate given the proprietary nature of the supplements, although the trends toward improvement with no side effects warrant further consideration. Several small studies in the German literature have also reported a benefit of *Vitex* for acne, with self-reports of improvements of up to 70%.⁴³

Dosage

Vitex products are available in many different forms, including fresh and dried berries, capsules containing powdered chaste berries, and liquid preparations, such as extracts and tinctures. The German Commission E recommends 30-40 mg of dried fruit extract daily, 2.6-4.2 mg of dry native extract (standardized to 0.6% casticin or agnuside), or 40 drops of tincture. Fluid extract ([1:1] g/mL) dosage ranges from 0.5-1.0 mL daily.

Precautions

Animal and human studies indicate *Vitex* may interfere with oral contraceptives and hormone therapy. Based on in vitro data, *Vitex* may also interact with dopamine agonists (e.g., bromocriptine, levodopa). Use during pregnancy is not recommended.

Complementary Healing Approaches

Acupuncture

Acupuncture has the potential to influence PCOS through its effects on the sympathetic nervous system, the endocrine system, and the neuroendocrine system.^{46,47} In a 2009 study, one group of women with PCOS was treated for 4 months with electroacupuncture, another group of women was given heart rate monitors and told to exercise three times a week, and a third control group was educated about the importance of exercise and a healthy diet but received no instructions. The investigators found that women who received acupuncture or who exercised had decreased sympathetic activity. The women who received electroacupuncture treatments also had more regular menstrual cycles, reduced testosterone levels, and reduced waist circumference. Experimental observations from animal and clinical studies indicate acupuncture exerts beneficial effects on insulin resistance and ovulation. Although research studies are limited, acupuncture may be considered as an adjunctive therapy in many women for its direct impacts on PCOS parameters in addition to associated mood disorders and stress.

Mind-Body Therapy

Women with PCOS have a significantly increased prevalence of depression and anxiety.⁴⁸⁻⁵⁰ Mood disorders may be directly related to biochemical imbalances (altered androgen levels or insulin resistance), and may be exacerbated by stress related to body image issues and infertility. Addressing these concerns through mind-body approaches, self-care, and cognitive-behavioral therapy should be encouraged for all women. A randomized, controlled trial has shown that women with PCOS who participated in an 8-week mindfulness and stress management program experienced significant reductions in stress, depressive, and anxiety symptoms, along with an increase in life satisfaction and quality of life. The results of this study indicate mindfulness techniques can be used to supplement PCOS care to the benefit of patient mental health⁵⁸ (see [Chapter 100](#)).

Pharmaceuticals

Medication decisions should be based on the predominant symptoms and goals of individual patients. Major classes of pharmaceutical treatments for PCOS include insulin sensitizers, weight loss medications, and hormone modulators.

Insulin Sensitizers

Metformin improves insulin resistance and hyperandrogenism.⁵¹ Metformin is also associated with regulation of menstruation and ovulation, and may benefit up to 79% of women attempting to conceive. Metformin is considered weight neutral, as opposed to many other medications used for glucose regulation.

Dosage

Start with 500 mg daily for 1 week, titrate to 500 mg twice daily in week 2, and as required thereafter. The maximum daily dose is 2.5 g in two or three divided doses.

Precautions

Side effects are predominantly gastrointestinal and include nausea and diarrhea. Metformin should be avoided if creatinine clearance is less than 30 mL/minute.

Thiazolidinediones are less thoroughly studied in PCOS compared with metformin. This class of medications is associated with weight gain, thus making it an unattractive choice for many women struggling with PCOS. Studies of troglitazone (now off the market due to hepatotoxicity), pioglitazone, and rosiglitazone have demonstrated improvements in insulin sensitivity, hyperandrogenemia, and ovulatory rates. Given the potential for adverse effects, this class of medications is best reserved for patients with established diabetes mellitus.

Weight Loss Medications

Orlistat, given with an energy-restricted diet, has been shown to improve insulin resistance in addition to lowering free testosterone in obese women in some, but not all, studies.⁵²⁻⁵⁴ As the trials were short term (3 to 6 months), further studies are required to determine the utility of orlistat for the treatment of patients with PCOS.

Dosage

A dose of 120 mg three times daily containing fat (during or up to 1 hour after the meal) was used for 3-6 months in previous studies. Omit dose if meal is occasionally missed or contains no fat.

Precautions

Orlistat may cause fat-soluble vitamin deficiency and greasy stools.

Hormone Modulators

Oral Contraceptives

Oral contraceptive pills (OCPs) are first-line options for symptoms of androgen excess, such as hirsutism and acne, in accord with the 2008 Endocrine Society Clinical Practice Guidelines. OCPs reduce luteinizing hormone secretion and thus ovarian androgen secretion; additional reductions in free androgen concentration occur through increased levels of sex hormone-binding globulin.⁵⁵ OCPs provide additional benefit by protecting against endometrial hyperplasia in amenorrheic women with excess estrogen exposure.

Dosage

Appropriate choices include OCP preparations containing 30 to 35 mcg of ethinyl estradiol combined with a progestin with minimal androgenicity, such as norethindrone, norgestimate, desogestrel, or drospirenone.

Precautions

Risks and side effects of OCPs are similar to those for women without PCOS. OCPs may increase cardiovascular risk factors, such as inflammatory markers and insulin resistance. Absence of pregnancy should be documented before OCPs are initiated. In patients with no menstrual period for 6 or more weeks, withdrawal bleeding should be induced by administration of 5 to 10 mg of medroxyprogesterone acetate daily for 10 days before initiation of OCP treatment (to minimize breakthrough bleeding when starting the pill).

Although the oral contraceptive pill (OCP) helps many women overcome the troublesome symptoms of polycystic ovarian syndrome (PCOS), these drugs have been associated with an increased risk of cardiovascular disease in the general population.^{56,57} The risk of cardiovascular disease is associated with increased age, smoking, and hypertension. Additional concerns include a negative impact on inflammatory markers and diabetes risk. Further studies are required in the PCOS population to assess the long-term benefit-to-risk ratio of using OCPs. For now, increased awareness and regular follow-up of metabolic and cardiovascular markers are critical for all patients taking the OCP.

Progestins

Progestins are appropriate for women who require endometrial protection but are not interested in, or appropriate for, the OCP. Cyclic progestins promote withdrawal bleeding and prevent endometrial hyperplasia.

Dosage

Synthetic progestin: medroxyprogesterone acetate 5–10 mg orally daily for 7 to 10 days every 1 to 2 months. Bio-identical progestin:

micronized progesterone 200–400 mg orally daily for 10 days every 1 to 2 months. Bio-identical progesterone cream has not been evaluated in research studies, and whether such creams can provide consistent levels sufficient for uterine protection is unclear.

Precautions

Sedation or confusion may occur.

Antiandrogens

Antiandrogens, which block androgen binding to its receptor, are often used off label for hirsutism.⁵⁸ The most commonly prescribed antiandrogen is spironolactone. Flutamide is another option despite an association with greater side effects.

Dosage

Spironolactone, 50 to 200 mg/day; flutamide, 250 mg two to three times a day.

Precautions

Contraception is essential as an antiandrogens, such as spironolactone, may be teratogenic if pregnancy occurs. Discontinuation 3 months before conception is therefore recommended. If spironolactone is used alone, endometrial protection may be required.

Clomiphene Citrate

Clomiphene citrate is an antiestrogen and an effective option for ovulation induction for women with PCOS. Approximately 80% of women with PCOS ovulate in response to clomiphene citrate, and approximately 50% conceive.

Dosage

The strategy is to use the lowest dose of clomiphene possible to initiate ovulation, starting with 50 mg/day for 5 days (usually days 5 to 9). If no follicle development occurs with this dose, the dose or duration of

treatment can be increased.

Statins

There is debate in the literature regarding the cardiovascular and endocrine benefit of statins in women with PCOS. The results of an initial study of 40 patients with PCOS randomly assigned to atorvastatin at 20 mg daily or placebo were promising.⁵⁹ After 12 weeks, the researchers reported an absolute reduction in free androgen index (−32.7%) and total testosterone (−24.6%), and increased sex hormone–binding globulin (+13.7%) in the atorvastatin group compared to the placebo group. Patients in the atorvastatin group had lower serum insulin levels and homeostasis model of insulin resistance (HOMA-IR) values compared to the placebo group. Conversely, a study published in 2010, in which 20 patients with PCOS who had low-density lipoprotein levels higher than 100 mg/dL took atorvastatin at 40 mg/day or placebo for 6 weeks of treatment, reported reductions in androgen levels, biomarkers of inflammation, and blood pressure.⁶⁰ However, atorvastatin worsened hyperinsulinemia and failed to improve endothelial function in women with PCOS. Until the potential benefit of statins in PCOS has been fully evaluated, reserving statin use for the treatment of hyperlipidemia rather than the treatment of hyperandrogenemia or insulin resistance seems prudent.

Dosage

Doses are as per usual recommendations for hyperlipidemia.

Precautions

Statins are considered to have teratogenic potential in pregnancy. The usual concerns regarding liver and muscle issues apply.

Surgery

When severe symptoms are not controlled with the therapies described above and a patient has morbid obesity, bariatric surgery may be considered. Results of two small studies on the effects of bariatric surgery have been published.⁶¹ A retrospective study evaluated 30 women with PCOS who underwent laparoscopic Roux-en-Y gastric

bypass. Postoperative benefits included resolution of menstrual irregularity (100%), improvement in hirsutism (75%), resolution of type 2 diabetes, and ability to cease medications for hypertension (78%) and hyperlipidemia (92%). These results were confirmed in a prospective study evaluating 17 women with PCOS.

Surgery may also be performed for ovulation induction in the management of clomiphene citrate-resistant anovulatory women with PCOS. Various types of ovarian surgery can be employed (e.g., wedge resection, electrocautery, laser vaporization, multiple ovarian biopsies), and all procedures result in an altered endocrine profile postoperatively. A plausible mechanism for the benefit of surgery for patients with PCOS is the restoration of appropriate gonadotrophin release due to rapid reductions in the secretion of all ovarian hormones restoring feedback to the hypothalamus and pituitary. These surgical procedures provide an option, albeit one used less often now, when natural and pharmaceutical approaches are unsuccessful in anovulatory patients with PCOS.

Prevention Prescription

- Maintain appropriate weight and a regular aerobic exercise routine.
- Avoid excessive amounts of saturated fat such as those found in red meat, fried foods, and dairy.
- Replace vegetable oils with olive or canola oil for cooking.
- Consume omega-3-rich fats found in cold-water fish, nuts, greens, and ground flaxseed.
- Encourage soy-based foods, such as soy milk, edamame, tempeh, miso, soy nuts, and nongenetically modified tofu. Try to eat 1 to 2 oz of soy-based foods per day.
- Avoid dietary supplements or environmental exposures that may increase circulating hormone levels, such as pesticides, herbicides, and bovine growth hormone-rich dairy products.
- Avoid supplements or drugs that include dehydroepiandrosterone, androstenedione, testosterone, or human growth hormone.

Therapeutic Review

Lifestyle approaches are first-line recommendations for PCOS, both in conventional and integrative medicine approaches. Many women with

PCOS do well with attention to diet, exercise, supplements, and acupuncture. A proportion of women require medications to achieve improvements when metabolic derangements are greater.

Lifestyle

- Remove exacerbating factors. Minimize exposure to hormone-disrupting chemicals.

Nutrition

- Promote weight loss to achieve an ideal body weight. Start with achievable goals and provide adequate support. 
- Eat 1 to 2 servings of soy-rich foods daily. Each 1 oz serving (approximately the size of the palm of the hand) provides approximately 25 mg. 
- Encourage a low-carbohydrate diet that takes into account the glycemic index of foods. 
- Encourage foods rich in omega-3 fatty acids (e.g., salmon, nuts, or ground flaxseeds). 

Physical Activity

- Recommend moderate exertion for 30 to 60 minutes daily. 

Supplements

- Vitamin D3: 2000 units daily (dose based on serum 25-OH vitamin D level) 
- Chromium picolinate: 1000 mcg daily 
- d-chiro-inositol/pinitol: 600 mg once or twice per day 
- Selenium: 200 mcg per day for 8 weeks 

Botanicals

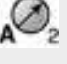

- *Cinnamomum cassia*: 1/4 to 1 teaspoon 
- Licorice root in conjunction with spironolactone for the amelioration of side effects and complementary action 

- Chaste tree berry (*Vitex*): 60 drops of tincture or 175 mg of extract, standardized to 0.6% agnusides 

Complementary Therapies

- Acupuncture may reduce sympathetic nervous system tone and improve menstruation. It has additional benefits for stress reduction and mood. 
- Mind-body therapies can help women cope with stress, depression, and anxiety related to PCOS. 

Pharmaceuticals

- Insulin sensitizers include metformin at 500 to 1000 mg twice daily. 
- If patients are unable to achieve satisfactory weight loss, consider support with orlistat. 
- Medications such as clomiphene may be prescribed in consultation with a reproductive endocrinologist for ovulation induction. 
- Antiandrogens for hirsutism include spironolactone at 50 to 200 mg/day, or flutamide, at 250 mg two to three times a day. 
- Oral contraceptive pills are prescribed for amenorrhea, hyperandrogenism, and uterine protection. 

Surgical Therapy

- Consider referral for bariatric surgery for patients with morbid obesity and significant comorbidities despite the measures listed above. 
- Ovarian surgery may be indicated for infertility.

CHAPTER 36

Osteoporosis

Louise Gagné, MD, and Victoria Maizes, MD

Osteoporosis is defined as a generalized skeletal disorder characterized by compromised bone strength, which predisposes individuals to an increased risk of fracture. Osteoporosis is a significant cause of pain, disability, and death throughout the world. Integrative medicine makes use of a range of strategies to reduce the risk of osteoporosis, including an antiinflammatory diet, supplements, stress reduction, and lifelong exercise habits.

Epidemiology and Pathophysiology

The incidence of osteoporotic fractures varies by more than 10-fold in different regions of the world. Rates are highest in Europe, Iran, and Argentina and much lower in China, India, and South Africa.¹ More than 10 million people in the United States have osteoporosis and more than 2 million osteoporotic fractures occur each year.² Women are at higher risk of osteoporosis than men and account for approximately 75% of all cases; however, men are at greater risk of dying of a hip fracture should they sustain one (20.7% vs. 7.5%).³ The costs to the U.S. health care system attributable to osteoporosis are significant, totaling more than \$16 billion annually. As the population ages, the costs related to osteoporosis prevention and treatment are expected to continue to climb.⁴

Osteoporosis is a multifactorial disease arising from genetic, hormonal, metabolic, mechanical, and immunological factors. Bones provide the support structure for our bodies, protect vital organs, and play a central role in mineral and acid–base balance. The two main types of bone cells are osteoblasts (which synthesize the organic bone matrix and mediate calcification) and osteoclasts (which resorb bone to allow for metabolic requirements and for repair and remodeling).

Bone mass reaches its peak by around 30 years of age, but repair and renewal of bone continue throughout adult life, with approximately 15% of bone mass turning over each year. Bone is dynamic and constantly responding to a range of hormonal, metabolic, neurological, and mechanical signals. Bone loss usually begins in the fourth decade in both men and women. Women typically lose 0.5% to 0.9% of bone density per year during the perimenopause, 1% to 3% during menopausal years, and 1% per year into old age. On average, women lose 35% of their cortical bone and 50% of their trabecular bone over their lifetimes. Men are half as likely as women to experience a fracture as they reach higher peak bone mass, have a larger cortical thickness, and have better preservation of bone microstructure.³

Assessing Bone Strength and Fracture Risk

Bone strength is determined by bone quality in addition to bone mass. Bone quality is influenced by bone geometry, microarchitecture, and the properties of constituent tissues. Although a number of techniques, such as a quantitative CT and high-resolution MRI, are being studied; no method is readily available to assess bone quality in a clinical practice setting.⁵ Bone mass is most commonly assessed using a dual energy x-ray absorptiometry (DEXA) scan.

Osteoporosis is defined as a bone mineral density (BMD) more than 2.5 standard deviations (SD) below the mean for young adults. Osteopenia is defined as a BMD 1 to 2.5 SD below the young adult mean. However, BMD has limitations as the sole predictor of fracture risk. Most fractures occur in individuals with a BMD above the cutoff of 2.5 SD from the mean.⁶ Further, BMD is unable to differentiate between cortical and trabecular bone or characterize the three-dimensional structure of bone. Although some studies have shown a strong correlation between low femoral neck BMD and risk of hip fracture,⁷ a wide overlap exists between the bone densities of women who will eventually suffer a fracture and those who will not.⁸ Overall, less than 60% of the variation in femoral bone strength is related to BMD.⁹

The Fracture Risk Algorithm (FRAX) developed by the World Health Organization (WHO) uses a number of additional risk factors to more accurately predict fracture risk. These risk factors are: history of prior fracture, thinness, smoking, rheumatoid arthritis, excessive alcohol intake, and history of a hip fracture in a parent. FRAX in combination with BMD has been shown to be superior to either FRAX or BMD alone.⁶

The North American Menopause Society (NAMS) recommends that BMD be measured in all women 65 years old or older, and in women age 50 and older with one or more FRAX risk factors.¹⁰

Other risk factors for osteoporotic fracture should also be assessed. These include nutritional deficiencies, high alcohol intake, excessive caffeine consumption, premature menopause, malabsorption disorders, autoimmune disease, small body frame, white/Caucasian or Asian descent, impaired vision, dizziness or balance problems, fainting or loss of consciousness, physical frailty, and use of medications such as corticosteroids, aromatase inhibitors, proton pump inhibitors, anticonvulsants, sedatives, anticholinergics, antihypertensives, heparin, cyclosporine, and medroxyprogesterone acetate.

Role of Inflammation

Chronic inflammation is implicated in the process of aging,^{11,12} and posited to play a role in the development of a wide range of diseases, including cardiovascular disease, Alzheimer's disease, diabetes, and cancer.^{13,14} Growing evidence indicates that osteoporosis is also, in part, a result of chronic low-grade inflammation.¹⁵⁻¹⁷ Proinflammatory cytokines, such as interleukin-6 (IL-6), interleukin-1 (IL-1), and tumor necrosis factor-alpha (TNF-alpha), promote accelerated bone loss by the activation of osteoclasts, inhibition of collagen production in osteoblasts, and enhanced breakdown of the extracellular matrix.¹⁷ Furthermore, suppression of proinflammatory cytokines appears to support the growth of new bone. For instance, TNF-alpha inhibitors, such as etanercept, have been found to improve BMD in patients with spondyloarthritis.¹⁸ It is widely recognized that patients with systemic inflammatory conditions, such as rheumatoid arthritis, inflammatory bowel disease, multiple sclerosis, and systemic lupus erythematosus, are at increased risk of bone loss.¹⁹

Reducing systemic inflammation can help promote bone density and strength.

Fruits and vegetables are rich sources of antiinflammatory and antioxidant compounds, and diets rich in fruits and vegetables are associated with both increased peak bone mass and improved bone health in older populations.²⁰⁻²³ The bone-building effects of fruits and

vegetables may result from several factors including: antiinflammatory and antioxidant phytonutrients; alkalinizing effects; the provision of nutrients such as potassium, vitamin K, and vitamin C; and the presence of other unknown compounds and synergistic effects. Thus an antiinflammatory diet that includes abundant fruits and vegetables, whole grains, legumes, and healthy fats is recommended as the foundation of an integrative bone health plan (see [Chapter 88](#)).

Acid–Base Issues

The skeleton plays a key role in acid–base homeostasis.²⁴ In bone, minute reductions in the local pH can stimulate osteoclast activity while also impairing the activity of osteoblasts.²⁵ A diet high in animal protein and low in fruits and vegetables tends to produce a chronic low-grade metabolic acidosis that may be harmful to the skeleton.^{26–30} Fruits and vegetables generate bicarbonate that can buffer the acidifying effects of animal protein, alkalinize the urine, and significantly lower urinary calcium excretion.³¹ In a study by Buclin et al., acid-forming diets increased calcium excretion by 74% as compared to base-forming diets.³² Balanced diets with adequate protein along with abundant fruits and vegetables are therefore recommended.^{33,34}

In addition to effects on acid–base balance, the benefits of plant foods also appear to be related to pharmacologically active components, including specific monoterpenes,³⁵ flavonoids, and phenols,³⁶ that may be responsible for the observed beneficial effects on bone.

Muhlbauer described 25 plant foods as “bone resorption inhibitory food items” (BRIFI). These include garlic, rosemary, Italian parsley, sage, thyme, parsley, dill, onion, arugula, prune, fennel, orange, leek, yellow boletus, wild garlic, field agaric, red cabbage, celeriac, red wine, and lettuce.³⁷

Microbiome and Bone Health

There is emerging evidence that the human microbiome plays a significant role in many dimensions of health, including brain function, immune response, levels of inflammation, body weight, and cancer risk.^{38,39} The gut microbiome has also been shown to influence bone

health. In animal studies, prebiotic feeding aimed at enhancing production of short chain fatty acids by intestinal bacteria resulted in increased fractional calcium absorption and increased bone density and strength.⁴⁰ A study by Ohlsson et al. found that treatment with probiotics can diminish bone loss related to sex-steroid deficiency in mice.⁴¹ Several human trials in adolescent girls and boys have found that prebiotic supplementation can increase the numbers of bifidobacteria, enhance calcium absorption, and increase bone mineralization.^{42,43} In general, a healthy, diverse microbiome can be supported by including cultured and fermented foods in the diet, eating a diet rich in “microbiota-accessible carbohydrates” (MACs),⁴⁴ and avoiding unnecessary antibiotics. Ongoing research may clarify how the health of the microbiome can be supported and enhanced in order to sustain bone health.

Vegetarian and Vegan Diets

Plant-based diets are associated with a lower risk of chronic disease and reduced overall mortality.⁴⁵ In 2009, the American Dietetic Association issued a position statement stating: “...appropriately planned vegetarian diets, including total vegetarian or vegan diets, are healthful, nutritionally adequate, and may provide health benefits in the prevention and treatment of certain diseases.”⁴⁶ In practice, vegetarians and vegans are more likely to have low intakes of vitamin D,⁴⁷ calcium, vitamin B12, and omega-3 fatty acids. Vegetarian sources of zinc are also less bioavailable. On the other hand, healthy vegetarian diets contain plentiful amounts of magnesium, potassium, vitamin K, and antioxidant and antiinflammatory phytonutrients. A number of studies have shown that vegetarian, and particularly vegan, diets may increase the risk of osteoporosis and bone fractures.⁴⁸ In a meta-analysis by Ho-Pham et al., BMD was, on average, 4% lower in vegetarians (all types) and 6% lower in vegans.⁴⁹ The EPIC-Oxford study examined fracture risk in more than 34,000 meat eaters, fish eaters, vegetarians and vegans, and reported fracture risk was highest in vegans. However, when only subjects with adequate calcium intakes were included, no differences in fracture risk were observed between any of the groups.⁵⁰ A longitudinal study of Asian vegans and omnivores reported a higher rate of bone loss in the omnivore group, with fracture risk found to be the same in both groups. Lower body weight, higher intakes of animal protein and fats, and corticosteroid use were all associated with a greater rate of bone loss.⁵¹ If vegetarians and vegans follow the principles of an antiinflammatory diet

and ensure adequate intake of calcium and vitamin D, they should be able to reap the benefits of a plant-based diet without increasing their risk of osteoporosis.

Integrative Therapy

Nutrition and Nutritional Supplements

Calcium

Calcium is an essential nutrient for building and maintaining healthy bones, and 99% of total body calcium is found in bones. However, high calcium intakes do not guarantee strong bones, and lower calcium intakes do not necessarily lead to weaker bones.⁵⁶⁻⁵⁸ Calcium requirement is determined by the amount of calcium absorbed versus the rate that calcium is lost via the bowels, kidneys, skin, hair, and nails.⁵⁹ To improve calcium absorption and/or decrease calcium losses: ensure an optimum intake of vitamin D⁶⁰ and vitamin K,⁶¹ increase fruits and vegetables,³¹ aim for a balance of essential fatty acids,⁶² consider cutting back on animal protein (although protein intake also increases calcium absorption),³¹ keep dietary sodium to <2400 mg/day,^{63,64} avoid excess caffeine,⁶⁵ and eat fewer highly refined carbohydrates.⁶⁶ It is estimated that adequate calcium intake may range from ~450 mg to ~1150 mg depending on the influence of a variety of factors, such as those listed previously. For instance, it is estimated that a low animal protein intake of 20 g/day, coupled with a low sodium intake of 1.15 g/day may lower the amount of calcium required by 390 mg/day. Maximal calcium absorption from optimal vitamin D intake may lower calcium requirements further.⁵⁹

The collective effects of various dietary and lifestyle factors may help to explain the “calcium paradox,” whereby hip fracture rates are less common in developing countries where calcium intakes are lower.⁵⁹

In 2010 the Institute of Medicine (IOM) issued an update of the dietary reference intakes (DRIs) for calcium and vitamin D ([Table 36.1](#)). Before recommending supplemental calcium, the sum of all existing dietary sources of calcium, including baseline intake (~250 mg/day), dairy products, fortified beverages, and calcium that may be present in multivitamins or other supplements, should be calculated. The difference between this total and the DRI can then be used to determine if a supplement is required. A meta-analysis by Tang et al. found that men

and women over the age of 50 had significantly lower fracture risk and reduced rate of bone loss with 1200 mg of calcium alone or in combination with vitamin D.⁶⁷ Some studies have linked the use of calcium supplements with an increased risk of cardiovascular disease.⁶⁸ However, several studies have questioned the validity of these findings.⁶⁹⁻⁷¹ A study by Langsetmo et al. found that increased calcium intake from diet and supplements may lower mortality in women.⁷² When dietary intake is inadequate, calcium supplementation is recommended but should always be part of a broader strategy that includes adequate vitamin D, vitamin K2, and other bone-building foods and nutrients. Even without dairy products, it is possible to meet daily requirements for calcium from vegetarian sources (Tables 36.2 and 36.3).

TABLE 36.1
Dietary Reference Intakes for Calcium and Vitamin D

Life Stage Group	Calcium			Vitamin D		
	Estimated Average Requirement (mg/day)	Recommended Dietary Allowance (mg/day)	Upper Level Intake (mg/day)	Estimated Average Requirement (μg/day)	Recommended Dietary Allowance (μg/day)	Upper Level Intake (μg/day)
Infants 0-6 mo	*	*	1000	†	†	1000
Infants 6-12 mo	*	*	1500	†	†	1500
1-3 yr	500	700	2500	400	600	2500
4-8 yr	800	1000	25,000	400	600	3000
9-13 yr	1100	1100	1900	400	600	4000
14-18 yr	1100	1300	3000	400	600	4000
19-30 yr	800	1000	2500	400	600	4000
31-50 yr	800	1000	2500	400	600	4000
51-70 yr (M)	800	1000	2000	400	600	4000
51-70 yr (F)	1000	1200	2000	400	600	4000
Older than 70 yr	1000	1200	2000	400	600	4000
14-18 yr, pregnant or lactating	1100	1100	3000	400	600	4000
19-30 yr, pregnant or lactating	800	1000	2500	400	600	4000

* For infants, adequate intake is 200 mg/day for 0 to 6 months of age and 260 mg/day for 6 to 12 months of age.

† For infants, adequate intake is 400 IU/day for 0 to 6 months of age and 400 IU/day for 6 to 12 months of age.

From Committee to Review Dietary Reference Intakes for Vitamin D and Calcium. In: Ross AC, Taylor CL, Yaktine AL, Del Valle HB, eds. *Dietary reference intakes for calcium and vitamin D*. Washington, DC: National Academies Press; 2011.

Vitamin D

One key role of vitamin D, in relation to bone health, is that is necessary for calcium absorption. The hormonally active form of vitamin D (1,25[OH]D) induces active transport of calcium across the intestinal epithelium. Vitamin D also stimulates the absorption of phosphate and

magnesium ions, and acts synergistically with vitamin K to directly stimulate bone mineralization. In addition, vitamin D has beneficial effects on skeletal muscle and can reduce the risk of falls and increase muscle strength, function, and balance.⁷³

Serum levels of 25-hydroxyvitamin D (25[OH]D) are required to be at least 34 ng/mL for maximal calcium absorption.⁶⁰

Hypovitaminosis D is common in the United States and rates of vitamin D deficiency are rising.^{74,75} Breast-fed infants, women, older adults, obese persons, and people with darker skin tones are at higher risk of vitamin D deficiency. An international epidemiological study found that 64% of postmenopausal women seeking medical care for osteoporosis had inadequate vitamin D concentrations (less than 30 ng/mL).⁷⁶ Supplementation with 800 IU vitamin D per day is associated with reduced fracture risk and a number of other positive health outcomes.⁷⁷ Population-wide screening for vitamin D deficiency in adults age 65 and older has been shown to be a cost-effective public health strategy.^{78,79} It may be reasonable to screen patients of all ages for vitamin D deficiency, since inadequacy is also common in younger age groups.^{80,81} Supplementation should be given to achieve a serum 25(OH)D of at least 34 ng/mL.⁷⁷ The ideal level for bone health may be considerably higher, with a meta-analysis concluding that optimum fracture prevention is not achieved until a level of 40 ng/mL is reached.⁸²

TABLE 36.2
Dairy Calcium Sources

Food	Amount (oz)	Calcium (mg)
Milk	8	300
Yogurt	8	275–325
Hard cheeses high in calcium (cheddar, Swiss, Edam, Monterey Jack, Provolone, Parmesan, Romano, part-skim mozzarella)	1	200–300
Soft cheeses low in calcium (Brie, Neufchatel)	1	20–50

TABLE 36.3
Nondairy Calcium Sources

Food	Amount	Calcium (mg)
White beans	1 oz cooked	161
Spinach	½ cup	122
Turnip greens	½ cup	99
Soybeans	½ cup cooked	90
Broccoli	1 cup cooked or fresh	90
Bok choy	½ cup cooked or fresh	80
Almonds	1 oz dry roasted	80
Salmon	3 oz, canned with bones	180
Dried figs	10	269

Vitamin D can be obtained through sunlight exposure, from a limited number of foods, or from supplements. Sunlight exposure of 10 to 15 minutes without sunblock at the appropriate latitude and season is a good source of endogenously produced vitamin D. Only a few foods are naturally rich in vitamin D. Food sources include fatty ocean fish, such as salmon, sardines, and black cod; sun-exposed mushrooms; and fortified foods including some brands of orange juice, fortified milk substitutes, cow's milk, and some yogurts. Vitamin D supplementation is an inexpensive and reliable way to ensure an optimum serum level.

Dosage

In adults, doses of 1500–2000 IU/day may be needed to maintain a serum 25(OH)D level above 30 ng/mL.⁸³ Vitamin D₃ (cholecalciferol) is the preferred form⁸⁴ and should be taken with meals.

Precautions

Minimal if kept within therapeutic limits.

Essential Fatty Acids

Both omega-6 (n-6) and omega-3 (n-3) fatty acids are essential nutrients that are incorporated into cell membrane phospholipids, where they influence membrane characteristics and become precursors for eicosanoids, such as prostaglandins, leukotrienes, and thromboxanes. Western diets tend to be relatively high in n-6 fats and low in n-3 fats, with typical ratios in the United States being ~16:1 (n-6 to n-3).⁸⁵ The ideal ratio is thought to be between 1:1 and 2:1 (n-6 to n-3).⁸⁶ The balance between these fats plays an important role in regulating the inflammatory response.

Omega-3 fatty acids are known to have antiinflammatory effects and suppress production of interleukin 1-beta (IL-beta), TNF-alpha, and IL-6.⁸⁷ Certain n-6 fatty acids, such as gamma-linolenic acid (GLA), also have antiinflammatory effects. On the other hand, the n-6 fatty acid, linoleic acid (LA), tends to have proinflammatory effects and promotes increased production of IL-beta, TNF-alpha, and IL-6.

Omega-3 fats appear to play an important role in bone health via a number of mechanisms including: increased calcium absorption, antiinflammatory effects, and promotion of osteoblastogenesis in the bone marrow.⁸⁸ In animal studies, fish oils rich in omega-3 fatty acids have been found to attenuate bone loss associated with estrogen withdrawal.⁸⁹ Animal studies have also shown that the omega-3 fatty acid, eicosapentaenoic acid (EPA), enhances calcium absorption, reduces calcium excretion, and increases calcium deposition in bone.⁹⁰ In a study of postmenopausal Korean women, higher red blood cell (RBC) levels of the omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), were associated with a lower risk of osteoporosis.⁹¹ In elderly women, supplementation with calcium, EPA, and GLA resulted in a decrease in bone turnover and an increase in lumbar and femoral bone density.⁹⁰ In the Rancho Bernardo study, higher ratios of n-6 to n-3 fatty acids were associated with lower BMD in the hip for all women studied and lower BMD in the spine for women not on hormone therapy (HT).⁹² A study of postmenopausal Chinese women found that higher intake of sea fish, rich in omega-3 fats, as opposed to freshwater fish, was associated with greater bone mass and a lower risk of osteoporosis.⁹³

Despite substantial supporting evidence, a systematic review by Orchard et al. found inconclusive confirmation of a positive effect of omega-3 fatty acids on bone health. However, beneficial effects were found in studies conducted over longer periods of time (≥ 18 months); with the use of a mixture of fatty acids along with calcium; and, in particular, with increased intake of alpha-linolenic acid (ALA) as opposed to eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA).⁹⁴ Although further studies are required, n-3 fatty acids appear to enhance calcium absorption, reduce calcium excretion, and improve mineralization of bone matrix and bone strength.⁶² There are also known health benefits to having an optimal proportion of omega-6 and omega-3 fatty acids in the diet.⁸⁵ The majority of individuals will need to increase their intake of omega-3 fats and decrease their intake of omega-6 fats to achieve this balance.

Protein

Protein is essential for the growth and maintenance of healthy bones.⁹⁵ Protein has anabolic effects on bone by providing the structural matrix of bone, increasing insulin-like growth factor (IGF-1) levels, and increasing intestinal absorption of calcium.⁹⁶ Protein also increases urinary calcium losses; however, other components in foods, such as phosphorus in meat and potassium in legumes, can at least partially offset this effect.⁹⁷

Studies of the effect on bone of animal versus plant proteins and high versus low protein intakes have reported conflicting results. Several studies have found that high levels of animal protein in the diet are associated with increased fracture rates and accelerated bone mineral loss.⁹⁸⁻¹⁰⁰ In the Nurses' Health Study, protein intakes higher than 95 g/day were associated with significantly higher forearm fracture rates than protein intakes lower than 68 g/day.⁹⁹ A separate study found that lowering protein intakes to current RDA guidelines (0.8 g/kg) resulted in significant reductions in urinary calcium excretion and in markers of bone resorption.¹⁰¹ A number of studies have also shown that an increased ratio of vegetable to animal protein is protective against fractures.^{102,103} On the other hand, the Framingham Osteoporosis Study found that higher protein intakes (60–83 g/d in quartiles 2–4 vs. 46 g/d in the lowest quartile) in elderly men and women were associated with a 37% decreased risk of hip fracture.¹⁰⁴ The Women's Health Initiative data reported that a 20% increase in protein intake (from 15% to 18% of energy intake) improved BMD maintenance and marginally lowered forearm fracture risk.¹⁰⁵ A systematic review by Calvez et al. concluded that, "...no clinical data support the hypothesis of a detrimental effect of HP (high protein) diet on bone health, except in the context of inadequate calcium supply."¹⁰⁶ Other studies have found that, in the presence of adequate dietary calcium and vitamin D, increasing protein intake may have a favorable effect on bone health.^{96,107} It is important to note that the majority of studies evaluating "higher" protein diets have examined modest increases in protein intake rather than the effects on bone of protein intakes in the range of 30% of energy intake.

An adequate but not excessive intake of protein is recommended as part of a balanced diet that includes abundant fruits and vegetables and adequate calcium. Choosing vegetarian sources of protein, such as quinoa and soy foods, is also highly recommended for bone and overall

health.

Vitamin K

There are two naturally occurring forms of vitamin K in foods: phylloquinone (K1), synthesized by plants; and menaquinones (K2), synthesized by bacteria. Vitamin K works synergistically with vitamin D to stimulate bone mineralization.^{108,109} Menaquinones play a particularly important role in the prevention and therapy of osteoporosis.¹⁰⁸⁻¹¹⁰ Vitamin K2 is required for gamma carboxylation of osteocalcin, which stimulates the synthesis of osteoblastic markers and inhibits bone resorption by inhibiting the formation and activity of osteoclasts.^{111,112}

A number of studies have reported a link between higher vitamin K status and reduction of fracture risk. Booth et al. found that elderly men and women in the highest quartile of dietary vitamin K had a relative risk for hip fracture of 0.35.¹¹³ Women who consume one or more servings of lettuce per day (a source of K1) reportedly have a relative risk of 0.55 for hip fracture.¹¹⁴ Patients with osteoporotic fractures of the spine and femoral neck have been found to be markedly deficient in K1 and the MK-7 and MK-8 forms of K2.^{115,116} A review by Cockayne et al. suggested that the majority of vitamin K intervention studies have demonstrated a reduction in BMD loss and improved bone biomarkers.¹¹⁷ A 3-year trial of vitamin K2 (mk-7, 180 mcg/day) in postmenopausal women reported preservation of BMD in the lumbar spine and slowing of the rate of bone loss in the femoral neck.¹¹⁸ On the other hand, the ECKO trial in postmenopausal women with osteopenia used 5-mg vitamin K1 daily did not show any significant change in BMD.¹¹⁹

Vitamin K1 comes from plants and vitamin K2 is produced by gut bacteria. Vitamin K works with vitamin D to mineralize the bone.

Subclinical vitamin K deficiency is common, with typical dietary intakes below the levels associated with decreased fracture risk.¹²⁰ The DRI for vitamin K is 90 mcg for adult women and 120 mcg for adult men; however, amounts of 254 mcg/day or higher may be required for optimum bone health.¹²¹ A number of researchers have called for unique DRI's for each form of vitamin K because K2 appears to have an important role in the prevention of vascular calcification and cancer.⁶¹ The best sources of K1 are green leafy vegetables, such as lettuce,

collards, spinach and kale, and other vegetables rich in chlorophyll, such as broccoli. Sources of vitamin K2 include animal foods, such as cheese, egg yolks, butter, goose liver, chicken liver, chicken and beef. Natto, a fermented soybean food, is a particularly rich source of K2.¹²²

Dosage

Adequate vitamin K1 can be readily obtained from green vegetables. If supplementation is needed, the mk-7 form of vitamin K2 is recommended because it results in significantly higher and more stable vitamin K serum levels when compared to K1 or the mk-4 form of K2.^{123,124} The recommended dose of mk-7 is 45–90 mcg daily. Vitamin K is a fat-soluble vitamin and thus is best absorbed when taken with a fat-containing meal.

Precautions

Vitamin K supplements should not be used by patients taking anticoagulants.¹²⁵ For others, vitamin K supplementation does not affect coagulation and has an excellent safety profile. The Institute of Medicine does not list a safe upper limit for vitamin K¹²⁶ and, in Japan, studies are commonly conducted using doses of vitamin K2 that are 500 times or more higher than the daily recommended intake in the United States, with no significant side effects reported.¹²⁷

Magnesium

In comparison to calcium, the relationship between magnesium and bone health has been much less well studied. Epidemiological studies have linked higher magnesium intakes with increased BMD.^{10,128} Low magnesium intakes can decrease the number and function of osteoblasts, increase the number and activity of osteoclasts, and promote inflammation and oxidative stress.¹²⁹ Magnesium is also required for the conversion of vitamin D to 1,25-dihydroxycholecalciferol (calcitriol).¹²⁹ Some intervention trials of magnesium supplementation have shown an increase in BMD, as well as reduced fracture rates.^{130,131} Almost half of the U.S. population does not obtain the daily recommended intake for magnesium.¹³² Low magnesium intakes are also associated with a number of other chronic health conditions, such as type 2 diabetes and

hypertension.¹³² Good sources of magnesium include dark green leafy vegetables; nuts and seeds; legumes; and whole grains. Supplemental magnesium is readily-available singly or in combination with calcium. Magnesium citrate has superior bioavailability and has been recommended as the best form to use.¹³³

Trace Minerals

Several trace minerals, including zinc, copper, boron, and manganese, act as cofactors for specific enzymes important for bone metabolism. Serum concentrations of zinc and copper have been found to be lower in osteoporotic women than in controls.¹³⁴ A varied, whole foods diet in addition to a good-quality multivitamin/mineral supplement should ensure an adequate supply of these nutrients.

Vitamin C

Vitamin C (ascorbic acid) is a required cofactor for the formation of collagen, a key component of the bone matrix. Vitamin C is also a major water-soluble antioxidant in the body. Plasma levels of vitamin C and other antioxidants have been found to be substantially lower in postmenopausal women with osteoporosis compared with age-matched controls.¹³⁵ The Framingham Osteoporosis Study found that elderly men and women in the highest tertile of total and supplemental vitamin C intake had significantly fewer hip and nonvertebral fractures, with a total intake of ~200 mg/day associated with the lowest prevalence of fracture.¹³⁶ A case-control study of elderly Chinese individuals found that higher dietary intakes of vitamin C, vitamin E, beta-carotene, and selenium were associated with a lower risk of hip fracture.¹³⁷ The best dietary sources of vitamin C are fruits and vegetables, such as papaya, pineapple, oranges, broccoli, and bell peppers. An antiinflammatory diet should easily supply adequate amounts of vitamin C.

Green leafy vegetables are super foods in relation to bone health as they contain vitamin K, magnesium, vitamin C, and calcium.

Soy

Soybeans are good sources of high quality plant protein, phytoestrogens, minerals, vitamins, essential fatty acids, and fiber. However, results from

studies of soy foods and soy isoflavones (SI) in relation to bone health have been mixed. A 3-year trial of SI in postmenopausal women demonstrated nil effects other than a modest bone-sparing effect at the femoral neck.¹³⁸ On the other hand, a systematic review of SI supplements by Wei et al. found that isoflavones increased BMD by 54% and decreased deoxyypyridinoline (DPD), a bone resorption marker, by 23%. The effects were greatest for postmenopausal women receiving an SI dose > 75mg/d.¹³⁹ Several large population-based studies of soy food intake have also reported beneficial effects. The Shanghai Women's Health Study found a relative risk of fracture of 0.63 in the highest quintile of soy protein intake (≥ 13 g/day).¹⁴⁰ This study, which examined food frequency questionnaires of 75,000 Chinese women aged 40 to 70 years old, also found a significant reduction in fracture risk, even in women in the second quintile, at soy protein intakes of 5 g/day (21 mg/day of isoflavones). This study examined the intake of traditionally-eaten whole soy foods, such as tofu and fresh soybeans, rather than isolated isoflavones. The Singapore Chinese Health Study also studied intake of traditional soy foods and found a significant reduction in hip fracture risk for women but not for men with higher soy intakes.¹⁴¹ However, data from this study also demonstrated that both men and women had significantly lower hip-fracture risk following an overall dietary pattern labeled "vegetable-fruit-soy."¹⁴²

There is reason to believe that a dietary pattern that includes whole soy foods as they have been traditionally eaten is more beneficial to bone health than isolated constituents of soy.^{143,144}

Dosage

Based on available evidence, 1–2 servings/day of whole soy foods, such as tofu, tempeh, and edamame, are recommended.

Considerations in Childhood, Adolescence, and Young Adulthood

Up to 90% of peak bone mass is attained by age 18 in girls and by age 20 in boys.^{145,146} Thus, osteoporosis prevention programs should begin early in life. Peak bone mass is influenced by genetic factors as well as by diet and physical activity during childhood, adolescence, and young

adulthood. Regular physical activity and adequate calcium intake are key factors for achieving peak bone mass.¹⁴⁷ Sufficient vitamin D throughout bone-building years is also important.¹⁴⁸

Botanicals

Numerous in vitro and animal studies, and a smaller number of human trials, have investigated the potential of herbal medicines to enhance bone health.³⁷ A study of Shen Gu (mixture for nourishing kidney and strengthening bone: *Fructus psoraleae* 16 g, *Radix codonopsis* 16 g, *Rhizoma drynariae* 16 g, *Cortex eucommiae* 16 g, *Radix Rehmanniae preparata* 20 g, *Radix astragali* 20 g, *Radix glycyrrhizae* 6 g; the treatment group was given 25 mL of the formula twice a day for 6 months) in 96 osteoporotic patients found significant favorable effects on bone.¹⁴⁹ The Ayurvedic preparation Reosto (ingredients per tablet: *Terminalia arjuna* 45 mg, *Withania somnifera* 45 mg, *Commiphora wightii* 235 mg, *Sida cordifolia* 45 mg, *Vanda roxburghi* 50 mg, *Godanti bhasma* 120 mg, *Kukkutandatvaka bhasma* 35 mg; the treatment group received two tablets twice a day for 12 months) has been found to significantly increase BMD.¹⁵⁰ Deng et al. published the first study of Fufang (herbal formula: *Herba epimedii*, *Rehmannia glutinosa*, *Dioscorea batatas*, *Cornus officinalis*, *Cinnamomum cassia*, *Drynaria fortunei*, *Morinda officinalis*; the treatment group received a dose of 10 g/day of dried granules; the doses of each herb are not available) using fracture as one of the primary endpoints. Postmenopausal women were found to have improvements in BMD and an impressive 43% reduction in fragility fractures over a 5-year period.¹⁵¹ *Dioscorea spongiosa*,^{152,153} *Astragalus membranaceus*,¹⁵⁴ walnut extract (*Juglans regia* L.),¹⁵⁵ and curcumin, a compound found in turmeric root (*Curcuma longa*),¹⁵⁶ have also demonstrated osteoprotective effects in laboratory and animal studies. Further research is required to elucidate the role of botanical medicines in the prevention and treatment of osteoporosis.

Tea (*Camellia sinensis*)

Tea has antiinflammatory effects, cardiovascular benefits, and cancer protective properties.^{157,158} Tea drinking appears to have beneficial effects on bone, with several studies linking tea consumption to modest increases in BMD.^{158,159}

Mind-Body Connection

Chronic stress, through activation of the sympathetic nervous system, tends to exert catabolic effects on the body that result in the breakdown of energy stores and body tissues. In animal studies, both chronic stressors and the administration of glucocorticoids have been shown to stimulate bone resorption.^{160,161} Major depression¹⁶² and anorexia nervosa¹⁶³ are both associated with elevated serum cortisol levels and increased bone loss. Increased sympathetic nervous system activity stimulates resorption of bone by osteoclasts and inhibits bone formation by osteoblasts.¹⁶⁴

Stress reduction, using mind-body practices, such as meditation, self-hypnosis, guided imagery, breath work, or biofeedback, is highly recommended as part of an integrative plan to support bone health and overall well-being.

Exercise

In addition to high-quality nutrition, exercise is the other major factor required to build and maintain strong bones. Bone is a dynamic tissue that responds to physiological and biomechanical signals. Both general physical activity and mechanical loading contribute to building peak bone mass, beginning in the prepubertal years.^{165,166}

Bone density at all skeletal sites is strongly correlated with muscle mass, and muscle mass is strongly linked to physical activity.¹⁶⁷ Muscle mass generally increases until approximately the age of 30 years and begins to decline after 50 years of age. Muscle strength losses tend to be most striking after the age of 70 years. However, regular exercise at any age, even in very old persons, can result in increased muscle strength, balance, and functional capacity.^{168,169}

Exercise training programs in premenopausal and postmenopausal women have been consistently shown to prevent or reverse bone loss in both the lumbar spine and the femoral neck.¹⁷⁰ The Bone Estrogen Strength Training (BEST) Study found that postmenopausal women who received 800 mg/day of calcium citrate, along with a structured exercise program, increased their muscle mass by 11% to 21% and BMD by approximately 2%.¹⁷¹ Even women with established osteoporosis can improve their bone mass with a low-impact exercise program.¹⁷² Fracture risk can also be decreased with exercise programs. Walking for at least 4 hours per week has been found to decrease hip fracture risk by 41%.¹⁷³ A

separate study of postmenopausal women found a reduced risk of vertebral fractures after a 2-year program of back-strengthening exercises.¹⁷⁴

In the Senior Fitness and Prevention (SEFIP) study, 246 women older than 65 years were randomized to an 18-month exercise program or a wellness program. Participants in the exercise program demonstrated an increase in BMD at the spine of 1.77% (compared to an increase of 0.033% in controls) and at the femoral neck of 1.01% (compared to a decrease of 1.05% in controls). Further, fewer falls occurred in the exercise group (1.0 per person compared with 1.66 in the control group) and health care costs were lower in the exercise group.¹⁷⁵ A meta-analysis of the effects of exercise on BMD concluded that “mixed loading impact” exercise is associated with significant increases in BMD at the lumbar spine and femoral neck.¹⁷⁶

Dosage

Recommended physical activities include walking, gentle and vigorous aerobic exercise, jumping, running, weight training, and racquet sports. Ideally, individuals should aim for 30 to 45 minutes of exercise, five or more times per week. Weight training is best performed on alternate days. Tai chi may have a number of beneficial effects, including reducing fall frequency, improving balance and strength, and maintaining BMD.^{177,178}

Substances That May Be Harmful to Bone Health

Sodium

The mean sodium intake in the US (3500 mg/day) exceeds the recommended intake of <2400 mg/day, and high salt diets are known to increase urinary calcium excretion.⁶³ The DASH II diet (Dietary Approaches to Stop Hypertension and Sodium Reduction), which included 9.5 servings of fruits and vegetables per day, low fat dairy products, whole grains, and reduced meat and sodium intake, resulted in decreased calcium losses and reduced bone turnover.¹⁷⁹ The bone benefits of the DASH II diet appear to be related to its overall dietary composition rather than to a reduction in sodium intake per se. Increasing calcium and potassium intakes can substantially offset the

urinary losses of calcium caused by high sodium intakes.⁶⁴ However, a high sodium intake along with a low calcium intake may lead to detrimental effects on bone health.¹⁸⁰ Because many individuals do not obtain adequate calcium in their diets, patients should be advised to stay within the recommended sodium intake of <2400 mg/day.

Caffeine

Some studies have found that excessive caffeine intake is associated with a modest increase in the risk of osteoporotic fracture.⁶⁵ The increased risk appears to occur in women who consume >300 mg of caffeine/day or approximately 4 cups of coffee and who also have a low calcium intake. Individuals with optimal calcium intakes should not experience any negative effects of moderate intake of caffeinated beverages on bone health.¹⁸¹ Furthermore, a study that followed over 60,000 women for 20 years found that those drinking 4 or more cups of coffee per day had slight decreases in BMD but no increased fracture risk.¹⁸² Accordingly, although it is prudent to avoid excessive intake, caffeine does not appear to be a major risk factor for bone disease.

Vitamin A

Vitamin A (retinol) intakes of >5000 mcg/day have been associated with an increased risk of hip fracture¹⁸³; however, more recent data has failed to confirm this effect. An intervention study found no increase in fracture risk among more than 2000 adults who took a controlled, high-dose retinol supplement (25,000 IU retinyl palmitate/day) for up to 16 years.¹⁸⁴

Smoking

Cigarette smoking is an independent risk factor for low BMD and the negative effect increases with amount and duration of smoking.¹⁸⁵ Smoking also has negative effects on bone health unrelated to BMD.¹⁸⁶ The effect of smoking on fracture risk may be related to lower body mass, earlier age of menopause, estrogen-lowering effects, impaired calcium absorption, or increased production of free radicals.¹⁸⁷ In the Nurses' Health Study, smokers had a relative risk of 1.2 for hip fracture, and this figure rose to 1.4 for those who smoked \geq 25 cigarettes/day.¹⁸⁸ A meta-analysis involving >59,000 men and women found that smokers have a relative risk of 1.13 for any fracture and a relative risk of 1.6 for hip fractures.¹⁸⁹ Clearly, for many reasons, men and women should be

encouraged not to begin smoking. Current smokers who quit will obtain benefits related to bone health after a period of 10 years.¹⁸⁸

Alcohol

Animal studies showed that chronic heavy alcohol consumption, particularly during adolescence and young adulthood, can significantly damage bone health.¹⁹⁰ On the other hand, low or moderate consumption of alcohol in adulthood appears to have protective effects on bone health.^{191,192} Moderate alcohol consumption has recognized cardiovascular benefits¹⁹³ but can also increase the risk of breast cancer in women¹⁹⁴ and has other potentially detrimental effects on health.¹⁹⁵ Men may benefit from a daily alcoholic beverage, whereas women should be advised to have fewer than seven alcoholic drinks per week.

Pharmaceuticals

Osteoporosis is best approached with a lifelong, comprehensive prevention program. Women of all ages should be informed of the diet and lifestyle choices listed previously to support bone health, with secondary causes of osteoporosis corrected whenever possible. In addition, pharmacological therapy may be recommended for the prevention or treatment of osteoporosis. Guidelines for initiating therapy currently vary between organizations. The 2010 North American Menopause Society (NAMS) guidelines recommend treatment in postmenopausal women:

- with prior vertebral or hip fracture
- with hip or spine T-scores lower than -2.5
- and with T-scores between -1.0 and -2.5 and a FRAX score that indicate a 10-year hip-fracture risk of $\geq 3\%$ or an overall osteoporotic risk of $\geq 20\%$ ¹⁹⁶

The number needed to treat (NNT) is a useful communication tool for discussing the benefit and potential risks of medications. The NNT for osteopenia or osteoporosis depends on the degree of risk for a fracture. This number is especially instructive in osteoporosis because the NNT to prevent one fracture in low risk women tends to be quite high. A useful clinical tool comes from the physicians who created thennt.com. Their review of the literature led to a recommendation against bisphosphonate preventive therapy for women without a history of fracture or very low BMD because no fractures were prevented over a 3-year period and side

effects occurred.¹⁹⁷ The same authors recommended the use of bisphosphonate therapy for women with a prior history of fracture or very low bone density. The NNT was 20 to prevent a vertebral fracture and 100 to prevent a hip fracture in the latter group.¹⁹⁸ NNT allows a frank and specific discussion of the potential usefulness of pharmaceuticals for preventing osteoporosis. When the NNT is high or when the number needed to harm (NNH) is low, women with a preference for taking fewer medications or addressing health challenges with a more natural approach may decide to use lifestyle measures and reassess prior to, or instead of, taking a medication.

Role of Estrogen

Bone loss accelerates as estrogen levels fall in the years following menopause. The primary action of estrogen on bone is to inhibit osteoclast activity by increasing the amount of osteoprotegerin produced by osteoblasts.¹⁹⁹ Estrogen also has antiinflammatory effects and suppresses the production of bone-resorbing cytokines. Consequently, at the time of menopause, the concentration of inflammatory cytokines involved in the induction of osteoclastogenesis rises.²⁰⁰

Postmenopausal hormone therapy (HT) has beneficial effects on bone, reduces the risk of colon cancer, and can alleviate hot flashes and vaginal dryness. Conversely, women who use HT have an increased risk of cardiovascular disease, stroke, thromboembolic events, and breast cancer.²⁰¹ In the WHI trial, women receiving HT with conjugated equine estrogen, either alone or with medroxyprogesterone acetate, had increased BMD and lower fracture rates.²⁰¹

The dose of HT required to enhance bone health without increasing the risks of other diseases remains unknown. For example, a 2-year randomized controlled trial (RCT) of 417 postmenopausal women who received transdermal estradiol at a dose of 0.014 mg per week compared to placebo reported that the active group had increased lumbar and hip bone density as compared to the placebo group. Bone turnover markers were reduced and endometrial hyperplasia was not increased by HT in this study.²⁰² Because long-term studies of ultra-low dose transdermal estradiol have not been performed, the associations with breast cancer and heart disease are unknown. The NAMS acknowledges the aforementioned limitations of long-term HT and recommends the use of the lowest effective dose possible.²⁰³ The United States Preventive Services Task Force recommends against using HT to prevent chronic

disease.²⁰⁴ Clearly, the use of HT should be individualized based on a careful exploration of the risks and benefits for individual patients.

Bisphosphonates

Bisphosphonates are indicated for both the prevention and treatment of postmenopausal osteoporosis. As an antiresorptive therapy, bisphosphonates reduce fracture risk by inhibiting the activity of osteoclasts and reducing bone turnover, thus increasing bone mass. The most common side effects of bisphosphonates are dyspepsia, nausea, esophagitis, and abdominal pain. Rare but serious adverse effects include atypical femur fractures, esophageal cancer, and osteonecrosis of the jaw. Vitamin D and calcium status should be assessed and addressed prior to initiating the administration of bisphosphonates.

FDA-approved bisphosphonates for the prevention and/or treatment of osteoporosis in the United States include alendronate (Fosamax, Fosamax Plus D), risedronate (Actonel, Actonel with Calcium, Atelvia), etidronate (Didronel), ibandronate (Boniva), and zoledronic acid (Zometa, and Reclast). They are variably dosed daily, weekly, monthly, or yearly, and either orally or intravenously.

Alendronate was the first bisphosphonate studied for osteoporosis, and it has been shown to increase BMD and reduce the incidence of fractures of the spine and hip in women with osteoporosis.²⁰⁵⁻²⁰⁷ The usual dose range of alendronate is 35 mg (for prevention) to 70 mg (for treatment) once weekly. Risedronate was studied in two large trials and was shown to increase BMD and reduce vertebral and some nonvertebral fracture rates.^{208,209} The usual dose of risedronate is 35 mg once weekly. Ibandronate is convenient in that it may be given as a once-per-month dose of 150 mg, with two studies supporting its use.^{210,211} Ibandronate has not been demonstrated to reduce nonvertebral fractures. Of the three oral forms, alendronate has the lowest 3-year NNT for the prevention of vertebral fractures (NNT = 15; Tables [36.4](#) and [36.5](#)).

Zoledronic acid is an intravenous form of bisphosphonate approved for postmenopausal osteoporosis. The usual dose is 5 mg once a year. Patients find the annual dosing to be more convenient, and it minimizes the gastrointestinal side effects common with oral bisphosphonates. However, intravenous administration is associated with acute phase reaction symptoms, such as myalgia, arthralgia, fever, mild headache, and flu-like symptoms. Zoledronic acid has been found to increase BMD and reduce hip and vertebral fractures.²¹²

The choice of bisphosphonate depends on multiple clinical factors as

well as patient preferences.²¹³ If hip fracture prevention is of primary concern, current evidence is strongest for alendronate and zoledronic acid. Annual intravenous administration is associated with better compliance and is preferred by many women over weekly oral administration.²¹⁴ Atelvia need not be taken on an empty stomach, easing its administration. In women with high risk of breast cancer, raloxifene (discussed in the following) may represent the most appropriate choice.

The optimal length of bisphosphonate treatment has become clearer since the Fosamax Fracture Intervention Trial Long-Term Extension (FLEX) trial which reported no difference in vertebral fractures between women who continued alendronate for 10 years and those who stopped treatment after 5.²¹⁵ The FDA recommends that some patients may be able to stop bisphosphonates after 3–5 years and maintain the benefits of treatment.²¹⁶

Selective Estrogen Receptor Modulators

Selective estrogen receptor modulators (SERMs) act as estrogen agonists or antagonists depending on the tissue. Raloxifene, a second-generation SERM, has been shown to be an estrogen agonist in bone and liver, maintain bone density, and lower LDL cholesterol. It does not stimulate the endometrium and is a potent estrogen antagonist in breast tissue. It has been studied for the prevention and treatment of osteoporosis.²¹⁷⁻²²⁰ The 3-year NNT to prevent vertebral fractures is 16 for women with a history of prior fracture and 46 for women at increased risk.²²¹ Raloxifene also significantly reduces the risk of breast cancer and improves lipid profiles. The usual dose of raloxifene is 60 mg/day. Side effects include hot flashes, deep vein thrombosis, and pulmonary embolism.

Bazedoxifene is a third generation SERM that has been studied and approved for osteoporosis. Bazedoxifene is an agonist in bone and lipid metabolism and an antagonist in breast and endometrium. It has been shown to prevent both vertebral and nonvertebral fractures.²²² Side effects include hot flashes and leg cramps in addition to venous thromboembolism, a more serious complication. In the United States, bazedoxifene is currently only available in combination with conjugated estrogen for use in preventing postmenopausal osteoporosis.

TABLE 36.4

Vertebral Fracture Prevention Studies

Medication	Dose	3-year NNT to Prevent Vertebral Fracture	Trial
Alendronate (Fosamax)	5 mg/day for 2 yr then 10 mg/day	15/34	FIT
Ibandronate (Boniva)	2.5 mg/day or 20 mg eod for 12 doses every 3 months	21	BONE
Risedronate (Actonel)	2.5 or 5 mg/day	20	VERTA-NA
Zoledronic acid (Reclast)	5 mg IV every yr	14	HORIZON
Raloxifene (Evista)	60 mg/day	46/59 (no prior fracture) 16/10 (with prior vertebral fracture)	MORE
Denosumab	60 mg sq every 6 months	21	FREEDOM
Teriparatide (Forteo)	20 mcg sq/day	12	—

Calcitonin

Calcitonin is produced by thyroid C cells and acts to inhibit bone resorption by inhibiting osteoclast activity. Calcitonin from salmon was initially approved by the FDA in 1984 to treat osteoporosis in women and is effective in reducing the pain associated with acute compression fractures of the vertebrae. It may reduce the incidence of vertebral fractures. Side effects are usually minor and include flushing, nausea, and diarrhea. Recent data has revealed an increased risk of malignancy

which will likely limit the applicability of calcitonin in the treatment of acute fracture pain.²⁰⁰ Calcitonin is usually dosed as a daily intranasal spray of 200 IU.

Teriparatide

Teriparatide (PTH 1-34) is a medication that includes a sequence of the final 34 amino acids contained in parathyroid hormone. Teriparatide has anabolic effects on bone and stimulates bone formation in addition to bone remodeling. Two large trials, the Fracture Prevention Trial (n = 1637) and the Treatment of Osteoporosis with Parathyroid Hormone (n = 2532) reported a reduced incidence of vertebral and nonvertebral fractures in postmenopausal women following the use of teriparatide.^{223,224} The European Study of Forsteo followed three groups of women for a second year of treatment. The women who received a second year of Teriparatide had further increases in bone density, those switched to raloxifene maintained bone density, and those switched to placebo had a reduction in bone density.²²⁵ The 3-year NNT to prevent vertebral fractures was reported to be 12. Teriparatide is administered as a once-daily subcutaneous injection (20 mcg) for a period of up to 2 years, which may then be followed by an antiresorptive agent (in rats, osteosarcoma has occurred with longer treatment duration and higher doses). Side effects include nausea and headaches.

Denosumab

Denosumab is a human monoclonal antibody that binds to RANKL (receptor activator for nuclear factor kappa-B ligand), thereby blocking binding to RANK and inhibiting osteoclast activity, decreasing bone resorption, and increasing bone density. Prescribed at a dose of 60 mg subcutaneously every 6 months, denosumab has been FDA-approved for the treatment (but not prevention) of osteoporosis. The NNT from the Fracture Reduction Evaluation of Denosumab in Osteoporosis Every 6 Months (FREEDOM) trial, which randomized 7868 women, was 21.²²⁶ Side effects include urinary and respiratory infections, cataracts, constipation, rashes, and joint pain. Rare but serious infections observed in the FREEDOM extension trial include osteonecrosis of the jaw and atypical fractures.²²⁷ Because RANK and RANKL are members of the tumor necrosis factor superfamily, concern remains that inhibiting RANKL may increase the risk of cancer.

Pharmaceuticals to Avoid

Many pharmaceuticals can negatively impact bone density. Commonly prescribed medications with this effect include: antidepressants from the selective serotonin inhibitor class, antiseizure medications, breast cancer treatment (aromatase inhibitors and Tamoxifen), chemotherapeutic agents, gonadotropin releasing hormones used for fertility treatment or medroxyprogesterone acetate used for contraception, proton pump inhibitors, steroids, and any excess use of thyroid hormone.

Prevention Prescription

Recommendations to build and maintain healthy bones:

- An antiinflammatory diet that includes an abundance of fruits and vegetables, healthy fats, whole grains, legumes, and antiinflammatory herbs, teas, and spices
- Adequate calcium intake from diet +/- supplements
- A serum 25-OH vitamin D concentration in the range of 40 ng/mL
- An intake of vitamin K1 and K2 equaling at least 90 mcg for women and 120 mcg for men
- A balanced ratio of omega-6 to omega-3 fatty acids
- Adequate but not excessive protein (0.8 g/kg), including some vegetarian protein sources
- One to two servings per day of whole soy foods
- A good-quality multivitamin and mineral supplement
- Physical activity for 30 to 45 minutes most days of the week that includes weight-bearing, aerobic, and weight-lifting exercise
- A daily mind-body practice
- Avoidance of smoking and avoidance of excess alcohol intake
- Reduction of the risk of falls and, if possible, avoidance of medications that harm bone or increase the risk of falls
- Pharmaceutical therapies that are individualized, with risk and benefits explored with each patient

Therapeutic Review

An integrative approach encompassing diet, exercise, supplements, and mind-body therapies, as well as pharmaceutical medications when

indicated, is recommended to prevent and treat osteoporosis. The same strategies that help people build healthy bones will also protect them against heart disease, diabetes, depression, and a host of other chronic conditions.

Lab Evaluation

- 25-hydroxy vitamin D level
- Dual x-ray absorptiometry bone scan
- Consider high sensitivity C-reactive protein, thyroid-stimulating hormone, calcium, and alkaline phosphatase.

Lifestyle

- Avoid first-hand and second-hand smoke exposure. 

Exercise

- 30 to 45 minutes/day of aerobic, weight-bearing, and weight-lifting exercise (patients with osteoporosis should consult with a health professional to plan an appropriate, safe exercise program) 

Nutrition

- Limit sodium 
- Antiinflammatory diet 
- Calcium-rich diet (see [Table 36.2](#)) 
- Adequate protein intake from plant sources more than from animal sources; one to two servings a day of whole soy foods 
- Vitamin K-rich foods 
- Tea (*Camellia sinensis*): 2 cups a day 

Supplements

- Vitamin D: 1000 to 2000 units/day 
- Calcium citrate or carbonate as required such that total daily intake from diet, in addition to supplements, is at least 800 mg/day. 
- Multivitamin and multimineral: minerals should include zinc, copper,

magnesium, boron, and manganese. 

Mind-Body Therapy

- Meditation, self-hypnosis, guided imagery, biofeedback, and breath work 

Pharmaceuticals

Prevention

- For women with osteopenia alone, pharmaceutical treatment is no longer recommended due to NNH exceeding NNT.

Treatment

- Consider a bisphosphonate in women with a previous osteoporotic fracture, or a T-score between 1.0 and -2.5 and FRAX score with 10-year hip fracture risk of $\geq 3\%$ or overall osteoporotic risk of $\geq 20\%$. 
- Consider raloxifene in women who fail bisphosphonate therapy due to GI side effects and/or are also at increased risk of breast cancer  (for  nonvertebral fractures).
- Note: For hip fracture prevention, etidronate and ibandronate (bisphosphonates), and raloxifene (SERM) lack evidence of superiority compared to placebo. 
- Consider teriparatide in patients who fail bisphosphonate therapy. 
- Consider denosumab in patients who fail bisphosphonate therapy. 
- Limit use of calcitonin to treat pain associated with vertebral compression fracture.

CHAPTER 37

An Integrative Approach to Obesity

James P. Nicolai, MD, Junelle H. Lupiani, RD, and Andrew J. Wolf, MEd

Introduction

Pathophysiology

Definition of Overweight and Obesity

In 2004, obesity was reclassified by Medicare as a chronic disease. Obesity is characterized by an excess of body fat and is most often defined by the body mass index (BMI), a mathematical formula that correlates well with excess weight at the population level. The BMI is measured by taking weight in kilograms divided by height in meters squared (kg/m^2). Worldwide, adults with a BMI of 25 to 30 are categorized as overweight, whereas obesity is classified according to stages or grades ([Table 37.1](#)). Grade III obesity was formerly known as morbid obesity; however, the term was appropriately changed for several reasons: morbidity may not occur at a BMI higher than 40 but certainly can be found at BMIs lower than that. BMI can sometimes be inaccurate because it does not distinguish between fat and muscle, nor does it predict body fat distribution. On a population level, however, BMI does seem to track trends in adiposity as opposed to muscularity, and individuals with large muscle mass and resulting high BMIs are easily distinguishable from those with large amounts of adipose tissue.

In a clinical setting, the most valuable measurement strategy for classifying weight other than the BMI is waist circumference. The presence of extreme abdominal fat has been shown to be an independent

risk factor for diabetes, high blood pressure, and cardiovascular disease.⁶ Waist circumference is obtained by placing a measuring tape in a horizontal plane around the waist at the level of the umbilicus and the superior iliac crests.

Risk of obesity and associated diseases is increased if waist circumference is greater than 40 inches in male patients and greater than 35 inches in female patients.

In children, the term obesity is generally not used because of the potential prejudicial issues that may ensue when a child is labeled with such a title. As a result, being overweight in children is defined conservatively as being at or higher than the 95th percentile of age- and sex-adjusted weight. Children who are at the 85th to 94.9th percentile for weight are considered overweight. Increasing concern about the potentially high numbers of overweight children not classified correctly has prompted an ongoing initiative to revise the definition.

Obesity-Related Health Risk and Morbidity

The disease risk profile based on BMI and waist circumference is described in [Table 37.2](#). Evidence shows that obesity is a proinflammatory state that increases the risk of several chronic diseases, including hypertension, dyslipidemia, diabetes, cardiovascular disease, asthma, sleep apnea, osteoarthritis, and several cancers.⁷ Excess weight may also promote gallstone formation, fatty liver, gastroesophageal reflux, menstrual abnormalities, infertility, stress incontinence, gout, carpal tunnel syndrome, and low back pain.⁸⁻¹² Obese adults have more annual admissions to hospitals, more outpatient visits, higher prescription drug costs, and worse health-related quality of life than do adults of normal weight.¹³

More information on this topic can be found online at ExpertConsult.com.

Pathogenesis

The challenge with understanding the etiology and pathogenesis of obesity is that this condition is, ultimately, the result of a relatively straightforward series of outcomes (uncontrolled weight gain) achieved

by a set of complex and dynamic interactions. The notion that obesity is a direct result of long-term mismatches in energy balance, with daily intake of energy greater than daily output, may not be true. The state of positive energy balance may not be due to too many calories in and not enough calories out, but may be a direct result of a complex set of interactions producing a multitude of genetic, hormonal, and metabolic signals that produce a state of fat storage versus fat burning.²³

The United States stands at the center of a global obesity epidemic in both adults and children. According to data from the World Health Organization (WHO), 1.6 billion adults worldwide were overweight in 2005. At least 400 million adults were obese, and 20 million children younger than 5 years of age were overweight. Some 2.3 billion adults will be overweight, and 700 million will be obese by the year 2015.¹ On the U.S. soil, being overweight and obesity affect 65%–80% of adults and a rising proportion of children, with the prevalence of obesity increasing year by year. Evidence suggests that the more extreme degrees of obesity are rapidly increasing over time compared with being overweight.²

This finding is deeply worrisome because central adiposity points toward an increased risk of insulin resistance, metabolic syndrome (hypertension, dyslipidemia, and type 2 diabetes), and its eventual transition to cardiovascular disease. The health implications of an increasing, uncontrollable rise being overweight and obese predict a corresponding rise in the chronic health risks that accompany these conditions.

The impact of obesity on children demonstrates the dire seriousness of this epidemic. Since 1990, because of childhood obesity, type 2 diabetes has been transformed from a disease that once affected adults in midlife to a pediatric epidemic affecting children as young as 6 years old.¹⁴ At current rates of incline, type 2 diabetes in children is projected to soon be higher than rates of type 1 diabetes. Obesity in children produces a risk profile similar to that of adults thus raising the risk of several conditions, including hypertension, dyslipidemia, gallstones, and sleep apnea as well as increasingly elevated levels of androgens, promoting orthopedic abnormalities (e.g., slipped capital epiphyses), and increased intracranial pressure.¹⁵

Calories encompass the value that determines this state of energy balance. We eat food, and various metabolic processes in our bodies break it down into energy. The relationship between energy and matter is under the control of the laws of physics, specifically the first law of thermodynamics, proved by Sir Isaac Newton, which states that all

energy in the universe is conserved. In relation to food, when more energy is taken in by the body relative to the energy consumed, the surplus is ultimately converted into matter. This works well in a vacuum, but it may not be easily translated into the real world. Although energy intake is relatively determined by food and drink, with each having a particular caloric value, the nature of that matter can vary. Thus calories may not be equal and can translate into differing amounts of energy burned by the body over a fixed period of time. Although a pound of lead and a pound of feathers may drop in a vacuum at the same speed, when a similar experiment is conducted outside, air resistance causes the lead to drop like a stone and the feathers to float to the earth at a leisurely pace. Calories operate in a similar fashion. The calories you eat are absorbed at different rates and have different amounts of fiber, carbohydrates, protein, and fat, along with other chemicals and nutrients that may translate into different metabolic signals that affect the energy equation.²⁴ Consequently, if it is true that calories are not equal, calorie type may influence energy balance as much as amount. A study from the Harvard School of Public Health confirmed this to be true; overweight patients fed 300 more calories per day actually lost more weight than did their counterparts who were eating food of different composition.²⁵

TABLE 37.1
Adult Classification of Being Overweight

Classification	Body Mass Index (kg/m²)
Underweight	18.5
Normal weight	18.5–24.9
Overweight/preobese	25.0–29.9
Obese	
Class I	30.0–34.9
Class II	35.0–39.9
Class III	40.0 or higher

Adapted from the National Heart, Lung and Blood Institute, National Institutes of Health. *The Practical Guide: Identification, Evaluation, and Treatment of Overweight and Obesity in Adults*. NIH publication no. 00–4084. Bethesda, MD: U.S. Department of Health and Human Services, 2000.

Whereas we are beginning to discover the inherent complexity on the left side of the energy equation (calories in), measuring energy output has always been a much more intricate calculation because of the complex interaction and number of variables that determine how calories are consumed. Energy output is expressed as the sum of various processes, including resting energy expenditure, basal metabolic rate, physical activity, rates of growth, and thermogenesis. Studies have confirmed that macronutrient distribution, endocrine factors, and diverse genetic predispositions may contribute important mitigating influences at any given level of calorie consumption.² We are also discovering that the vast microbiome of the gut may play a critical role in how these complex interactions are affected.²⁷

Although the pathogenesis of obesity involves a set of complex multifactorial details to explain a relatively simple condition, what should not be forgotten is that human physiology is much the same as it has always been. The increase in obesity prevalence in the past few decades cannot be explained by changes in the human gene pool, but rather by environmental changes and their interactions with us that have not been seen previously in our collective history. An environment that promotes excess food intake of poor quality and discourages physical activity will most surely produce obesity in a species that has adapted itself to survive by responding to caloric scarcity within the confines of a world that demands a significant level of energy expenditure.¹³

TABLE 37.2

Classification of Overweight and Obesity and Associated Disease Risk

Classification ^a	BMI (kg/m ²)	Obesity Stage	Disease Risk: (Relative to Normal Weight and Waist Circumference) ^b	
			Waist Circumference	Waist Circumference
			Men: up to 40 in. (up to 102 cm); women: up to 35 in. (up to 88 cm)	Men: more than 40 in.; women: more than 35 in.
Underweight	Lower than 18.5	—	—	—
Normal	18.5–24.9	—	—	—
Overweight	25.0–29.9	—	Increased	High
Obese	30.0–34.9	I	High	Very high
	35.0–39.9	II	Very high	Very high
Extremely obese	40.0 or higher	III	Extremely high	Extremely high

BMI, body mass index.

^a For persons 20 years old and older.

^b Disease risk for type 2 diabetes mellitus, hypertension, and cardiovascular disease. Increased waist circumference can be a marker for increased disease risk, even in persons of normal weight.

Adapted from World Health Organization. *Preventing and Managing the Global Epidemic of Obesity*. Report of the World Health Organization Consultation of Obesity. Geneva: World Health Organization; 1997.

Integrative Assessment

Ideally, assessment and treatment of obesity should be done within the setting of a multidisciplinary team designed to manage medical, nutritional, emotional, and exertional components of the desired lifestyle intervention—in this case, weight loss. This ideal setting is often unavailable or unrealistic, however, and in a primary care setting, an obesity management strategy can still be implemented successfully with simple interventions by a single practitioner. Initial goals should focus on modest weight loss of 5%–10% of total body weight over a 12- to 16-week period of time. Such weight loss has been shown in studies to improve blood glucose control in obese patients with type 2 diabetes.²⁸ Modest weight loss has also been found to prevent the progression of diabetes and cardiovascular disease in those obese individuals with impaired glucose tolerance and insulin resistance²⁹ (Table 37.3). Improvements can be seen in most obesity-related conditions, from lipid disorders and hypertension to joint pain, muscle weakness, and lung function, after such a modest 5%–10% reduction in total weight.

TABLE 37.3

Clinical Identification of Metabolic Syndrome

Risk Factor	Defining Level
Abdominal adiposity	Waist circumference
Men	102 cm (40 inches)
Women	88 cm (35 inches)
Triglycerides	150 mg/dL
HDL cholesterol	
Men	40 mg/dL
Women	50 mg/dL
Blood pressure	130/85 mm Hg or higher
Fasting blood glucose level	110 mg/dL or higher

HDL, high-density lipoprotein.

Third Report of the Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III): *National Cholesterol Education Program*. Bethesda, MD: National Institutes of Health; 2004. Adapted from National Heart, Lung and Blood Institute, National Institutes of Health.

An integrative assessment of obesity should include a thorough medical history and physical examination with anthropomorphic measurements, weight history, nutritional and dietary history, assessment of current and past physical activity, diagnostic laboratory evaluation, electrocardiogram (if considering weight loss medications), and screening for current levels of motivation, emotional status, availability of support systems, and potential barriers to treatment.

Current medications should be assessed for their potential promotion of weight gain. Psychiatric medications are notorious for contributing to weight gain and include antipsychotics, some antidepressants, and antiseizure medications. Other commonly used drugs that promote weight include long-acting steroid medications, some oral contraceptives, certain diabetic medications, and drugs for the treatment of blood pressure. A recent study reviewed several trials and summarized drugs associated with weight gain versus weight loss.³¹ Weight-neutral alternatives are available and should be considered if weight loss is a priority ([Table 37.4](#)).

Weight history should assess the progression of weight gain over time to illustrate the use of any previous weight loss strategies, such as special diets, exercise programs, meal replacements, nutritional supplements, medications, or surgical procedures. The practitioner should understand how much weight was lost and over what period of time, what was the period of weight maintenance, and what promoting factors caused weight regain, if any. “Yo-yo” dieting, consisting of repetitive patterns of weight loss followed by weight regain, may provide information about previous successful strategies, as well as recurrent negative behavioral patterns.

Laboratory testing is an important adjunct to information obtained from a patient’s history, and patients should be screened for obesity-related conditions, such as hypothyroidism, liver disease, metabolic syndrome, dyslipidemia, glucose intolerance, insulin resistance, diabetes, and, if suspected, polycystic ovarian syndrome (PCOS) and Cushing syndrome. Because obesity is a proinflammatory condition, the prudent approach may be to assess inflammatory markers, such as high-sensitive C-reactive protein. Serum 25-(OH) vitamin D levels should be obtained in light of research demonstrating the trend toward significant vitamin D deficiency and decreased bioavailability of vitamin D in the obese

population.³² Vitamin D deficiency is associated with muscle weakness, fatigue, and pain in bones, joints, and muscles, among other things. Normalizing vitamin D status in the obese population should be a priority.

TABLE 37.4
Medications Associated With Weight Gain

Drug Class	Medications That May Promote Weight Gain	Alternative Drugs That May Be Weight Neutral or Promote Weight Loss
Psychiatric/Neurological		
Antipsychotics	Olanzapine, clozapine, risperidone	Ziprasidone, quetiapine
Antidepressants	SSRIs, tricyclics, lithium	Bupropion, nefazodone
Antiepileptics	Valproate, gabapentin, carbamazepine	Topiramate, lamotrigine, zonisamide
Diabetic Agents	Insulin Sulfonylureas Thiazolidinediones	Metformin, exenatide, ^a acarbose, miglitol, GLP-1 agonists
Steroid Hormones	Hormonal contraceptives	Barrier methods
	Corticosteroids	NSAIDs
	Progestational steroids	
Miscellaneous Agents	Antihistamines	Decongestants, inhalers
	Alpha-antagonists, beta-blockers	ACE inhibitors, calcium channel blockers

ACE, angiotensin-converting enzyme; NSAIDs, nonsteroidal antiinflammatory drugs; SSRIs, selective serotonin reuptake inhibitors.

^a Incretin mimetic.

Adapted from the North American Association for the Study of Obesity, Obesity Research, Stanford University Libraries, Stanford, CA.

Laboratory tests to consider in the evaluation of obesity include fasting blood sugar (100–125 mg/dL indicates prediabetes); triglycerides (high in metabolic syndrome); high-density lipoprotein (low in vitamin D deficiency); 25-hydroxyvitamin D; thyroid-stimulating hormone (hypothyroidism); cortisol, 8 a.m. spot, or 24-hour urine (Cushing disease); high-sensitive C-reactive protein (inflammation); and serum aspartate aminotransferase, alanine aminotransferase, and gamma-glutamyltransferase (steatohepatitis).

Dietary recall over the course of 1–2 days can provide an idea of food intake, eating patterns, and quality of choices. This approach is limited by the tendency of most people to underreport intake of food, as well as

uncertainty about identifying a representative day of eating in an individual's typical routine. Various software programs and online tools are available for performing nutrient analyses of dietary records and for calculating calories, macronutrient and micronutrient profiles, fiber, essential fats, and sources of each. This information can be useful to provide to clients who are undergoing nutritional counseling.

Even when reports of food intake are underreported or somewhat inaccurate, however, viewing the amount of calories one consumes over a 24-hour period can often be surprising and revelatory to the individual who is unaware of portion sizes and the nutritional content of food. Providing patients with a visual illustration of this can be valuable.

Ultimately, for an intervention to be successful, it must closely match the individual's readiness to change. Commitment to such behavioral change is maximized when goals are self-selected and fit with personal lifestyle and values. Gaining clarity on these values is obtained through interactions that allow the practitioner to understand and appreciate the world of the client. Techniques such as motivational interviewing can provide primary care providers with the kinds of counseling tools they need to improve the likelihood that their patients will implement the suggested strategies³³ (see [Chapter 101](#)).

Interventions must match readiness to change. Commitment to behavioral change is maximized when goals are self-selected and fit with personal lifestyle and values. Patient ambivalence is universal and should be recognized and acknowledged. Doing so will encourage the patient to argue for, instead of against, change.

Integrative Therapy

In general, the primary clinical intervention for weight management involves lifestyle modification. This includes attention to levels of activity, nutrition, stress management, sleep, sexual activity, relationships, and motivation. Lifestyle modification should be part of any program addressing excess weight, regardless of BMI. More aggressive approaches that include weight loss medications, low-calorie diets with or without liquid meal replacements, and various methods of fasting require a BMI of 30 or higher without comorbidities or BMI of 27 or higher with the presence of one or more comorbid conditions. These

strategies require frequent monitoring and, if implemented for longer than 3 months, should be administered by a medical professional trained in supervised weight loss strategies (i.e., a physician certified by the American Board of Bariatric Medicine). For patients who have given serious attempts to their weight loss without appropriate long-term results, surgical interventions should be evaluated as a viable option.

Therapeutic Counseling

Once the assessment has been made and initial treatment goals have been established, a regular visit schedule should be proposed and agreed on by the management team and patient. The more contact patients have with practitioners, the longer they will remain in a program and the greater potential they have to achieve and maintain their weight loss goals. Frequent visits with physicians and ancillary staff (dietitians, exercise physiologists or trainers, and counselors) are recommended and promote greater compliance, as do group support programs.³⁴⁻³⁷

Behavioral and nutritional counseling can be conducted by physicians or dietitians and coded for using Current Procedural Terminology (CPT) codes for individuals (97802) or groups (97804). A minimum of one visit per month is encouraged, and weekly or twice-monthly visits are recommended. Programs offering combination visits with a physician followed by ancillary practitioners can allow for efficient delivery of information in a multidisciplinary fashion without having to extend doctor visits. Obese individuals with eating disorders or who have comorbid psychological conditions such as depression or anxiety should be provided with the opportunity for psychotherapy and other counseling by licensed mental health professionals.

Exercise

When consulting with someone who is interested in using exercise as a weight management tool, assessment is essential to setting attainable goals and creating an action plan. For sedentary individuals who are starting an exercise program, the initial goal is simply to start moving. Creating a habit of exercise or movement that emphasizes enjoyment and adherence is an important first step. During this phase, the intensity of exercise is not of paramount importance, but adherence to a modest volume of movement is. Even with modest amounts of movement, one can experience favorable functional changes in strength and endurance

that can be a positive and encouraging first step. After a pattern of regular movement has been established and exercise tolerance has improved, the notion of increasing the frequency, duration, and intensity of activity becomes more realistic. Improvements to the thermoregulatory, muscular, and cardiovascular systems of the body operate synergistically to make higher intensities and longer durations more easily tolerated. Ratings of perceived exertion, pedometers, and heart rate monitors are all tools that can be used when making the transition to this next phase of exercise. Although this more detailed phase of exercise prescription is not absolutely needed for managing obesity, it can be very helpful. Exercise has only mild effects on resting metabolic rate, but exercise of sufficient intensity can alter aerobic capacity and improve an individual's capacity to burn calories. Given that most exercise bouts are limited to the 20- to 60-minute window, the productivity of an exercise session can be the key to success.

Aerobic capacity or Vo_{2max} refers to the number of liters of oxygen that can be consumed per minute at maximal aerobic workloads. This workload has been traditionally expressed in terms of metabolic equivalents (METs) or in terms of milliliters of oxygen consumed per minute per kilogram ($mL O_2 / min / kg$). The more oxygen someone can consume per minute or the more METs they can produce per minute, the more calories they can burn. For example, two people seem identical on the surface. Both women are 55 years old, are 5 foot 4 inches tall (165 cm), and weigh 165 pounds (75 kg). Subject number 1 can produce 12.8 METs ($45 mL O_2 / min / kg$) during a treadmill test, whereas subject number 2 can produce 8 METs ($28 mL O_2 / min / kg$) during her treadmill test. Both women achieve maximal heart rates of 165 beats per minute at the end of the tests. Translated into exercise (30 minutes on a treadmill) at a comfortable heart rate for both women (127 beats per minute), the differences are substantial. Subject 1 will burn approximately 13.0 calories per minute for 30 minutes and 390 calories during the 30-minute exercise bout. Subject 2 will burn approximately 8 calories per minute and 240 calories for the 30 minutes. Having a very clear picture of what your clients' abilities are—even determining their aerobic capacity—before creating an exercise prescription is a powerful tool for anyone facilitating weight loss.

During a period of weight loss, clients will inevitably have some losses in lean mass, as well as losses in fat mass. Given the protein-sparing effects induced by resistance training, the addition of resistive muscular work makes sense. Full body exercise routines that engage as many

muscles as possible not only save time but also can have beneficial effects on the hormonal response to resistance training.³⁸ A twice-weekly regimen is sufficient to produce these results.

Nutrition

Diet and its role in weight loss have been studied abundantly over the decades, with evidence to support restriction of calorie-containing macronutrients (carbohydrates, fats, and proteins) as an effective means of achieving weight loss.³⁹ However, further research suggests that macronutrient-restricted diets may be no better than overall calorie-restricted diets for achieving long-term results.⁴⁰⁻⁴² Moreover, dietary adherence, rather than type of diet, predicts the greatest success regarding weight lost over time.⁴³ These three points suggest that personal preference is an important consideration when tailoring individualized dietary interventions for successful weight loss. Assessment tools, such as 24-hour dietary recall and food frequency questionnaires, are important methods for identifying personal preference as a means of recommending dietary approaches to reduce calorie intake.

Popular Diets and Common Weight Loss Programs

Many people seek out recommendations from popular diets and common weight loss programs, most of which have minimal evidence or formal studies to show their effectiveness. However, evidence studying the efficacy of four popular diets (Atkins, Zone, Weight Watchers, and Ornish) for weight loss showed modest reduction in body weight. The study showed that increased adherence was associated with greater weight loss and cardiac risk factor reduction for each diet group.⁴⁴ This finding further supports individualized dietary interventions based on personal preference as an important factor in recommending therapy.

Although questions remain about long-term effects and mechanisms, data suggest that a low-carbohydrate, high-protein, high-fat diet may be considered a feasible alternative recommendation for weight loss.⁴⁵ Three popular examples are the Atkins diet, the South Beach diet, and the Zone diet. The Atkins diet focuses on eliminating the majority of carbohydrate sources with no modification of fat or protein calories. The South Beach diet offers a 2-week elimination of all carbohydrates followed by the addition of low-glycemic sources in moderate amounts. The Zone diet encourages physical activity, exercise, and hydration and limits

carbohydrates. Another popular diet that achieves weight loss, by what is most likely calorie restriction, is the Ornish diet, predominantly a very low-fat vegetarian plan that combines dietary approaches with group support, stress reduction, and moderate exercise. Research from Stanford University in California studied the Atkins, Zone, LEARN (Lifestyle, Exercise, Attitudes, Relationships, Nutrition), and Ornish diets by specifically looking at macronutrient quality and concluded that weight loss diets focusing on macronutrient composition should attend to the overall quality of the diet, including the adequacy of micronutrient intakes. Concerning calorie-restricted diets, those providing moderately low carbohydrate amounts and containing nutrient-dense foods may have a micronutrient advantage.⁴⁵

Each year, millions of U.S. residents enroll in commercial and self-help weight loss programs. Health care providers and their patients know little about the clinical utility of these programs because of the absence of systematic reviews. The University of Pennsylvania in Philadelphia performed an evaluation of major commercial weight loss programs in the United States (eDiets.com, Health Management Resources, Take Off Pounds Sensibly, Optifast, and Weight Watchers). The outcome of the systematic review showed that use of the major commercial and self-help weight loss programs involved in the trial, with the exception of Weight Watchers, is suboptimal.⁴⁶ The study noted limitations related to lack of control for high attrition rates. The investigators also reported that many of the programs were associated with high costs and a high probability that participants will regain 50% or more of lost weight in 1–2 years. This study further supports the need for controlled trials to assess the efficacy and cost effectiveness of commercial weight loss interventions.

Additional commercial programs that lack research but continue to gain popularity are Jenny Craig and LA Weight Loss. These programs, like Weight Watchers, provide weight loss services including prepackaged food, planned menus, and psychological support. The limitations are overall cost, sales promotions that encourage on-the-spot commitment to prepaid contracts, and the cost of food and additional vitamins.

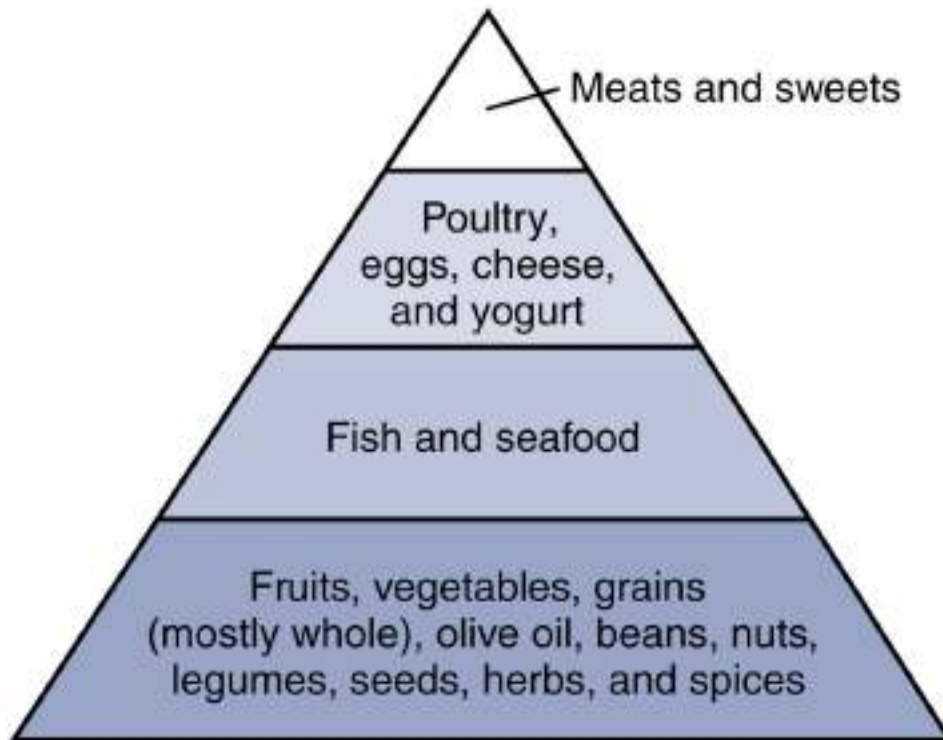

In February 2011, the Department of Geriatrics and Metabolic Diseases in Naples, Italy, evaluated the effect of Mediterranean diets on body weight in randomized controlled trials using a meta-analysis. This research found that the Mediterranean diet could be a useful tool to reduce body weight, especially when it is calorie restricted, associated with physical activity, and followed for more than 6 months. The Mediterranean diet was not found to promote weight gain, a finding that

removes the objection to its relatively high fat content.⁴⁷ This research further supports evidence suggesting that macronutrient-restricted diets may be no better than overall calorie-restricted diets in achieving long-term weight loss. Key components of the Mediterranean diet emphasize exercise, primarily plant-based foods (fruits, vegetables, whole grains, legumes, and nuts), olive oil and canola oil, two or more servings of fish and seafood weekly, and limitations on red meat ([Fig. 37.1](#)). The diet also recognizes the importance of enjoying meals with family and friends (see [Chapter 88](#)).

The antiinflammatory diet designed by Andrew Weil, MD, based on principles found in the Mediterranean diet, is not intended as a weight loss program, although people have found they have lost weight while adhering to it. General dietary recommendations include eating as much whole, fresh, and unprocessed food as possible (fruits, vegetables, whole and cracked grains, beans and legumes, nuts, avocados, and seeds), with an emphasis on variety of these foods. The diet also limits consumption of processed foods, “fast foods,” and foods high in saturated fat sources. The elimination or significant limitation of these foods is most likely an important factor contributing to weight reduction. The diet is based on a 2000 calorie per day plan that provides adequate vitamins, minerals, essential fatty acids, dietary fiber, and protective phytonutrients. At this point, no research has been conducted to study the effects on weight loss associated with the Weil antiinflammatory diet.

Ultimately, dietary restriction as a management strategy for weight reduction can often be used as a sole intervention. Evidence suggests, however, that its use in combination with other strategies such as exercise, behavioral therapy, surgery, and pharmacological treatments may increase overall success.

MEDITERRANEAN DIET PYRAMID

Food groups	Guidance
Meats and sweets	Less often
Poultry, eggs, cheese, and yogurt	Moderate portions, daily to weekly
Fish and seafood	Often, at least two times a week
Fruits, vegetables, grains (mostly whole), olive oil, beans, nuts, legumes, seeds, herbs, and spices	Base every meal on these foods

FIG. 37.1 Mediterranean Diet Pyramid.

(From Oldways Preservation and Exchange Trust. www.oldwayspt.org ; 2009. Accessed

The best nutritional plan for weight loss is the one to which the patient will adhere.

Pre-Meal Water Loading

Preloading with 500 mL of water 30 minutes before a meal was reported to be associated with a mean weight loss of 2.4 kg after 12 weeks compared to the control group that imagined their stomach's being full 30 minutes before a meal, which lost 1.2 kg, a difference of 1.3 kg.

Those who used the water preload three times a day lost even more, 4.5 kg (~10 lbs) compared to those who only used it zero to one time a day (0.8 kg or 1.7 lbs).⁴⁸

One could also add soluble fiber to the 500 mL of water. The fiber has the added benefit of soaking up water and expanding in the stomach, enhancing the effects of satiety. Fiber also binds to the carbohydrate of the meal, lowering the glycemic index of the foods eaten and also inhibiting the absorption of cholesterol. This is a low-cost, low-harm treatment for overweight patients with diabetes and elevated cholesterol. Examples of soluble fiber to add to the 500 mL of water would include 1–2 teaspoons of psyllium, oat bran, guar gum, ground flax seed, or methylcellulose.

Supplements

Omega-3 Fatty Acids

Omega-3 fatty acids have been shown in various studies to have significant positive effects on cardiovascular health.⁴⁹ They are an integral part of an antiinflammatory diet and are indicated for the treatment of elevated triglyceride levels.⁵⁰ Omega-3 fatty acids should be considered in the obese patient with cardiovascular comorbidities because clinical studies show that disease risk decreases as the ratio of omega-3 to omega-6 in the diet increases.⁵¹ Supplements are available in prescription form as omega-3-acid ethyl esters under the trade name Lovaza. Omega-3 fatty acids have not been found to help with weight loss but may reduce risk associated with obesity.

Dosage

For improvement of cardiac disease risk, the recommended dose is 1–3 g daily, and the ratio of eicosapentaenoic acid (EPA) to docosahexaenoic acid (DHA) should be greater than 1. For the treatment of high triglyceride levels, the recommended dose is higher, at 2–4 g of combined EPA and DHA.

Precautions

Individuals with allergies to fish or shellfish should use caution when taking fish oil. Omega-3 fatty acids have antiplatelet and antithrombin effects, which may cause bruising or may interact with additional blood thinning agents. However, the bleeding effects of fish oils taken alone have not been shown to be clinically significant even in large doses.⁵⁰ Side effects include a fishy aftertaste and mild gastrointestinal upset.

Vitamin D

Overweight individuals tend to have lower blood levels of vitamin D because excess adipose tissue absorbs and stores this fat-soluble vitamin. In addition, unlike normal-weight individuals who turn over fat tissue, those with relatively immovable fat stores cannot liberate the vitamin D they have. As a general rule, obese individuals are less active outdoors and are exposed to less ultraviolet radiation, a situation that compounds their vitamin D deficiency. Studies have validated that obese individuals tend to have significantly low levels of vitamin D, with symptoms of muscle weakness, muscle aches, bone pains, and fatigue, all of which are potential manifestations of vitamin D deficiency.⁵² Additional research has validated the lower comparative bioavailability of vitamin D in obese individuals; they need more of it compared with nonobese subjects.³² Higher levels of calcium in the presence of adequate serum vitamin D levels has been shown to inhibit fatty acid synthase, an enzyme that converts calories into fat, whereas diets low in calcium increase the enzyme activity by as much as five-fold.⁵³

Dosage

First, the clinician should determine the patient's serum 25-hydroxyvitamin D levels. Recommended adequate blood levels of vitamin D are between 30 and 60 ng/mL.⁵⁴ Supplementation should be adequate to correct deficiencies if present. Obese individuals may need two to three times more vitamin D daily than those needed for normal weight, somewhere between 3000 and 6000 units daily, without posing any risk of toxicity.⁵³

Precautions

Gastrointestinal effects of larger doses of vitamin D have been reported. This effect may result from the gelatin capsule of prescription formulations and not the preparation itself. These symptoms may be remedied by opening the capsule and ingesting the liquid form. Vitamin D toxicity is often difficult to diagnose. This condition depends on blood levels of calcium (usually above 10.4 mg/dL) and occurs when 25-hydroxyvitamin D levels are usually higher than 200 ng/mL. Hyperphosphatemia and hypercalcemia that occur in vitamin D toxicity can cause constipation, confusion, depression, increased thirst, urination, and electrocardiographic changes, ultimately causing calcification of organs and tissues leading to damage and organ failure.⁵³

Green Tea and Green Tea Extract

Animal studies suggested a fat-burning, weight loss, and cholesterol-lowering effect of green tea extracts. This effect seems to be synergistically improved with the addition of exercise. A small Asian study validated significant reductions in body weight, BMI, waist circumference, body fat mass, and subcutaneous fat area after 12 weeks of consuming one bottle of tea with 690 mg catechin antioxidants per day.⁵⁶ Another Japanese study found that green tea contains ingredients besides caffeine that stimulate thermogenesis and burn fat.⁵⁷

Dosage

Studies found that fat-burning results occurred with tea containing 690 mg of catechins daily. Depending on the brand, the recommended dose consists of two to three cups of green tea per day (for a total of 240–320

mg polyphenols) or 100–750 mg per day of standardized green tea extract. Caffeine-free products are available.

Precautions

One cup of green tea typically contains approximately 50 mg of caffeine as compared with 90–150 mg of caffeine for a percolated cup of coffee. Individuals with heart problems, kidney disorders, stomach ulcers, anxiety, and sleep disorders should not take green tea. When considering green tea, pregnant and breast-feeding women should consult their obstetricians.

Individuals who drink excessive amounts of caffeine for prolonged periods may experience irritability, insomnia, heart palpitations, and dizziness. Caffeine overdose can cause nausea, vomiting, diarrhea, headaches, and loss of appetite.

Probiotics

Although there is insufficient evidence available to confidently use probiotics to help with weight loss, there are interesting findings associated with nutrition, types of bacteria, and efficiency of energy storage that may guide future therapy.

A novel study of overweight and normal weight human twins showed that transplanting the stool of each resulted in remarkable changes when it was placed in sterile mice. Bacteria from the overweight twin caused mice to gain more weight. However, when that same strain of mice was fed a high fiber, low fat diet, the obesogenic effect of the stool transplant was negated.⁵⁸ This finding indicates nutrition consumed can influence the type of bacteria that grow in the gut, potentially reducing those that are associated with the most weight gain. Obesity is generally associated with more *Firmicutes* and less *Bacteroidetes*. *Firmicutes* are “hard to kill” bacteria with firm outer coats such as *H. pylori*.

The importance of establishing a healthy microbiome from a young age may also influence obesity rates later in life. Cattle are often given antibiotics to increase weight. A Finnish study found this also causes weight gain in humans. This study of 12,062 healthy children evaluated the frequency, age of administration, and type of antibiotics provided. There was a linear trend in weight with the number of antibiotic exposures and a younger age at which antibiotics were given.²⁷ As with cows, increased weight gain and height were observed, particularly in

boys. Administering broad-spectrum antibiotics early and often to children may increase the risk of pediatric obesity ([Fig. 37.2](#)).

Caution for Supplements Used for Weight Loss

A study of emergency department visits for adverse events related to dietary supplements found that the most common visits were related to sympathomimetic side effects from weight loss supplements. The main side effects were palpitations, tachycardia, and chest pain. Most supplements used for these purposes contain ingredients that have stimulant properties.⁵⁹ Because many patients take these products as a “quick fix” with the impression of safety since a prescription is not needed to obtain them, they will often take excessive doses. [Table 37.5](#) lists the most common ingredients of these products that the clinician should be aware of for patients who present with sympathomimetic side effects.

Common ingredients found in weight loss supplements can cause sympathomimetic side effects, including tachycardia, palpitations, and elevated blood pressure.

Mind-Body Therapy

Mind-body therapies, such as mindfulness and mindful eating programs, meditation, hypnosis, and biofeedback, are popular strategies used to facilitate weight loss plans with a specific target on emotional eating patterns. Stress reduction and improved emotional regulation can potentially allow individuals to make better food choices, feel fuller faster, and recognize abnormal eating habits. By accessing the parasympathetic nervous system more often, the balance of stress hormones, including epinephrine and cortisol, can be shifted in a positive direction. Studies have confirmed that stress-induced cortisol secretion is linked to abdominal obesity, endocrine abnormalities such as increased insulin, metabolic derangements in blood lipids, and hemodynamic changes in blood vessels.⁶⁰ Decreasing cortisol levels can aid in a positive strategy to address weight gain proactively.

TABLE 37.5

Supplements With Sympathomimetic Effects

--

Ma huang	This is the plant source of ephedra, which is banned in the US due to its numerous adverse effects.
Guarana	A plant source of caffeine. The seeds contain about 5% caffeine compared to a coffee bean, which contains about 1%.
Caffeine	Coffee bean, tea leaves (<i>Cemellia sinensis</i>), yerba mate, kola nut.
Bitter orange	The peel and fruit contain adrenergic agonists, synephrine, and octopamine, which are similar to norepinephrine.
Hoodia	From a cactus that grows in the South African desert. Traditionally used to suppress appetite. Documented side effects include hypertension and tachycardia.
Ginseng	The three most common ginsengs are American, Panax, and Siberian. American is the most stimulating.

FIG. 37.2 A, Amount of weight gain associated with any antibiotic in boys aged <2 yrs (increase of 5.2%). B, Amount of weight gain associated with early and multiple antibiotics that included broad-spectrum macrolides (increase of 11%).

Unfortunately, the available literature on these therapies in the obese population is relatively scarce. Preliminary studies have reported that mindfulness meditation can reduce episodes of binge eating and nighttime eating disorder.⁶¹ Some studies investigating the role of biofeedback techniques and hypnosis in weight loss showed a mildly positive effect.⁶² At present, recommending these strategies to the right individuals who are open to them seems prudent as an adjunct to an ongoing lifestyle management program.

Pharmaceuticals

Pharmacological treatment may be considered an adjunct to lifestyle modification in patients who have not lost at least 1.1 lb (0.5 kg) per week after 3–6 months of implementing their lifestyle program.⁶³ These medications are appropriate for patients with a BMI 30 or higher or 27 or higher in the presence of comorbid conditions. At present, two classes of drugs are used for weight control: (1) drugs that suppress appetite and augment thermogenesis (phentermine, topiramate, lorcaserin) and (2) drugs that prevent the absorption of fat through the gastrointestinal tract (orlistat). Recent combination medications have been FDA-approved for the treatment of obesity and have begun to be used in this patient population. However, the withdrawal of sibutramine by Abbott Laboratories from both the U.S. and European markets because of an increased risk of stroke and heart attacks has raised concern about the long-term effects of stimulant medications and prompted petitioning for higher standards of review and implementation for weight loss medications.⁶⁴

Phentermine

Phentermine (Adipex-P) is a norepinephrine reuptake inhibitor with schedule IV identification (debated in some medical circles) that has been approved by the U.S. Food and Drug Administration (FDA) for short-term use (12 weeks) since 1959. Phentermine is the most commonly prescribed weight loss medication to date, probably because of its low cost, long history of use, and, contrary to popular belief, low addictive potential. To illustrate this point, the *Drug Abuse Warning Network (DAWN)* report, published in 2006 by the Substance Abuse and Mental Health Services Administration of the U.S. Department of Health and Human Services, showed that anorectics such as phentermine had among the lowest drug misuse or abuse rates per 100,000 emergency room visits, even lower than ibuprofen.⁶⁵ Unfortunately, many of the current guidelines for prescribing phentermine reflect recommendations that are more than 50 years old, rather than current evidence of efficacy and safety.⁶⁶ Because it has a molecular structure similar to that of amphetamine, phentermine was originally labeled a schedule IV drug; however, over many decades of clinical use, phentermine has proved to have little to no addictive value, and no abuse or withdrawal syndromes are associated with its use.⁶⁵ Continuous use beyond 12 weeks is a common off-label use pattern in bariatric medicine and has validation in

the international literature.⁶⁷ Putting time limits on medication use for the treatment of a chronic illness such as obesity seems inappropriate when (and only when) the risk of taking the medication is less than the risk of leaving the illness untreated. Weight loss during drug therapy should perhaps not be considered an indication to stop treatment any more than a positive outcome would be for the treatment of other chronic diseases. For this to happen, however, the long-term safety of agents must be assessed and documented in the literature.⁶⁸ The literature suggests the effectiveness of phentermine in helping patients lose weight and maintain weight loss for at least a year, if not longer.⁶⁹

Dosage

Phentermine is often prescribed in doses of 15–37.5 mg once daily, typically in midmorning. It is occasionally prescribed in half doses given early in the morning then at midmorning, to extend its effects toward evening, when individuals tend to have higher calorie intake. Phentermine has been combined with topiramate (Qsymia) and offered in 3.75/23 mg (phentermine/topiramate), 7.5/46 mg, and 11.25/92 mg to be prescribed once daily and slowly titrated.

Precautions

Side effects include insomnia, dry mouth, palpitations, hypertension, and constipation. When considering drug therapy with phentermine (or other stimulant medication), the clinician should conduct a careful review of medical history, drug interactions, and potential side effects. Evaluation of a recent electrocardiogram is recommended to assess cardiac health before administering medications with known stimulant effects, and aggressive regular monitoring (1- to 2-week visits) should be performed during initial treatment to assess vital signs and tolerance to therapy. Longer-term therapy should also prompt regular medical supervision with at least monthly visits.

Contrary to popular belief, phentermine has a low addiction potential.

Lorcaserin

Lorcaserin (Belviq) works as a serotonin 3C receptor agonist (whereas fenfluramine primarily acted as a 2B agonist) to increase food-specific receptors affecting satiety and satisfaction. A year-long study reported a weight loss of 7.3 kg with lorcaserin compared to the control group who lost 3.7 kg. Over 2 years, however, patients gained 25% of their weight back.⁷⁰ It is recommended to stop the drug if people fail to lose 5% of their weight after 12 weeks.

Dosage

Larcarsarin is prescribed in doses of 10 mg taken twice daily as part of a complete weight loss program including dietary and exercise modification. If using this drug with another serotonin agent, use extreme caution and careful observation.

Precautions

Common adverse effects in nondiabetics include headaches, dizziness, fatigue, nausea, dry-mouth, and constipations. In patients with diabetes, side effects include low blood sugar, back pain, cough, and fatigue. There was concern that Belviq may cause heart-valve defects; however, according to research, there was no statistical difference in valvular disease between drug and placebo group at this dose. It is important to take precaution in patients with preexisting heart-valve abnormalities or CHF.

Orlistat

Orlistat (Xenical) works by inhibiting lipases in the gastrointestinal tract such that fat absorption is partially blocked. Orlistat is FDA approved for up to 2 years of continuous use, and it has been shown to be effective for significant and sustainable weight loss, as well as for improving lipid levels, enhancing glucose metabolism, and lowering blood pressure.⁷¹ The discontinuation rate of orlistat is relatively high because of gastrointestinal side effects related to fat malabsorption and roughly equates to 33% in various studies.⁷² In one study, lifestyle intervention and orlistat treatment for 4 years delayed the development of type 2 diabetes in obese subjects by 37%, a finding perhaps attributable, in part, to the weight loss achieved.⁷³ Orlistat is now available in half-strength (60

mg per dose) over-the-counter under the brand name Alli.

Dosage

Orlistat is prescribed in doses of 120 mg taken three times daily with meals, and the dose can be omitted when patients ingest a low-fat meal. Starting orlistat once daily with the fattiest meal (usually dinner) and then advancing the dose to three times daily as needed can help lessen the intensity and frequency of side effects.

Precautions

Common adverse effects include bloating, flatulence, and fatty or oily stools. Oily spotting, increased fecal urgency or incontinence, and abdominal pain can also be experienced, especially when patients are noncompliant with a low-fat diet. Use of fiber supplements, especially psyllium, can be helpful in reducing side effects. Patients should also take a daily multivitamin, independently of orlistat, to compensate for the potential decreased absorption of fat-soluble vitamins (A, D, E, and K).

Pharmaceuticals for Combined Weight Loss and Type II Diabetes Mellitus

Metformin

Metformin (Glucophage) is indicated for the treatment of type 2 diabetes, but it has also been used off label for the treatment of insulin resistance syndromes, especially in PCOS. Studies have suggested a mild weight loss effect in abdominally obese women with PCOS.⁷⁵ Metformin has also been shown to promote weight loss in morbidly obese children and in men with normoglycemic hyperinsulinemia.⁷⁶

Dosage

500 mg twice daily. Increase to 1000 mg bid.

Precautions

Avoid in those with renal failure as metformin can increase the risk of metabolic acidosis. GI intolerance, including cramping and diarrhea, is the most common side effect.

Liraglutide

Liraglutide is a glucagon-like peptide-1 (GLP-1) hormone that is secreted after a meal. Because it is released by eating food, GLP-1 increases insulin to store energy, reduces glucagon to shut down glucose production by the liver, and slows gastric emptying. Mimicking the effects of this hormone with GLP-1 agonists lowers glucose and can result in weight loss by making people feel full and less hungry. Liraglutide does not affect metabolic energy expenditures. Liraglutide is one of the few diabetes medicines that have also been approved for treating obesity.

Dosage

The amount of weight loss and severity of side effects was reportedly dose dependent, with greater amounts of both with the 3.0 mg dosing. However, there was no significant difference in HbA_{1c} changes between the 3.0 mg and 1.8 mg dosing (0.19% difference). Accordingly, if liraglutide is being used mainly for diabetes control, the dosing of 1.8 mg will likely achieve the sweet spot of least side effects with the most reduction in HbA_{1c}. However, if it is being used to achieve the most weight loss, titrating up to 3.0 mg would be more likely to achieve this goal. Start at 0.6 mg subcutaneously daily and increase by 0.6 mg every week until you achieve the desired dose, which would be 3 weeks to achieve 1.8 mg and 5 weeks to achieve 3.0 mg.

Precautions

As one might expect through its mechanism of action, gastrointestinal intolerance is the main concern with liraglutide. The most common symptom, nausea, is dose dependent, which may explain how it influences weight loss. The other most common side effects are vomiting, dyspepsia, diarrhea, constipation, and abdominal pain. In a study of 846 subjects following for 56 weeks, there were no cases of pancreatitis; however, elevations of serum amylase and lipase levels were common and resolved with discontinuation of the drug.²⁷ There

was a rebound weight gain when the medicine was stopped in the above study and long-term side effects of treatment were not evaluated. In animal studies, liraglutide has been found to increase the risk of thyroid cancer, and there is a concern regarding an increased risk of colorectal cancer. Longer studies are needed to establish the safety of liraglutide with chronic use.

Combination Pharmaceuticals for Weight Loss

Combinations of phentermine with topiramate (Qsymia) and bupropion with naltrexone (Contrave) have been recently approved for weight loss treatment, with studies validating their effectiveness in reducing HbA_{1c} levels modestly ([Table 37.6](#)). Bupropion (Wellbutrin) is a norepinephrine and dopamine reuptake inhibitor that is approved for the treatment of depression and has been shown to have a dose-dependent weight-loss effect in a double-blind, placebo-controlled study. In this study, 83% of patients achieved weight loss of more than 5% of initial body weight when they took 400 mg/day of sustained-release bupropion as compared with 59% of subjects taking 300 mg/day and 46% treated with placebo.⁷⁸ Topiramate (Topamax) is an antiepileptic drug that has shown positive weight loss effects during clinical trials in smaller doses than achieved for seizure control.⁷⁹

Surgery

Bariatric surgery is well established as the most effective treatment for obesity; however, it is indicated only for the management of severe obesity, with or without comorbidities, when other therapies have been tried without long-term success.⁸⁰ Surgical interventions are currently indicated for patients with a BMI of 40 or higher or 35 or higher with comorbid conditions and reduced quality of life (i.e., hypertension, sleep apnea, or diabetes). Typically, reimbursement for surgical procedures will be granted only after at least a 6-month trial of medically supervised weight loss.

Bariatric surgery rapidly evolved with the advent of laparoscopic approaches in the mid-1990s. Currently, most bariatric surgery is initially attempted in laparoscopic fashion. Surgical weight loss falls into the category of restrictive procedures, malabsorptive procedures, or a combination of the two. Strictly malabsorptive procedures such as jejunioileal bypass and duodenal switch are seldom performed. Purely

restrictive procedures include the vertical banded gastroplasty (rarely performed these days), adjustable gastric banding, and vertical sleeve gastrectomy (an emerging procedure). The Roux-en-Y gastric bypass, involving restriction of stomach size along with bypassing a large part of the stomach and duodenum, is an example of a combined restrictive and malabsorptive procedure. Roux-en-Y gastric bypass is still the most popular procedure; however, restrictive techniques are beginning to emerge as competitive procedures that are less invasive and have fewer side effects.

A Cochrane Review compared different surgical procedures, all of which were found to be more effective in promoting weight loss than were nonsurgical methods.⁸¹ Roux-en-Y gastric bypass was more effective than laparoscopic adjustable gastric banding and just as effective as vertical sleeve gastrectomy. Weight loss of up to 33% has been maintained after gastric bypass surgery for up to 10 years, with loss of 50% or more of excess weight achieved with either of the procedures, again an outcome superior to that of nonsurgical approaches.⁸¹ In addition, resolution of comorbidities is often common. Meta-analyses have demonstrated complete resolution of type 2 diabetes in 31%–77% of patients who underwent laparoscopic banding and in 72%–100% of patients who underwent Roux-en-Y bypass.⁸² Similar resolution of blood pressure abnormalities has been verified. A Swedish study demonstrated a substantially reduced 10-year mortality rate with bariatric surgery as compared with nonsurgical treatment of obesity.⁸³

Bariatric surgery is typically safe, with surgical mortality approaching as low as 0.1%–0.3%, whereas postoperative complications occur in 4%–10% of patients.^{84,85} Emerging evidence indicates that bariatric surgery may be beneficial for patients with BMIs lower than 35 and comorbidities; however, it is still too early to recommend surgery to such individuals.⁸⁶

TABLE 37.6
New Weight Loss Medications and Diabetes

Drug	MHA	(HbA1C vs. Control)	Dose	SE
Phentermine/Topiramate (Qsymia)	↓Appetite, ↑satiety	0.4% ^a	3.75/23 mg daily + 14 days than 7.5/46 mg daily	Parosmia, constipation, dry mouth, insomnia
Lorcaserin (Belviq)	↑Satiety through serotonin cell action	0.5% ^a	10 mg bid	Headache, URI, constipation/diarrhea
Orlistat (Xenical)	↓Fat absorption	0.5% ^a	120 mg with each meal, tid	Oil diarrhea, flatulence, vitamin malabsorption
Bupropion/Naltrexone (Contrave)	↓Appetite, ↑energy expenditure, ↓cravings	0.5% ^a	90/80 mg/d = 1 week, ↑ by one tablet each week until two tablets bid by week 4	Nausea, constipation, headache, dizziness

URI, upper respiratory tract infection.

These medicines are indicated for obesity with a BMI ≥ 30 or a BMI ≥ 27 in those with a comorbidity of type II diabetes mellitus, hypertension, or dyslipidemia.

Individuals considering bariatric surgery require thorough preparation for the effects of such a procedure on their long-term lifestyle. This preparation should be facilitated by a multidisciplinary team of surgical and nonsurgical practitioners. Coordination of treatment has been cited as one of the most important advances in the care of patients undergoing these surgical procedures.⁸⁷ Postoperative challenges include malabsorptive nutritional deficiencies, dumping syndrome that involves profuse diarrhea and stomach pain after overeating refined carbohydrates in patients who underwent bypass procedures, changing dietary patterns to accommodate effects of the procedure, and the physical and emotional changes that occur when experiencing large amounts of weight loss.

Regular access to behavioral experts is essential for patients as they lose weight. Often, maladaptive patterns of eating are a defense mechanism used by patients to deal with elevated levels of emotional stress. When those options are eliminated by a surgical process, the potential for other patterns of behavior to emerge is evident. Having a management strategy to support patients through these psychological adaptations and providing them with proactive alternatives to stress response other than with food can create life-changing opportunities.

Prevention Prescription

- The basis for prevention of weight gain is learning how to follow an antiinflammatory diet that emphasizes vegetables and fruits from all parts of the color spectrum, whole grains, fish and other sources of omega-3 fatty acids, vegetable protein more than animal sources,

monounsaturated fats, and low-fat dairy. To make this a long-term lifestyle change, fruits, vegetables, and high-fiber grains must be used to displace high-calorie processed foods of poor nutritional content (see [Chapter 88](#)).

- Fostering a healthy relationship with food and becoming aware of reactive, habitual patterns of eating are vital to preventing weight gain. Learning techniques of mindful eating can facilitate this process.
- Physical activity may play a role in the prevention of weight gain⁹³; 30 minutes/day, 5–7 days/week of any physical activity should be encouraged (see [Chapter 91](#)).

Therapeutic Review

All patients should undergo the following assessments. Appropriate therapy can then be determined.

Medical History

- Assess for comorbid diseases and concomitant medications that induce weight gain.

Nutrition History

- Determine previous weight loss attempts and use 24-hour recall and food frequency questionnaires.
- Rule out clinically significant eating disorders (anorexia and bulimia nervosa, binge-eating disorder, nighttime eating syndrome).

Anthropometric Measurements

- Weight, height, BMI, waist circumference, body composition, blood pressure, and heart rate

Laboratory Tests

- Complete blood count, metabolic profile, fasting lipids, thyroid-stimulating hormone, liver function tests, fasting serum glucose and insulin, hemoglobin A_{1c} (if diabetic), high-sensitive C-reactive protein, 25-(OH) vitamin D
- Electrocardiogram of starting medications with cardiac effects, unless

a recent one (within 12 months) is available for review

General Evaluation

- Assess for motivation, importance, and confidence for weight loss, barriers to change, and realistic weight loss goals.
- Assess exercise history, sleep patterns, relevant stressors, and social support.

Therapeutic Options

BMI 25 or Higher

- Promote a balanced hypocaloric diet and physical activity, and provide behavioral modification counseling.
- Reduce caloric intake from baseline by 500–1000 cal/day to yield a 1- to 2-lb weight loss per week. 
- Consider pre-meal water load of 500 mL with one teaspoon of a soluble fiber, such as psyllium, guar gum, ground flax seed, or methylcellulose. 
- Encourage purposeful activity for at least 60 minutes daily 6–7 days of the week. Total time may be broken into short bouts of 10–15 minutes each during the initial adoption of an exercise program only. 
- Stress management techniques including mind-body therapies, such as meditation, mindful eating, biofeedback, or hypnosis. 
- Ensure adequate sleep and treatment of any concomitant sleep disorders. 
- Suggest interactive individual or group support sessions for nutrition education and behavioral modification. 
- Refer to a dietitian, mental health professional, or exercise specialist as needed. 

BMI 30 or Higher or 27 or Higher With Comorbid Conditions

- Full liquid fast, protein-sparing modified fast, and pharmacotherapy

- with dietary intervention are suitable for this BMI level. 
 - Orlistat, 120 mg orally three times daily, is the first option. This medication is localized to the gut and can be used in combination with phentermine. 
 - Phentermine can be taken alone (15–37.5 mg daily) or in combination with orlistat (approved for 3-month use by the Food and Drug Administration). 
 - Suggest omega-3 fatty acids at 2–4 g/daily to manage risks associated with obesity. 
 - Treat vitamin D deficiency appropriately to achieve serum 25-(OH) vitamin D levels between 40 and 60 ng/mL. 
 - Other dietary supplements should be used, if at all, on an individualized basis determined by risk-to-benefit ratio and by evaluating the efficacy and safety of each product or combination.
- 

BMI 40 or Higher or 35 of Higher With Comorbid Conditions

- Weight loss surgery, if other treatment modalities are ineffective, is suitable for this BMI level. 

Key Web Resources

MyFitnessPal assessment and analysis services: This company is a leader in the field of diet and physical activity assessment, and their Web site is the official source of the Block Food Frequency Questionnaire and other dietary and physical activity questionnaires developed under the guidance of Dr. Gladys Block. Block Assessment Tools are designed and tested for usability and have a long history of validation in various demographic subpopulations. These tools are available in both paper and electronic format.	http://www.myfitnesspal.com/assessment
Basal metabolic rate calculator: This tool calculates how many calories your body requires each day.	http://www.calculator.org/calculator/calculator-for-basal-metabolic-rate.aspx
Mayer Clinic calorie calculator: This calculator includes individual activity in the calculation.	http://www.mayerclinic.com/health/calorie-calculator/ML100998
FitDay.com: This website allows you to track your nutrition and fitness goals online.	http://www.fitday.com
The Center for Mindful Eating: This organization helps people learn how to eat using as a mindful process that brings awareness to what we are eating, thus leading to healthier food choices and reduced calorie consumption.	http://www.cmea.org/

CHAPTER 38

MTHFR, Homocysteine and Nutrient Needs

Thomas G. Williams, PhD

The science of nutrigenetics defines the interrelationship between a person's genetics and their need for, or utilization of, a particular nutrient. As DNA sequencing and nutritional research have become more sophisticated in the past few decades, numerous clinically-relevant nutrigenetic relationships have come to light. Among the most well known are the various polymorphisms in the gene *MTHFR* that encodes the enzyme methylenetetrahydrofolate reductase (MTHFR) needed to synthesize the active form of folate.* In fact, it is likely that *MTHFR* polymorphisms are the most widely-studied of all nutrigenetic-related polymorphisms, the testing for which is now a common clinical practice. This chapter will not attempt to review the vast amount of published data related to the health risks associated with common *MTHFR* polymorphism (and other mutations).¹ Instead, after describing the biochemistry related to one-carbon metabolism and the role of MTHFR, we will discuss the utility of testing for common polymorphisms to quantify risk in subjects and discuss the available evidence for the use of nutrient supplements to modify a patient's risk based on their *MTHFR* genetics. We will especially focus on the data involving the supplementation of various folates (food folates, folic acid, folinic acid, and 5-MTHF) to reduce risk in patients related to *MTHFR* genetic status, especially as it relates to elevated homocysteine levels (Hcy).

Pathophysiology

Methylenetetrahydrofolate Reductase—The

Folate Activator

MTHFR is a key enzyme in the one-carbon metabolic pathway that regulates methylation via folate and homocysteine metabolism (Fig. 38.1).² Specifically, MTHFR catalyzes the reduction of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate (5-MTHF). MTHFR is a flavoprotein, which uses flavin adenine dinucleotide (FAD, a riboflavin derivative) as a cofactor and nicotinamide adenine dinucleotide phosphate (NAD[P]H, a niacin derivative) as an electron donor. This reaction is irreversible and provides the only endogenous source of 5-MTHF to the cell. The only known function of 5-MTHF is as a methyl donor in the conversion of homocysteine to methionine, a reaction catalyzed by the enzyme methionine synthase using cobalamin (B12) as a cofactor.³ Deficiencies in the MTHFR activity lead to reduced cellular availability of 5-MTHF, resulting in elevated serum or urine homocysteine levels.⁴ The mechanisms by which MTHFR deficiency influences metabolic dysfunction and disease include the following:

- **Elevated homocysteine.** Elevated plasma total homocysteine (tHcy) is an independent risk factor (or marker) for a wide range of diseases.⁵ There are many proposed mechanisms that implicate homocysteine in direct actions on a variety of tissues, although many researchers believe that homocysteine is simply a surrogate biomarker of folate status and/or kidney function and not directly involved in the progression of disease.⁶ However, many of the clinical trials in which homocysteine-lowering therapies failed to improve event outcomes were in secondary-prevention populations prescribed a polypharmacy of CVD drugs prior to vitamin consumption (statins, 80%; aspirin, 88%; beta-blockers, 90%; and ACEI, 30%), had baseline tHcy levels below 13 $\mu\text{mol/L}$, or were unable to achieve posttreatment tHcy levels below 9 $\mu\text{mol/L}$.⁷⁻⁹ A wide range of intervention trials have shown that homocysteine-lowering therapies in subjects with mild-to-moderate hyperhomocysteinemia can achieve statistically significant and clinically meaningful benefits.¹⁰⁻¹³

In 358 older adults studied in a community cohort, those with a homocysteine levels $\geq 13 \mu\text{mol/L}$ were almost twice more likely to show decline in memory and global cognitive testing.¹⁰

- **Increase in the amount or ratio of other folate metabolites.** MTHFR

deficiency leads to the likelihood of lower 5-MTHF levels and increasing levels of 5,10-methylenetetrahydrofolate or other nonmethylated forms of folate. While some of these forms are substrates for other metabolic pathways (e.g., for dTMP synthesis; see [Fig. 38.1](#)), others may have negative consequences. Some have suggested that elevated 5,10-methylenetetrahydrofolate levels and the subsequent increase in the conversion of dUMP to dTMP may have biological advantages (DNA replication and protection), explaining the high penetration of *MTHFR* polymorphisms in some populations. While no reproductive advantage has yet been attributed to humans with such mutations, recent animal studies have suggested that protection against malaria may account for the high 677T variant in humans.¹⁴

FIG. 38.1 Overview of folate metabolism. Enzymes are provided in boxes. *DHF*, dihydrofolate; *dTMP*, deoxythymidine monophosphate; *dUMP*, deoxyuridine monophosphate; *MTR*, methionine synthase (gene); *MTRR*, methionine synthase reductase (gene); *SAM*, S-adenosylmethionine; *SAH*, S-adenosylhomocysteine; *TS*, thymidylate synthetase; *THF*, tetrahydrofolate.

- Lower methionine, S-adenosylmethionine, and overall methylation.

Reduced availability of 5-MTHF results in lower amounts of intracellular methionine available as a precursor for the synthesis of S-adenosylmethionine (SAM), the major methyl-donor for methyltransferase enzymes. Lower levels of methylated metabolites (e.g., methylated proteins or neurotransmitters) may be an immediate consequence of decreased SAM levels, although alterations in DNA and histone methylation can have a long-term effect on gene regulation (epigenetic effects).¹⁵

Methylenetetrahydrofolate Reductase Mutations and Polymorphisms ([Table 38.1](#))

Over 40 different genetic variants (i.e., mutations) in the *MTHFR* gene have been identified in patients with homocystinuria.¹⁶ Two of these variants, usually called *polymorphisms* due to their relative frequency in the population, have gained particular attention in the research community; both of these are single nucleotide polymorphisms (SNPs). Of these two *MTHFR* polymorphisms, 677C → T and 1298A → C, we will focus mostly on the former where the majority of the risk (and research) exists.

MTHFR 677C→T Polymorphism (a.k.a. C677T)

Kang et al. first described a thermolabile form of the MTHFR enzyme in CHD patients with mild hyperhomocysteinemia in 1991.¹⁷ Several other researchers confirmed the connections between this thermolabile MTHFR enzyme with both elevated homocysteine levels and CVD risk.¹⁸⁻²⁰ It was later discovered that a common *MTHFR* single nucleotide difference at base pair 677 (C → T substitution) expressed a protein with a valine (instead of alanine) at amino acid 222, a substitution that alters the active site of the enzyme rendering it thermolabile and less biologically active.²¹ The past two decades since this discovery have seen thousands of publications reporting on the population frequencies and differential health risks between subjects expressing both wild-type alleles (homozygous 677CC), those expressing both mutant alleles (homozygous- 677TT), and those that are heterozygous (677CT). [Table 38.2](#) shows the frequency of the 677C → T allele in different populations based on country and ethnicity.

TABLE 38.1

Nutrient-Gene Nomenclature

Nutrigenetics: How a person's genes (i.e., DNA sequence or genotype) impacts their need for, or utilization of, a specific nutrient. Often the particular gene expresses an enzyme that metabolizes the nutrient, uses the nutrient as a cofactor, or is involved in the transport/signaling of the nutrient. The relationship between *MTHFR* genetics and folate is a classic example of nutrigenetics.

Nutrigenomics: How nutrients or their metabolites function to turn on (or off) genes. One of the best examples of this is vitamin D, which activates the vitamin D nuclear receptor (VDR) in the regulation of numerous different genes. *Nutrigenetics* and *nutrigenomics* are closely related concepts and can influence one another. For instance, genetic differences in the *VDR* gene can impact the need for vitamin D (*nutrigenetics*) while also influencing the relative genomic impact of vitamin D (*nutrigenomics*).

Nutrient Epigenetics: Epigenetics describes noncoding alterations in the genome that influence gene expression or cell function. These alterations are semipermanent over many cell divisions and even heritable if they are found in germ-line cells. The two most common types of epigenetic alterations are DNA methylation and histone modification. A person's epigenome is influenced by both nutrigenetic and nutrigenomic mechanisms. For example, cellular 5-MTHF levels can alter the expression of DNA methyltransferase genes (a nutrigenomic effect with epigenetic implications); at the same time, these same folate levels are directly influenced by *MTHFR* genetics (*nutrigenetics*).⁶⁸

MTHFR 1298 A→C Polymorphism (a.k.a. A1298C)

A few years after the discovery of the thermolabile 677C → T polymorphism, a second common polymorphism was identified in humans. This was also a single nucleotide polymorphism of the *MTHFR* gene at base pair 1298 (A → C), which expressed a protein with an alanine (instead of glutamate) at amino acid 429, a substitution in the regulatory domain of the enzyme.²² This enzyme variant is not thermolabile and does not appear to be associated with elevated homocysteine levels, even in homozygous individuals (1298CC).²³ However, individuals who are compound heterozygous for both SNPs (i.e., 1298AC and 677CT) have elevated homocysteine levels similar to homozygous 677TT individuals. The frequency of the 1298A → C polymorphism is highest in populations of European descent; homozygous frequency for the 1298CC ranges from 4% to 12% ([Table 38.3](#)).²⁴

Health Risks Associated With Methylenetetrahydrofolate Reductase Polymorphisms

The relative chronic disease risk associated with the expression of one or two *MTHFR* 677C → T alleles, or combined with the 1298A → C polymorphism, is not straightforward. While many early case-control studies showed a strong risk for cardiovascular disease, stroke, neural tube defects, Alzheimer's disease, osteoporosis, depression, thrombotic conditions, and a variety of cancers in those expressing the mutant alleles (highest risk usually in homozygous 677TT), many later studies suggested that some or all of the measured risk was dependent on a person's folate status, homocysteine levels, and ethnicity. It is now well understood that the *MTHFR* genotype-to-phenotype expression can be greatly influenced by environmental and dietary factors, as well as other (non-*MTHFR*) genes related to methylation.⁴ In other words, clinicians should assess and treat the phenotype of the patient, rather than assume their risk based solely on genotype. Recent meta-analyses and systematic reviews* are available for *MTHFR* genotype-related risk for cardiovascular disease,²⁵ hypertension,²⁶ thrombotic conditions,²⁷ stroke,^{28,29} neural tube defects,³⁰ osteoporosis,³¹ Alzheimer's disease,³² depression and related disorders,³³ and various cancers.³⁴

Testing for Methylenetetrahydrofolate Reductase Polymorphisms

There is wide disagreement within the health care community on the utility of testing patients for *MTHFR* polymorphisms. Whereas nearly all published guidelines recommend against the use of *MTHFR* genetic testing, even when homocysteine is elevated (the exception is the American Heart Association, which does recommend *MTHFR* genetic testing when total homocysteine (tHcy) is >13 μmol/L), it is still one of the most common genetic tests ordered by both integrative and conventional medicine physicians. According to a recent analysis of *MTHFR* polymorphism tests performed by 77 different institutions in the United States between 2010 and 2012, only 14.5% were ordered for

individuals with previously diagnosed hyperhomocysteinemia (tHcy >13 $\mu\text{mol/L}$), suggesting that the majority of clinicians that order such tests are unaware of or are disregarding published guideline recommendations for *MTHFR* genetic testing.³⁵

Determining *MTHFR* genetic status in subjects with a homocysteine level <13 $\mu\text{mol/L}$ is unlikely to alter the clinical recommendation of diet and lifestyle changes; genetic testing in such cases is rarely indicated.

The reason for the discrepancy in the use of *MTHFR* genetic testing may be rooted in a philosophical difference about how risk should be measured and prevented. Should risk be measured by statistically significant relative risk calculations derived through meta-analysis of the primary end-points of large clinical trials (using hard clinical outcomes like MI or death) or should risk be based on the biochemical vulnerability of reduced methylation that is likely to exist in these patients, especially when correlated to epidemiological data? The community writing the guidelines exclusively considers the former, while it appears integrative clinicians, as well as many conventional clinicians, favor the latter and believe that testing individuals is of some clinical value. Integrative clinicians are also more likely to consider homocysteine levels between 9 and 13 $\mu\text{mol/L}$ as a biomarker of poor methylation, a condition that increases long-term metabolic risk through genomic/epigenetic influences.

As previously mentioned, genotype does not always predict phenotype. Chronic health risk related to an individual's *MTHFR* polymorphism status is highly dependent upon folate intake, actual enzyme activity (best indicated by folate status and homocysteine levels), ethnicity, and other factors that influence methylation outcomes. Nonetheless, knowing a person's *MTHFR* genetics may have potential benefits. In the absence of an individual's historical homocysteine or folate status, clinicians may be able to gauge the potential influence of hypomethylation on a patient's chronic disease risk based on *MTHFR* genetics as well as their diet and supplementation history. While this information alone may not dictate a specific therapeutic strategy, it may help predict future vulnerabilities and explain why certain therapeutic strategies may be more successful than others. Nonetheless, we recommend that analysis for the *MTHFR* polymorphisms be reserved for

patients with coronary artery disease, acute myocardial infarction, peripheral vascular artery disease, stroke, depression or venous thromboembolism who have elevated homocysteine levels (>13 $\mu\text{mol/L}$), or an abnormal methionine-load test.

Integrative Therapy

The therapeutic strategies for lowering risk in individuals with *MTHFR* polymorphisms, particularly in homozygous 677TT individuals, is influenced greatly by a clinician's perspective of the risk related to *MTHFR* genetics, homocysteine levels, and methylation potential. On the basis of folate status-adjusted relative risk data and the failure of homocysteine-lowering therapies to alter primary end-points in large controlled clinical trials, the majority of guidelines recommend against testing *MTHFR* genetics as their authors do not believe there is adequate evidence to recommend any remedial therapies.³⁶ Our focus in this section is to review the available evidence of measurable differences in therapies based on a patient's *MTHFR* genetics, mostly as it relates to dietary and supplemental changes in folate status. However, in the absence of elevated homocysteine levels or reduced folate status, therapies based solely on *MTHFR* genotype alone may not be warranted.

Assessing Folate Status

Red blood cell folate (erythrocyte folate) is the best single measure of folate status as it reflects the body folate store (use lab reference ranges).

Serum folate measures can be helpful, but are influenced by recent consumption of dietary folates. Combined with elevated serum homocysteine (>13 $\mu\text{mol/L}$), this will often help define a low folate status.

Diet history of low consumption of green leafy vegetables and unfortified foods is also an indicator of a past history of low folate status.

Dietary and Supplemental Folates

There is a close association between folate status and *MTHFR*

polymorphism/ activity status. RBC and plasma folate levels are generally lower in individuals carrying one or two 677C → T alleles, or in compound heterozygous individuals (677CT/1298AC), and conversely, chronic disease risk measurements related to these polymorphisms are higher when folate status is low.³⁷ Therefore the majority of interventions associated with risk modification in individuals with differing *MTHFR* genotypes have focused on improving folate status through dietary intervention or supplementation, or by homocysteine-lowering therapies through dietary changes and/ or supplementation (mostly using folates in combination with other vitamins).

Folate is the generic term for naturally-occurring food folates, folic acid (the fully oxidized monoglutamate form of the vitamin used in dietary supplements and fortified foods), folinic acid, and 5-MTHF. The current recommended daily allowance (RDA) in the United States is measured in Dietary Folate Equivalents (DFE, see the following), although label-claim daily value levels of folate/ folic acid are measured by weight in micrograms.* The most recent RDA (1998) is based primarily on the adequacy of red blood cell-folate concentrations at different levels of folate intake, as judged by the absence of abnormal hematological indicators. Use of the DFE reflects a higher bioavailability of synthetic folic acid found in supplements and fortified foods compared to that of naturally occurring food folates.

- 1 mcg of food-derived folate provides 1 mcg of DFE.
- 1 mcg of folic acid taken with meals or within a fortified food provides 1.7 mcg of DFE.
- 1 mcg of folic acid (supplement) taken on an empty stomach provides 2 mcg of DFE.

Without food fortification and supplementation of folic acid, deficiency of folate intake is prevalent in the U.S. NHANES data gathered from 2003 to 2006 show that nearly 90% of Americans consume below the estimated average requirement (EAR) for folate; though after fortification this drops to only 10%.³⁸ Due to the relationship of widespread folate insufficiency with neural tube defects in early pregnancy, the U.S. instituted mandatory folic acid fortification of all enriched grain products in 1998.

Plant-derived dietary folates exist mostly in polyglutamate forms, while commercially available folates, such as folic acid, folinic acid, and 5-MTHF, are monoglutamates ([Fig. 38.2](#) and [Table 38.4](#)).

Polyglutamate folates from the diet must first be hydrolyzed to their monoglutamate forms by the action of folate hydrolase before being

absorbed. Thus when establishing food recommendations, the bioavailability of food-derived folate is commonly estimated at 50% of folic acid (already a monoglutamate).³⁹ Monoglutamate forms that are not fully reduced (e.g., folic acid) or methylated (e.g., both folic acid and folinic acid) prior to absorption will be reduced and methylated to form 5-MTHF within the mucosa or liver prior to circulation. Once in the target cell, additional glutamate molecules are added to 5-MTHF, to again form a polyglutamate.

Adequate synthesis of 5-MTHF requires sufficient amounts of reduced folates and adequate function of the MTHFR enzyme. Impairment of the MTHFR enzyme can result in elevated conversion of 5,10-methylenetetrahydrofolate to formylated (rather than methylated) folate forms in the cell. Researchers have reported that RBC folate levels in homozygous 677TT individuals contain elevated levels of formylated THF forms and RBC folate in 677CC individuals is exclusively 5-MTHF.⁴⁰ Although various studies have suggested that the MTHFR activity in 677TT individuals is reduced by nearly 70% compared to wild-type individuals (677CC), one study showed that only 30% of the RBC folate in 677TT individuals is in the formylated form, a figure which is similar to the approximate 20% increase in homocysteine levels seen in these individuals based on genotype.^{25,41}

Three forms of folate are currently used in dietary supplements: folic acid, folinic acid, and 5-methyltetrahydrofolate (5-MTHF). Folinic acid (e.g., calcium folinate) is a 5-formyl derivative of tetrahydrofolic acid (THF). Synthetic 5-MTHF used in medical foods and in dietary supplements (both calcium and glucosamine salt forms are available) is not derived from “natural sources” and is not, as some describe it, a dietary folate. These compounds would be considered bioequivalent (or bioidentical) synthetic analogs (5-MTHF, when naturally found in foods, is mostly in a polyglutamyl, not monoglutamyl form). Commercially available 5-MTHF is organically synthesized using folic acid as a starting material. After reduction to tetrahydrofolate and methylation, a racemic mixture (R,S) of a monoglutamyl 5-MTHF is formed. Crystallization and separation of the two stereoisomers allows for a purified S-form, which is then stabilized using calcium or glucosamine ions (the “S” describes the specific stereochemistry at the #6 carbon; this is often also called the “L” form due to the way this isomer reflects light). Therefore 5-MTHF is sometimes labeled as (6S)-5-methyltetrahydrofolate. Other names include levomefolic acid or L-methylfolate. Unfortunately, this process results in a raw material that is about 200 times more expensive than an equimolar

amount of folic acid.

Supplemental folic acid, which must be fully reduced and methylated, is often less capable of increasing serum 5-MTHF levels in 677TT individuals compared to 677CC individuals.⁴² Clinical studies comparing the ability of folic acid with 5-MTHF supplementation to change serum folate levels or effect changes in homocysteine in both 677TT and 677CC subjects are limited, as most studies did not recruit sufficient 677TT individuals to reach a statistically significant conclusion.⁴³ Some studies show no statistical difference, or only slight benefit for 5-MTHF, while others show a statistical benefit for 5-MTHF supplementation, particularly in bioavailability studies. In a recent study comparing a single dose of either 400 mcg of folic acid or equimolar levels of 5-MTHF (416 mcg) in women homozygous for either the CC or TT polymorphism, 5-MTHF supplementation was able to increase plasma folate levels (AUC) by nearly twice that of folic acid in 677TT individuals and by 60% in 677CC subjects.⁴⁴ On the other hand, after 13 weeks of folate treatments (using either a folate-rich diet, folic acid, or 5-MTHF) equivalent to 200 mcg of folic acid, each folate form was equally capable of RBC folate benefits and homocysteine lowering in subjects (Italian) with moderate hyperhomocysteinemia (mean baseline level, tHcy 14.1 $\mu\text{mol/L}$).⁴⁵

FIG. 38.2 Structure of folic acid (*top*) and reduced folate polyglutamates from foods (*middle*). Table shows the positions and oxidation states of folate one-carbon substitutions. (From Shane B. Folate, vitamin b12 and vitamin B6. In: Stipanuk MH, ed. *Biochemical, physiological, and molecular aspects of human nutrition*. Philadelphia: WB Saunders; 2000.)

TABLE 38.4 Foods Highest in Dietary Folates

- Green leafy vegetables (cooked/boiled)
- Lentils (cooked/boiled)
- Garbanzo beans/chickpeas (cooked/boiled)

- Asparagus (cooked, boiled)
- Spinach (cooked, boiled)
- Lima beans (large, mature seeds, cooked, boiled)
- Orange juice (raw)
- Most commercial products made with flour (fortified with folic acid)

Beyond bioavailability and homocysteine-lowering effects, other issues may be important when comparing folic acid versus 5-MTHF supplementation. The first is that high-dose folic acid supplementation (>5 mg/day) results in an increase in serum levels of unmetabolized folic acid.⁴⁶ However, this is likely due to overwhelming the capacity of the dihydrofolate reductase (DHFR) enzymes in both the intestine and liver, rather than specific deficiencies in the MTHFR enzyme.^{47,48} Nonetheless, while there is no clear evidence of a demonstrable negative consequence for these elevated levels of unmetabolized folic acid, supplementation above 5 mg/day of folic acid, when warranted, should be performed with caution or substituted with 5-MTHF supplementation.⁴⁹ The second issue often cited is that high doses of folic acid can mask (not cause) an underlying vitamin B12 deficiency; supplementation with 5-MTHF appears to be less likely to have this consequence, although this has not been confirmed by rigorous clinical trials. Because it is routinely recommended that vitamin B12 be used with any high-dose folate/folic acid supplementation therapy, this issue is of little clinical concern.

In general, pregnant women with a *MTHFR* 677TT genotype are at higher risk for fetal neural tube defects (NTDs); *MTHFR* A1298A → C polymorphisms play only a minor role in NTD risk.⁵⁰ For decades, folic acid was the primary folate used in dietary supplements and in nearly every clinical trial to improve folate status in pregnant women. While no intervention studies using 5-MTHF during pregnancy have been published to date, there are many researchers and clinicians recommending the use of 5-MTHF, rather than folic acid, for preconception and prenatal supplementation.⁵¹ With the exception of additional cost, this recommendation should result in no harm to the mother or child and is likely to increase folate status in these women to a greater extent than a similar level of folic acid.

According to the IOM, the daily recommended intake for folate during pregnancy (defined as a dietary folate equivalent-DFE) is 600 mcg.⁵² Technically, this is equal to 300 mcg of a folic acid supplement because the IOM deems 1 mcg of folic acid equal to 2 DFEs. As of December 2014, the daily value (DV) used for folic acid by the FDA to label prenatal supplement (i.e., the 100% DV in the supplement facts box) is 800 mcg, differing both from the 600 mcg DFE recommendation and its 300 mcg folic acid equivalent.⁵³ Regardless of these discrepancies, NHANES data show that folate/folic acid intake in women of child-bearing age is well below the recommended amount. Therefore we recommend 800–1000 mcg/day of folic acid or 5-MTHF should be added through supplementation starting 8 weeks before conception through the end of breastfeeding. While we do not believe folic acid is either unsafe or ineffective in such patients, those with *MTHFR* 677CT or 677TT polymorphisms may realize additional benefits using 5-MTHF rather than folic acid.

Dosage

Folic acid: 200 mcg to 5 mg based on starting and target homocysteine levels. Avoid using more than 1 mg of folic acid in 677TT (choose the 5-MTHF form).

5-MTHF: 200 mcg and above based on starting and target homocysteine levels. Consider using in place of folic acid in subjects that are 677TT, 677CT, or compound heterozygous (677CT/1298AC) or when using greater than 5 mg/day of supplemental folate in any subject.

Related Homocysteine Lowering Therapies

Nearly all other diet and nutrient interventions that have been investigated in subjects with *MTHFR* polymorphisms (mostly 677C → T) are related primarily to their ability to lower homocysteine; many of which were investigated in combination with supplemental folate compounds. To the extent that homocysteine lowering is the intended therapeutic goal and 677TT individuals are known to have elevated homocysteine levels, these therapies may be considered helpful in these subjects, although none, except riboflavin, have specifically been shown

to directly improve the function of the MTHFR enzyme.

Cobalamin (Vitamin B12)

Cobalamin (B12) is a necessary cofactor for methionine synthase, the enzyme that transfers the methyl group from 5-MTHF to homocysteine using methyl-cobalamin as an intermediate. Vitamin B12 should be used when supplementing folates, especially folic acid. While there are clinicians that prefer one form of B12 over another (cyanocobalamin, methylcobalamin, hydroxocobalamin, or adenosylcobalamin), or claim that one is more effective in subjects with MTHFR polymorphisms, to date, there is no published data to suggest a difference between these forms in such subjects. The biochemistry of cobalamin forms would suggest little in the way of functional differences, although hydroxocobalamin may be favorable in some rare genetic defects in cobalamin metabolism.⁵⁴ Oral doses of 1 mg or more are considered equivalent to intramuscular doses for increasing markers of B12 repletion.⁵⁵

Dosage

For homocysteine lowering, an oral dose of 1 mg is safe, tolerable, and adequate for most subjects regardless of intrinsic factor or vitamin B12 status. Multivitamin doses starting at 200 mcg are likely adequate for subjects without vitamin B12 insufficiency and normal homocysteine levels.

Precautions

There are no safety concerns related to vitamin B12 supplementation and no known toxicity reported for long-term vitamin B12 use; the IOM has set no tolerable upper safety level.

Riboflavin (Vitamin B2)

Riboflavin is the precursor for the MTHFR's stabilizing cofactor, FAD. Low riboflavin levels have been associated with elevated homocysteine, especially in subjects with the *MTHFR* 677TT genotype.⁵⁶ Riboflavin supplementation, even as low as 1.6 mg/day, has been shown to reduce homocysteine levels in homozygous 677TT subjects.⁵⁷ Riboflavin-5-

phosphate is often marketed as an “activated” or natural form of riboflavin to integrative medicine clinicians. As it turns out, this synthetic “bioidentical” form must be dephosphorylated prior to transport into the body and offers no advantages when taken orally.^{58,59}

Dosage

Oral dose of 2.0–50 mg of riboflavin USP.

Precautions

None. Higher doses of riboflavin can result in a harmless intense yellowing of urine (flavinuria).

Pyridoxine (Vitamin B6)

Vitamin B6 is not directly involved in the MTHFR reaction. However, it is a cofactor in the reaction that converts homocysteine to cysteine (transsulfuration pathway) catalyzed by cystathionine β -synthase. Therefore, low vitamin B6 levels can exacerbate the health risk in subjects with low folate and/or MTHFR polymorphisms. Vitamin B6 supplementation has been shown to effectively lower homocysteine levels, especially when added to folate supplementation.⁶⁰

It is common for some manufacturers to include pyridoxal-5-phosphate (P5P) in their formulas, marketing this ingredient as an “active” or “natural” form of supplemental B6. While also being “bioidentical,” this ingredient is synthesized from pyridoxine HCl, which increases its cost by approximately seven-fold. When taken orally, P5P must be dephosphorylated prior to absorption and has no clinical advantages over pyridoxine HCl.^{61,62}

Dosage

Oral dose of 2–50 mg pyridoxine HCl USP. Higher doses are unnecessary for homocysteine-lowering.

Precautions

None at the recommended dose. Avoid exceeding the tolerable upper limit (100 mg/day) unless following a therapy known to be safe and

effective. Toxic levels (1000 mg a day) can cause sensory neuropathy.

High doses of vitamins B6 (80 mg/day) and B12 (20 mcg a day) can trigger a flare of rosacea with red papules, pustules, and nodules, which can take months to resolve.

Betaine and Choline

Human liver and kidney cells can remethylate homocysteine to methionine using betaine (trimethylglycine) as a methyl donor using the enzyme betaine homocysteine methyltransferase (BHMT).

Supplemental betaine (or its precursor choline) have been shown to effectively reduce hyperhomocysteinemia, although studies in patients stratified by MTHFR polymorphisms have not been reported.⁶³ Higher doses of betaine (~6 grams/day) may be needed to see changes in fasting tHcy,⁶⁴ while smaller doses (500–1000 mg) are effective in reducing postmethionine load elevations in homocysteine.⁶⁵

N-Acetylcysteine

Kidney clearance of homocysteine requires that it is unbound, although the majority of homocysteine (75%) in the serum is bound to protein via a disulfide bond. The common dietary supplement ingredient, N-acetylcysteine (NAC), can reduce the disulfide homocysteine-protein bond providing more free homocysteine to the kidney for clearance. The effect is dose-dependent at oral doses between 600 and 1800 mg/day in patients with normal kidney clearance.⁶⁶ ESRD patients may require higher doses (5 mg) and several studies have provided NAC intravenously to these subjects.⁶⁷

Side Effects With Methyl Donors

Unpublished clinical reports and online discussions of side effects related to consuming methyl donors have been increasing in subjects of all genotypes. This has often been dubbed as “overmethylation.”

Symptoms are usually described as headaches, anxiety, palpitations, or unexplained pains after high doses of methyl donors, especially 5-MTHF. While the etiology of this phenomenon has not been investigated, we suggest precaution and gradual dose-escalation, especially in subjects with historically low folate and presumed low

methylation. Monitoring changes in tHcy levels or choosing modest targets for tHcy (9–13 $\mu\text{mol/L}$) may represent a way of mitigating the side effects associated with methyl-donor therapies.

Prevention Prescription

- Consume a diet high in folate (fruits and vegetables, traditional Mediterranean, or DASH diet).
- If necessary, consider reducing methionine in the diet (methionine increases homocysteine). Foods containing high levels of methionine include eggs, cheese, meats, and soy protein concentrates.
- Monitor homocysteine levels, maintain below 9 $\mu\text{mol/L}$ through diet, and, if warranted, provide daily B-multivitamins.
- Avoid smoking and high consumption of coffee (>6 cups/day).
- Avoid excess alcohol consumption.

Therapeutic Review

Risks associated with MTHFR polymorphisms are greatest in homozygous 677TT and compound heterozygous (677CT/1298AC), and least in 677CT heterozygous individuals. However, in all cases, an individual's phenotype, measured according to homocysteine and folate status, is more predictive of risk compared with the genotype. These recommendations are related both to improving risk related to MTHFR genetics and reducing homocysteine levels.

MTHFR Genetic Testing

Should be reserved for patients with coronary artery disease, acute myocardial infarction, peripheral vascular artery disease, stroke, depression, or venous thromboembolism who have elevated homocysteine levels (>13 $\mu\text{mol/L}$). Patients need only to be tested once, as genotype does not change. In the absence of elevated homocysteine levels or reduced folate status, therapies based solely on *MTHFR* genotype alone may not be warranted.

- MTHFR genetic testing when tHcy >13 $\mu\text{mol/L}$ 

- MTHFR genetic testing when tHcy <13 $\mu\text{mol/L}$ 

Diet

- Folate-rich diet (Mediterranean/DASH-based, increase vegetables and fruits) 
- Low-methionine diet (dietary methionine can elevate homocysteine levels) 

Supplements

- Folates: 200 mcg–5 mg/day to normalize homocysteine levels
 - Folic acid: Avoid using more than 1 mg in subjects with *MTHFR* 677TT 
 - 5-MTHF: Preferable in subjects with *MTHFR* 677TT or 677CT/1298AC genotypes, or when using folate therapies above 5 mg 
- Vitamin B12: 200–1000 mcg/day oral (all cobalamin forms) 
- Riboflavin USP: 2.0–50 mg/day 
- Vitamin B6 (Pyridoxine HCl): 2–50 mg/day 
- Betaine (trimethylglycine): not to be confused with Betaine HCl (used to deliver HCl for lowering stomach pH): 500 mg–6 g (higher is better) 
- Choline: as a precursor to betaine, 3–6 g 
- N-acetylcysteine (NAC) to increase free homocysteine for kidney clearance
 - 600–1800 mg/day oral in subjects with normal kidney clearance 
 - Up to 5 g/day intravenously in ESRD/dialysis

* The gene and the expressed enzyme are both designated with the same letters. The enzyme is designated in capital letters (MTHFR), while the gene is shown in capital italics (*MTHFR*).

* Meta-analysis and systematic reviews have limitations and are often not reflective of the nuances seen in the clinic due to their strict inclusion/exclusion criteria, data adjustments or statistical variances. We suggest that readers consult the references listed if they want to understand these details and judge the merits of their conclusion.

* The FDA has changed to the DV for folates and folic acid in foods and dietary supplements to fix this discrepancy. As of mid-2018, labels must distinguish food-derived folates from folic acid, though it does not specify how to include supplemental 5-MTHF on a food or supplement label as it is neither.

CHAPTER 39

Adrenal Fatigue

Jacqueline Redmer, MD, MPH

The Natural Stress Response

The human body is well equipped to handle stress. A wide array of hormones and neurotransmitters exist to maintain homeostasis in response to physical and psychogenic stressors. The adrenal glands, which are located at the top of the kidney, are at the center of the body's stress response system. The cortex forms approximately 90% of the adrenal mass, the remaining core being the adrenal medulla. In the adult, the cortex can be morphologically and functionally divided into three layers (the glomerulosa, fasciculata, and reticularis). Each layer has a distinct histological appearance and secretes different steroid hormones (aldosterone, cortisol, and androgens, respectively). The inner 10%–20% of the gland is the adrenal medulla, secreting the catecholamines epinephrine and norepinephrine¹ ([Fig. 39.1](#)).

The body responds to physical, emotional, psychological, and biochemical stresses by releasing cortisol. Stress is sensed by the hypothalamus, which then releases corticotropin hormone (CRH). This stimulates the anterior pituitary to produce adrenocorticotrophic hormone (ACTH), which triggers receptors in the adrenal cortex to release the appropriate amount of cortisol. When the sympathetic (fight or flight) nervous system is activated, the adrenals respond by releasing epinephrine, norepinephrine, and cortisol, all of which increase heart rate and blood pressure diverting blood to the brain, heart, and skeletal muscle² ([Fig. 39.2](#)).

Adrenal insufficiency is a well-documented condition in which the adrenals cannot keep up with the stress response of the body. This can happen if there is destruction of the adrenal cortex (primary) or if factors outside of the adrenal glands stimulate them to produce less cortisol

(secondary). In primary adrenal insufficiency, the symptoms reflect a loss of glucocorticoid and mineralocorticoid hormones, whereas secondary deficiency usually results only in a loss of cortisol.³

Although not widely accepted by allopathic medicine, many alternative medicine practitioners believe that a subclinical adrenal fatigue or burnout can develop when the adrenals have been working hard to keep up with high physical, psychological, or emotional stress demands over time^{2,4} ([Table 39.1](#)). It is hypothesized that sustained levels of high cortisol may lead to decreased responsiveness in the pituitary and adrenal glands. Changes in hypothalamic-pituitary-adrenal (HPA) axis may be due to the following mechanisms: (1) reduced biosynthesis or release of the respective hormone on different levels of the HPA axis (CRH from the hypothalamus, ACTH from the pituitary, or cortisol from the adrenal glands); (2) hypersecretion of one hormone with a subsequent downregulation of the respective target receptors; (3) enhanced sensitivity to the negative feedback of cortisol; (4) a decreased availability of free cortisol; and/or (5) reduced effects of cortisol on the target tissue, resulting in a relative cortisol resistance.^{5,6}

Adrenal fatigue and chronic fatigue syndrome (now recognized as Systemic Exertion Intolerance Disease) overlap a good deal clinically, and some people view adrenal fatigue as a subset of CFS. A meta-analysis of 19 studies from 2013 on this subject evaluated this relationship. It was found that 24-hour measures of absolute cortisol output did not clearly correlate with fatigue symptoms. However, attenuation of the cortisol diurnal variability, particularly with disruption of waking and circadian rhythms, seems to have more impact on the development of CFS.⁹ Other reviews have suggested that HPA axis activity (or dysfunction) may not be at the core of CFS, but instead occur as a result of certain behavioral changes associated with the illness.¹⁰

Diagnosing Adrenal Fatigue

In most cases, a diagnosis of adrenal fatigue is based on clinical history and the exclusion of other conditions based on basic lab work. In patients suspected of having adrenal fatigue, however, it may be reasonable to screen for frank adrenal insufficiency. With normal diurnal variations in cortisol, glucocorticoids are lowest at 12 a.m.–1 a.m. and highest at 6 a.m.–8 a.m. In conventional medicine, cortisol adequacy is usually tested for with an 8 a.m. fasting serum cortisol test. In healthy patients, the

cortisol level is usually 10–20 mcg/dL. An early morning low serum cortisol concentration less than 3 mcg/dL has a high specificity (100%) and low sensitivity for adrenal insufficiency (36%). Using a higher serum cortisol of 10 mcg/dL as the criterion for adrenal insufficiency increases the sensitivity to 62% and reduces the specificity to 77%. Thus a low morning serum cortisol concentration alone is not a reliable predictor of deficient adrenal function.¹¹

Among practitioners, there is controversy regarding the best measurement of cortisol, with many people feeling strongly that salivary, not serum, levels more accurately reflect adrenal function.^{12–15}

Controversy exists concerning the validity of such testing materials and potential confounding variables, such as dietary interference, salivary viscosity, oral contaminants, and oral diseases such as gingivitis.

However, some data suggest that salivary collection is preferable because it adjusts for bioavailable cortisol and is unaffected by cortisol binding globulin level, which rises with oral contraception pills, hypoalbuminemia, cirrhosis, nephrotic syndrome, and pregnancy.

Salivary cortisol testing is easy to collect, although testing may not be widely available and testing criteria have not been uniformly accepted.¹⁶

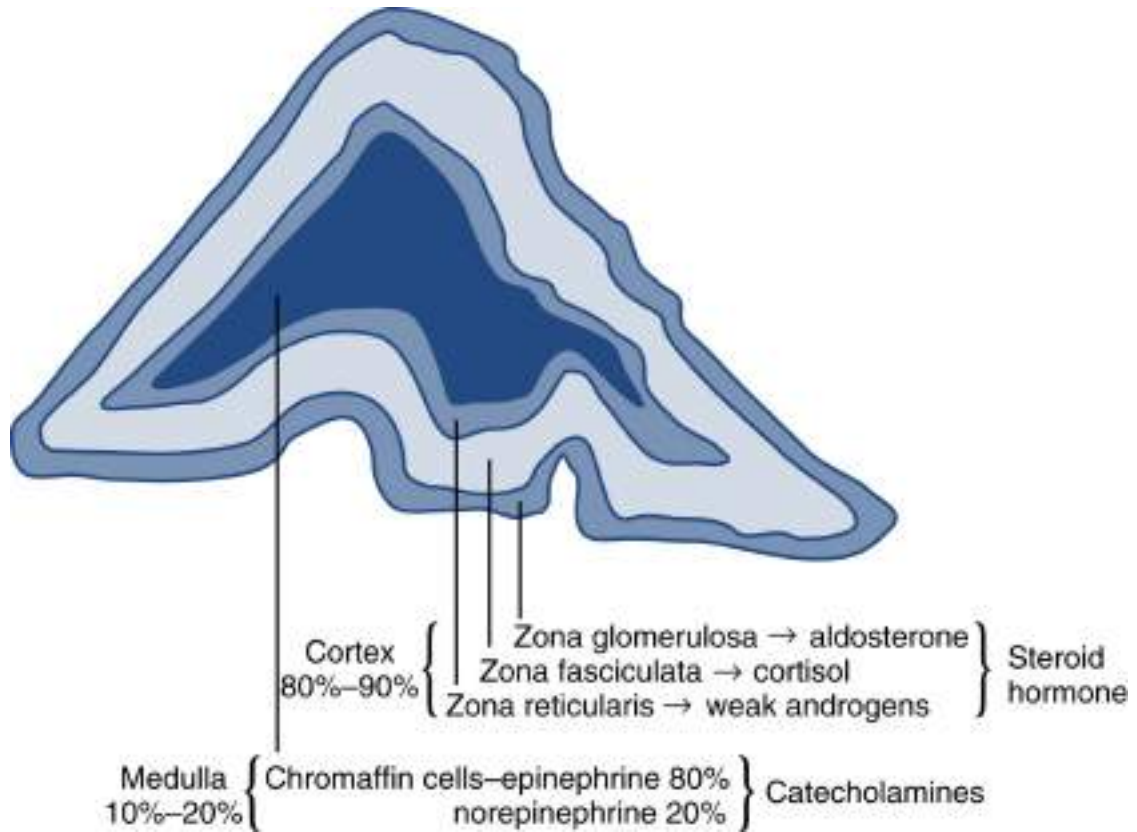

FIG. 39.1 Histology of the adrenal gland. (From White B, Porterfield S. The Adrenal Gland, In : *Endocrine and reproductive physiology* , St. Louis, Elsevier, 2013:147-176.)

FIG. 39.2 The hypothalamic-pituitary axis. (From Kutikov A. Pathophysiology, evaluation, and medical management of adrenal disorders. In: Wein AJ, Kavoussi LR, Partin AW, Peters CA, editors: *Campbell-Walsh urology*, ed. 11 . Philadelphia, Elsevier, 2012:1685-1736.e8.)

When evaluating a patient for adrenal fatigue, consider the following

tests to rule out other causes for their symptoms: polysomnography; PHQ-9 testing for depression; and labs including TSH, T3, T4, CBC, ferritin, CMP, magnesium, zinc, and vitamin B12.

Due to the pulsatile nature and diurnal variation of cortisol secretion, many integrative medicine practitioners use a four-point salivary testing technique to assess for patterns suggestive of adrenal fatigue and derangements of the HPA axis. With most protocols, salivary cortisol is checked from 7 a.m.–9 a.m., 11 a.m.–1 p.m., 3 p.m.–5 p.m., and 10 p.m.–12 a.m. These methods assume the assessment of cortisol and DHEA trends is more helpful than a random or 24-hour assessment because of the dramatic variation throughout the day. There is a growing body of evidence supporting the validity of salivary testing for adrenal disorders; however, in general, evidence to support the use and interpretation of four-point testing as a measure of adrenal function remain limited.¹⁷⁻¹⁹ That said, the trends revealed by four-point testing may be informative when assessing a patient for clinical symptoms of adrenal fatigue.

If true adrenal insufficiency is suspected based on an unusually low early morning cortisol level, further testing may include:

ACTH/cosyntropin stimulation test. The ACTH stimulation test is the most commonly used test for diagnosing adrenal insufficiency. In this test, the patient is given an intravenous (IV) injection of synthetic ACTH, and cortisol levels are measured before and after the injection. The normal response after an ACTH injection is a rise in blood and urine cortisol levels. People with Addison's disease or secondary adrenal insufficiency have little or no increase in cortisol levels.⁷

CRH stimulation test. When the response to the ACTH test is abnormal, a CRH stimulation test can help determine the cause of adrenal insufficiency. In this test, the patient is given an IV injection of synthetic CRH, and cortisol levels are taken before and after the injection. People with Addison's disease respond by producing high levels of ACTH, yet no cortisol. People with secondary adrenal insufficiency do not produce ACTH or have a delayed response.⁷

TABLE 39.1

The Effects of Stress on the Body

Adrenal Insufficiency Symptoms ⁷	Adrenal Fatigue Symptoms ⁸	Adrenal Fatigue—Activity Patterns ⁸
<ul style="list-style-type: none"> • Fatigue • Body aches • Weight/muscle loss • Low blood pressure • Lightheadedness • Loss of hair • Nausea/vomiting and diarrhea • Hyperpigmentation 	<ul style="list-style-type: none"> • Fatigue • Difficulty with morning waking • Prone to infection • Craving sweet or salty food • Difficulty concentrating • Hypoglycemia • Decreased libido • Depression 	<ul style="list-style-type: none"> • Waking fatigue, even after an adequate night's sleep • Midmorning low energy—often treated with caffeine or sugar • Afternoon low between 2 p.m. and 5 p.m. • Improved energy after 6 p.m. • "Second wind" around 11 p.m., lasts until 1 a.m.–2 a.m.

Integrative Therapy

Fortunately, many of the harmful effects of chronic stress and adrenal fatigue are reversible, at least to some extent. There are various interventions that can decrease the effects of adrenal fatigue, including nutritional therapies, exercising regularly, supplements, and the incorporation of stress management strategies.

Although lifestyle management alone might not reverse all symptoms of adrenal fatigue, this must be an important component of any treatment plan since unhealthy lifestyle and poor adaptive stress management techniques usually contribute to this condition.

Lifestyle Interventions⁸

Advise patients to:

1. Minimize the sources of psychological, physical, and emotional stress in their lives.
2. Reduce commitments and emphasize unstructured free time in which patients can participate in activities they enjoy.
3. Set a goal to obtain adequate sleep (7–9 hours for adults).
4. Laugh as much as possible. Prescribe laughter therapy. This might include the use of humorous books, movies, stories, YouTube clips, jokes, memories, or anything that makes them laugh.
5. Limit alcohol; in the moment, having a drink feels relaxing but alcohol interferes with sleep and depresses mood.
6. Make good dietary choices; sugar and refined carbs worsen the body's response to stress, even though they may feel satisfying in the short term.

7. Engage in activities that give their lives meaning and purpose.

Nutrition

Patients with adrenal fatigue are encouraged to avoid hypoglycemia because this can raise cortisol levels. Patients should minimize consumption of simple carbohydrates and focus on consuming small, frequent meals. Salt restriction is not necessary²⁰ (see [Chapter 87](#)).

Botanicals

Adaptogens are phytochemicals, which are believed to stabilize physiological processes and encourage homeostasis in the body. Adaptogens helpful in the treatment adrenal fatigue include:

Licorice

Glycyrrhiza licorice appears to have modest glucocorticoid activity and may act synergistically with cortisol. Components of licorice (primarily glycyrrhizin, which is structurally similar to corticoids) can bind to glucocorticoid and mineralocorticoid receptors, weakly mimicking the role of endogenous steroid hormones. There is some evidence that licorice may also reduce the breakdown of hydrocortisone to inactive cortisol products.

Dosage

Licorice powdered root 1–4 g daily three times daily.^{2,21}

Precautions

Licorice, like steroids, can cause salt retention, elevated blood pressure, and hypokalemia. Potassium and blood pressure should be monitored in those taking licorice root. This effect is removed in deglycyrrhizinated forms (DGL), but these also lack the active ingredient used for treating fatigue.

Ashwaganda

Ashwaganda is considered to be the preeminent adaptogen in the

Ayurvedic medical system. When administered to animals, ashwaganda has been shown to counteract many of the biological changes that accompany severe stress, including changes in blood sugar and cortisol levels.

Dosage

Powdered herb 2–3 g twice daily.^{2,21}

Precautions

Well tolerated at recommended doses. High doses can cause GI intolerance.

Siberian Ginseng

Also known as *Eleutherococcus senticosus*. Most data on Siberian ginseng has been completed by Russian scientists to improve athletic performance in Olympic athletes and is not available in English. However, one review indicates Siberian ginseng increases the ability to accommodate adverse physical conditions and improves mental performance.

Dosage

Variable based on preparation.^{21,22}

Precautions

Siberian ginseng should be used cautiously in those with heart disease as it can precipitate palpitations, tachycardia, and hypertension. High doses can also cause anxiety and irritability.

Panax Ginseng

While the antistress mechanisms of Panax ginseng are not completely understood, research suggests a variety of actions on both the adrenal glands and the HPA axis. At the level of the brain or HPA axis, ginseng appears to stimulate ACTH and subsequent cortisol production and may also increase binding of corticosteroids to certain regions of the brain.

Dosage

Dried root powder 200–600 mg daily.²¹

Precautions

The most common side effect is insomnia. Be careful not to give close to bedtime. As with other ginseng's common side effects are related to overstimulation. Ginseng is difficult to grow and harvest. Adulterated products are common so recommend a dependable source.

Rhodiola Rosea

The adaptogenic properties and CNS activities of *Rhodiola* have been attributed primarily to its abilities to influence the levels of the neurotransmitters, serotonin, dopamine, and norepinephrine, by inhibiting the enzyme responsible for their degradation.

Dosage

100–300 mg three times daily.^{21,22}

Precautions

Can cause dry mouth and dizziness.

Supplements

Vitamin B Complex

Studies have shown the B vitamins are protective nutrients for the adrenals, decreasing the stress-induced cortisol response. The B vitamins support sleep quality and are also important cofactors in the production of neurotransmitters.^{2,21}

Dosage

Consider a B-complex vitamin daily.

Precautions

Safe at regular doses.

Vitamin C

Vitamin C is important for numerous physiological functions, including the metabolism of the neurotransmitters dopamine and norepinephrine.² The adrenals need more vitamin C than any other organ or tissue in the body, especially during times of stress.²³ For most healthy individuals, the body can only hold and use approximately 250 mg of vitamin C a day, and any excess is lost through urine.

Dosage

250 mg twice daily.

Precautions

High doses can cause diarrhea.

L-Carnitine

This supplement may be useful for boosting metabolism and increasing energy levels. L-Carnitine helps to move fatty acids into the mitochondria where they are used to produce energy. Several studies have shown that L-carnitine supplementation in healthy, elderly subjects results in a reduction of total fat mass, an increase in total muscle mass, a decrease in fatigue, and improvement in cognitive function.^{24,25}

Dosage

2 g twice daily.

Precautions

May decrease effectiveness of thyroid hormone supplementation.

Dehydroepiandrosterone

Although commonly used for adrenal fatigue, there is minimal evidence to support the use of dehydroepiandrosterone (DHEA). In a study of patient with Sjogren syndrome with fatigue and documented low DHEA

levels, replacement with 50 mg of DHEA had no benefit in fatigue scores over placebo.²⁶

Adrenal Glandulars

The safety and effectiveness of adrenal glandulars are unknown. Glandular products include ground-up animal adrenal glands (often from pigs), which contain adrenal hormones including cortisol and catecholamines. The dose is not standardized and there is potential for harm (osteoporosis and hypertension) with long-term use. In general, adrenal glandular supplements are not recommended as they may further suppress the hypothalamic-pituitary-adrenal axis.

Mind-Body Interventions

Very little evidence exists for the use of mind-body techniques in the treatment of adrenal fatigue. However, research shows there are many modalities that can lower cortisol and mediate the effects of stress.

Breathing Practices

Diaphragmatic breathing is relaxing and therapeutic, reduces stress, and is a fundamental procedure of Pranayama yoga, Zen, transcendental meditation, and other meditation practices. Analysis of oxidative stress levels in people who meditate has indicated that meditation correlates with lower oxidative stress levels and lower cortisol levels. One study reported that diaphragmatic breathing after exercise increased antioxidant defense and lowered cortisol levels.²⁷ Studies have shown that mindfulness based stress reduction programs can also lower cortisol levels in the blood²⁸ (see [Chapters 94](#) and [100](#)).

Yoga

Yoga has been used in many clinical settings to decrease stress-related illness and concerns. Although the psychological and physiological benefits likely occur in multiple ways, a recent systematic review showed that yoga increases positive affect and self-compassion and leads to lower salivary cortisol levels.²⁹

Progressive Muscle Relaxation

Several studies have found lower levels of postintervention heart rate,

anxiety, perceived stress, and salivary cortisol, as well as increased levels of self-report levels of relaxation in subjects instructed on progressive muscle relaxation (PMR) versus controls.³⁰ In a PMR session, patients are instructed to create tension in a specific muscle group, noticing what tension feels like in that area, and then to release this muscle tension and begin to notice what a relaxed muscle feels like as the tension drains away (see [Chapter 94](#)).

Biofeedback

Participants in one study were asked to complete a biofeedback training program for 5 minutes a day to decrease heart rate and increase cerebral blood flow. After 28 days, those in the intervention group had significantly lower salivary cortisol than those in the control group.³¹

Bioenergetic Interventions

Reiki

In another study, participants received ten 20-minute reiki sessions over the course of 2.5–12 weeks while being guided through relaxation exercises. Salivary cortisol levels were measured and found to be significantly lower in participants who received reiki and not just instruction in relaxation techniques.³²

Therapies to Consider

It stands to reason, then, that other modalities which mediate the physiological effects of stress on the body such as hypnosis, imagery, TCM, ayurveda, homeopathy, journaling, and massage would all have the beneficial effect of lowering sympathetic tone, thereby providing supportive treatment for adrenal fatigue.

Prevention Prescription

Prevent the onset of adrenal fatigue, by encouraging patients to:

- Minimize psychological, physical, and emotional stress
- Reduce commitments and emphasize unstructured free time
- Adopt good self-care patterns and learn stress management techniques

- Set a goal to obtain an adequate sleep (7–9 hours for adults)
- Follow an antiinflammatory, low-glycemic index diet, specifically encouraging sugar and alcohol use in moderation
- Engage in regular physical activity

Therapeutic Review

Lifestyle

- Minimize psychological, physical, and emotional stress
- Reduce commitments and emphasize unstructured free time
- Adopt good self-care patterns and learn stress management techniques
- Set a goal to obtain an adequate sleep (7–9 hours for adults)
- Follow an antiinflammatory diet, specifically encouraging sugar and alcohol use in moderation
- Engage in regular physical activity

Nutrition

- Eat small, frequent meals and minimize simple carbohydrates to avoid hypoglycemia
- No salt restriction

Supplements

- *Glycyrrhiza licorice* powdered root 1–4 g daily three times daily 
- Ashwaganda powdered herb 3 g twice daily 
- *Panax ginseng* dried root powder 200–600 mg daily 
- *Rhodiola rosea* 100–300 mg three times daily 
- Vitamin B complex 
- Vitamin C 250 mg daily 

Mind-Body

The following mind-body techniques have been shown to reduce cortisol levels

- Breathing practices, including meditation and yoga 
- Biofeedback 
- Progressive muscle relaxation 

Key Web Resources

<p><small>Reportable web resources on this topic are limited, which may be due to the variable acceptance of adrenal fatigue within the scientific community. General information on adrenal insufficiency can be found at:</small></p>

SECTION VII

Nephrology

OUTLINE

[Chapter 40. Chronic Kidney Disease](#)

CHAPTER 40

Chronic Kidney Disease

Natalia O. Litbarg, MD

Introduction

Chronic kidney disease (CKD) is associated with multiple comorbidities, loss of quality of life (QOL), and significant health care costs, and has a high prevalence in most high-income countries (e.g., 5.3% in the UK and 13.7% in the USA) (United States Renal Data System, 2014, <http://www.usrds.org/adr.aspx>).^{1,1a} Early recognition of CKD is important for timely therapeutic interventions and prevention of progression to end-stage renal disease (ESRD).

Definitions

CKD is defined as persistent abnormalities in the kidney structure or function, which are manifested by a decline in glomerular filtration rate (GFR) below 60 mL/min/1.73 m² and/or the presence of persistent albuminuria, proteinuria, hematuria, and/or electrolyte imbalances (http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO). The prognosis of CKD depends on GFR and the degree of proteinuria (Fig. 40.1). The estimated GFR (eGFR) can be obtained from several formulas using serum creatinine and/or cystatin C levels^{2,3} (<http://nkdep.nih.gov/lab-evaluation/gfr-calculators.shtml>). eGFR is very important for the early recognition of CKD because serum creatinine may be “normal” in a patient with diminished muscle mass. In addition, a significant nephron reserve can be lost before either serum creatinine or GFR changes are detectable; this is due to renal compensatory mechanisms such as hypertrophy and hyperfiltration.⁴

Risk Factors

Advancing age, proteinuria, smoking, cardiovascular disease (CVD), certain ethnicities (e.g., African-American, Native-American, and Asian-American), abnormal cholesterol, previous episode(s) of acute kidney injury, exposure to nephrotoxins, and a family history of kidney disease are well-recognized risk factors for developing CKD. In addition, diabetes, hypertension, obesity, and high triglyceride levels have now been identified as early risk factors, which can be present for 30 years or more before a diagnosis of CKD.⁵ Many of these risk factors are modifiable and preventable. For example, diabetes and hypertension account for about 44% and 28%, respectively, of all ESRD cases in the US (http://www.cdc.gov/diabetes/pubs/pdf/kidney_factsheet.pdf).

It is likely that many additional risk factors for kidney disease are still not well defined. For example, a lower GFR might be associated with factors in prenatal development (e.g., low birth weight),⁶⁻⁸ conditions in early life (e.g., formula vs. breastfeeding),⁹ or lifetime exposures to environmental toxins (e.g., living near major roads).¹⁰ Atopic diseases have been linked to some idiopathic glomerular diseases.¹¹

Pathophysiology

The triggering factors for CKD are diverse; however, endothelial dysfunction, chronic inflammation, and oxidative stress are the main contributors to the progression of CKD from any etiology,^{12,13} and are common in the pathophysiology of cardiovascular disease (CVD). Independent of the cause of the initial insult, progression of renal parenchymal injury follows a characteristically uniform pattern,¹⁴ that is, initial loss of nephrons induces adaptive mechanisms, including hypertrophy and hyperfiltration of the remaining functional nephrons. At a certain threshold of renal parenchymal loss, these compensatory mechanisms trigger maladaptive changes and lead to an increase in oxidative stress, production of proinflammatory cytokines, activation of the renin-angiotensin-aldosterone system, and cellular apoptosis (Fig. 40.2), which ultimately promote further nephron damage and loss by glomerulosclerosis, tubular atrophy, and interstitial fibrosis.¹⁵

Conventional Approach to CKD Management

Any patient with a persistent and unexplained decline in GFR,

albuminuria, proteinuria, or hematuria should be referred to a nephrologist, as well as patients with persistent serum electrolytes abnormalities, recurrent nephrolithiasis, hereditary kidney disease, and hypertension that is refractory to treatment with four or more antihypertensive agents

http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO

The specific treatment of CKD depends on the underlying causative entity. Glomerular diseases are usually treated based on the renal biopsy diagnosis, and, for the most part, require immunosuppressive and/or cytotoxic medications, while the management of other renal diseases is mostly conservative. The established CKD management of complications is usually according to the Kidney Disease Improving Global Outcomes (KDIGO) guidelines

http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO

PROGNOSIS OF CKD BY GFR AND ALBUMINURIA CATEGORY

Prognosis of CKD by GFR and albuminuria categories: KDIGO 2012				Persistent albuminuria categories Description and range		
				A1	A2	A3
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g <3 mg/mmol	30–300 mg/g 3–30 mg/mmol	>300 mg/g >30 mg/mmol
GFR categories (ml/min/1.73 m ²) Description and range	G1	Normal or high	≥90			
	G2	Mildly decreased	60–89			
	G3a	Mildly to moderately decreased	45–59			
	G3b	Moderately to severely decreased	30–44			
	G4	Severely decreased	15–29			
	G5	Kidney failure	<15			

 Low risk (if no other markers of kidney disease, no CKD)	 High risk
 Moderately increased risk	 Very high risk

FIG. 40.1 Prognosis of CKD according to GFR and albuminuria. (From Levey AS, de Jong PE, Coresh J, et al. The definition, classification, and prognosis of chronic kidney disease: a KDIGO controversies conference report. *Kidney Int* 2011;80:17-28.)

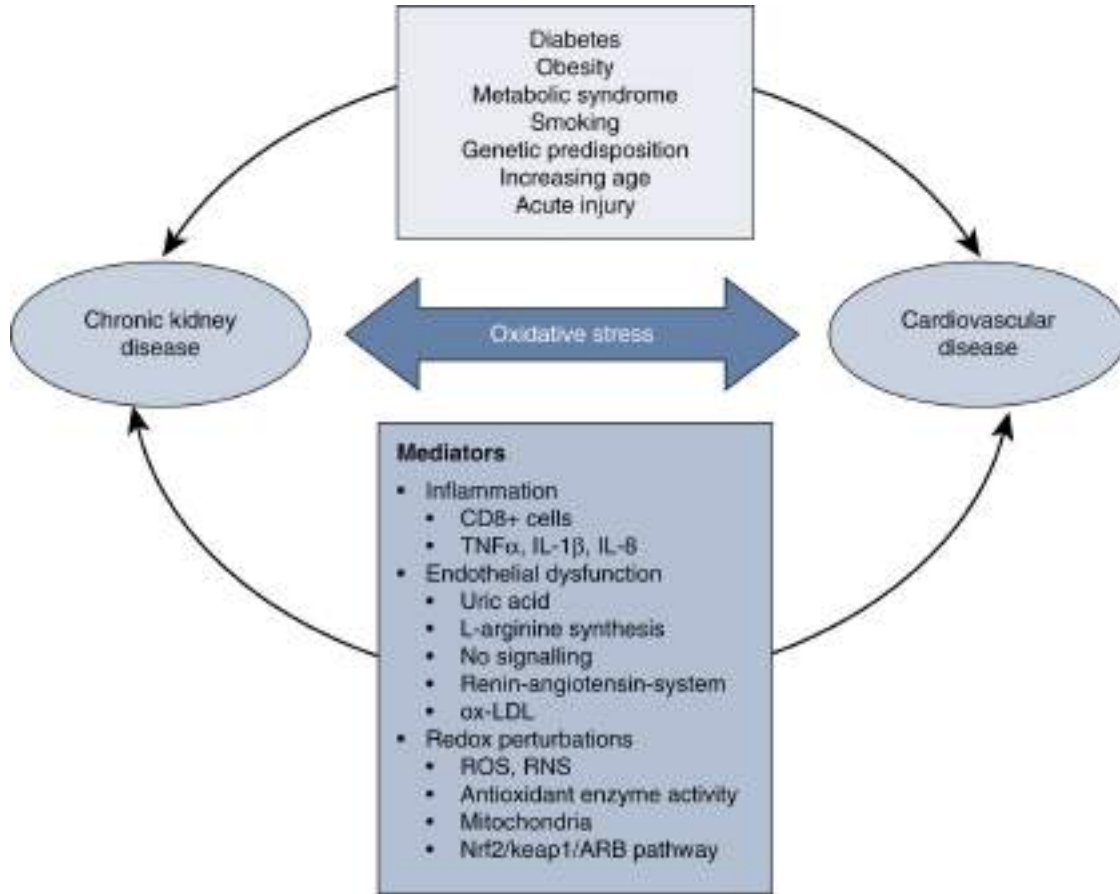

FIG. 40.2 Factors contributing to the progression of CKD and CVD. (From Small DM, Gobe GC. Oxidative stress and antioxidant therapy in chronic kidney and cardiovascular disease. In Morales-Gonzales, JA (ed.): *Oxidative stress and chronic degenerative diseases—a role for antioxidants* . InTech. © 2013 Small DM, Gobe GC. Published in [short citation] under CC BY 3.0 license. Available from: <http://dx.doi.org/10.5772/51923> .)

Following, the current evidence for integrative strategies in patients with mild to moderate CKD (stage 1–3) is summarized.

Integrative Therapy

Pharmaceuticals

Antihypertensive Agents

According to the 2012 KDIGO guidelines (<http://www.kdigo.org>) and the Eighth Joint National Committee (JNC 8),¹⁷ angiotensin converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) are suggested in adult patients with CKD (recommendation grade B). The majority of CKD patients develop volume expansion that requires the use of diuretics. Thiazide diuretics frequently have low efficacy in patients with an eGFR of <45 mL/min/1.73 m²; therefore, loop diuretics are most frequently used in patients with CKD stage 3 and higher. The addition of aldosterone antagonists or other potassium-sparing diuretics is considered, especially in patients with hypokalemic tendency.¹⁸ However, similar to ACE inhibitors and ARBs, they can increase the risk of hyperkalemia.

Uric Acid-Lowering Agents

Multiple prospective studies, as reviewed by Jalal et al.,¹⁹ involving from 56 to 177,570 subjects who were followed for several years, have demonstrated an association between elevated levels of serum uric acid and the progression of CKD; this was also shown in more recent studies.²⁰⁻²² In addition, hyperuricemia was found to be a risk factor for all-cause and CVD mortality,²³ and contrast-induced nephropathy.²⁴ Treatment of hyperuricemia appeared to lower blood pressure in adolescent patients,²⁵ patients with immunoglobulin A (IgA) nephropathy,²⁶ and diabetics with CKD.²⁷ In four studies involving 50 to 113 patients with CKD and hyperuricemia who were followed from 3 months to 6 years, treatment with allopurinol was associated with decreased progression of CKD.^{28,28a-28c}

In five studies involving 60 to 1086 subjects with CKD and hyperuricemia, febuxostat, which is a uric acid-lowering agent with a safer toxicity profile than allopurinol,²⁹ was associated with better lowering of uric acid levels and a slower decline in renal function.^{30-33,33a} In two of these studies, febuxostat had a stronger renoprotective effect than allopurinol.^{33,33a} Losartan³⁴ and irbesartan³⁵ were also shown to

lower uric acid.

There are no recommendations for the treatment of hyperuricemia in CKD in the KDIGO guidelines (<http://www.kdigo.org>, guideline 3.1.20). The toxicity profile of allopurinol includes severe hypersensitivity reactions, which are rare but potentially lethal. Allopurinol should be started at low dosages (50 mg daily) in patients with CKD and slowly titrated up to achieve the desired lowering of uric acid.³⁶ A febuxostat dosage of 10–40 mg/day was safe in patients with ESRD who were on dialysis,³⁷ while the usual doses of 40–120 mg/day have not been studied in patients with an eGFR of <30 mL/min/1.73 m². The main associated adverse drug reactions were gout flare-ups²⁹ (see [Chapter 69](#)).

Alkalinizing Therapy

The KDIGO guidelines suggest a correction of serum bicarbonate levels to >22 mmol/L in patients with CKD (grade 2B evidence) (<http://www.kdigo.org>) in order to improve bone disease and the progression of CKD. Newer data continue to emerge in support of the use of this therapy,³⁸ and as reviewed by Dobre et al.³⁹ and Chen et al.⁴⁰ The optimal bicarbonate range has yet to be established. Sodium bicarbonate or Shohl's solution can be used, and the base deficit can be calculated (<http://www.globalrph.com/bicarb.htm>) or replaced empirically and gradually to achieve a bicarbonate level of 22–24 mmol/L. **Caution:** avoid base and sodium overload with bicarbonate supplements,⁴¹ especially in cirrhotic and pregnant patients. Alkalosis has been linked to an increased risk of heart failure in a cohort study⁴² and the promotion of vascular calcification in vitro.⁴³

Adverse Drug Reactions in CKD

Multiple medications can cause a variety of renal complications.⁴⁴⁻⁴⁸ The most well recognized are nonsteroidal antiinflammatory drugs (NSAIDs), antibiotics, and chemotherapeutic agents. More recently, acute phosphate nephropathy following exposure to phosphate-containing bowel preparations,⁴⁹⁻⁵² acute interstitial nephritis associated with proton pump inhibitors,^{53,54} and focal segmental glomerulosclerosis (FSGS) and ESRD due to excessive doses of anabolic steroids⁵⁵ have been described.

Adverse renal reactions to excipients are less well recognized. A case of silicate nephrolithiasis was reported with nutritional supplements containing silica dioxide.^{55a} Sucrose-stabilized intravenous immunoglobulins were associated with acute kidney injury.⁵⁶ Aluminum

found in commercial drugs, calcium, and iron supplements^{57,57a} can cause neurological and bone toxicity in patients with impaired renal function.⁵⁸

Case reports and cohort studies of up to 106 patients highlighted a possible link between various vaccinations and their components (e.g., influenza, hepatitis B, meningococcal C conjugate, tetanus, diphtheria, and poliomyelitis) and glomerular diseases.^{59,59a-i}

Nutriceuticals and Supplements

Magnesium

The association between low serum levels of magnesium and increased cardiovascular and all-cause mortality in the general population,⁶⁰⁻⁶² and in patients with CKD⁶³⁻⁶⁵ is well documented. Hypomagnesemia has also been linked to incident CKD and ESRD,⁶⁶ and has been found to contribute to CKD progression in diabetic,^{64,67-69} nondiabetic,⁷⁰ and post-transplant patients.⁷¹

The serum concentration of magnesium might be normal in the presence of intracellular magnesium deficiency, especially in patients with CKD.⁷² Oral magnesium supplementation can be considered for patients with CKD, especially patients with diabetes, patients with a poor diet, and patients taking diuretics, proton pump inhibitors, and calcineurin inhibitors. Foods rich in magnesium include dark leafy greens, coffee, nuts and seeds, fish, legumes, and whole grains.

Monitoring is required to avoid magnesium overload, especially with magnesium-containing laxatives in patients with CKD.

Vitamin D 25-OH

Expert opinions suggest supplementation with vitamin D 25-OH in CKD stage 3–5 for levels <30 ng/mL

(http://www2.kidney.org/professionals/KDOQI/guidelines_bone/Guidelines)

Multiple observational studies have suggested that vitamin D deficiency is associated with overall and cardiovascular mortality, increased levels of albuminuria, proteinuria, and decreased GFR. However, there is no consensus on the benefits of supplementation, goals for levels, or choice of vitamin D supplements in CKD.⁷³⁻⁸³ Although some studies have suggested that there are no adverse effects,⁸⁴ caution with vitamin D

replacement in CKD is advisable because it can cause increased calcium and phosphate absorption.

Omega-3 Fatty Acids

Several animal^{84a,84b} and small clinical studies^{85,86,86a-d} and meta-analyses^{86e,86f} have suggested beneficial effects of omega-3 fatty acid supplementation on renal function at doses between 0.4–7.7 g/day; however, the evidence is weak and largely based on patients with IgA nephropathy and lupus nephritis.^{86c}

Coenzyme Q10 (CoQ10)

Antioxidant CoQ10 has demonstrated renoprotective effects in ischemic, diabetic, and hypertensive animal models of kidney injury.⁸⁷⁻⁹¹ In 100 patients who underwent extracorporeal shock-wave lithotripsy, CoQ10 200 mg/day, given for one week before and after the procedure, was associated with a significant increase in GFR and decrease in the urine albumin/creatinine ratio.⁹² In a randomized controlled trial of 97 patients with advanced CKD, treatment with hydrosoluble CoQ10 at 180 mg/day appeared to reduce serum creatinine levels and the need for dialysis.⁹³ Conversely, in a study of 85 patients with CKD stage 3–4, CoQ10 supplementation of 200 mg/day for 8 weeks had no effect on renal function, blood pressure, albuminuria, or proteinuria.⁹⁴

Dosage

CoQ10 at doses of 100–200 mg/day appears to be safe in CKD.

N-Acetylcysteine

N-acetylcysteine (NAC) is a precursor of endogenous antioxidants.¹⁵ Furthermore, it might have heavy metal detoxification effects⁹⁵⁻⁹⁷ and homocysteine-lowering properties. NAC is currently recommended as part of the prevention against acute kidney injury in at-risk patients undergoing intravenous contrast administration (<http://www.kdigo.org>). The benefits of NAC for renal function preservation have been demonstrated in an animal model⁹⁸ and in two small studies performed in patients already on dialysis with residual renal function,^{99,100} but not in a placebo-controlled, randomized, open,

crossover trial of 20 patients with nondiabetic CKD.¹⁰¹

Dosage

The commonly prescribed dose of 600 mg twice daily was not associated with side effects in any of the previous studies. Wheat grass is a good nutritional source of NAC.

Precautions

NAC should not be prescribed to patients with cystinuria (Cysteine, University of Maryland Medical Center,

<http://umm.edu/health/medical/altmed/supplement/cysteine#ixzz3Y>

Protocol for Preventing Contrast-Induced Nephropathy (Consider in Patients With Cr > 2.5 mg/dL)

- NAC 1200 mg IV bolus prior to procedure.
- 600 mg orally twice daily for 48 hr after procedure.
- Hydrate with 1 cc/kg (or 0.5 cc/kg in patients with congestive heart failure) normal saline per hour for 12 hours after procedure.

Prebiotics, Probiotics, and Synbiotics

The restoration of intestinal integrity and the microbiome is beneficial in any inflammatory condition.^{102,103} In recent years, there has been a greater appreciation of the role of the intestinal microbiome in renal disease.^{102,104} Dysbiosis can be caused by CKD due to increased intestinal urea secretion, resulting in excess ammonia, metabolic acidosis, intestinal wall edema, and slow colonic transit, which is frequently complicated by fiber-deficient diets and an increased use of iron and antibiotics.¹⁰⁵ In turn, dysbiosis can contribute to CKD by causing systemic inflammation, endothelial dysfunction, and atherosclerosis, which are related to increased intestinal permeability, bacterial translocation with subclinical endotoxemia, and abnormal colonic bacteria overproduction of uremic toxins.¹⁰⁶⁻¹⁰⁸ Several small studies on probiotic supplementation in patients with CKD stage 3–5 demonstrated variable beneficial results with no adverse effects. The spectrum of benefits included decrease in blood urea nitrogen, creatinine, uric acid, serum uremic toxins levels, improved quality of life, nutritional status, bowel movements, and

bacterial dysbiosis.¹⁰⁹⁻¹¹³ In a systematic review and meta-analysis of randomized, controlled trials, patients on probiotics had mildly improved blood pressures.^{114,114a} In general, probiotics are considered to be safe; however, they have been linked to cases of sepsis.¹¹⁵⁻¹¹⁷ Prebiotics, including inulin, lactulose, and oligofructose, can act synergistically with probiotics to optimize uremic gut dysbiosis. Several studies of prebiotic and synbiotic supplements proved beneficial in patients with ESRD^{118,119,119a}; however, no studies are available for the earlier stages of CKD.

Other Supplements and Vitamins With Potential Benefits in CKD

Niacin was found to be beneficial in rats with CKD^{120,121} and lowered phosphate levels in patients with CKD.^{121a-c} However, when added to statins, niacin did not improve cardiovascular outcome or kidney function, and was associated with higher all-cause mortality in patients with CKD.¹²²

High-resistant starch *fiber* supplementation was demonstrated to attenuate oxidative stress, inflammation, and severity of renal dysfunction in a rat model of CKD.¹²³ High-amylose corn starch (Hi-maize 260) reduced serum levels of uremic toxins in patients with ESRD on hemodialysis, with minimal gastrointestinal side effects.¹²⁴

Vitamin K deficiency is prevalent,¹²⁵⁻¹²⁷ and a higher than recommended daily intake of vitamin K was associated with a lower risk of all-cause and CVD mortality in advanced CKD;¹²⁷ however, the dose and benefit/risk profiles are currently unknown.¹²⁸

Lowering homocysteine levels with *folic acid*, *vitamin B6*, and *vitamin B12* supplements in patients with CKD (GFR < 60 mL/min) for 5 years was not found to influence cardiovascular outcomes.^{128a} A Cochrane systematic review concluded that there was no evidence to recommend the use of *vitamin B* therapy for delaying the progression of diabetic kidney disease. In a single study, *thiamine* was found to be beneficial for reducing albuminuria.¹²⁹

Palmitoylethanolamide (PEA), a derivative of palmitic acid and the commonest fatty acid present in palm tree oil, meats, and dairy products, was shown to be a safe antiinflammatory agent in several animal studies and one observational study in humans,¹³⁰ and improved kidney disease in an animal model, as reviewed by Impelizzeri et al.¹³¹

Short-chain fatty acids (acetate, propionate, and butyrate) are present in

high-quality dairy products (e.g., butter and ghee) and are produced by intestinal bacteria.^{132,133} Short-chain fatty acid supplementation was found to improve renal function in animals with various models of acute kidney injury.¹³⁴⁻¹³⁶

Herbals

Turmeric and Curcumin

The common Asian spice turmeric (*Curcuma longa*) with its most active ingredient curcumin has been used in Oriental medicine for centuries as an antiinflammatory, antioxidant, anticarcinogenic, and antimicrobial agent. Many of these properties have been scientifically confirmed in the last few decades.¹³⁷ Numerous studies have demonstrated the benefits of curcumin in various animal models of kidney injury.¹³⁷⁻¹³⁹ In small randomized trials, turmeric has been shown to reduce proteinuria and serum levels of proinflammatory cytokines in patients with diabetic nephropathy,¹⁴⁰ as well as proteinuria, hematuria, and systolic blood pressure in patients with relapsing or refractory biopsy-proven lupus nephritis¹⁴¹ without adverse events.

Dosage

Generally accepted doses are between 500–2000 mg/day. The bioavailability of curcumin is increased by 2000% by the addition of black pepper¹⁴² (Ayurvedic formulation: 1 part black pepper to 16 parts turmeric).

Precautions

Use with caution in doses >600 mg/day in patients at risk of bleeding and hypoglycemia, and in pregnancy, gallbladder disease, and in combination with certain medications. (National Institute of Health MedlinePlus: Turmeric

<http://www.nlm.nih.gov/medlineplus/druginfo/natural/662.html>)

Astragalus

Astragalus membranaceus (huang qi) was found to have renal protective effects in 1804 diabetic patients with nephropathy based on a meta-

analysis of studies from China,¹⁴³ in a Cochrane review of 22 studies of 1323 participants with CKD,¹⁴⁴ and in a Cochrane systematic review of nine studies in patients with nephrotic syndrome.¹⁴⁵ Small participant numbers and suboptimal methodological and reporting quality prevented definitive conclusions on the basis of these studies. In Chinese medicine, astragalus is used either alone or in combination with other herbs in various doses and forms. Allergic reactions were the most commonly reported adverse events; however, not all studies reported adverse events. Caution is advised in pregnancy.¹⁴⁶

Cordyceps

Cordyceps sinensis mushroom has been prescribed for centuries in Chinese, Indian, and Tibetan medicine as a tonic.¹⁴⁷ Some animal and human studies have suggested benefits of cordyceps in renal disease.¹⁴⁸ A recent Cochrane review of cordyceps for the treatment of CKD, which included 22 studies with 1746 participants (all published in Chinese), suggested that cordyceps preparations, when used as an adjuvant therapy to conventional medicine, decreased serum creatinine and proteinuria, and increased creatinine clearance, hemoglobin, and serum albumin. The treatment duration ranged from 1 to 6 months, and the doses and preparations varied. The quality of evidence was considered to be low.¹⁴⁹

Dosage

In general, at doses of 1–3 g/day, cordyceps appears to be safe.

Precautions

Use with caution in pregnancy/lactation and in patients with autoimmune disease or on immunosuppressive agents.

Rheum officinale

Rhubarb (*Rheum officinale*, or yào yòng dà huáng) root is a common ingredient in virtually all herbal therapies used in Chinese medicine to treat renal failure. In several clinical studies from China, the use of herbal formulations containing *Rheum officinale* was reported to slow the progression of CKD. The study sizes varied from 30–100 subjects, and the etiologies and degrees of renal failure varied. Oral decoction at doses

ranging from 1–15 g/day was used for 3 weeks to 40 months.^{146,150-153} A Cochrane review of nine studies (682 participants) concluded that the evidence for the efficacy of *Rheum officinale* in improving CKD was scant and of low quality.¹⁵⁴

Precautions

Rheum officinale preparations have high potassium and oxalate content, are reported to cause gastrointestinal problems, electrolyte disorders, and liver toxicity with long-term use,¹⁵⁵ and are even reported to cause AKI.¹⁵⁶

***Tripterygium wilfordii* Hook F**

A Cochrane systematic review found that *Tripterygium wilfordii* Hook F (a traditional Chinese herb léi gōng téng) may have a favorable effect on remission in patients with primary nephrotic syndrome when added to conventional treatment with prednisone or cyclosporine.¹⁵⁷

Dosage

A meta-analysis of four randomized controlled trials with 188 participants found that when used in conjunction with ACE inhibitors, ARBs, or prednisone, it improved remission rates and urinary protein in patients with IgA nephropathy at doses of 60 mg/day or 1–1.5 mg/kg/day.¹⁵⁸

Precautions

Drugs containing *Tripterygium wilfordii* have a narrow therapeutic window, the dose depends on the extraction method, and adequate safety studies are limited. More serious complications include leukopenia, intestinal bleeding, respiratory and liver failure, and even death.¹⁵⁹ Cautious use in geriatric and pediatric populations, and avoidance in pregnancy is recommended.¹⁴⁶

Ligustrazine

Ligustrazine is a bioactive component contained in Chuan Xiong, a dry

rhizome of *Ligusticum chuanxiong*, which is traditionally used in Chinese medicine for the treatment of cardiovascular diseases, headache, and vertigo. It has been used in China for more than 30 years in its purified synthetic form for renal failure, lung fibrosis, and stroke. In a meta-analysis of 25 randomized controlled trials that included a total of 1645 patients with stage 3–4 diabetic nephropathy, treatment with ligustrazine was shown to result in significant therapeutic improvement in blood urea nitrogen, serum creatinine, and urinary protein.¹⁶⁰ Some data from the Chinese literature suggest that ligustrazine might be helpful in nondiabetic CKD, nephritic syndrome (in combination with prednisone), and in the prevention of gentamicin nephrotoxicity (<http://www.itmonline.org/arts/ligustrazine.htm>).

Dosage

Ligustrazine is given as an injection with doses ranging from 40 to 400 mg daily and treatment duration ranging from 10 days to 12 weeks.

Precautions

No adverse events have been reported.

Herbal Toxicities

Many herbal remedies can cause significant renal complications ([Table 40.1](#)) as described in several reviews.¹⁶¹⁻¹⁶⁴ Herbal supplements can be contaminated with or contain heavy metals as part of the therapeutic prescription.¹⁶⁵⁻¹⁶⁷ Many herbal supplements have the potential for interaction with prescription medications.^{168,169} The KDIGO guidelines recommend that herbal remedies should not be used in patients with CKD (evidence strength 1B) (http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO_recommendation_4.4.5). On the other hand, there are very little data comparing the complications caused by herbal medicines and pharmaceuticals.

Nutrition

In multiple studies, healthier diets *rich in plants, whole grains, fiber, calcium, magnesium, and potassium*, such as the Mediterranean diet, have been associated with lower incidence, progression, and mortality in CKD

when compared to Western-style diets that are high in fried foods, nondairy animal products, organ meats, cholesterol, and sweetened beverages.¹⁷⁰⁻¹⁷⁶

Heavy consumption of oxalate-rich juices has been reported to precipitate renal oxalosis and acute kidney injury.¹⁷⁷ Be careful when recommending juicing diets for patients with CKD.

Current guidelines (evidence strength 2C) suggest avoiding high protein intake (>1.3 g/kg/day) in adults with CKD at risk of progression (<http://www.kdigo.org>). However, the accumulation of data on the risks of high animal protein intake and the benefits of *animal protein restriction* in patients with CKD is ongoing.^{178,179}

TABLE 40.1
Herbal Remedies With Nephrotoxic Potential

Plant Species	Common Name	Toxic Compound	Adverse Renal Effects
<i>Azadirachta indica</i> Mill. ¹⁸⁰			Acute kidney injury, death
<i>Azorella imbricata</i> , <i>Azorella procera</i> , <i>Azorella pseudoperyspera</i> , <i>Platanus mexicana</i> ^{181,182}			Acute kidney injury, acute tubular necrosis
<i>Azorella spicata</i> ^{183,184}	Winkson, papawoo	Aristoselinic acid	Acute tubular acid nephropathy with progressive and extensive interstitial fibrosis and proximal tubular atrophy, Fanconi syndrome, osteomalacia and rickets
<i>Azorella stricta</i> ¹⁸⁵	Waterwood		Chronic tubulointerstitial and acute kidney injury after ingestion of waterwood oil
<i>Azorella stricta</i> ^{186,187}	Star fruit	Oxalic acid	Acute kidney injury, acute nephropathy
<i>Capparis</i> ¹⁸⁸			Acute kidney injury
<i>Cerbera manghut</i> ¹⁸⁹	Yellow oleander		Acute kidney injury
<i>Cerbera manghut</i> , <i>Cerbera manghut</i> , <i>Cerbera manghut</i>		Oxalic acid	Acute kidney injury requiring dialysis, acute tubulointerstitial lesions with polymorphous cell infiltration, edema, loose fibrosis, and epithelial necrosis
<i>Cerbera manghut</i> E. Hoffm. ¹⁹⁰	Morning Glory	Terpenoids	Acute kidney injury with acute tubular necrosis, acute interstitial nephritis, hemoglobin casts
<i>Ephedra sinensis</i> ^{191,192}	Ma Huang, qingdu	Ephedrine	Septic shock
<i>Glycyrrhiza glabra</i> ^{193,194}	Licorice	Glycyrrhizin	Hypotensive nephropathy, hypotensive rhabdomyolysis with secondary acute kidney injury
<i>Larrea tridentata</i> ¹⁹⁵	Cholla or cholla bark		Renal cysts, renal cell carcinoma
<i>Passiflora foetida</i> ¹⁹⁶	Yohimbin	Yohimbin	Lupus-like syndrome with progressive renal failure
<i>Pithecolobium lobatum</i> , <i>Pithecolobium jiraguá</i> , <i>Arachidocarpus jamaicensis</i> ^{197,198}	Djongoi beans	Djongoic acid	Acute tubular necrosis, nephritic crisis, obstructive nephropathy, hematuria
<i>Rhus glabra</i> ¹⁹⁹	Sage	Oxalic acid	Acute kidney injury
<i>Sida acuta</i> (synonym: <i>malabarica</i>) ^{200,201}		Cycloprop-3-ene carboxylic acid	Rhabdomyolysis and acute kidney injury
<i>Uncaria tomentosa</i> or <i>Uncaria tomentosa</i> ²⁰²	Cat's claw Uña de gato		Acute kidney injury attributed to acute allergic interstitial nephritis (renal biopsy not done)

Existing guidelines recommend *sodium restriction* to <2 g (or <5 g of sodium chloride)/day in patients with CKD (evidence grade 1C) (<http://www.kdigo.org>). Recent studies introduced further controversy to these recommendations.^{180,181,181a-c} A Cochrane review on dietary salt intake in CKD patients analyzed eight studies (24 reports, 258 participants) and found a gap in critical evidence for the long-term effects of salt restriction on mortality and progression to ESRD, despite

the fact that salt restriction considerably reduced blood pressure and proteinuria.¹⁸² Low sodium diets are contraindicated in patients with renal sodium wasting.

Several studies have demonstrated an association of *higher potassium* intake (>2.7–3.3 g/day vs. <1.7 g/day) with lower blood pressures (Mente et al. 2014)¹⁸³ and improved renal outcomes in various populations (Smyth et al. 2014);¹⁸⁰ however, there are no established recommendations for patients with CKD¹⁸⁴ (see [Chapter 89](#)).

Hyperphosphatemia in patients with CKD can cause metabolic bone disease, and is associated with an increased prevalence of CVD and mortality. The KDIGO guidelines recommend dietary phosphorus restriction and phosphate binders for hyperphosphatemia (evidence strength 2D) (<http://www.kdigo.com>). It has been suggested that *inorganic phosphate additives* from processed foods contribute to the progression of CKD in healthy and at-risk individuals,¹⁸⁵ while a vegetarian diet appeared to be beneficial for phosphate balancing in patients with CKD.¹⁸⁶ This can be explained by the significantly lower content and availability of organic phosphates naturally present in plant-based foods (20%–50% absorption) as compared to inorganic phosphate additives in processed foods (90%–100% absorption)^{187,188} with a 60% higher content.¹⁸⁹ Inorganic phosphate additives are not indicated on food labels in the US.

Processed foods contain phosphate that is 90%–100% absorbed compared to phosphates naturally found in whole foods, which are 20%–50% absorbed. Therefore, whole foods are safer in patients with CKD.

In two cohort studies, *high dietary fiber* has been associated with better kidney function, and lower inflammation and mortality risk.^{190,191} Consumption of *whole grains* that are rich in fiber has been associated with improved glycemic control, circulation, dyslipidemia, and inflammation.¹⁹²⁻¹⁹⁵

In two small studies, *alkalinizing diets*, which are rich in plant-based foods and low in meat and processed foods,¹⁹⁶ have been shown to result in an equal reduction of urine albumin and GFR loss as administration of sodium bicarbonate in patients with CKD.^{197,197a} Higher dietary acid load has been associated with lower serum bicarbonate¹⁹⁸ and increased risk of ESRD¹⁹⁹ in the general US population.

Raw nuts are an important source of healthy fats, magnesium, and protein, and their intake in any amount has been found to decrease the risk of mortality related to CKD.²⁰⁰ **Caution:** excessive intake of nuts should be avoided in CKD due to the potential risk of hyperphosphatemia and oxalate nephropathy.²⁰¹ Recommend a handful, not a canful.

High sugar diets contribute to obesity, diabetes, hyperuricemia, and hypertension,²⁰² and can potentially be damaging to the kidneys.²⁰³ *Artificial sweeteners* have been associated with a decline in renal function in women.²⁰⁴

Dietary sources of *probiotics* include fermented dairy products (e.g., yoghurt, lassi, and kefir), vegetables (e.g., kimchi, sauerkraut, olives, and pickles), and soybeans (e.g., miso and natto). Dietary sources of *prebiotics* include chicory root, okra, taro root, dandelion greens, asparagus, bananas, and the garlic and onion family. Caution regarding the amount of salt in fermented products and phosphorus in dairy products should be advised in patients with CKD.

A cohort study of 5746 participants found an inverse relationship between *alcohol* consumption and the risk of developing CKD;²⁰⁵ however, based on a systematic review, the beneficial role of alcohol consumption on renal function has not been consistently demonstrated.²⁰⁶

Multiple case reports have suggested a link between *food sensitivity* and idiopathic glomerular lesions (minimal change disease, membranous glomerulonephritis, type I diabetic nephropathy, IgA nephropathy, and membranoproliferative glomerulonephritis), and some have reported successful outcomes with *avoidance of gluten and/or dairy*^{59,207-222,222a} (see [Chapter 86](#)).

Environmental Toxins

Large-volume filtration of the blood enhances renal exposure to circulating toxins and renders the kidneys highly susceptible to injury.²²³ It is well known that significant exposure to heavy metals, organic solvents, and certain food additives causes nephrotoxicity.²²⁴⁻²³⁵ Recent findings have indicated that even low-dose exposure to toxins might be associated with kidney disease,^{233,236,237} with potential synergy in toxic effects.²³⁸ In Sri Lanka and Central America, the combination of water and dietary pollutants, heavy metals, herbicides, and increased ambient temperatures has been implicated in newly described clusters of CKD of

unknown etiology (CKDu).²³⁹⁻²⁴³ Excessive risks of kidney disease have been documented in minority and disadvantaged populations, suggesting disparities in the environmental exposures.²⁴⁴

Information on this topic, including information about heavy metals, organic solvents, plastics, pesticides and herbicides, flame retardants, food and cosmetic additives, and air and water pollution, can be found online at ExpertConsult.com.

Diagnosis and Treatment of Environmental Toxicities

Diagnosis of toxicities by environmental pollutants is challenging because the safety margin for exposures is unknown, measurements of levels are not routine, clinical symptoms can be vague, progression of renal disease is multifactorial, and physicians' awareness is low due to the scarcity and controversies in evidence. A thorough history of environmental exposures should be obtained.

Recent studies from China suggest some benefits of lead-chelating therapies with calcium disodium EDTA (ethylenediaminetetraacetic acid) on reducing progression of CKD in patients with high-normal body lead burden^{245,246} (see [Chapter 107](#)). However, these treatments are cumbersome and serious complications, including renal toxicity²⁴⁷ and death (due to hypocalcemia), have been reported (<http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5508a3.htm>). Other chelating therapies that have been studied in heavy metal poisoning include British antilewisite (BAL) or dimercaprol, meso-2,3-dimercaptosuccinic acid (DMSA), 2,3-dimercaptopropanesulfonic acid (DMPS), and thiamine tetrahydrofurfuryl disulfide (TTFD). Only EDTA and DMSA are FDA approved; however, all have the potential for complications, including chelation of vitamins, renal complications, and neuro- and hepatotoxicity (Food and Drug Administration 14 October 2010). Chelating agents that have been proposed but not studied in CKD include modified citrus pectin (Pectasol), seaweed extract sodium alginate, oral adsorbent activated charcoal, vitamins E and C, selenocysteine, NAC, N-acetylcysteine amide (NACA), and alpha-lipoic acid. However, the only recommendations at this time are avoidance and discontinuation of toxic exposure along with a general healthy lifestyle (see [Chapter 108](#)).

Lifestyle Modifications

Weight Loss

Achieving a healthy weight with a body mass index (BMI) of 20–25 is recommended by renal guidelines (www.kdigo.org), and is supported by multiple studies linking obesity with negative outcomes in patients with CKD.²⁴⁸⁻²⁵¹

Heavy Metals

At high levels, heavy metals have been known as *nephrotoxins* since ancient times. It is becoming increasingly recognized that even low-level exposures can cause renal toxicity.^{355,356} Heavy metals are ubiquitous in the environment and are found in air, dust, water, soil, foods, cosmetics, industrial and household chemicals, and medicinal herbal preparations^{309,357-359} (<http://emedicine.medscape.com/article/814960-overview>).

Cadmium and *lead* have established toxicity even at low levels. The major exposure sources in the general population are foods (likely from crops contaminated by pesticides and seafood), tobacco smoke, dust and air in communities near industrial sites (nonferrous smelters), gasoline, and certain occupational settings involved with electroplating, pigments, plastics, nickel cadmium batteries production, and brazing³⁵⁶ (<http://emedicine.medscape.com/article/1174752-overview#a0101>). High levels of lead are well known to cause kidney damage, hyperuricemia, and hypertension.³⁶⁰ Recent studies have revealed a link between low-level lead and/or cadmium exposure and a higher incidence of CVD and CKD.^{237,238,361-365}

Mercury is linked to nephrotoxicity^{230,366} and glomerular disease (minimal change disease and membranous nephropathy).³⁶⁷⁻³⁶⁹ It occurs in several chemical forms (e.g., elemental, inorganic, and organic) and each can affect the kidneys, depending on the dose and duration of exposure (<http://emedicine.medscape.com/article/1175560-overview>). The most common occupational exposure is caused by outgassing of mercury from dental amalgam,³⁷⁰⁻³⁷⁴ and this reportedly affects the cardiovascular system.³⁷⁵ Chlor-alkali plants use mercury in the production of high-fructose corn syrup, and mercury was found in 45% of analyzed samples.³⁷⁶ Atmospheric mercury is derived from coal burning and mining build-ups in soil and water, and, once it is converted by microorganisms into the organic form, accumulates in the tissues of wildlife and humans. Fish at the top of the food chain accumulate the highest levels of mercury

(<http://www.nrdc.org/health/effects/mercury/guide.asp>). Before 1990, mercury was used as an antimildew agent in paints, and for seed and grain preservation. Mercury is still used in the manufacture of batteries, thermometers, barometers, mirrors, agricultural fungicides, various antiseptic agents, energy-efficient fluorescent lights, paper and pulp products, and skin-lightening cosmetic products.³⁶⁸

Exposure to *arsenic* can occur from groundwater, pesticides, seafood, and inhalation of fumes from burning treated wood (<http://emedicine.medscape.com/article/812953-overview>). Arsenic has been proposed as a potential cause of kidney damage.^{377,378} A recent 25-publication review on epidemiological evidence found a positive association between arsenic and albuminuria and proteinuria; however, there was limited evidence for the causality of CKD.³⁷⁹ A recent epidemic of CKD of unknown etiology in Sri Lanka has been linked to arsenic from phosphate pesticides;³⁸⁰ however, there remains controversy over this.³⁸¹

Organic Solvents

Organic solvents are volatile, and human exposure to these compounds in the industrial world is nearly ubiquitous. They are commonly used in chemical syntheses and found in dry cleaning (e.g., tetrachloroethylene), paint thinners (e.g., toluene, turpentine), nail polish removers, glue solvents (e.g., acetone, methyl acetate, and ethyl acetate), spot removers (e.g., hexane, petrol ether), detergents (citrus terpenes), and perfumes (ethanol). *Hydrocarbon* is used as a safe combustible fuel source, a propellant for aerosol sprays, and as asphalt (bitumen). *Methane*, *butane*, *pentane*, and *hexane* are used in gasoline, jet fuels, roofing and pavement compounds, wood preservatives (the creosote series), and shear-resisting liquids. Exposure to mixed organic solvents was shown to cause renal injury in rats,³⁸² and was linked to various glomerular diseases (e.g., IgA nephropathy, membranous nephropathy, and FSGS), and progression of CKD and ESRD in humans.^{224,226,228,231,234,235}

Plastics

Evidence suggests that bisphenol A, which is used in the manufacture of plastic food and beverage containers, and phthalates, which are commonly found in foods and a broad array of consumer products, produce inflammation and oxidative stress.³⁸³⁻³⁸⁷ Urinary metabolites of phthalate and bisphenol A have been associated with microalbuminuria³⁸⁸ and increased blood pressure³⁸⁸ in children in the

US. Avoidance of plastic containers and processed foods decreases exposure to these chemicals.³⁸⁸⁻³⁹³

Pesticides and Herbicides

An animal study demonstrated that the pesticide *methoxychlor* has potential to promote the epigenetic transgenerational inheritance of diseases, including kidney disease.^{393a} CKD patients were found to have significantly higher blood levels of *organochlorine pesticides*, which significantly correlated with markers of oxidative stress.^{393b} *Glyphosate herbicide* was associated with nephrotoxicity in animals,^{394,395} and was linked to a recent epidemic of CKDu in Sri Lanka.^{242,380}

Flame Retardants

High levels of melamine in baby formula were found to cause acute kidney injury and nephrolithiasis in more than 50,000 Chinese children in 2009.²³² While it is a common component of fabrics, glues, housewares, and flame retardants, its effects have not been well studied at lower doses or in vulnerable populations.³⁹⁶ Polychlorinated biphenyls (PCBs), which are also encountered in various industrial fluids and diluents, appeared to induce nephrotoxic injury in rats.³⁹⁷

Other Food and Cosmetic Additives

It is becoming increasingly recognized that many food additives such as glucose, salt, emulsifiers, organic solvents, gluten, microbial transglutaminase, and nanoparticles have a potential to increase intestinal permeability, and increase inflammation and autoimmune disease as reviewed by Lerner et al.³⁹⁸ Emerging evidence has implicated common cosmetic and food additives as potential nephrotoxins, e.g., *MSG, melamine, potassium bromate, aluminum chloride, beta-myrcene, tartrazine, borax, aloe, sodium nitrite, aspartame, diazoaminobenzene, sodium metabisulphite, methyleugenol, N-nitrosodimethylamine, sodium-o-phenylphenate, d-limonene, thiabendazole, butylated hydroxyanisole, cinnamaldehyde, and butylated hydroxytoluene* as reviewed by Gowder,³⁹⁹ and the coal-tar derivative *paraphenylene diamine*.^{399a} Several reports suggest that *genetically modified foods* and *glyphosate herbicide* might be associated with nephrotoxicity.^{394,400,401} *Carrageenan* extracted from seaweed is widely used as a thickener and stabilizer in foods in the US. It has proinflammatory properties as reviewed by Tobacman,⁴⁰² and has

been found to cause kidney injury in animal models.^{403,404} The potent mycotoxin *aflatoxin* can be a contaminant of various foods (especially peanuts and foods of tropical origin), and has been linked to kidney damage as reviewed by Bbosa et al.⁴⁰⁵

Air Pollution

Heavy metals, organic solvents, and other pollutants can be emitted into the air from industrial processes, fuel combustion, wood and coal burning, cigarette smoke, household products use, and even chewing (on dental amalgam). Living near a major roadway (within 50 m vs. >1000 m) has been associated with lower eGFR in a cohort of patients who presented with acute ischemic stroke.¹⁰

Water Pollution

A variety of renal toxicities can be caused by *water-borne infections* (e.g., *Schistosoma*, leptospirae, typhus, hantavirus, malaria, *Escherichia coli*, and *Shigella*)⁴⁰⁶ and contamination with *cyanobacterial toxins*, such as alkaloids from contact with calm, nutrient-rich water.^{407,407a} With the acceleration of urbanization and industrial growth worldwide, water pollution with *heavy metals* and *organic chemicals* should be regarded as a serious concern in kidney disease. Several studies have suggested renal toxicity from *fluoride* in water in vulnerable populations such as children and patients with CKD, likely in combination with other trace elements.^{240,408-411} The safety of *chlorine* water additives in kidney patients remains to be established.⁴¹²

Smoking Cessation

Smoking, including secondhand smoking, is a well-recognized risk factor for CKD onset and progression,²⁵²⁻²⁵⁹ and, in combination with hypertension, is associated with the newly described pathological lesion of nodular glomerulosclerosis.²⁶⁰⁻²⁶²

Exercise

For patients with CKD, KDIGO guidelines recommend physical activity that is compatible with cardiovascular health and tolerance, aiming for at least 30 minutes 5 times/week (www.kdigo.org). Exercise in patients with CKD has been shown to improve physical capacity and quality of life,^{262a} and, in several studies, has been shown to correlate with slower

progression of CKD.^{262b-f}

Sleep

Low quality of sleep is common in CKD patients, even in the early stages.²⁶³ An animal model of circadian rhythm disruption was associated with severe renal disease.²⁶⁴ In human subjects, obstructive sleep apnea (OSA) was associated with increased serum creatinine,²⁶⁵ cystatin C,²⁶⁶ urinary albumin,^{267,268} accelerated renal function loss,²⁶⁹ and diabetic nephropathy.²⁷⁰ Inversely, CKD was also associated with OSA,²⁷¹ and CKD progression was accompanied by a worsening of sleep quality.²⁷²

Stress

Stress can have a negative impact on kidney disease through alterations in the hypothalamic-pituitary-adrenal axis, sympathetic nervous system, and inflammatory cytokines, leading to the development of insulin resistance, metabolic syndrome, obesity, hypertension, type 2 diabetes, and vascular disease.²⁷³

Mind-Body Therapies

Meditation has been shown to decrease blood pressure, sympathetic activity, and improve quality of life in normal subjects and patients with CKD.²⁷⁴⁻²⁷⁹

Yoga might be beneficial in CKD based on its effects on reducing oxidative stress, psychological stress, and inflammatory conditions.²⁸⁰ **Caution:** complete inverted poses and fast breathing practices can increase sympathetic activity and raise blood pressure. Yogic cleansing procedures may precipitate electrolyte imbalances and increase the toxic workload on the kidneys.

Tai chi has been found to be beneficial in a small randomized trial of patients with CKD and CVD by improving renal and cardiovascular parameters.²⁸¹

Therapies to Consider

Traditional Chinese Medicine

CKD can be caused by variable element imbalances and deficiencies in

traditional Chinese medicine (TCM).^{151,282,283,283a} The current evidence of the benefits of TCM in CKD is mostly from small nonrandomized trials.²⁸⁴ Moreover, the reporting of adverse reactions has been suboptimal.^{283a} TCM therapies have been associated with significant adverse reactions, including nephrotoxicity, possibly due to adulteration of herbal remedies with heavy metals, pesticides, and undeclared drugs.²⁸⁵⁻²⁸⁷

Acupuncture

In animal models, *acupuncture* modalities were found to improve hypertension,²⁸⁸ decrease kidney damage,²⁸⁹⁻²⁹² and ameliorate skeletal muscle atrophy in CKD.²⁹³ A small clinical trial found acupuncture to be effective in improving renal function in patients with acute gout attacks and renal damage.²⁹⁴ Many studies on acupuncture are available exclusively in Chinese.

Ayurveda

Ayurvedic protocols are individualized for each patient with CKD based on variable Dosha imbalances. Multiple Ayurvedic herbs have demonstrated benefits in various animal models of kidney injury.²⁹⁵⁻³⁰⁰ There is limited evidence on the efficacy of Ayurvedic detoxification (panchakarma) in humans.³⁰¹ Most human studies that have demonstrated benefits of Ayurvedic treatments in CKD are case reports from India,³⁰²⁻³⁰⁴ with a few multi-patient (67 to 150 subjects) cohort studies.³⁰⁵⁻³⁰⁷ Treatment protocols vary; however, the most frequently used herbs are Purnava (*Boerhaavia diffusa*) and Gokshur (*Tribulus terrestris*). Nonherbal Ayurvedic interventions, such as diet, mind-body, and aromatherapy, are likely to be safe; however, the evidence is limited.

Up to 20% of Ayurvedic formulas (up to 40% if Rasa Shastra) were reported to contain unsafe levels of heavy metals,^{308,309} and treatments have been reported to cause nephrotoxicity.³¹⁰⁻³¹²

Prevention Prescription

- Avoid nephrotoxic medications
- Avoid fluid depletion

- Optimize weight
- Control hypertension, diabetes, and dyslipidemia
- Maintain a balanced, antiinflammatory, low pollutant, alkalinizing diet
- Eat more vegetables, greens, legumes, whole grains, raw nuts, healthy oils, and magnesium-, potassium-, and fiber-rich foods
- Eat less salt, animal protein, simple sugars
- Give preference to organic foods, fish with high omega-3 fatty acids and low levels of mercury
- Avoid processed food, added sugars in all forms, artificial sweeteners, food additives, high-mercury fish, and high-oxalate diet
- Include probiotics and prebiotics in the daily diet
- Avoid exposure to environmental pollutants:
 - Drink pure water
 - Avoid smoking, including secondhand smoking
 - Avoid herbal medicines with heavy metal contaminants
 - Avoid mercury in dental amalgam, herbals, and fish
 - Avoid air pollution by keeping a distance from major roads and industrial sites
- Exercise regularly
- Avoid stress and sleep deprivation, aim for high quality sleep, practice meditation and other mind-body techniques, such as yoga or tai chi
- Maintain proper oral hygiene and treat periodontitis

Therapeutic Review

General

- Optimize weight, control hypertension, diabetes mellitus, and dyslipidemia 
- Avoid potential nephrotoxic medications and volume depletion 

Diet

- Maintain a balanced antiinflammatory, low pollutant, alkalinizing

diet 

- Lower animal protein and sodium 
- Avoid sugar, processed food, inorganic phosphate additives, and artificial sweeteners 
- Add raw nuts, prebiotics, probiotics, and fiber-containing foods 
- Elimination diet (gluten-, dairy-, casein-free) in cases of glomerulonephritis 
- Avoid high-oxalate and high-purine diets 

Lifestyle

- Exercise regularly 
- Smoking avoidance/cessation 
- Practice mind-body modalities, such as gentle yoga, tai chi, and meditation 
- High quality sleep, address obstructive sleep apnea, minimize stress 

Detoxification

- Discontinue exposure to environmental toxins 
- Chelation for heavy metal toxicity 
- Chelation to decrease heavy metal total body burden 
- Dental amalgam removal 
- Avoid herbal medicines and fish contaminated with heavy metals 
- Avoid plastic food and beverage containers 
- Drink pure water 

Pharmaceuticals

For the management of hypertension, anemia, bone disease, lipids in CKD follow the KDIGO and/or Kidney Disease Outcome Quality

Initiative (KDOQI) guidelines (variable levels of evidence)

- Magnesium (not to exceed upper limits of normal) 
- Sodium bicarbonate or Shohl's solution (to keep serum bicarbonate levels between 22–24 mmol/L) 
- Febuxostat 10–40 mg/day for hyperuricemia 
- Losartan 50 mg/day or irbesartan 50–150 mg/day for hyperuricemia with hypertension and type 2 diabetes mellitus 
- Allopurinol 50–300 mg/day for hyperuricemia 

Supplements

- Omega 3 fatty acids 2–6 g/day 
- Vitamin D 25-OH 
- Probiotic supplements 

Herbals

- Turmeric (Curcumin) 500–2000 mg/day 
- *Astragalus membranaceus* (huang qi)* 15–40 g/day 
- *Cordyceps sinensis** 1–5 g/day 
- *Ligusticum wallichii* (*Ligusticum chuanxiong*, ligustrazine)* 40–400 mg/day 
- *Tripterygium wilfordii* Hook F (lei gong teng)* 12–15 g/day 
- Rhubarb root 6–15 g/day 

Alternative Therapies

- Ayurveda 
- Traditional Chinese medicine 
- Acupuncture 

* These herbals are mostly studied in Chinese patients, usually in the setting of a TCM

approach.

CHAPTER 41

Irritable Bowel Syndrome

Patrick J. Hanaway, MD

Functional changes in bowel patterns are the hallmark of irritable bowel syndrome (IBS) and were described by Hippocrates as the triad of abdominal discomfort, irregular bowel movements, and various degrees of bloating and rectal urgency. IBS is a chronic relapsing disease in which symptoms vary significantly over time. The undulating course of this symptom complex has limited the ability of studies of the natural history of IBS to distinguish between treatment effects and normal variation. In fact, this is why IBS has been considered to have a more psychosocial overlay. IBS has been considered a “diagnosis of exclusion,” defined by the presence of symptoms (abdominal pain/discomfort, bloating, and diarrhea or constipation) and a lack of clearly defined pathology. However, this understanding has evolved significantly over the past 10 years, with the emergence of a view (long-held by integrative and naturopathic physicians) that IBS is multifactorial in nature, involving a dynamic interplay between host factors (genetics and family history), intestinal function (digestion, intestinal permeability, gut microflora, inflammation/immune activation, motility, and visceral sensitivity) in addition to environmental factors, particularly stress and diet.^{1,2} This systems-based, integrative approach is, in part, supported by current clinical practices and the consensus of most physicians, though randomized controlled trials (RCTs) are necessary to validate this approach.³

Pathophysiology

The pathogenesis of IBS is multifactorial, with contributions from diet,⁴ digestive function,⁵ modified permeability,⁶ enteric infection,⁷ altered GI flora,^{8,9} food sensitivities/allergies,¹⁰ visceral hypersensitivity,¹¹ altered

motility,¹² neuroendocrine dysfunction,¹³ psychosocial factors,¹⁴ stress,¹⁵ and other factors.¹⁶ Different subsets of patients will present with different functional imbalances, as well as different patterns of interactions between the components of the overall system. This variable presentation may explain why responses to single therapies are so common with IBS. Recent studies of IBS treatments have focused on diet and nutrition, psychoneuroendocrinology, gut microflora, and the immune system, whereas as earlier research predominantly focused on the gut–brain interactions that involve visceral perception and autonomic response.¹⁷ However, more recent studies of postinfectious IBS (PI-IBS), low grade inflammation, small intestinal bowel overgrowth, and altered gut microflora have yielded more effective clinical improvements.¹⁸

Digestive Function

Digestion of food, through mastication, activation of proenzymes by highly acidic gastric environment, stimulation of the pancreas and gall bladder, and absorption of macro/micronutrients with the support of intact microvilli provide the necessary conditions for digestive function to occur.

Intestinal Permeability

Increased small bowel and colonic permeability has been observed in up to 40% of patients with IBS-D¹⁹ and is associated with visceral hypersensitivity, as well as increased risk of comorbid autoimmune diseases.²⁰ Alterations in microflora, infections, food allergies, and stressors will all serve to increase permeability promoting symptom exacerbation and acting as trigger for other disease. Permeability issues can be assessed using a “double-sugar” lactulose-mannitol urine test or through the presence of diffusely positive IgG food antibody testing.

Gut Microflora

Studies have increasingly linked the gut microflora to the symptoms and pathophysiology of IBS.^{21,22} Findings of these studies include a 3.5-fold increase in patients developing IBS after an enteric infection²³; increased risk of IBS after antibiotic usage²⁴; and multiple molecular studies have demonstrated a decreased diversity of the gut microflora, particularly in aerobic species.²⁵ Additionally, concerns regarding gut microflora

overgrowth in IBS have been raised by the work of Pimentel and colleagues²⁶ who reported that the eradication of small intestinal bacterial overgrowth (SIBO) using the nonabsorbable drug rifaximin eliminated IBS symptoms in 41% of patients over placebo. This type of overgrowth may provide a better understanding of the bloating and distention common in IBS.²⁷ Note that while multiple courses of rifaximin can be used safely, it is necessary to understand and treat the underlying cause of SIBO in each patient. For example, proton pump inhibitors may create the conditions required for SIBO.

Immune Dysfunction and Inflammation

Abnormal activation and dysregulated immune function with chronic, low-grade inflammation appears to be an important feature of IBS. Often mediated via mast cells, the role of gastrointestinal flora in immune activation is currently being explored across the continuum of functional bowel disease.²⁸ The presence of inflammation within the GI tract potentiates activation of visceral perception, motility, and hypersensitivity, even after the original infection has cleared.²⁹

Probiotic and dietary prebiotic therapies have been used to correct these deficiencies with good results. Each species and strain of probiotic is unique, with different biochemical effects and specific interactions with the mucosal immune system (see [Chapter 105](#)). Additionally, stress has been shown to promote an inflammatory phenotype in patients with IBS. Chronic stress in IBS patients suppresses TH₁ and TH₂ responses and increases IL-6 expression. As stress and inflammation increase, so do symptoms. Accordingly, future treatment strategies should consider each of these phenotypic subsets.³⁰

Enteric Nervous System

It is well understood clinically that there is a bidirectional influence of the gut's enteric nervous system (ENS) on the brain's central nervous system (CNS) and vice-versa. We commonly discuss "gut feelings" and recognize stress and emotions affect GI function, modify the gut microbiome, and change symptoms in IBS patients.³¹ In addition to elevations in cortisol, patients with IBS have significantly higher postprandial serotonin levels, which are associated with altered gastric emptying, increased small bowel contractions, faster small bowel transit time, and altered pain perception.³²

Dr. Michael Gershon first described the enteric nervous system (ENS) as the “second brain”³³ that detects nutrients, monitors the progress of digestion, and modulates the pressure/ motility of the GI tract. Alterations in the gut–brain axis observed with functional magnetic resonance imaging (MRI)³⁴ and brain network function testing³⁵ highlight the role of emotions and mood in the perception of pain in patients with IBS. Recent studies recognize the importance of gut microflora, as well as diet, in bidirectional communication with the brain. That is, brain signaling changes the gut environment while changes in gut microflora can affect both emotions and pain perception through CNS signaling via vagal afferent nerves.³⁶ Specific mechanisms through which this may occur include short-chain fatty acids (SCFA), bile salts, modified microbiome composition, metabolite production, and protease activity. Imbalances in microbiota composition and metabolism may modify signaling, as well as mucosal permeability (creating potential “downstream” consequences). There is a synergistic effect on signaling when inflammatory mediators are also present, leading to a further increase in visceral hypersensitivity.³⁷

Microflora, metabolism, serotonin-producing enterochromaffin cells, and localized inflammation also contribute to gut signaling. Pharmacological approaches have focused on the use of agents to bind enteric serotonin receptors; however, the untoward side effects of these agents have resulted in a high risk/benefit ratio. Integrative medicine takes the root cause of individual imbalances into account, leading to therapies that focus on the aforementioned areas of diet, digestion, intestinal permeability, gut microflora, inflammation/infection, stress, and mood.

TABLE 41.1**Rome III Criteria for the Diagnosis of Irritable Bowel Syndrome (IBS)**

Symptoms present for at least 3 days per month in the last 3 months (with symptom onset at least 6 months previously) and at least two of the following features:

- Pain improved with defecation.
- Onset of pain associated with change in stool frequency.
- Onset of pain associated with change in stool form.

From Longstreth GF, Thompson WG, Chey WD, et al. Functional bowel disorders. *Gastroenterology*. 2006;130:1480-1491.

TABLE 41.2

“Alarm Signs” in the History of a Patient With Irritable Bowel Syndrome

Weight loss
Fever
Overt or occult blood in stool
Frequent nocturnal bowel movements
Abnormal laboratory tests
Family history of inflammatory bowel disease
Family history or early colon cancer
Onset of symptoms after the age of 50

From Thompson WG, Longstreth GF, Drossman DA, et al. Functional bowel disorders and functional abdominal pain. *Gut*. 2000;45:S243-S247.

Ninety-five percent of the body’s serotonin is in the gut rather than the brain.

Diagnosis

Diagnosis (derived from the Greek words *Dia*, way; and *gnosis*, knowing) is predicated simply upon delineation upon a set of agreed upon criteria, as noted by the symptom-based Rome III determination of IBS ([Table 41.1](#)), with diagnostic testing not necessarily required to confirm the diagnosis. However, the multifactorial nature of IBS complicates treatment recommendations. The emphasis on “alarm signs” ([Table 41.2](#)) within the Rome classification has not effectively stratified patients at

risk because the majority of patients are unlikely to have these signs at the time of evaluation.³⁸ The Rome III criteria place emphasis on IBS subtypes (IBS-C [constipation], IBS-D [diarrhea], and IBS-M [mixed]) and symptom-based treatment. Recent studies, however, indicate that IBS subtypes do not remain stable over time.³⁹ Similar to the limitations of the Rome III criteria, subtype stratification does not facilitate integrative treatment based on the underlying physiological changes. IBS is diagnosed according to the exclusion of other disease, so it remains necessary to rule out specific illnesses that may mimic IBS.⁴⁰ GI imbalances to consider⁴¹ include celiac disease, lactose intolerance, fructose intolerance, food sensitivities, food allergies, small intestinal bacterial overgrowth, dysbiosis, pancreatic insufficiency, acute infection (bacterial, viral), parasitic infection (acute or chronic),⁴² *Clostridium difficile* infection, inflammatory bowel disease, and colorectal cancer.

TABLE 41.3
Differential Diagnosis of IBS

Differential Diagnosis	Testing
Infection/ parasite	Stool testing for fecal leukocytes, culture, ova, and parasites
Celiac disease	Transglutaminase IgA (tTG IgA) + antideaminated gliadin (DGP IgA) and endomysial (EMA IgA) antibodies Total IgA antibodies
Pancreatic insufficiency	Pancreatic elastase
<i>C. difficile</i> colitis	<i>C. difficile</i> toxin
Food sensitivity	Skin prick testing, elimination diet
Lactose and fructose intolerance	Elimination diet
Small intestinal bacterial overgrowth	Hydrogen breath testing (for lactose or glucose)
Inflammatory bowel disease	Fecal calprotectin, endoscopy
Colorectal cancer	Endoscopy, fecal immunochemical testing for hemoglobin (FIT), and fecal DNA testing (<i>Cologuard</i>)
Dysbiosis	Comprehensive diagnostic stool analysis with microbiology

Diagnostic considerations include, first and foremost, an extensive medical history with an understanding of dietary inputs and the utilization of antibiotics, laxatives, fiber, and herbs. In addition, one must elicit the current pattern of bowel movements including frequency, history, abdominal pain, gas, bloating, relationship to meals, and duration. It is surprising how many patients consider their altered bowel movements to be normal. Western medicine does not have a defined norm regarding bowel movement consistency and frequency, while other forms of healing, such as Ayurveda and traditional Chinese medicine, view the regular functioning of the gastrointestinal tract to be a critical

barometer of health and well-being, with one to two well-formed bowel movements per day to be the norm.⁴³

Etiological factors—infection, parasites, pancreatic insufficiency, celiac disease, food sensitivities, and *C. difficile* infection—should be considered in the differential diagnosis of IBS before the initiation of treatment ([Table 41.3](#)).

Integrative Therapy

We must look beyond symptom-based diagnosis and suppression-based treatment to understand the underlying causes of imbalance and illness. Irritable bowel syndrome represents an imbalance within the digestive system. The essential components of that system—nutrition, gut flora, immune system, constitution, thoughts, and environment—work optimally when they are in balance and harmony. This integrative approach highlights the unique needs of the individual patient.

Nutrition

Numerous studies and surveys have reported that the vast majority of individuals with IBS (65%–90%) indicate that their symptoms are triggered by specific foods.⁴⁴ A detailed dietary history can often provide insight into common food triggers for IBS, including gluten, lactose, fructose, fatty foods, and fiber⁴⁵; as well as the role of fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs)⁴⁶ described in [Chapter 90](#).

Dietary factors can cause all of the symptoms of IBS—pain, bloating, discomfort, and alterations in bowel pattern. Up to 50% of patients with IBS describe a worsening of symptoms after meals,⁴⁷ and 84% report symptoms related to one food item eaten.⁴⁸ Cordain et al. described the dietary patterns most common today and compared them with the characteristics of ancestral diets,⁴⁹ observing significant differences in glycemic load, fiber content, essential fatty acid composition, pH balance, and macronutrient/micronutrient composition. All of these factors have substantial effects on the balance of the commensal flora and nutrient delivery within the gastrointestinal tract. This observation is an important reference point, as are the unique and simple food rules that

author Michael Pollan offers—“Eat food. Mostly plants. Not too much.”⁵⁰ Many IBS patients will experiment with their diet before seeking medical attention, particularly by removing wheat, corn, dairy, eggs, coffee, tea, and citrus.⁵¹

Dietary approaches provide the most effective means of correcting dysfunction within the gastrointestinal system, and there are many opportunities for the delivery of these tools to patients. However, the profound dietary changes that man has adopted over the past 10,000 years, and accelerated over the past 100 years, have created discord with the nutritional input that our genetic structure has evolved to maximize.⁵² This discordance requires a much more complex set of clinical approaches to regain balance and optimal function.

Food Allergies and Sensitivities

Research has noted that food allergies and food sensitivities account for approximately 8%–14% of patients with GI symptoms, though the prevalence of food sensitivity appears to be increasing while the rate of food allergy appears stable.⁵³ Accordingly, differentiation between food allergy, food sensitivity, and food intolerance is necessary. Food intolerance is poorly defined and will not be considered in this chapter, although intolerance to lactose, fructose, MSG, tyramine, histamine, and other agents may induce IBS symptoms. Food allergy is IgE-mediated and is more prevalent in young children and decreases throughout childhood. Recent reviews have highlighted the increasing prevalence of food allergy; however, there is controversy regarding the diagnostic methodology. IgE-mediated food allergies can be measured but are present only 2% to 4% of the time using the gold standard of Double-Blind Food Challenge.⁵⁴ Other studies have reported the prevalence of physician-diagnosed food allergy to range between 6.5%–7.6% among IBS patients.⁵⁵ Interestingly, IgE-mediated hypersensitivity responses to food increase in the setting of altered gastric pH.⁵⁶ Additionally, changes in IgE-mediated food allergy can have an effect on increasing intestinal permeability, inflammation, and immune response.⁵⁷

Food allergy is distinct from the more controversial term, “food sensitivity”; an IgG-mediated phenomenon that is difficult to assess with current laboratory measures. Typically, the diagnosis of food sensitivity is made with the use of an elimination diet, during which the symptoms resolve when the patient has removed the offending food and symptoms recur when the offending food is returned to the diet (see [Chapters 31](#)

and 86). Atkinson et al.⁵⁸ used an enzyme-linked immunosorbent assay to evaluate food sensitivity in patients with IBS. A therapeutic diet was administered in one cohort (based on IgG assay results identifying foods to which subjects had raised IgG levels) and a sham diet (i.e., the foods eliminated were not those identified as those to which subjects had sensitivities, according to the IgG assay results) was provided to the control population. A 26% decrease in IBS symptoms was observed when test subjects consumed the therapeutic diet, and symptoms returned when they returned to an unrestricted diet. The diagnostic approach of measuring serum IgG and IgG4 levels is controversial, with conflicting results reported.^{59,60} Newer technologies using confocal endomicroscopy have demonstrated that anatomic changes begin within 5 minutes of food challenge in patients with IBS who are positive for clinical food sensitivity.⁶¹ Future studies comparing this technology with IgG testing will help to elucidate the clinical utility of this assessment method. In fact, IgG food antibody testing may be more representative of intestinal permeability (a.k.a. “leaky gut”) than specific food sensitivity.

Gluten Sensitivity and Celiac Disease

Approximately 4%–5% of patients with IBS have celiac disease, more than four-fold higher than people without IBS.⁶² Antibody testing for celiac disease is quickly becoming a standard of care in patients with IBS. Nonceliac gluten sensitivity (NCGS) is a term used to describe the condition in which gluten leads to a clinical and/or serological reaction that improves with gluten elimination. Biesiekierski et al. demonstrated clinical improvements in IBS following the removal of gluten in patients who were negative for celiac disease. In fact, there was only a small clinical improvement in the subset of patients who were genetically predisposed to celiac disease by HLA DQ2/DQ8.⁶³ It has also been demonstrated that individuals without celiac disease who have IgG antigliadin antibodies (AGA) feel significantly better when gluten is removed from their diet.⁶⁴ However, AGA testing is not definitive for the diagnosis of NCGS due to a high false negativity, thus further clinical trials are necessary. Celiac testing should occur before (or within 4–6 weeks of) removing gluten from the diet in order to prevent false-negative celiac testing. Increased awareness and understanding of gluten sensitivity has led to an emergence of many “gluten-free” options in the marketplace, but many of them use processed grain flours that may create other problems. Gluten is a fermentable carbohydrate (see [FODMaPs](#) in the following) and has been posited to act via prebiotic

carbohydrate expression in addition to its roles in mucosal permeability and immunological antigenicity.⁶⁵

Lactose and Fructose Intolerance

The most common form of food intolerance is that to lactose, which affects approximately 25% of adults in the United States and 35%–40% of patients with IBS. Of the IBS patients who restrict lactose in their diets, more than half will have symptom improvement.⁶⁶ Sorbitol and fructose intolerances are also quite common. Polyols are sugar alcohols, such as sorbitol, lactitol, and xylitol, which are found in sugar-free products. At least 70% of polyols are not absorbed in healthy individuals.⁶⁷ One study found that nearly a third of patients with IBS had significantly more symptoms due to fructose malabsorption and dietary fructose intolerance.⁶⁸ A 14-day trial of a fructose-free, lactose-free, sorbitol-free diet should be performed to determine whether symptoms resolve. Foods with these constituents should be added back to a dietary challenge one at a time every 3 days.

As sorbitol-containing chewing gum can be a common trigger of IBS, clinicians should screen for its use when taking a medical history.

Fermentable Carbohydrates (FODMaPs)

An extension of the idea to avoid simple sugars is the concept of a diet restricting fermentable oligo-, di-, monosaccharides and polyols (FODMaPs). These fermentable substrates (apples, pears, dried fruit, sugar alcohols, mushrooms, avocado, milk, cheese, wheat, rye, onions, artichokes, and inulin) act as prebiotics, and stimulate bacterial growth and gas production. There are several dietary interventions that seek to change prebiotic foods, thus changing gut microbiome expression. As there is no singular gut microbiota across populations, individuals with different microbiota may respond differentially to varied prebiotic foods, as represented by FODMsPs (see [Chapter 90](#)), as well as the Specific Carbohydrate Diet (SCD), which has been anecdotally been posited as effective for IBS and IBD.⁶⁹

Fiber

Dietary fiber intake in the United States averages less than 15 g/day, well

short of the recommended intake of 25 to 35 g/day, or the 115 g/day found in the paleolithic diet. Although fiber appears to ease constipation symptoms in a proportion of patients, the ability of dietary fiber to improve abdominal pain and diarrhea has been limited. Multiple randomized, controlled trials have failed to demonstrate a benefit of combined soluble and insoluble fiber supplementation for the multiple symptoms of IBS.⁷⁰ Soluble fiber and insoluble fiber have been found to have different effects on IBS symptoms. Many studies have been complicated by the use of wheat bran as a source of fiber as wheat bran is a common source of food sensitivity and contains fructans, thus potentially altering symptoms in these studies. Soluble fiber (e.g., psyllium, ispaghula, inulin, and modified citrus pectin) reportedly led to significant improvement, whereas insoluble fiber (corn, wheat bran) worsened clinical outcomes.⁷¹ Soluble fiber is recommended for patients with constipation, with dosages titrated to 20–30 g/day in food or as a supplement. Additionally, soluble fiber increases the production of short-chain fatty acids (SCFA), including n-butyrate, which is a substrate for energy production in the colonic mucosal cells and acts as an antiinflammatory. n-Butyrate and SCFAs can be measured by stool analyses and are essential metabolic products of gut microbiota.

Soluble fiber (psyllium, ispaghula, inulin, and modified citrus pectin) improves symptoms, whereas insoluble fiber (corn, wheat bran) may worsen symptoms in some cases.

Exercise

Regular physical exercise has been demonstrated to improve stress-coping, enhance well-being, and decrease feelings of depression and anxiety. Physical activity decreases bowel transit time and increases frequency of bowel movements,⁷² and structured exercise programs have been shown to improve overall IBS symptoms.⁷³ Moderate exercise is recommended and encouraged for all patients with IBS.

Sleep

Poor sleep quality is observed in patients with IBS, further compromising their quality of life.⁷⁴ Poor sleep predicts symptoms of IBS, rather than

vice versa.⁷⁵ Good sleep hygiene is an important consideration and often requires supporting the entire family unit to adopt this approach (see [Chapter 9](#)).

Supplements

Probiotics

The gastrointestinal (gut) microbiome plays a critical role in the normal development and functioning of the gastrointestinal tract and is broadly influenced by genetics and environment. The fecal microbiota of IBS patients differs significantly from controls due to diet, antibiotics, infection, and stress. Evidence indicates alterations in the gut microbiota in not only the expression of the intestinal manifestations of IBS, but also the psychiatric morbidity that coexists in up to 80% of patients with IBS.⁷⁶

Recent trials have focused on altering gut microflora with the therapeutic use of probiotics; live microbial organisms that are administered in foods or supplements. Probiotics are nonpathogenic, of human origin, resistant to gastric acid and bile, adhere to intestinal epithelium, and are able to colonize the GI tract.⁷⁷ Probiotics appear to decrease fermentation, improve competition against imbalanced and potentially pathogenic flora, and stimulate proper immune functioning. Probiotics have been shown to balance inflammatory cytokines in IBS patients.⁷⁸ The human gut microflora plays a critical role in maintaining host health both within the GI tract and systemically through the absorption of metabolites. An “optimal” gut microflora establishes an efficient barrier against the invasion and colonization of the gut by pathogenic bacteria, produces a range of metabolic substrates that in turn are utilized by the host (e.g., vitamins and short-chain fatty acids), promotes development, and provides balance for the immune system.

Earlier studies and clinical experience pointed to the beneficial role of broad-based probiotic therapy, and recent systematic reviews have clearly confirmed that probiotics are effective therapies for IBS, including in the management of global symptoms, abdominal pain, bloating, and flatus.⁷⁹ The fecal microflora has been shown to be abnormal in IBS-D,⁸⁰ with a loss of bacterial diversity in combination with significantly higher levels of detrimental enterobacteriaceae and lower levels of beneficial fecalibacterium.⁸¹ Changes in the colonic flora may lead to altered fermentation and immune dysregulation of the intestinal mucosa. In patients with IBS-C, altered bacterial fermentation patterns are seen, with lower levels of lactate-utilizing, hydrogen-consuming, methane-

generating, and acetate-generating organisms. Sulfate-reducing organisms are increased in IBS-C and produce toxic sulfide compounds and concomitant symptoms.⁸²

Information from studies of clinical utility cannot be “transferred” across different strains and different bacteria. The specific species and strain of probiotic is of great importance in the effectiveness of treatment, with strain heterogeneity in clinical studies resulting in heterogeneity among the results. Initial studies have focused on several strains of probiotic, with positive effects reported for the *Bifidobacterium* genus, *Bifidobacterium infantis* 35624, *Lactobacillus plantarum*, *E. coli* Nissl 1917, *Streptococcus faecium*, and (the high potency, 8–strain combination) VSL#3.⁸³

Dosage

Recommend a mixture of 50/50 *L. plantarum*/*B. breve* at 25 billion colony-forming units (cfu) twice daily for 6 to 8 weeks; then decrease to 10 billion cfu/day. Other probiotic combinations may be considered on the basis of fecal flora (see [Chapter 105](#)).

Precautions

Avoid in severely immunocompromised patients, including those with severe pancreatic disease.

Altered gastrointestinal flora (i.e., dysbiosis) is considered a critical factor in immune dysregulation and altered function. Correction of dysbiosis is required for successful treatment of IBS.

Prebiotics

Prebiotics are simple carbohydrate molecules that selectively stimulate normal GI flora to proliferate, thus competing with abnormal flora and pathogens for space, food, and adherence. The term, prebiotic, is becoming increasingly problematic as nearly all foods are now recognized to affect the gastrointestinal microbiota. Synbiotics are the combination products of prebiotics and probiotics.

Fructooligosaccharides (FOSs) and inulin are the most commonly used supplemental prebiotics at this time, and have been shown to increase bifidobacteria in the stool. Animal studies have reported beneficial effects on microflora balance,⁸⁴ and human studies have demonstrated in vivo

activation of bifidobacteria⁸⁵ but no improvement in IBS.⁸⁶ Overall, clinical experience emphasizes the use of foods as prebiotics, with different FODMaP and SCD carbohydrates stimulating differential growth of intestinal microbiota. Thus, it is usually beneficial to balance the gut microbiome with food, probiotics, and antimicrobial agents before promoting the use of supplemental prebiotics.

Dosage

See FODMaP diet. Do not recommend prebiotics unless or until there is a rebalancing of the gut flora. Common food sources include apples, pears, dried fruit, mushrooms, avocado, milk, cheese, wheat, rye, onions, artichokes, and inulin.

Pancreatic Enzymes

One of the conditions to be considered diagnostically with IBS is that of pancreatic insufficiency. Pancreatic insufficiency can be a primary process, with depletion of exocrine pancreatic function, or can be secondary to villous atrophy, insufficient cholecystokinin production, or decreased vagal nerve stimulation of the exocrine pancreas. These conditions lead to a decrease in the production of pancreatic elastase in the stool, identification of which can determine the need for supplemental pancreatic enzymes. Laboratory data reveals that 7% of patients with IBS have moderate to severe pancreatic insufficiency.⁸⁷ Studies of pancreatic enzyme supplementation in patients with IBS symptoms are now underway.

Dosage

Dosing of pancreatic enzymes is standardized according to lipase activity (e.g., Creon 12 = 12,000 IU Lipase activity). Animal glandulars of pancreatin 10× USP have relatively fixed ratios of lipases, proteases, and amylases. Pancreatic elastase can be used to monitor exocrine pancreatic function without being affected by pancreatic enzyme supplementation.

Stool for pancreatic elastase is a relatively inexpensive test to check for pancreatic insufficiency.

Botanical Medicines

Peppermint Oil

Peppermint (*Mentha piperita*) has been used for GI disturbances for millennia. Menthol and methyl salicylate, the main active ingredients, have antispasmodic actions and calming effects on the stomach and GI tract. The physiological effect in reducing smooth muscle contraction and providing relaxation appears to be due to the effect of menthol as a calcium channel blocker on smooth muscle cells.⁸⁸ Peppermint also has analgesic properties, mediated through activation of κ -opioid receptors to help block transmission of pain signals. Peppermint oil has been evaluated in a number of randomized trials. A 2006 Cochrane Review confirmed these initial reports, with 79% of IBS patients having alleviation of abdominal pain,⁸⁹ and a meta-analysis⁹⁰ concluding a beneficial effect after 2 weeks of therapy.

Dosage

The recommended dosage of peppermint oil is one to two 0.2 mL (200–400 mg) enteric-coated capsules three times/day between meals. Smaller doses are effective in children (100–200 mg).⁹¹

Precautions

Nonenteric-coated capsules, as well as free peppermint oil, can decrease lower esophageal sphincter tone, resulting in heartburn, although this effect is typically transient. Skin rash has been reported at a rate of approximately 2%.

Ginger

Ginger (*Zingiber officinale*) can be used nutritionally in cooking or as an herbal remedy and has been evaluated in the treatment of postoperative nausea and vomiting. The active gingerols act as an antispasmodic and improve the tone of intestinal muscles. A recent small study demonstrated benefit in both the ginger and placebo groups, with fewer

side effects in the ginger group.⁹² Ginger is available in many forms, and ginger root tea is particularly helpful after overeating.

Dosage

Powdered root, 250–500 mg 3–4 times/day. Prepare ginger tea by chopping a piece of ginger the size of the patient's fifth digit; place in 150 mL of boiling water for 5–10 minutes and strain. Drink one cup before meals.

Aloe

Aloe (*Aloe spicata* and *Aloe vera*) is commonly considered safe for internal ingestion and is used commonly with IBS. Aloe vera is classified by the U.S. Food and Drug Administration (FDA) as a class 1 harsh stimulant laxative because anthraquinones in aloe significantly increase colonic peristalsis. Aloe should be regarded as being in the same class as other anthranoid laxatives, such as cascara (*Cascara sagrada*) and senna (*Cassia senna*). Although these agents may be used for short-term relief of constipation, they are not suitable for use in IBS due to their powerful action and tendency for dependency.⁹³

Combination Herbal Therapies

Traditional Chinese Medicine

One of the most often cited studies of integrative medicine in IBS was published by Bensousson et al. in *JAMA*.⁹⁴ These researchers demonstrated a beneficial effect of a combination Chinese patent medicine (tong xie yao fang [TXYF]—a generic prescription for presumed spleen qi deficiency and liver–spleen disharmony) used over 16 weeks. Symptoms improved significantly during treatment but returned after the medicine was stopped. However, individualized herbal therapies demonstrated sustained improvement, even at 14 weeks after the individualized herbal medicines were stopped. Thus individualized traditional Chinese medicine (TCM) treatment is recommended. An additional study of TXYF was recently conducted with 120 IBS patients and reported decreased mast cell activation; however, this study did not include a placebo control.⁹⁵

Padma Lax

Padma lax is a complex Tibetan herbal formula for constipation and contains aloe extract, calumba root, cascara bark, frangula bark, rhubarb root (all known laxatives), and other herbs/minerals with antispasmodic and antidiarrheal effects. Several studies have demonstrated the effectiveness of padma lax in constipation-predominant IBS, including a 63% reduction in symptom severity and 90% reduction in the number of patients with severe symptoms.^{96,97}

Dosage

For IBS with constipation, padma lax two capsules/day for 3 months; decrease dosage to one capsule daily if loose stool is noted.

STW-5

STW-5 is a mixture of aqueous ethanolic plant extracts from *Iberis amara* (clown's mustard), chamomile flower, caraway fruit, peppermint leaves, greater celandine, licorice root, lemon balm leaves, angelica root, and milk thistle fruit. In a 2001 randomized, multicenter study of 208 patients with IBS, STW-5 reduced total abdominal symptoms by approximately 54%, compared with 27% for the placebo, at 4 weeks.⁹⁸

Dosage

A common brand name of this product is *Iberogast*. *Iberogast* can be mixed with water in the following dosages:

Adults and children over 12 years: 20 drops, 3 × day

Children 6–12 years: 15 drops, 3 × day

Children 3–6 years: 10 drops, 3 × day

Children 3 months to 3 years: 8 drops, 3 × day

Mind-Body Therapies

Throughout the past two centuries, IBS was believed to be a nervous disorder that developed in response to external stress and internal neuroses, such as depression and anxiety.⁹⁹ Early epidemiological studies

demonstrated a 2:1 female-to-male predominance, as well as a higher prevalence of emotional, physical, or sexual abuse in patients with IBS.¹⁰⁰ These vulnerability factors are part of the “enhanced stress responsiveness” that is observed in IBS, manifesting as an inability to turn off the stress response.¹⁰¹ Higher cortisol levels in morning urine and saliva have been reported in subjects with IBS than in controls, indicating a state of chronic stress.¹⁰² Stress increases intestinal permeability as well as susceptibility to colonic inflammation.¹⁰³

The evolution of mind-body-medicine, research in psychoneuroimmunology, and practical tools in heart rate variability biofeedback have increased understanding of the intrinsic relationship between external stressors, emotions, and physiological changes. Integrative treatment of IBS requires an array of therapeutic approaches that treat the patient on mental, emotional, and physical levels.

Mind-body therapy, in the form of relaxation therapy, biofeedback, hypnosis, counseling, or stress management training, has been shown to reduce symptom frequency and severity and to enhance the results of standard medical treatment of IBS. The majority of these therapies focus on correcting maladaptive coping skills that engender emotional stress, which then manifests as GI symptoms.

Stress Management

Lifestyle changes that incorporate stress reduction and stress management strategies, along with progressive muscle relaxation, have proved to be more effective than medical therapy¹⁰⁴ (see [Chapter 94](#)).

Hypnosis

Trials conducted in the United Kingdom have reported that weekly hypnosis sessions, in combination with self-hypnosis techniques for 12 weeks, improved the symptoms of abdominal pain, bloating, and disturbed defecation, as well as anxiety scores, but did not alter rectal tone or pain threshold.¹⁰⁵ Specific “gut-directed” hypnotherapy programs are now available (see [Chapter 95](#)).

Psychotherapy and Cognitive Behavioral Therapy

Cognitive behavioral therapy (CBT) combines cognitive therapy and behavioral therapy. Behavioral therapy helps patients weaken the connections between troublesome situations and habitual reactions to

them. Cognitive therapy teaches how certain thinking patterns cause symptoms. When combined into CBT, these therapies provide powerful tools for eliminating symptoms. CBT, behavioral therapy, hypnosis, and psychotherapy have all been shown to significantly improve symptoms (30%–40%) in patients with moderate to severe IBS in comparison with education or self-administered therapies.¹⁰⁶

Patients with IBS symptoms often have a combination of mental/emotional stressors and alterations in the psychoneuroimmunological axis. Ensuring a proper gut milieu along with stress management strategies is necessary for optimal gut function.

Acupuncture

In 2006, a Cochrane Review analyzed six RCTs using acupuncture in IBS and concluded there was no evidence to support the use of acupuncture in treating IBS.¹⁰⁷ A more recent study by Lembo et al. demonstrated a benefit of both real and sham acupuncture. It is interesting that the nonspecific placebo effects of acupuncture appear to be therapeutically effective.¹⁰⁸

Placebo Effects

It has been well documented that RCT research in the treatment of IBS has observed very high placebo response rates. Kaptchuk et al. developed a unique study to evaluate the benefit of openly offering a placebo treatment, which was found to be efficacious!¹⁰⁹

Pharmaceuticals

Oral Cromolyn

Several studies have compared oral cromolyn with a placebo in randomized, double-blind crossover trials. In one study, an 8-week treatment resulted in significant symptom reduction and a long carryover effect in the group initially treated with cromolyn.¹¹⁰ Two large unblinded studies have compared oral cromolyn with an elimination diet. The largest trial involved 409 patients with well-defined IBS who were monitored for 4 months.¹¹¹ Symptom improvement was noted in

60% of patients treated with elimination diet and in 67% of those receiving cromolyn.

Dosage

The recommended dose of cromolyn is 200 to 400 mg (1–2 gel caps) four times/day, before meals and 30 minutes before bedtime.

Precautions

Cromolyn is well tolerated but may cause diarrhea and headaches.

Antibiotics

The “shotgun” use of antibiotic treatments may lead to significant alterations in the GI microflora, which can be deleterious in the long-term.¹¹² Most recently, rifaximin (a nonabsorbable antibiotic) has been demonstrated to significantly improve IBS symptoms and is now FDA-approved for the treatment of IBS-D.¹¹³ Rifaximin has also been shown to be useful in the treatment of small intestinal bacterial overgrowth (SIBO), a source of bacterial fermentation, gas, and bloating. SIBO can be diagnosed with a lactulose or glucose breath test. Rifaximin treatment was not found to affect the overall composition of the gut microbiota but diminished potentially detrimental bacteria, such as *Clostridium*, and increased the presence of some species, such as *Faecalibacterium prausnitzii*.¹¹⁴

Dosage

Rifaximin 550 mg three times/day for 10–14 days in patients with SIBO.

Precautions

Rifaximin is not systemically absorbed so most side effects are related to GI function including flatulence, abdominal pain, and stool urgency. Any antibiotic or antimicrobial herb may affect the diversity and quantity of the microbiome and care should be taken to optimize the GI ecosystem in order to replenish a healthy and diverse microbiome.

Antidepressants

A recent meta-analysis reported that tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs) significantly lessened abdominal pain and diarrhea in patients with diarrhea-predominant IBS.¹¹⁵ SNRIs were not effective. Patients able to tolerate TCAs are likely to have symptomatic benefit; however, many patients experience unacceptable side effects.

Therapies to Consider

Betaine Hydrochloride

A basic evaluation of digestion and absorption is often not part of the initial evaluation of GI function in patients with IBS. Factors that affect digestion of food include mastication, hypochlorhydria, and pancreatic insufficiency. Mastication is a simple clinical point to make with patients and is often overlooked. Pancreatic insufficiency and benefit of digestive enzyme supplementation have been discussed previously. Research indicates stomach acid declines with age. Decreased pH limits the activation of peptidases and other critical enzymes necessary for digestion and absorption. Betaine hydrochloride, Swedish bitters, and Gentian violet can be used as supplements to support the reactivation of proper digestion by stimulating gastric acid production.

Dosage

325 to 650 mg before a protein-containing meal.

Precaution

Reduce the dose if a warm or burning sensation develops after ingestion.

Osteopathic Medicine

It is often thought that osteopathy and other related manual therapies are used only for musculoskeletal problems. However, recognition of a somatovisceral pathway amenable to manipulation has led to use of these approaches for relief of symptoms in patients with IBS. The somatic areas that are commonly affected include the external oblique muscles

(particularly the lower portion), internal oblique muscles, and rectus abdominis muscle; the lower segments of the thoracic spine (T10–T12); the iliocostalis thoracis/lumborum and longissimus thoracis/lumborum muscles; and the quadratus lumborum muscles. Individuals with this somatovisceral connection are often unaware of these tender points until they are discovered by careful palpation. This indirect technique seeks to release the strained somatic segments through initiation of a reciprocal counterstrain of the antagonist muscles (see [Chapter 109](#)).

Prevention Prescription

Primary Prevention in the First 2 Years of Life

- Limit/avoid antibiotics and antimicrobial herbs to maximize opportunity for bowel microflora to develop.
- Practice breastfeeding on demand for the first 12 months of life; avoid formula feeding, if possible.
- Introduction of solid foods—delay introduction of grains until after age 6 months, preferably at 8–10 months of age or when the child’s pincer grasp allows them to self-feed.

Primary Prevention at All Ages

- Carbohydrates—avoid or minimize simple sugars because they provide the substrate for abnormal bacteria to perpetuate in the GI tract.
- Importance of taking time to eat, preparing food, and eating it with others. Increase vagal tone.
- Learn to reduce stress or the internalization of emotion.
- Paleolithic diet—fewer processed foods, fewer grains, more vegetables.

Therapeutic Review

This is a summary of the therapeutic options for IBS. An initial diagnostic evaluation is necessary to target effective therapies. A celiac panel should be performed in all patients and include tTG IgA and DGP IgA (reflex to EMA IgA) and total IgA. For patients with mild to

moderate symptoms of IBS without any clear source of etiology, this ladder approach is appropriate.

Mind-Body Therapies

- Cognitive behavioral therapy 
- Hypnotherapy 

Nutrition

- Elimination/challenge diet (see [Chapter 86](#)) 
- FODMAPs diet (see [Chapter 90](#)) 
- Some patients may need additional motivation through diagnostic testing (IgG food allergy testing).

Supplements

- Probiotics: 50 billion cfu/day as 25 billion cfu/day of *Bifidobacterium* and 25 billion cfu/day of *Lactobacillus*  or *B. infantis* 36524 at 5 billion cfu/day 
- Soluble fiber (psyllium, guar gum) 15 g/day with meals 

Botanicals

- Peppermint oil: one to two enteric-coated capsules three times/day between meals 
- TCM herbs: tongxie yaofang 
- Tibetan herbs/padma lax for IBS with constipation, two capsules/day for 3 months 
- STW-5, 20 drops three times/day for 4 weeks 

Pharmaceuticals

- Oral cromolyn 200 mg (2 capsules) four times/day before meals and before bedtime 
- Antibiotics: rifaximin 400 mg tid for 10 days in patients with evidence

of small intestine bowel overgrowth 

- Tricyclic antidepressants: such as amitriptyline, 10–25 mg/day with lower doses to start

CHAPTER 42

Gastroesophageal Reflux Disease

David Kiefer, MD

Gastroesophageal reflux disease (GERD) occurs when there is abnormal passage of acidic stomach contents, or refluxate, into the esophagus, causing symptoms or complications. GERD is one of the primary causes of the informal name and symptom *heartburn*, and is a common phenomenon. Estimates are that 15% to 20% of people in the United States have heartburn or regurgitation at least once a week.¹⁻⁵

Symptoms of GERD may include any or all of the following: retrosternal burning, acid regurgitation, nausea, vomiting, chest pain, laryngitis, cough, and dysphagia.³ Injury to the esophagus can include esophagitis, stricture, the development of columnar metaplasia (Barrett esophagus), and adenocarcinoma.² A poor correlation exists between the severity of symptoms and the pathophysiological findings in the esophagus.² For example, GERD is not the only phenomenon in the differential diagnosis of heartburn. Many individuals with GERD have no endoscopic evidence of esophagitis, and up to 40% of patients with Barrett esophagus did not report heartburn in a clinical study.^{2,4} The confusing nature of GERD has limited the development of concrete screening recommendations for advanced disease.

People may turn to complementary and alternative medicine to help with their gastrointestinal symptoms. The 2002 National Health Interview Survey, based on 31,044 interviews in the United States, documented that 3.7% of people used complementary and alternative medicine for stomach or intestinal illnesses,⁶ though this percentage had dropped to 1.2% by 2007.⁷

Pathophysiology

Symptoms of GERD result from the interplay of many factors, including

the amount of time the esophagus is exposed to refluxate, the degree of refluxate causticity, and the susceptibility of the esophagus to damage.^{4,8,9} Three main mechanisms or factors prevent refluxate from entering the esophagus: the lower esophageal sphincter (LES), the crural diaphragm (which acts as an external esophageal sphincter), and the location of the gastroesophageal junction below the diaphragmatic hiatus.^{1,4} Dysfunction or malalignment in any or all of these structures may lead to symptoms of GERD, although the major pathological mechanism is abnormal LES tone.

The LES normally exists in a contracted state and relaxes during the swallow mechanism to allow material into the stomach ([Fig. 42.1](#)). The LES also relaxes to vent swallowed air and allow retrograde expulsion of material from the stomach.^{4,8} For approximately an hour after meals, people may normally have up to five transient episodes of reflux; however, the symptoms of GERD may develop if these episodes continue.^{4,8}

Decreased tone of the LES occurs with many substances, medications, and other factors ([Table 42.1](#)).^{1,4} Certain beverages may exacerbate symptoms of GERD, with some affecting LES tone. For example, coffee, including instant, decaffeinated, and ground coffee, decreases LES tone initially and, in some people with sustained decreased tone, for up to 90 minutes after ingestion. Caffeinated coffee seems to cause more gastric acid production¹⁰ and greater decreases in LES tone at low pH values.¹¹ A separate study found an association between pH and titratable acidity and the frequency with which some beverages, such as juices, sodas, coffee, and tea, caused heartburn symptoms in 394 individuals with GERD.¹² Caffeine itself has been shown to have the ability to decrease LES tone.¹³

Symptoms of GERD may result from other factors. For example, increased intraabdominal and gastric pressure, such as from obesity, ascites, pregnancy, or even tight clothes, may lead to GERD.^{1,4,14} In addition, GERD may occur when gastric contents are located near the gastroesophageal junction, such as in the recumbent position, while bending over, or in patients with a hiatal hernia.¹ Furthermore, any conditions that decrease the production of saliva may predispose to GERD due to the neutralizing effect of saliva on acid.¹

Patients report that stress exacerbates GERD, a finding that has been borne out in clinical trials. For example, stress has been shown to increase GERD symptom reports without necessarily being correlated with objective physiological changes, such as increased esophageal acid

exposure or duration of acid exposure.¹⁵⁻¹⁷ This phenomenon particularly occurs in people with high levels of anxiety.¹⁶ Other well-known examples are documented worsening of GERD symptoms with job stress¹⁸ and after devastating events, such as the World Trade Center attack in 2001.¹⁹ The enteric nervous system, with innervations throughout the gastrointestinal tract, is now referred to as the *brain-gut axis* and¹⁷ is involved in the contribution of stress to worsening of GERD; however, this system is complex.⁸

Diagnostic testing can be used to determine the cause of patient symptoms and any pathophysiological correlates. For example, barium swallow, upper endoscopy, ambulatory pH, and a trial of proton pump inhibitor (PPI) medications are the most commonly used diagnostic tests.²⁰ Ambulatory pH testing, estimated to have a sensitivity of 79% to 96% and a specificity of 85% to 100% for GERD, may also be used with impedance testing to explore the correlation of symptoms with refluxate volume regardless of acidity (weakly acidic or nonacid reflux).^{2,20} One approach is to consider diagnostic testing (upper endoscopy, ambulatory pH, or impedance testing) if a patient is unresponsive to PPI therapy.²⁰

FIG. 42.1 Normal Swallow Mechanism.

A continuous tracing of esophageal motility showing two swallows, as

indicated by the pharyngeal contraction associated with relaxation of the upper esophageal sphincter (*UES*) and followed by peristalsis in the body of the esophagus. The lower esophageal sphincter (*LES*) also displays transient relaxation (*arrow*) unassociated with a swallow. An episode of gastroesophageal reflux (*asterisk*) is recorded by a pH probe at the time of the transient LES relaxation. (From Behrman RE, Kliegman RM, Jenson HB, eds.

Nelson Textbook of pediatrics. 17th ed. Philadelphia: Saunders; 2004.)

Special Considerations for Pediatric Patients

In children, GERD is the most common esophageal disease.⁹ In infants, symptoms often peak at 4 months of age and resolve by 12 to 24 months, whereas the clinical course may wax and wane in children, resolving in approximately half of cases.⁹ Infants may present with postprandial regurgitation, irritability, arching, choking, gagging, feeding aversion, failure to thrive, obstructive apnea, or stridor. Signs and symptoms in older children include abdominal pain, chest pain, asthma, laryngitis, and sinusitis.⁹ Studies in infants with suspected GERD have found both a high incidence of allergy to cow's milk protein²¹ and symptomatic improvement when infants with intractable symptoms were changed to a diet free of cow's milk protein.²²

TABLE 42.1

Factors Associated With Decreased Tone of the Lower Esophageal Sphincter

Factor	Examples
Dietary supplements	Arginine may cause lower esophageal sphincter relaxations through the nitric oxide system Carminative herbs such as peppermint (<i>Mentha piperita</i>), spearmint (<i>Mentha spicata</i>), and other mint family (Lamiaceae) plants Essential oils (high doses)
Foods and beverages	Alcohol Chocolate (probably through the methylxanthines) Coffee (caffeinated more than decaffeinated) Cow's milk Fat Orange juice Spicy foods Tea Tomato juice
Lifestyle	Smoking
Medications	Aminophylline Anticholinergics Beta-adrenergic agents Biphosphonates Calcium channel blockers Nitrates Phosphodiesterase inhibitors, including sildenafil
Physiological, by stomach dilation	Acid hypersecretion After meals Gastric stasis Pyloric obstruction
Trauma, irritation, and miscellaneous factors	Esophagitis Scleroderma-like diseases Surgical damage

Data from references [1](#), [16](#), [17](#), and [27](#).

Cow's milk protein is a common cause of gastroesophageal reflux disease in infants, and a trial of elimination should be considered.

Integrative Therapy

Lifestyle

In mild cases of GERD, lifestyle modifications are the first line of therapy and can lead to improvement or elimination of symptoms. For example, GERD symptoms may improve if smokers quit and if obese patients lose weight.^{1,5,23-26} Patients should avoid the foods, supplements, and, if possible, the medications listed in [Table 42.1](#) because of their relaxing effect on the LES. In addition, patients should avoid eating large meals or consuming large quantities of fluids with meals.¹

TABLE 42.2

Botanical Medicines Useful in Gastroesophageal Reflux Disease

Common Name	Scientific Name (Family)	Mechanism of Action	Dose	Adverse Effects
Chamomile	<i>Matricaria recutita</i> (Asteraceae)	Anti-inflammatory, antispasmodic	1–3 g (2 g equals 1 tablespoon) of an infusion of the flowers three to four times daily	Occasional allergic reactions in people allergic to plants in the daisy family (Asteraceae)
Licorice	<i>Glycyrrhiza glabra</i> (Fabaceae)	Anti-inflammatory	Two 200-mg DGL tablets before meals	Mineralocorticoid side effects avoided when DGL form is used
Mullein leaf	<i>Verbena officinalis</i> (Verbenaceae)	Mucoprotective	5–6 g of tea daily, in divided doses	Decreased drug absorption
Slippery elm	<i>Sanguinaria canadensis</i> (Liliaceae)	Antiacidic	1–2 g of the herb as infusion three times daily, 1–2 mL tincture three times daily	Confusion, ataxia, and twitching with high doses
Slippery elm	<i>Ulmus fulva</i> , <i>Ulmus rubra</i> (Ulmaceae)	Mucoprotective	1–2 tablespoons per glass of water three to four times daily	Decreased drug absorption
Valerian	<i>Valeriana officinalis</i> (Valerianaceae)	Antiacidic	1–2 g root infusion, two to three times daily, or a 150-mg capsule two to three times daily	Possibly increased effects of fentanyl, barbiturates, and benzodiazepines

DGL, deglycyrrhized licorice.

If nighttime symptoms are present, patients should elevate the head of the bed by 4 to 6 inches using blocks under the bed posts rather than extra pillows. Use of extra pillows could compress the abdomen and increase intraabdominal pressure, thereby exacerbating symptoms.^{1,2,23}

Exercise may benefit GERD indirectly by promoting weight loss; however, it may also have direct effects, with studies independently demonstrating that individuals who are more active have better digestion and less GERD.^{25,26}

Demulcent Botanicals

Several types of botanical treatments are useful for GERD ([Table 42.2](#)). Demulcent, or mucilaginous, botanical medicines can be used as mucoprotection of the esophageal mucosa, both to soothe irritated tissues and promote healing.^{23,27}

Slippery Elm (*Ulmus fulva*) Root Bark Powder

Slippery elm root bark powder is a demulcent botanical that can be used for symptomatic relief and promotion of healing of the irritated esophageal or gastric mucosa. Most health food stores, integrative pharmacies, and herbal dispensaries with botanical products for sale in bulk supply slippery elm.

Dosage

One to two tablespoons of root bark powder should be mixed with a glass of water and taken after meals and before bed. The proportions should be carefully titrated because the preparation can be very thick and difficult for some people to tolerate. To increase palatability, this supplement can be sweetened slightly with honey, stevia, or sugar.

Precautions

Slippery elm root bark powder is described by most sources as very safe, although the hydrocolloid fibers may bind simultaneously administered medications and decrease their absorption.²⁸

Marshmallow (*Althea officinalis*)

Marshmallow is another mucilaginous herb for GERD symptomatic relief. Its demulcent properties also make it useful for pharyngitis, wound healing, cough, and bronchitis.

Dosage

Marshmallow is usually taken at 5 to 6 g daily, in divided doses, as an infusion of the leaves or root.²⁹

Precautions

As with slippery elm, a decrease in absorption of orally administered drugs taken simultaneously with marshmallow may occur.²⁸

Antiinflammatory Botanicals

Antiinflammatory herbs are often used for GERD symptom relief and to improve healing of the irritated esophageal mucosa.²⁷ Examples include licorice (*Glycyrrhiza glabra*); meadowsweet (*Filipendula ulmaria*), which also reduces acidity; chickweed (*Stellaria media*); and chamomile (*Matricaria recutita*).

Licorice (*Glycyrrhiza glabra*)

Licorice is a well-known mucosa antiinflammatory botanical used for GERD, gastritis, and duodenal and peptic ulcers. For long-term use, it should be prescribed as deglycyrrhizinated licorice to prevent the side effects of one of its phytochemicals, glycyrrhizin (see box).

Dosage

Two 380-mg tablets of deglycyrrhizinated licorice (DGL) should be

taken before meals.²⁹

Precautions

The prolonged use of decoctions or infusions of dried, unprocessed licorice root may cause hypertension, hypokalemia, and edema due to the mineralocorticoid action of the saponin, glycyrrhizin, also called *glycyrrhizic acid*.²⁸

Chamomile (*Matricaria recutita*)

Chamomile is well known for its mild sedative actions and for its antispasmodic effects on the gastrointestinal tract. In GERD, it is used as a nondemulcent antiinflammatory agent.^{23,27}

Dosage

Chamomile is most commonly prepared as a hot water infusion (tea) of 1 to 3 g (2 g equals 1 tablespoon) of the flowers, steeped in a cup covered with a saucer, taken three to four times daily.²⁹

Precautions

Chamomile is generally well tolerated, although individuals allergic to other plants in the daisy family (*Asteraceae*) may experience an exacerbation of their allergic symptoms with consumption of chamomile.

Antianxiety Botanicals

Many herbal experts recommend botanicals as part of an overall approach to anxiety management, given the connection between anxiety and GERD (see previous). Examples are valerian (*Valeriana officinalis*) and skullcap (*Scutellaria lateriflora*)²⁷ (see [Chapter 6](#)).

Botanical Combinations

Mixtures of botanicals have also been studied either alone or in combination with pharmaceuticals. For example, two reviews have detailed the use of an 8-plant kampo (traditional Japanese medicine)

mixture, called *rikkunshito*, for GERD, including PPI-refractory GERD.^{30,31}

Pharmaceuticals

Both histamine-2 (H₂) receptor antagonists or blockers (H2Bs) and PPIs are commonly used for the symptoms of GERD. A meta-analysis concluded that both H2Bs and PPIs are effective in GERD symptomatic improvement; however, PPIs are significantly more effective than H2Bs.³² PPIs have also been used in a 1-week therapeutic trial to test and diagnose GERD empirically.¹ The optimal dosing time for PPIs is 30 minutes before a meal, although adherence to the ideal dosing regimen may or may not lead to better symptom control.³³ Some clinicians use H2Bs or PPIs indefinitely to control symptoms.² The use of PPIs is particularly important in cases of Barrett esophagus; premalignant changes in the cells of the distal esophagus. The evidence is compelling for a protective effect of PPIs on dysplastic esophageal cells.³⁴

Aggressive, long-term acid suppression can decrease the absorption of vitamin B₁₂.¹ Consider regular intramuscular injections or sublingual administration of vitamin B₁₂ for those individuals requiring long-term treatment with histamine-2 receptor blockers or proton pump inhibitors. Use of these drugs can also lead to iron malabsorption, increased risk of hip and spine fracture, *Clostridium difficile* diarrhea, cardiovascular mortality, and community-acquired pneumonia.^{4,5,35}

In one study, between 10% and 40% of people who took PPIs for GERD failed to respond symptomatically, partially or completely, whereas a separate study reported that 85% of patients taking PPIs had persistent GERD symptoms even though 73% of those patients were satisfied with the treatment.³³ Some debate exists regarding the reasons for certain patients not responding to PPIs. Investigators have hypothesized that these patients have functional or nonerosive reflux disease, or weakly acidic or alkaline refluxate.³³

Some nuances with the prescribing of the two primary classes of pharmaceuticals for GERD, PPIs and H2Bs, are noted in [Table 42.3](#). [Box 42.1](#) describes the protocol for tapering PPIs.

TABLE 42.3

Comparison of Proton Pump Inhibitors Versus Histamine-2 Receptor Blockers for Gastroesophageal Reflux Disease

PPIs	H2Bs
Greater rate of healing from esophagitis than H2Bs	Greater rate of healing from esophagitis than placebo
Slight benefit in healing esophagitis with twice the standard dose	
Unclear whether PPIs heal heartburn, as a symptom, more than H2Bs	Both PPIs and H2Bs heal heartburn more than placebo
Complete resolution of heartburn in approximately 40% of patients (compared with 15% for placebo)	

H2Bs, histamine-2 receptor blockers; PPIs, proton pump inhibitors.

Data from Kahrilas PJ. Gastroesophageal reflux disease. *N Engl J Med*. 2008;359:1700-1707.

Biomechanical Therapy

Some naturopathic physicians recommend hernial reduction adjustments, an abdominal manipulation technique, when GERD symptoms are complicated by the presence of a hiatal hernia.²³ Although no clinical trials have examined the efficacy of hernial reduction adjustments, referral to an experienced practitioner should be considered for patients with a documented hiatal hernia and symptoms of GERD. Aside from surgery, no documented allopathic interventions exist for the treatment of hiatal hernia.

Mind-Body Therapy

Relaxation training can improve symptoms of GERD by addressing the exacerbation of GERD symptoms due to stress, particularly in patients suffering from chronic anxiety.³³

BOX 42.1 Helping Taper off a Proton Pump Inhibitor

For those patients who have made positive lifestyle changes and may not need continued chronic acid suppression, it can often be difficult to discontinue proton pump inhibitors (PPIs) because they often cause rebound hyperacidity even if the underlying condition has resolved.¹

Plan:

1. Slowly taper off the PPI over 2 to 4 weeks (the higher the dose, the longer the taper).
2. While the taper is being completed, use the following for bridge therapy to reduce the symptoms of rebound hyperacidity:
 - a. Encourage regular aerobic exercise.
 - b. Encourage a relaxation technique, such as self-hypnosis, for

gastrointestinal disorders (see [Chapter 95](#)) or meditation (see [Chapter 100](#)).

- c. Suggest acupuncture one to two times per week.²
- d. Add one or more of the following:
 - i. Deglycyrrhizinated licorice, two 380-mg tablets, before meals or Sucralfate (Carafate) 1 g before meals
 - ii. Slippery elm, 1 to 2 tablespoons of powdered root in water three to four times per day
 - iii. A combination botanical product, Iberogast (clown's mustard, German chamomile, angelica root, caraway, milk thistle, lemon balm, celandine, licorice root, and peppermint leaf), 1 mL three times per day³
3. If the taper is successful, slowly taper the foregoing supplements (except for positive nutritional changes, exercise, and stress management). If symptoms return, start with one of the foregoing or a histamine-2 receptor blocker. If symptoms are still difficult to control, consider adding back the PPI.
4. Ideally, it is beneficial to avoid long-term acid suppression if possible because this can be associated with malabsorption of vitamin B₁₂ and iron,⁴ increased risk of community-acquired pneumonia,⁵ hip^{8,9} and spine^{10,11} fracture, *Clostridium difficile* diarrhea,¹² and cardiovascular mortality.³⁵

Other Therapies to Consider

Homeopathy

Homeopathy can be a therapeutic consideration. Many of the symptoms associated with GERD, such as indigestion and heartburn, or associated disorders such as hiatal hernia, are mentioned in homeopathy sources and treated with a wide variety of short-term remedies, such as phosphorus, nux vomica, pulsatilla, carbo vegetabilis, arsenicum, bryonia, china, anacardium, argentum, sepia, lycopodium, graphites, and kali bichromium³⁶ (see [Chapter 115](#)).

Traditional Chinese Medicine

Traditional Chinese medicine, which provides a complete assessment based on a unique cultural, diagnostic, and therapeutic approach, may

offer relief for patients suffering from GERD. In a study comparing acupuncture with doubling the dose of a PPI for GERD, acupuncture was found to be more effective in reducing symptoms.³⁷ With treatment suggestions incorporating diet, lifestyle, botanical medicines, and acupuncture or acupressure,³⁸ traditional Chinese medicine should be considered a therapeutic option based either solely on patient personal preference or on the requirement for adjuncts to incomplete or ineffective allopathic therapies.

Surgery

Surgical treatment is considered by many experts to be an option for people in whom lifestyle modification or adequate medical therapy fails or who are unwilling to take long-term medication.^{1,3,39,40} The most common surgical procedure is Nissen fundoplication, either open or laparoscopic, whereby the fundus of the stomach is wrapped wholly (total fundoplication) or partially (partial fundoplication) around the lower esophagus to create an area of high pressure to prevent refluxate from entering the esophagus and causing symptoms. Laparoscopic fundoplication provides long-term disease control similar to that seen with the open approach but with fewer incisional hernias.⁴⁰ One review examined health-related quality of life and GERD symptoms after 1 year in four studies involving 1232 people who underwent medical management versus laparoscopic surgical management.³ Overall, the surgical approach appeared to improve symptoms of GERD more effectively than medical management, although dysphagia (8% to 12% postoperatively),⁴⁰ costs after 1 year, and other adverse effects were more pronounced in the surgical group of some studies. One review and meta-analysis concluded that partial laparoscopic fundoplication was associated with less postoperative dysphagia than total fundoplication.⁴⁰

Special Considerations in Pediatrics

The treatment of GERD in infants usually involves dietary interventions such as the normalization of feeding techniques, volumes, and frequency, if these are abnormal.⁹ Formula can be thickened with one tablespoon of rice cereal per ounce to decrease the number of regurgitation events, increase calorie density, and reduce the number of crying episodes.⁹ One meta-analysis supported the concept that thickened feedings improve GERD symptoms in infants.⁴¹ A short trial of a hypoallergenic diet, in

particular to exclude milk and soy, can be helpful in children suspected of having allergies to those foods. Older children with GERD are advised to avoid tomatoes, chocolate, mint, and classically offending beverages (juices, sodas, and caffeinated beverages) and to lose weight, if applicable.

With respect to positioning during meals, infant GERD is worse when infants are seated, supine, or on their side and better when they are prone or carried upright. Due to the risk of sudden infant death syndrome, a prone position cannot be recommended for sleep.⁹ Older children may have some relief from GERD when they lie on their left side or with the head of the bed elevated. As with adults, children experience some symptomatic improvement with H2Bs and PPIs; the dose of PPIs is higher per kilogram than for adults (0.7 to 1.5 mg/kg/day).⁹

Prevention Prescription

- Avoid foods and supplements, and, when possible, medications known to decrease lower esophageal sphincter tone (see [Table 42.1](#)).
- Maintain ideal body weight.
- Reduce stress as much as possible through lifestyle change and stress management and mind-body techniques.
- Avoid large meals and consuming large quantities of liquids with meals.

Therapeutic Review

This summary of therapies is for patients with mild to moderate, short-term GERD. Patients with long-standing, more severe GERD should undergo an appropriate diagnostic workup, which may include a referral to a gastroenterologic specialist and for upper endoscopy to exclude esophagitis, ulcers, Barrett esophagus, and adenocarcinoma.

Removal of Exacerbating Factors

- Avoid foods, supplements, and, when possible, medications known to decrease lower esophageal sphincter tone (see [Table 42.1](#)).
- If applicable, quit smoking.
- If applicable, lose weight.

Lifestyle

- For nocturnal symptoms, elevate the head of the bed 4 to 6 inches. 
- Avoid large meals and consuming large quantities of liquids with meals. 

Mind-Body Medicine

- Practice stress management and relaxation techniques. 

Botanical Medicines

- Deglycyrrhizinated licorice: two 380-mg tablets before meals 
- Slippery elm: 1 to 2 tablespoons of powdered root in a glass of water, three to four times daily 
- Other botanical medicines that have potential benefit include chamomile, marshmallow, skullcap, and valerian (see [Table 42.2](#)).

Pharmaceuticals

- Start with a proton pump inhibitor , both for symptomatic relief and for diagnostic purposes.
- Histamine-2 receptor antagonists 
- Over-the-counter antacids, such as calcium carbonate, aluminum hydroxide, and magnesium hydroxide, can be helpful. 

Surgery

- For patients with intractable symptoms, fundoplication should be considered.

CHAPTER 43

Peptic Ulcer Disease

Joseph Eichenseher, MD, MAT

Pathophysiology

Each year approximately half a million people in the United States are newly diagnosed with peptic ulcer disease (PUD), with many more millions of undiagnosed cases likely.¹ PUD is caused by disturbances of the gastrointestinal (GI) mucosa. These disruptions are due to the loss of protective elements and/or damaging insults that result in mucosal erosions, most commonly located in the duodenum or stomach. People with PUD commonly complain of epigastric pain (particularly a few hours after meals), bloating, nausea, early satiety, altered bowel habits, and heartburn. Pain is usually improved with food or antacids. PUD may also occur without symptoms, particularly in older adults. Peptic ulcers may cause GI bleeding, which is a potentially life-threatening emergency necessitating urgent endoscopy and intensive care unit consideration. Ulcers may rarely perforate leading to intense pain and acute peritonitis, which is a surgical emergency. Patients with significant weight loss and PUD symptoms should undergo endoscopy to investigate for potential malignant diseases.

The loss of gastrointestinal mucosal integrity is typically multifactorial, with diminished protective elements (predominantly decreased acid buffering, reduced immune system functioning, and slowed wound healing) and increased insults (primarily *Helicobacter pylori* infection, the use of nonsteroidal antiinflammatory drugs [NSAIDs], increased acidity, and inflammation). Treatment efforts are focused on restoring protective factors and reducing harmful affronts.

Nonsteroidal antiinflammatory drugs, such as ibuprofen or naproxen,

should be avoided in patients with a history of peptic ulcer disease (PUD) and minimized in individuals with PUD symptoms who lack a formal diagnosis of PUD.

Peptic ulcers may occur at any time in life, although the incidence gradually increases with age.² In the early twentieth century, PUD was diagnosed in men at twice the rate as in women. However, PUD is now nearly equally distributed between genders, although gastric ulcers tend to be more common in women and duodenal ulcers more common in men.³

Historically, investigators were aware that smoking, stress, NSAIDs, and family history (risk increases three times with an afflicted first-degree relative)⁴ contributed to peptic ulcer formation. However, prior to the late 1970s, allopathic medicine had limited success in treating PUD until the arrival of two revolutionary developments: the invention of pharmaceuticals that reduced the amount of acid the stomach produced; and the discovery of the *Helicobacter pylori* bacterium ([Fig. 43.1](#)).

The development of gastric acid-suppressing medications, with the advent of histamine-2 receptor antagonists (H₂ blockers) in the late 1970s and proton pump inhibitors (PPIs) in the 1980s, heralded a new chapter in Western medicine's management of PUD. Previous efforts had focused on reducing risk factors, administering acid buffers (e.g., calcium carbonate) for symptom relief, and surgery (associated with significant morbidity and mortality). With the invention and administration of acid-reducing medications, the majority of cases of PUD are quickly attenuated. This approach has drastically reduced the need for surgery and increased the role of pharmaceuticals in PUD therapy.

H. pylori was identified in 1982, a discovery for which Drs. J. Robin Warren and Barry J. Marshall won the Nobel Prize for medicine in 2005. The more the medical world learns about this unique bacterium, the more our thinking about PUD treatment evolves. *H. pylori* infection has been shown to increase the incidence of PUD by at least four-fold.⁵ Rates of *H. pylori* infection vary worldwide according to age and economic status. Younger, more affluent individuals have rates as low as 20%, whereas up to 60% of all individuals in the developing world, and 50% of individuals older than 60 years in the United States, are colonized by the bacterium.⁶ Living in the harsh acidic environment of the human stomach, *H. pylori* appears to increase the risk of PUD by directly damaging the protective mucus lining of the GI tract and allowing for increased acidic damage. *H. pylori* also triggers an immune response that

causes damaging inflammation. Besides PUD disease, *H. pylori* has been also been linked to increased rates of gastric cancer, dyspepsia, vitamin B₁₂ deficiency, iron deficiency, and idiopathic thrombocytopenia (ITP).⁷ *H. pylori* may not be without benefits, with some studies indicating a correlation between *H. pylori* colonization and decreased rates of asthma, allergies, GERD, obesity, and esophageal cancer.^{7,8} Whether *H. pylori* is predominantly a symbiotic bacteria that has been with humanity for millions of years, occasionally running amok and causing PUD and stomach cancer, or strictly a pathogen that has an increasing niche in the modern world warranting global eradication efforts remains the focus of research efforts. The pending answer to this question will likely guide approaches to PUD treatment in the decades ahead. Although there have been promising *H. pylori* vaccine studies in animal models, indicating vaccines may eventually become the most powerful tool for treating PUD, successful clinical vaccine trials have yet to be reported. Even with a potential vaccine, complete global eradication of *H. pylori* is logistically challenging, despite *H. pylori* exclusively residing in humans, because there are currently an estimated 4 billion people infected worldwide. Further, only 10% to 20% of *H. pylori*-infected individuals develop PUD.⁵ Thus, current treatment efforts should focus on symptomatic carriers. Universal screening of asymptomatic individuals for *H. pylori* is not advised.

FIG. 43.1 *Helicobacter pylori*, the discovery of which revolutionized medical understanding and management of peptic ulcer disease. (Courtesy Yutaka Tsutsumi, MD.)

H. pylori and NSAIDs, in combination with other risk factors, account for the majority of cases of PUD.¹ The remaining cases are attributable to other independent risk factors and a few clinical “zebras,” such as Zollinger-Ellison tumors, carcinoid syndrome, other drugs, radiation, cytomegalovirus, and systemic mastocytosis.

Pharmaceutical acid suppression, and the discovery and subsequent antibiotic treatment of *H. pylori*, resulted in optimism that PUD was on the verge of elimination at the end of the twentieth century. However, due to increasing antibiotic resistance, increased knowledge of the harms of long-term pharmaceutical acid suppression, in addition to evidence of the potential benefits of *H. pylori* infection, there is now a requirement for more judicious use of antibiotics and the incorporation of more integrative PUD approaches in the years and decades ahead.

Diagnosis

The overlapping constellation of PUD symptoms with other diseases, such as gastritis, irritable bowel syndrome, gastroesophageal reflux

disease, Crohn's disease, pancreatitis, gallstones, and malignancy, makes the initial diagnosis of PUD challenging, particularly because endoscopy (an invasive, costly procedure) is the current standard for diagnostic testing and the next best tool is a barium GI series (with resulting radiation, cost, and potential inaccuracy). A study reported that the physical examination finding of epigastric tenderness decreases the likelihood of PUD.⁹ Thus, it is not surprising that many practitioners, in addition to patients without signs of serious disease (bleeding or weight loss), hesitate in electing to pursue these invasive diagnostic measures. Accordingly, the majority of cases of PUD may never be diagnosed with certainty. *H. pylori* testing in symptomatic patients increases the number of people diagnosed with *H. pylori* infection, but a positive test result indicates only a bacterial infection, and cannot differentiate between conditions such as gastritis and more serious PUD, although initial management is largely the same. There are various tests for *H. pylori*, but the stool antigen and urea breath tests are consistently the best for determining active infection.

Once a diagnosis of PUD is established, recurrence is reported in up to 74% of patients.¹⁰ PUD management therefore focuses on the prevention and symptomatic treatment, a good fit for an integrative approach ([Fig. 43.2](#)).

Integrative Therapy

Nutrition

Dietary constituents were linked to PUD long before the discovery of *H. pylori*, with subsequent research demonstrating certain foods to be protective against *H. pylori* infection. Accordingly, nutrition is considered a key component of ulcer prevention and symptom management.

Meal timing influences PUD, with skipping breakfast¹¹ and consuming large meals shortly before bedtime shown to increase the risk of PUD.¹²

Fruit and vegetable intake reduces the risk of developing ulcers, with epidemiological studies demonstrating that a diet high in plant-based fiber and vitamin A (e.g., carrots, spinach, mango, sweet potatoes, and apricots) helps protect against PUD.¹³ Flavonoids, compounds found throughout the plant world, have been found to be protective against *H. pylori* infection and are present in concentrated amounts in citrus, berries, onions, parsley, green tea, red wine, and dark chocolate.¹⁴ Sulforaphanes, which are phytochemicals found in vegetables such as Brussels sprouts,

broccoli, cabbage, cauliflower, bok choy, turnips, and radishes, are also protective against *H. pylori* infection.¹⁵

Studies have specifically shown that virgin olive oil (30 g daily for 2 weeks) or broccoli sprouts (70 g a day for 8 weeks) have the ability to decrease and potentially eliminate *H. pylori*.^{15,16} Foods containing capsaicin (chili) have been shown to be protective against ulcers.¹⁷ Capsules of chilies (fruit of the plant genus *capsicum*) are reviewed in the botanical section of this chapter for acute symptom relief. Other common foods demonstrating protective effects against *H. pylori* include banana, honey, garlic, ginger, okra, pomegranate, and apple.¹⁸⁻²⁴ There is likely synergy in ingesting combinations of these beneficial foods, a good example of “nutrition is medicine.”

Integrative PUD management

(If evidence of bleeding or significant weight loss occurs at any time, pursue endoscopy)

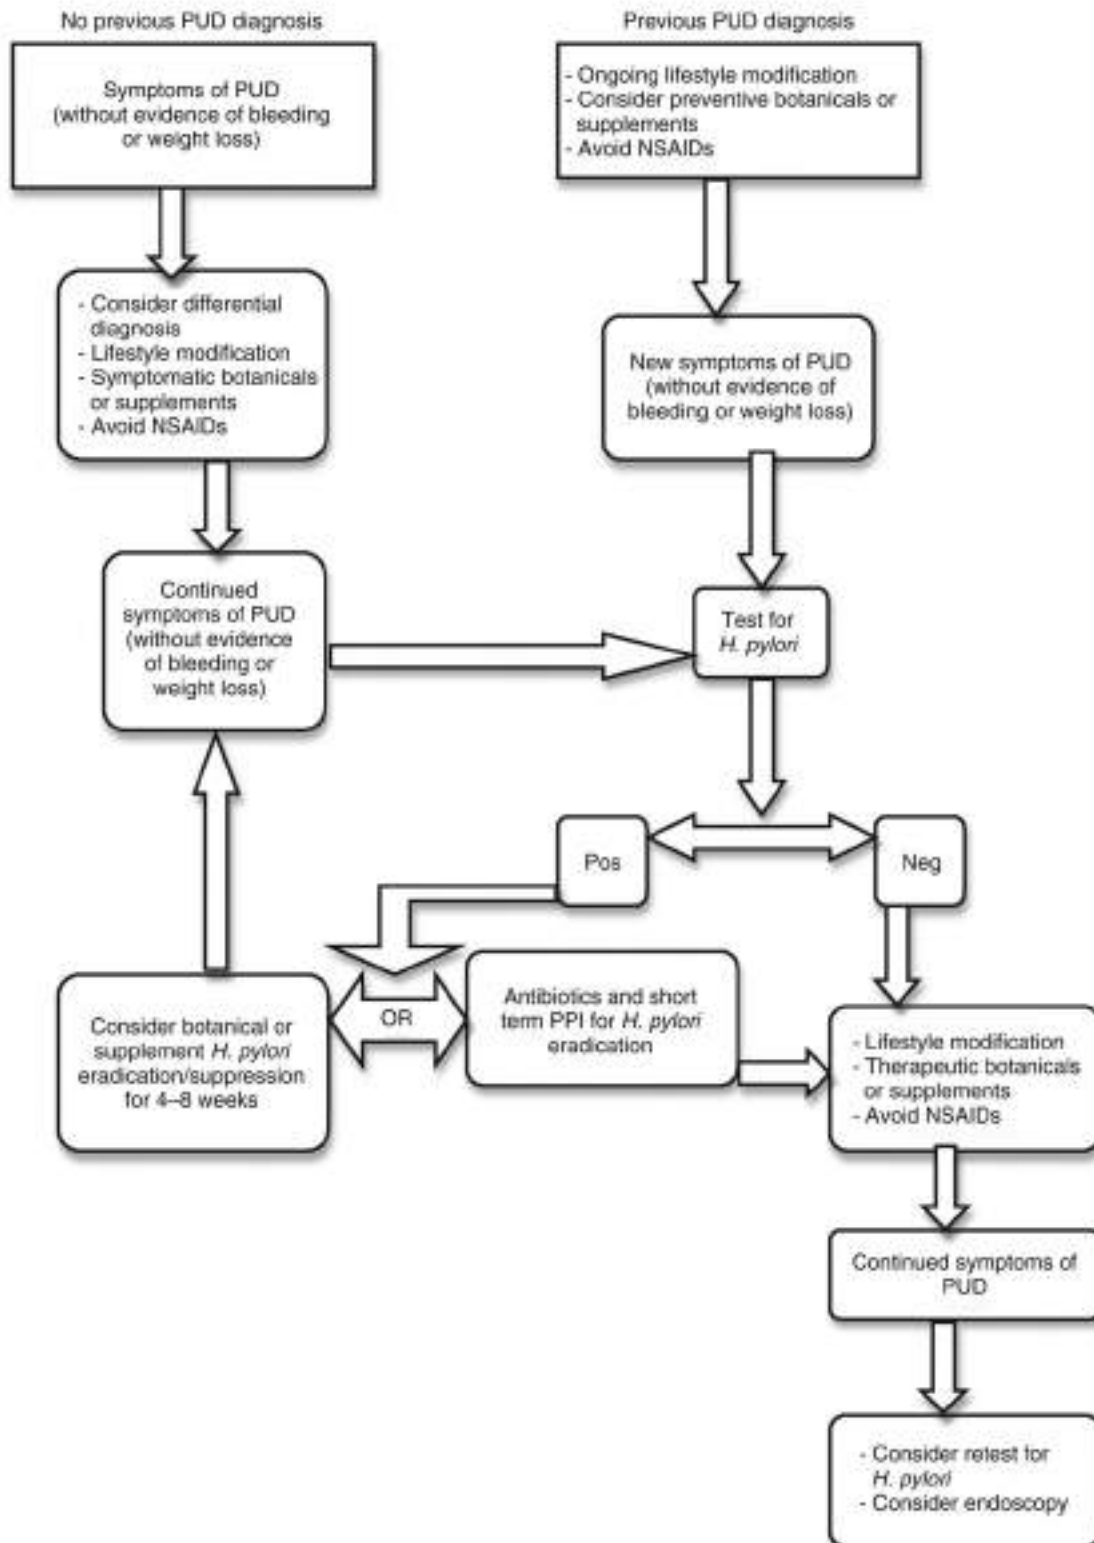

FIG. 43.2 Integrative management flow chart for peptic ulcer disease (PUD). Neg, negative; NSAIDs, nonsteroidal antiinflammatory drugs; Pos, positive; PPI, proton pump inhibitor.

Foods found to be associated with a reduced risk of *Helicobacter pylori* infection include fruits and vegetables rich in carotenoids (yellow, orange), flavonoids (purple and blue vegetables, red wine, and green tea), sulforaphanes (cruciferous vegetables, including cabbage and broccoli), olive oil, garlic, honey, apple, capsaicin (chili), and fermented foods rich in probiotics (yogurt, miso, aged cheese, and sauerkraut).

Milk increases PUD risk, likely due to increased stimulation of acid production.²⁵ Nonetheless, fermented dairy products and other food with probiotics, such as yogurt, aged cheeses, and sauerkraut, have been shown to be protective against *H. pylori*.^{26,27}

Evidence regarding coffee and caffeine, long thought to be risk factors for PUD, is lacking; however, they are known risk factors for reflux disease.

Physical Activity

Multiple studies have demonstrated that regular physical activity, when compared with a more sedentary lifestyle, is protective against PUD.^{28,29} One study specifically demonstrated that the risk for duodenal ulcers was 62% less in men who cumulatively walked or ran more than 10 miles per week.²⁹ Routine exercise should be recommended for almost all patients, particularly those with a previous history of PUD.

Stress Reduction

The relationship between stress and PUD is a classic example of the need for clinicians to keep in mind the social determinants of health ([Fig. 43.3](#)), over which our patients have varying degrees of control. Stress is largely a product of the social and environmental milieu, and convincing evidence indicates that stress plays a role in PUD. This connection is established early in life. Childhood stress, in the form of traumatic events, such as an illness of a family member, financial strain, or family conflict, is associated with a nearly 50% higher rate of PUD in

adulthood.³⁰ Studies have also shown that GI ulceration increases with both chronic stress and in times of acute stress, such as during an earthquake or war (e.g., during the bombing of London in World War II).^{31,32} A multipronged approach to stress reduction, in comparison with any single method, appears to provide more protection against PUD.³³ As a clinician, recommending individually tailored stress reduction programs, including yoga, tai chi, and other coordinated movements in addition to meditation, focused breathing, and any other culturally applicable relaxation methods, will likely be beneficial (see [Chapters 94](#) and [100](#)).

Sleep

Inadequate sleep is a risk factor for PUD,¹¹ likely the result of increased stress levels causing immune dysfunction and impaired lifestyle decisions. Maintaining good sleep hygiene is an important component of ulcer avoidance (see [Chapter 9](#)).

Tobacco Cessation

Smoking increases rates of PUD up to four times when compared with nonsmokers, likely due to decreased wound healing.²⁸ Accordingly, smoking cessation is essential in addressing PUD.

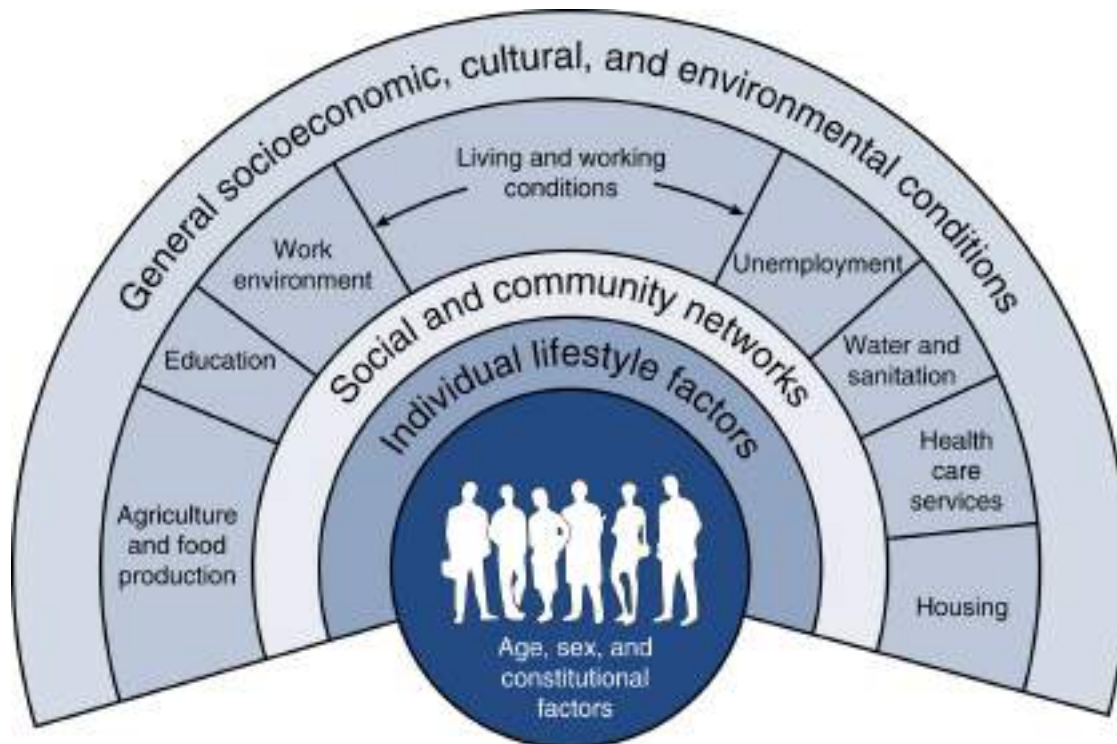

FIG. 43.3 Social determinants of health diagram. (From Dahlgren G, Whitehead M. *Policies and strategies to promote social equity in health*. Stockholm: Institute for Futures Studies; 1991.)

Alcohol Avoidance or Moderation

Alcohol, in large amounts, has been shown to be a risk factor for ulcers, likely as a result of mucosal damage. One epidemiological study reported that individuals who consumed more than 42 drinks per week had a greater than four-fold increase in the incidence of bleeding ulcers compared with individuals who consumed 1 drink per week or less.³⁴ However, red wine is reported to be protective against *H. pylori* infection, possibly attributable to the activity of bioactive compounds such as flavonoids.³⁵ Avoiding large quantities of ethanol, particularly higher-percentage drinks, is prudent in patients with a history or symptoms of PUD, whereas moderate red wine consumption should not necessarily be discouraged.

Nonsteroidal Antiinflammatory Drugs

Evidence indicates that NSAID use increases the baseline risk of PUD by

up to five times and the risk of bleeding ulcers in patients with established PUD by five times.³⁶ NSAIDs inhibit prostaglandin production and thus decrease mucoprotective elements in the GI tract. Although evidence indicates that the administration of medications such as sucralfate or misoprostol with NSAIDs can help ease ulcer symptoms and prevent ulcer recurrence,^{37,38} NSAIDs should be avoided as much as possible in patients with PUD symptoms or an existing history of PUD disease. As more than 80% of patients taking NSAIDs never develop PUD,³⁹ these drugs should not necessarily be avoided in asymptomatic patients without a history of ulcers.

Supplements

Probiotics

Certain helpful microorganisms have proven versatile in the treatment of PUD. Probiotics have been shown to reduce ulcer recurrence,⁴⁰ and individuals with higher intakes of probiotics have correspondingly lower rates of *H. pylori* infection.²⁶ Probiotics are likely effective in combating *H. pylori* as a result of increased GI mucus production, competition for mucosal binding sites, and production of compounds with activity against *H. pylori*. Further, results from animal models have indicated probiotics decrease the inflammatory response to *H. pylori*.⁴¹ The majority of reported studies were conducted with *Lactobacillus* strains commonly found in yogurt, yet evidence indicates that other strains of probiotics are also helpful.⁴² Thus, incorporating yogurt and other probiotic-containing foods, such as aged cheeses and sauerkraut, into a diet on a regular basis can be beneficial for PUD prevention and avoidance of ulcer recurrence. Many clinical studies have confirmed that probiotics, including both *Lactobacillus* and *Saccharomyces boulardii*, have synergy with antibiotics for *H. pylori* eradication and can decrease antibiotic-related side effects, such as diarrhea, bloating, nausea, and abdominal pain^{38,43-45} Although the evidence is weaker, there are numerous studies indicating probiotics alone, without antibiotics, can improve PUD symptoms and suppress (and sometimes eradicate) *H. pylori* infection⁴⁶ (see [Chapter 105](#)).

Dosage

For *H. pylori* antibiotic eradication therapy, available regimens include

Lactobacillus (acidophilus or GG) capsules, containing at least 1 billion organisms, twice daily, or *Saccharomyces boulardii*, 500 mg twice daily.

A regime of *Bifidobacterium bifidum*, 1×10^{10} CFU, daily for 12 weeks can be used for the suppression of *H. pylori* and PUD symptom relief.

Prevention

Probiotic-containing foods or supplements are recommended on a regular basis for patients with a previous history of PUD, a family history of ulcer disease, or other risk factors for PUD.

Precautions

Patients sensitive or intolerant to lactose may have GI discomfort with dairy products containing probiotics.

Vitamin C

Ascorbic acid (vitamin C) has been shown to have potential for *H. pylori* eradication; one study demonstrated a 10% eradication rate with 2 weeks of 1000 mg daily.⁴⁷ Vitamin C also has additive effects on antibiotic regimens for *H. pylori* eradication.⁴⁸ This anti-*H. pylori* capability has been supported by in vitro studies.⁴⁹ A 5-year Japanese study demonstrated lower PUD rates in persons taking vitamin C supplementation.⁵⁰ A steady dietary intake of vitamin C is recommended for anyone with current symptoms, a previous history or a family history of PUD, or other risk factors for ulcer disease.

Dosage

The recommended dose of vitamin C is 500 mg twice daily for *H. pylori* eradication or suppression (in addition to daily dietary intake).

Prevention

Eat foods containing vitamin C on a regular basis, including citrus, kiwi, broccoli, strawberry, and cauliflower.

Precautions

Dose-related potential adverse effects include kidney stones, diarrhea, nausea, and gastritis. Use with caution in patients with kidney disease.

Zinc

A clinical trial has reported zinc accelerates the healing of gastric ulcers up to three times faster than observed with placebo.⁵¹ This finding has been corroborated by more extensive animal studies.⁵² Enhanced healing is likely the result of the fundamental role of zinc in repair of damaged tissue. A compound not available in the United States, zinc acexamate, has been used in East Asia and Europe for PUD and has been found effective in numerous studies.⁵³

Dosage

The recommended dose of zinc is 40 mg daily for 4 weeks for gastric ulcer treatment.

Precautions

Potential side effects include nausea, vomiting, diarrhea, and altered taste. Zinc inhibits the absorption of other minerals, particularly copper.

Polyunsaturated Fatty Acids

Multiple polyunsaturated fatty acids (PUFAs) have been shown to have activity against *H. pylori* in vitro (including alpha-linolenic acid, eicosapentaenoic acid [EPA], gamma-linolenic acid [GLA], and linoleic acid).⁵⁴ A clinical study of the administration of 2 g a day of a 1:1 mixture of fish oil (EPA and docosahexaenoic acid) and black currant seed oil (GLA) for 8 weeks cleared *H. pylori* infection in more than 50% of participants.⁵⁵ Although elimination rates are significantly lower for PUFAs compared with antibiotics, PUFAs are reasonable to recommend for patients desiring *H. pylori* eradication without antibiotics.

Dosage

For *H. pylori* suppression or elimination, 1 g of fish oil and 1 g of GLA-containing oil (evening primrose, black currant seed, borage, or hemp seed oils) daily for 8 weeks.

Precautions

PUFAs may cause GI upset. Higher doses of omega-3 fatty acids (more than 3 g/day) may increase the risk of bleeding from anticoagulant effects.

Glutamine

In clinical trials, glutamine has been shown to prevent and cure PUD. A study of patients with burn injury demonstrated that glutamine can help prevent stress ulcers.⁵⁶ A separate trial reported more rapid healing of peptic ulcers in patients administered 400 mg of glutamine four times a day.⁵⁷ This limited clinical research has also been supported by results from animal studies.^{58,59} Glutamine supplementation is likely successful because it is a necessary amino acid for the repair and new growth of cells lining the GI tract. Dietary sources of glutamine include beef, chicken, fish, eggs, wheat, cabbage, beets, beans, spinach, and parsley.

Dosage

For PUD treatment, the recommended dose is 400 mg of glutamine powder in water four times daily.

Precautions

No significant adverse effects have been reported.

Botanicals

Turmeric (*Curcuma longa*)

Turmeric has been used for centuries in Chinese and Ayurvedic medicine for the treatment of dyspepsia and epigastric pain. A clinical trial, in which 600-mg turmeric root was administered five times daily to patients with PUD, reported ulcer resolution at 4 weeks and 12 weeks in 48% and 76% of patients, respectively.⁶⁰ The same study also demonstrated that turmeric markedly improves symptoms of dyspepsia in 1 to 2 weeks.⁶⁰ Turmeric and curcumin, a commercially available turmeric derivative, are known to have activity against *H. pylori* in vitro.^{61,62} A clinical trial failed to demonstrate turmeric's ability to eradicate *H. pylori* completely but did observe relief of dyspeptic symptoms.⁶³ Turmeric has been found to have H₂-blocking properties, which likely also explains much of its

healing potential.⁶⁴

Dosage

For the treatment of PUD and associated symptoms, the recommended dose of whole turmeric root or powder (capsules) is 600 mg five times daily for 12 weeks.

Precautions

Turmeric may cause nausea, diarrhea, heartburn, or kidney stones. Some evidence exists that it may increase the risk of bleeding secondary to antiplatelet activity.

Deglycyrrhizinated Licorice (Glycyrrhiza glabra)

Licorice has been used for medicinal purposes, including the treatment of epigastric pain and dyspepsia, since ancient Egyptian times and for at least 4000 years in China.⁶⁵ Deglycyrrhizinated licorice (DGL) does not have the adrenocorticoid effect of glycyrrhiza (sodium retention leading to hypertension) and is less hepatotoxic than the native plant. A small clinical trial demonstrated DGL to be as effective as H₂ blockers for duodenal ulcer resolution at 12 weeks, with fewer episodes of relapse.⁶⁶ A robust randomized, double-blinded, placebo-controlled study also reported that 2 months of DGL eliminated *H. pylori* infection in 56% of participants versus 4% for placebo.⁶⁷ These effects may be attributable to the bioactive flavonoids found in licorice.

Dosage

For PUD, the recommended dose of DGL is 380 mg three times per day for 12 weeks. For *H. pylori* eradication, 150 mg (root extract) daily for 60 days.

Precautions

Use with caution in patients with liver disease, renal insufficiency, or hypokalemia. Avoid in pregnancy due to a theoretical risk of preterm labor.

Deglycyrrhizinated licorice (DGL) does not contain the steroid-like component of natural licorice, glycyrrhizic acid, which can induce sodium retention, hypokalemia, and elevated blood pressure.

Mastic (*Pistacia lentiscus*)

Mastic is a member of the pistachio tree family found throughout the Mediterranean, and its resin has been harvested for more than 2000 years as a spice, for chewing gum, and for medicinal purposes. A double-blind, placebo-controlled trial of 350-mg capsules, taken three times a day for 3 weeks, demonstrated clinically significant improvement of dyspepsia.⁶⁸ Mastic has been shown to have activity against *H. pylori* both in vivo and in vitro.⁶⁹ A double-blind trial reported that mastic significantly improved duodenal ulcer healing when compared with placebo.⁷⁰

Dosage

For dyspepsia, the dose is 350-mg capsules three times a day for 3 weeks. For duodenal ulcer healing, the dose is 500-mg capsules twice daily for 2 weeks.

Precautions

Avoid in people with pistachio allergies. Use with caution in patients taking angiotensin-converting enzyme inhibitors because it may cause hypotension.

Cabbage (*Brassica oleracea*)

Clinical studies in the 1950s demonstrated the effectiveness of cabbage juice for gastric and duodenal ulcer healing when participants drank 1 L of fresh cabbage juice over the course of a day for 10 days.^{71,72} Because this research was conducted more than 50 years ago, and in light of subsequently improved diagnostic studies and greater understanding of PUD, further studies of cabbage juice are warranted. However, cabbage should be recommended for the treatment of PUD despite its safety profile and accessibility. Cabbage has been shown to be a rich source of glutamine and sulforaphanes, likely accounting for much of its healing effect.

Dosage

For PUD, the recommended dose of cabbage is 1 L of fresh juice (pasteurized juice was found to be ineffective) divided over the course of a day for 10 days.

Precautions

Due to its vitamin K content, cabbage may decrease the anticoagulant efficacy of warfarin.

Chili (Capsaicin)

Capsaicin is the active component of chili peppers (the fruits of plants of the genus *Capsicum*). Historically, chilies were thought to exacerbate PUD; however, more recent research has proved the opposite. Epidemiological studies have demonstrated that individuals with higher dietary intakes of capsaicin have correspondingly lower rates of PUD.^{17,73} A double-blind trial, in which patients took 2.5 mg of chili pepper in capsules daily for 5 weeks, demonstrated that chili was effective for epigastric pain and other symptoms of functional dyspepsia.⁷⁴ Animal models also demonstrated capsaicin, by decreasing gastric acidity, to be protective against ulcer formation.⁷⁵

Dosage

For epigastric pain and functional dyspepsia, the recommended dose of chili is 2.5 mg daily of chili pepper capsules (can divide doses) for 5 weeks. For PUD prevention, patients should follow a diet rich in capsaicin, as tolerated.

Precautions

Avoid in patients with pepper allergies. Use with caution in patients with diabetes (may cause hypoglycemia) and heart disease (may increase blood pressure). Chilies may cause GI upset. Skin contact may cause irritation.

Cranberry (*Vaccinium oxycoccos*)

A double-blinded clinical trial in *H. pylori*-positive patients demonstrated the ability of cranberry to suppress and eradicate *H. pylori* in patients who drank 500 mL of cranberry juice for 90 days. Although the study demonstrated only a 14% eradication rate, this rate was many times higher than observed with placebo.⁷⁶ In vitro studies of human gastric cells have demonstrated cranberry's ability to impair *H. pylori* adhesion to gastric cell walls, similar to its ability to prevent *Escherichia coli* from binding to the bladder wall in the prevention of urinary tract infections.⁷⁷

Dosage

For *H. pylori* suppression or eradication, the recommended dose is 500 mL of cranberry juice daily for 90 days.

Precautions

Patients with diabetes should consider sugar-free juice. High doses may cause stomach distress. Cranberry may affect warfarin efficacy.

Neem (*Azadirachta indica*)

In Ayurvedic medicine, the neem tree has been used for thousands of years for multiple purposes, including for epistaxis, parasites, asthma, diabetes, fever, and epigastric pain. This versatility has earned neem the nickname "the village pharmacy."⁷⁸ Clinical studies have reported that 30 mg of neem bark extract, taken for 10 days, reduced gastric acid secretion by 77% while promoting significant duodenal ulcer healing when taken for 10 weeks.⁷⁹ Animal studies have demonstrated the antiulcer properties of neem,⁸⁰ and elucidated that neem inhibits the proton pump, similar to pharmacological PPIs.⁸¹

Dosage

For duodenal ulcers, the recommended dose is 30 mg bark extract twice daily for 10 weeks.

Precautions

Use cautiously in patients with liver disease. Avoid in pregnant women

(due to abortifacient properties). Avoid in infants and children due to potential toxicities.

Additional Botanicals

Hundreds of other botanicals have demonstrated activity against *H. pylori* both in vitro and in vivo (animal studies). This list continues to grow, and more clinical trials are needed. Thus, we have limited our scope in this book to agents with convincing results in clinical studies. Over the millennia, most global cultures have developed natural remedies for PUD symptoms, many of which have since been proven to have efficacy in the treatment of *H. pylori* infection, including peppermint (*Mentha piperita*),⁸² silver wormwood (*Artemisia ludoviciana*),⁸² cinnamon (*Cinnamomum cassia*),⁸³ yarrow (*Achillea millefolium*),⁸⁴ chamomile (*Matricaria recutita*),⁸⁴ ginkgo (*Ginkgo biloba*),²¹ nutmeg (*Myristica fragrans*),²¹ hops (*Humulus lupulus*),⁸⁴ goldenseal (*Hydrastis canadensis*),⁸⁵ sage (*Salvia officinalis*),⁸⁵ green tea (*Camellia sinensis*),⁸⁶ red ginseng (*Panax ginseng*),⁸⁶ aloe (*Aloe vera*),¹⁴ fenugreek (*Trigonella foenum-graecum*),⁸⁷ and mugwort (*Artemisia douglasiana*).⁸⁸

For patients wishing to avoid antibiotics for *H. pylori* eradication, it is reasonable to try a regime of deglycyrrhizinated Licorice (DGL) root extract at a dose of 150 mg daily for 60 days. Cranberry, probiotics, PUFAs, vitamin C, olive oil, and broccoli sprouts all have some evidence for *H. pylori* eradication. There is likely synergy between each of these botanicals, although substantial research has only been conducted on individual agents. Treatment courses should be followed up with *H. pylori* breath testing to determine efficacy.

Pharmaceuticals

Antibiotics

Overwhelming evidence indicates that *H. pylori* eradication with antibiotics, in patients with PUD, dramatically improves symptom resolution and reduces ulcer recurrence.⁸⁹ Recommended eradication regimens typically include two to three antibiotics and a PPI, and historically have demonstrated up to 90% eradication rates.⁹⁰ However,

years after antibiotic treatment of *H. pylori* began, the bacterium has now proven tenacious and to have developed more and more resistance to standard regimens. The majority of studies of traditional three-drug therapies have reported eradication rates lower than 80%, with some less than 50%.⁹⁰ Specifically, *H. pylori* has demonstrated marked resistance to metronidazole and clarithromycin, thus necessitating the use of newer and potentially more toxic antibiotics.⁹¹ Because of the significant geographic differences in resistance patterns, prescribers should ideally be aware of local susceptibilities before patients are administered one of the numerous antibiotic regimens for the treatment of *H. pylori* infection.⁹² Widespread destruction of the GI microflora with antibiotics also creates the potential for *Clostridium difficile* infections and other flora imbalances, thus necessitating the administration of antibiotics with probiotics.⁹³ In light of this trend of increasing resistance and potential harms, it is becoming increasingly practical to consider other methods of *H. pylori* eradication or suppression, such as the integrative therapies discussed in this chapter.

Dosage

A typical *H. pylori* eradication regimen is as follows: amoxicillin, 1 g; clarithromycin, 500 mg; and omeprazole, 20 mg; this combination is taken twice per day for 14 days. (Probiotics are also recommended as adjuvant therapy.) If possible, check regional susceptibilities when choosing antibiotics.

Precautions

Common side effects of antibiotics used include diarrhea, altered taste, headache, and allergic reactions.

Acid-Suppressing Drugs

Since their introduction in the late 1970s, gastric acid suppression medications (H₂ blockers and later PPIs) have dramatically assisted in the relief of PUD symptoms and ulcer healing. PPIs have been shown to be more effective than H₂ blockers and are more frequently used today.⁹⁴ However, accumulating evidence indicates chronic acid suppression (longer than 2 to 3 months) has potential adverse effects, including increased rates of pneumonia, *Clostridium difficile* infection, and bone

fracture. These drugs also decrease absorption of certain minerals and nutrients, specifically calcium, vitamin B₁₂, iron, and magnesium.⁹⁵⁻⁹⁷ Animal models have also demonstrated an increased risk of gastric cancer with extended periods of acid suppression.⁹⁶

There is also concern that long-term use of acid-suppressing therapies is associated with increased rates of myocardial infarction and cardiac mortality.^{98,99}

Dosage

For PUD and PUD symptoms: PPI (e.g., omeprazole, 20 mg) or H₂ blocker (e.g., ranitidine, 150 mg) once or twice daily, per individual drug, for up to 8 weeks.

Precautions

Potential adverse effects of H₂-blockers include nausea, headache, dry mouth, rash, and confusion. PPIs can cause headache and nausea. Extended use may cause the adverse effects discussed earlier.

Long-term pharmaceutical acid suppression (particularly with proton pump inhibitors) is increasingly associated with adverse effects, such as infections, cardiac mortality, and decreased nutrient absorption, and should be limited to 8 weeks or less.

Antacids

Millions of years ago, our ancestors likely figured out that eating chalk or other natural acid buffers relieved epigastric pain and symptoms of PUD. Antacids are still potentially useful today in helping with symptom relief and are found in various nonprescription forms including calcium carbonate, aluminum hydroxide, magnesium hydroxide, and sodium bicarbonate. Theoretically, antacids cause increased gastric acid production due to rebound and, although some studies support this hypothesis, previous studies have demonstrated antacids to be safe at recommended doses.¹⁰⁰

Dosage

For PUD symptoms, patients may take over-the-counter antacids according to individual product instructions.

Precautions

High doses of calcium-containing antacids may cause kidney stones, constipation, renal failure, alkalosis, or hypercalcemia. Carbonate-containing antacids may cause alkalosis. Aluminum antacids, in high doses, may cause hypophosphatemia, osteomalacia, constipation, or renal insufficiency. Magnesium antacids should be used in caution in patients with renal disease and may cause hypermagnesemia.

Sucralfate

An older synthetic compound, sucralfate, has been shown to be effective in promoting ulcer healing and has been used since the late 1960s as a PUD treatment. Sucralfate has an impressively complex chemical formula of $C_{12}H_{54}Al_{16}O_{75}S_8$, yet the majority of its beneficial effects are attributed to two properties: its ability to act as an acid buffer and its ability to bind to ulcer sites, thus protecting against further insult. In clinical trials, sucralfate has been shown to be as effective as H_2 blockers for treatment of duodenal ulcers.¹⁰¹

Dosage

For duodenal ulcers, the recommended dose of sucralfate is 1 g four times daily, 1 hour before meals and bedtime, for up to 8 weeks.

Precautions

Sucralfate may cause bezoar formation and constipation.

Acupuncture

Controlled trials have shown that acupuncture is an effective treatment for epigastric pain.¹⁰² Case studies and animal models have also shown acupuncture to have efficacy in the treatment of PUD and for the prevention of ulcer recurrence.¹⁰³

Therapies to Consider

Traditional Chinese Medicine

Massage

In a limited study, 74.5% of patients with PUD who received 20 sessions (every other day) of traditional Chinese medical massage demonstrated complete ulcer resolution.¹⁰⁴ This trial was not randomized, however, and more rigorous investigations are warranted.

Herbs

Yangweishu is a traditional Chinese herbal medicine that is a combination of dang shen (codonopsis root), chen pi (tangerine peel), huang jing (Siberian solomon seal rhizome), shan yao (Chinese yam), xuan shen (ningpo figwort root), and wu mei (mume fruit). Yangweishu was shown in a randomized clinical trial with more than 400 participants to significantly improve ulcer healing and symptom relief when taken with antibiotics compared to antibiotics alone.¹⁰⁵ As formulations vary between manufacturers, clinicians should refer to package labels or TCM consultants for instructions regarding their use. These formulations should not be used by lactating women, during pregnancy, or by children.

Osteopathy

Although adequate clinical trials are lacking, osteopathy may provide symptom relief and prevent PUD. Manual medicine, in theory, can help the GI system to maintain sympathetic and parasympathetic balance, thus reducing excess acid production and restoring homeostasis. Osteopathy may also lead to relief of symptoms by manipulating somatovisceral pathways and is worth considering in patients with access to clinicians experienced in these techniques.

Prevention Prescription

- Eat a diet rich in fruits and vegetables (particularly those containing vitamins A and C).
- Eat foods containing capsaicin (chili), as well as those with flavonoids and sulforaphanes.

- Eat probiotics: yogurt, sauerkraut, active yeasts, and aged cheeses.
- Avoid nonprobiotic dairy products such as milk.
- Eat breakfast every day, and avoid eating large meals shortly before sleeping.
- Minimize use of nonsteroidal antiinflammatory drugs.
- Avoid smoking cigarettes.
- Avoid excessive alcohol consumption.
- Maintain a moderate exercise routine.
- Obtain adequate sleep.
- Develop and incorporate stress reduction activities.

Therapeutic Review

The following integrative therapeutic options are useful for different niches on the peptic ulcer disease (PUD) spectrum, from prevention, symptom relief, and *H. pylori* elimination to active ulcer healing. Being mindful of the individual end goals of therapy will guide clinical choices. Evidence of a bleeding ulcer or significant weight loss is a reason to refer patients for endoscopy and may constitute a medical emergency.

Lifestyle

- Tobacco cessation 
- Adequate sleep 
- Routine exercise 
- Stress reduction interventions 
- Abstention from heavy ethanol intake 

Nutrition

- Eat breakfast daily.
- Avoid eating shortly before sleeping. 
- Avoid milk.
- Eat probiotic-containing fermented foods, such as yogurt, aged cheeses, miso, and sauerkraut.

- Eat foods containing chili (capsaicin).
- Eat fruits and vegetables, particularly those containing vitamins A and C.

Supplements

- Probiotics during *H. pylori* antibiotic therapy: either *Lactobacillus (acidophilus* or GG) capsules, containing at least 1 billion organisms, twice daily; or *Saccharomyces boulardii*, 500 mg, twice daily 
- Probiotics for PUD symptom relief and *H. pylori* suppression: *Bifidobacterium bifidum*, 1×10^{10} CFU, daily for 12 weeks 
- Vitamin C for *H. pylori* suppression: 500 mg twice daily 
- Zinc for gastric ulcers: 40 mg daily for 4 weeks 
- Polyunsaturated fatty acids for *H. pylori* eradication: 1 g of fish oil and 1 g of gamma-linolenic acid-containing oil (evening primrose, black currant seed, borage, or hemp seed oils) taken daily for 8 weeks 
- Glutamine for peptic ulcers: 400 mg four times daily 

Botanicals

- Turmeric for peptic ulcers and PUD symptoms: whole root or root powder (capsules), 600 mg five times daily for 12 weeks 
- Deglycyrrhizinated licorice for duodenal ulcers: 380 mg three times per day for 12 weeks 
- Deglycyrrhizinated licorice for *H. pylori* eradication: 150 mg (root extract) daily for 60 days 
- Mastic for dyspepsia: 350 mg capsules three times a day for 3 weeks 
- Mastic for duodenal ulcers: 500 mg capsules twice daily for 2 weeks 
- Cabbage for duodenal or gastric ulcers: 1 L of fresh juice divided over the course of a day for 10 days 
- Chili (*Capsicum* fruit) for epigastric pain and dyspepsia: 2.5 mg daily of chili pepper capsules for 5 weeks 

- Cranberry for *H. pylori* eradication: 500 mL of cranberry juice daily for 90 days 
- Neem for duodenal ulcers: 30 mg bark extract twice daily for 10 weeks 

Pharmaceuticals

- Eliminate nonsteroidal antiinflammatory drugs for patients with PUD 
- Antibiotics and proton pump inhibitors (PPIs) for *H. pylori* eradication: amoxicillin, 1 g; clarithromycin, 500 mg; and omeprazole, 20 mg in combination to be taken twice daily for 14 days (check regional bacterial susceptibilities) 
- Acid suppression therapy for PUD and PUD symptoms: a PPI (e.g., omeprazole) or histamine-2 (H₂) receptor blocker (e.g., ranitidine) once or twice daily per individual drug for up to 8 weeks 
- Antacids for PUD symptoms: over-the-counter antacids according to individual product instructions 
- Sucralfate for duodenal ulcers: 1 g four times daily for up to 8 weeks 

Acupuncture

- Acupuncture for PUD and/or epigastric pain 

Therapies to Consider

- Traditional Chinese medical massage for peptic ulcers 
- Traditional Chinese herbs, yangweishu, as an adjuvant for *H. pylori* eradication with antibiotics 
- Osteopathy for PUD

CHAPTER 44

Cholelithiasis

Ann C. Figurski, DO

Gallstone disease is a common digestive disorder that affects 10%–15% of individuals in developed societies.¹ In the United States, the combination of a diet rich in processed foods and sedentary lifestyle create an environment prone to gallstone formation. Due to the influence of both environment and genetics on gallstone diseases, the occurrence of gallstones varies greatly, ranging from 2%–70% among different populations, with the highest incidence among Pima Indian women older than 30 years of age.²

Epidemiological studies have revealed many risk factors for gallstones. Some of these conditions are not modifiable, such as genetics, sex, age, ethnicity, and family history, whereas many conditions can be changed, such as diet, obesity, physical inactivity, medications, and stress.^{2,3} [Table 44.1](#) provides a list of conditions that increase the risk of gallstone disease.

Pathophysiology

Bile aids in the digestion and absorption of lipids from the intestines. Made by the liver, bile is composed of bile acids, cholesterol, and phospholipids. Bile is stored in the gallbladder until the stimulation of its release by cholecystokinin (a hormone released during eating). Conditions that lead to gallstone formation include supersaturation of bile with cholesterol, decreased bile acids that dissolve cholesterol, excess mucus production, and gallbladder dysmotility and stasis ([Fig. 44.1](#)). Gallstones are classified as either cholesterol or pigment. In industrialized countries, cholesterol stones account for up to 85%. Most people with gallstones remain asymptomatic. Approximately 20% will develop true biliary symptoms, such as severe pain in the right upper

quadrant that can radiate to the back or shoulder.

Integrative Therapy

Lifestyle

Gallstones are part a long list of diseases heavily influenced by lifestyle. A profound rise in the prevalence of chronic conditions, such as diabetes, hypertension, and heart disease, has caused Western medicine to reevaluate its treatments and enhance prevention methods. The causes of these conditions are multifactorial; however, a lifestyle of inadequate physical activity and the standard U.S. diet (highly processed foods) are major contributors. These chronic conditions are not isolated and are all thought to arise from a chronic proinflammatory state caused by these lifestyle factors. Gallstones can be grouped with these other chronic conditions because evidence indicates lifestyle factors, such as diet (macronutrient and micronutrient intake) and exercise, are linked to gallbladder disease.

Maintenance of a Healthy Weight

Obesity, particularly abdominal, is a well-known risk factor for gallstones and associated with increased cholesterol secretion into bile.^{2a} The recent trend of rising obesity in children correlates with increasing rates of hospitalizations for pediatric cholelithiasis.⁴ Gradual weight loss is important for obese individuals because rapid weight loss may also promote gallstone formation secondary to increased biliary cholesterol and bile stasis. Accordingly, weight loss should not exceed 1.5 kg (3.3 lb) per week in order to avoid this risk.⁵

Exercise

Physical activity is a necessary component of a healthy lifestyle and has a significant impact on many diseases. Studies have also shown that exercise can increase gallbladder motility.⁶ In postmenopausal women, physical activity is inversely related to the development of gallstone disease.⁷ In one report, women who sat for more than 60 hours a week were 2.32 times more likely to subsequently undergo cholecystectomy.⁸ Fortunately, even modest amounts of physical activity have a positive effect, with an observational study of more than 2000 people reporting just 2 hours of activity a week reduced the risk of gallstone disease by

40%.⁹

Stress Reduction

Despite a lack of randomized, placebo-controlled trials, stress is likely to contribute to the development of many diseases. Evidence from animal studies indicates that stress causes gallbladder dysfunction and bile stasis.³ The general benefits of stress reduction on both mind and body may also extend to the gallbladder. Consider recommending counseling, meditation, or other stress reduction techniques, as appropriate.

Nutrition

Several areas of nutrition overlap in gallbladder disease. For example, vegetarians have a lower rate of cholelithiasis.¹⁰ These findings may be attributable to higher consumption of fruits and vegetables, which are good sources of vitamins, minerals, fiber, and antioxidants, all of which have been linked to the inhibition of gallstone formation. In a study of diet differences, patients with gallstones consumed less fish, fruit, fiber, folate, magnesium, calcium, and vitamin C and also ate more cereal, sugar, calories, and saturated fat.¹¹ Specific dietary components are assessed individually in studies; however, the sum of their effects is likely greater than the individual contributions. Encouraging healthy, well-balanced nutrition (e.g., the Mediterranean diet) full of colorful vegetables and including healthy fats is a good place to start.

TABLE 44.1

Conditions That May Increase the Risk of Gallbladder Disease

Increased cholesterol saturation	Estrogen* (endogenous: pregnancy; or supplemented: hormone replacement therapy, oral contraceptives) Obesity High-cholesterol diet
Decreased bile salts (or increased ratio of secondary bile acids)	Low-fiber diet Ileal inflammation (Crohn disease) Cirrhosis Cystic fibrosis Fibrates Age
Stasis of bile flow	Parenteral nutrition Low-fat, weight loss diets Hypertriglyceridemia (impaired motility) Physical inactivity Ceftriaxone (biliary sludge) ² Octreotide ² Stress ³

: Estrogen Supplementation

A systematic review of multiple studies found that estrogen supplementation in postmenopausal women increased the likelihood of gallstones.⁵³ In addition, two randomized, placebo-controlled studies reported an increased risk of biliary disease with supplementation.⁵⁴ Both oral and transdermal estrogen supplements can increase biliary cholesterol saturation and decrease cholesterol nucleation time, which may increase risk of gallstones.⁵⁵ The Heart and Estrogen/Progestin Replacement Study revealed that supplementation in postmenopausal women with known coronary artery disease resulted in a significant increased risk for biliary surgery.⁵⁶ This additional risk should be considered when women elect hormone replacement therapy.

Fats

The type of fat consumed is very important in gallbladder disease. The diet should be low in saturated fats but contain sufficient sources of polyunsaturated fats and omega-3 fatty acids. A diet low in total fat may increase the risk of gallstones due to decreased stimulation of bile flow and stasis. Results from animal studies demonstrate that monounsaturated and polyunsaturated fats act as inhibitors of cholesterol cholelithiasis.¹² Fish oil may decrease biliary cholesterol saturation and enhance bile flow.¹³ A study comparing fish oil with fibrate therapy in men with hypertriglyceridemia reported that both approaches lowered triglyceride levels, whereas only fish oil increased bile acid synthesis. The same study also demonstrated that fish oil increased the ratio of cholic acid to chenodeoxycholic acid, which improves cholesterol solubility.¹⁴ Proinflammatory, arachidonic acid-rich saturated fats increase cholesterol saturation and disrupt the gallbladder epithelium.¹⁵ A separate study revealed that men with the highest consumption of long-chain saturated fatty acids (which includes arachidonic acid) had a 40% increased risk of cholecystectomy.¹⁶ The goal of treatment is to replace saturated fats with the antiinflammatory effects of healthy fats, such as omega-3 fatty acids (see [Chapter 88](#)).

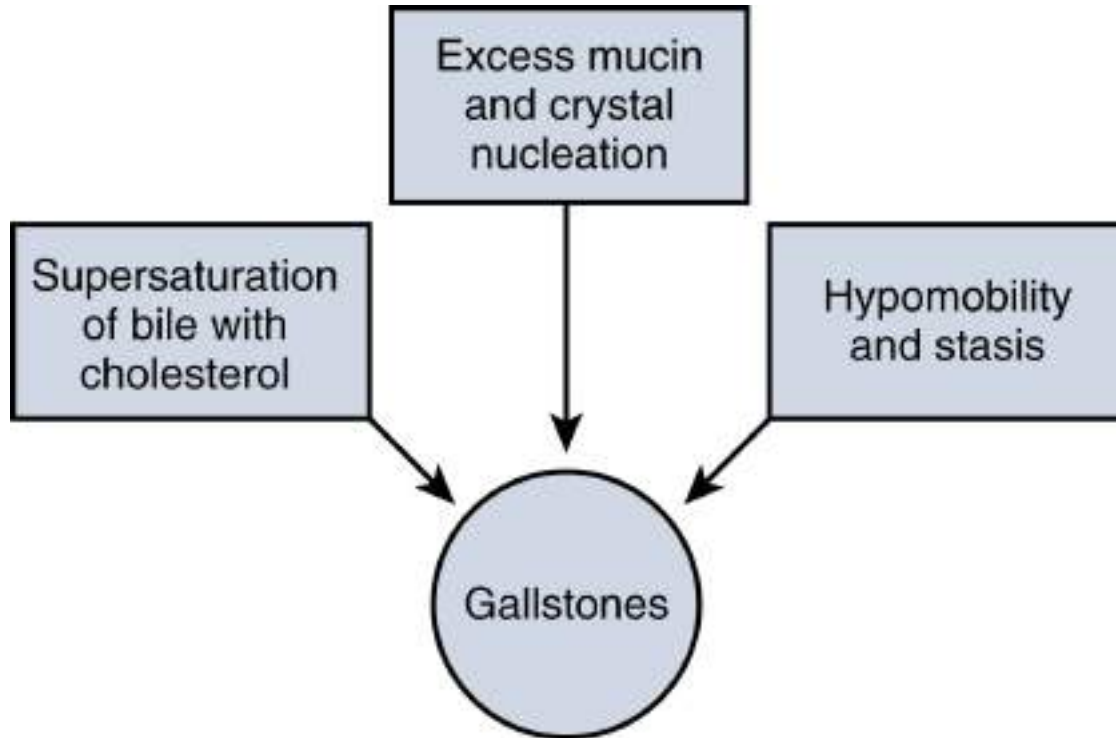

FIG. 44.1 Pathophysiology of gallstones.

Fiber

A higher intake of fiber is associated with a lower prevalence of gallstones. Fiber reduces the absorption of deoxycholic acid by decreasing its formation by intestinal bacteria. Deoxycholic acid is a secondary bile acid that increases the lithogenicity of bile.¹⁷ Water-soluble fiber found in fruits, vegetables, pectin, oat bran, and guar gum can bind this acid and may be helpful in preventing and treating gallstones.¹⁵ A prospective study of 77,000 women demonstrated that individuals consuming the most fruits and vegetables had a 21% reduced risk of gallstones.¹⁸

A good source of fiber is to mix one teaspoon of ground flaxseed (lignan) into 8 oz of apple juice or applesauce (pectin) and consume daily. This recipe has the added benefit of being a good source of omega-3 fatty acids.¹⁵

Nuts

In the Nurses' Health Study, a large prospective study, women who consumed nuts frequently had a more than 20% reduced risk of

cholecystectomy. This relationship persisted after controlling for multiple confounding variables, including fat intake.²⁰ Other research showed similar results in men. Men who frequently ate nuts had a reduced risk of gallstone disease. This inverse relationship existed independently of consumption of peanuts, other nuts, or a combination of both.²¹

Simple Sugars

Refined sugars increase the cholesterol saturation of bile and reduce the ratio of beneficial cholic acid to deoxycholic acid.²² Although consumption of refined sugars is associated with obesity, evidence indicates that simple sugars (monosaccharides and disaccharides) promote gallstone formation independently of obesity.¹⁶ A relationship also appears to exist between glucose intolerance and gallstones. Hyperinsulinemia may cause supersaturation of cholesterol in bile and gallbladder dysmotility. The prevalence of cholesterol gallstones is higher in diabetic patients, with fasting serum insulin levels reported to positively associated with gallstones among women without diabetes.²³ Sugar intake is reported to be positively correlated with serum triglyceride levels and inversely correlated with high-density lipoproteins, and this effect on lipoprotein metabolism may contribute to gallstone formation.²⁴ Additionally, diets with high glycemic load have been linked to increased rates of cholecystectomy in women²⁵ (see [Chapters 32](#) and [87](#)).

Foods associated with a reduced risk of gallstones include fiber-rich fruits and vegetables, whole grains, nuts, coffee, and alcohol in moderation.

Coffee

Individuals with gastrointestinal symptoms are often advised to avoid coffee. Interesting research has demonstrated that coffee can play a role in preventing gallstones, with numerous epidemiological studies corroborating this finding.² Coffee and its components have been shown to stimulate cholecystokinin release, enhance gallbladder contractility, and decrease cholesterol crystallization in bile.²⁶ A large prospective study demonstrated a 40% lower risk of cholecystectomy in men who drank two to three cups of coffee a day over a 10-year period.²⁷ Other

prospective studies have reported intake of caffeinated coffee to be associated with significantly reduced risk of cholecystectomy in women. This is not the case for other caffeinated beverages, with a positive association noted with caffeinated soft drinks.²³ Although some studies have failed to observe this link,^{28,29} it is reasonable to continue coffee consumption according to patient preference.

Food Allergy

Interest is growing in food allergies and their effects on health and wellness. A small amount of research, from as early as the 1940s, has described food allergy as a cause of gallbladder disease.¹⁷ In an uncontrolled study of 69 patients with gallstones or postcholecystectomy syndrome, 100% of patients reported symptom resolution after 1 week of initiating an elimination diet. The foods that most commonly evoked symptoms were eggs, pork, onions, fowl, milk, coffee, citrus, corn, beans, and nuts.³⁰ Thus, clinicians should keep in mind when giving dietary advice to patients with gallstones that simply advising patients to “avoid fatty foods” may be insufficient. An elimination diet may be a good option for those patients with biliary colic who wish to avoid surgery (see [Chapter 86](#)).

Water

Drinking six to eight cups of clean water a day will help maintain the water content of bile and prevent crystal agglomeration.¹⁵

Alcohol

Epidemiological evidence indicates gallstones are among a handful of diseases that are less common among individuals who consume a moderate amount of alcohol (no more than one drink/day for women and two drinks/day for men).^{31,32} A large prospective study found that moderate alcohol intake was associated with a decreased risk of cholecystectomy in women.³³ Health benefits are associated with regular consumption of small amounts of alcohol, rather than heavy sporadic drinking. The many hazards and potential health consequences of alcohol consumption must also be considered. Any recommendation for moderate alcohol intake must be evaluated carefully for each person.

Supplements

Vitamin C

Vitamin C (ascorbic acid) is involved in the conversion of cholesterol to bile acids, and vitamin C deficiency has been associated with gallstones in numerous studies.^{34,35} Vitamin C supplementation, at a dose of 500 mg four times a day for 2 weeks, has been shown to significantly prolong the time required for cholesterol crystal formation.³⁶ In an observational study of more than 2000 individuals, the prevalence of gallstones was half that of study participants who did not receive vitamin C supplements.⁹ Good sources of vitamin C include red pepper, kiwi, broccoli, strawberries, and citrus.

Dosage

The recommended dose of vitamin C is 200 mg twice daily.

Precautions

Gastrointestinal disturbance may occur, including diarrhea, nausea, vomiting, heartburn, and abdominal cramps. Other side effects include fatigue, flushing, headache, hyperoxaluria, and predisposition to urinary tract stones.¹⁴

Magnesium

Individuals who consume sufficient magnesium have lower rates of gallstone disease.¹¹ Additionally, magnesium deficiency is a common mineral deficiency among individuals consuming the standard American diet, also a risk factor for gallstones. A diet rich in magnesium may be a factor in preventing gallstones. Magnesium is found in green leafy vegetables, nuts, coffee, and whole grains. A study reported that men consuming high amounts of magnesium through diet and supplements (average, 454 mg/day) were 28% less likely to have gallstone disease compared with men consuming low amounts (average, 262 mg/day).³⁷

Dosage

The recommended dose of magnesium is 300 mg daily.

Precautions

Gastrointestinal symptoms, such as diarrhea, nausea, and abdominal cramping, may occur with the use of magnesium supplements. Magnesium should be used with caution in patients with renal failure. Toxic levels cause muscle relaxation and loss of deep tendon reflexes.

Vitamin E

Results from animal studies indicate a cholesterol-free diet deficient in vitamin E can lead to cholesterol gallstones.³⁸ Moreover, when animals were provided a high-fat diet in addition to vitamin E, they did not develop gallstones.³⁹ Therefore, supplementation with vitamin E may help to prevent gallstones.

Dosage

The recommended dose of vitamin E (mixed tocopherols) is 400 units/day.

Precautions

Side effects are rare but include nausea, diarrhea, intestinal cramps, fatigue, weakness, headache, blurred vision, rash, and creatinuria. Long-term use may increase cardiovascular risk in persons younger than 65 years old.

Calcium

Calcium preferentially binds secondary bile acids, such as deoxycholic and chenodeoxycholic acid, in the small intestine. These bile acids reduce the solubility of cholesterol, thereby reducing the risk of gallstones once cholesterol is bound and excreted. In a study that monitored the dietary intake of 860 men, calcium intake was inversely associated with gallstone disease.²⁴

Dosage

Calcium gluconate or citrate: 1000 to 1500 mg/day with meals. Calcium citrate is better absorbed in older adults but costs more.

Precautions

Calcium may cause constipation and gastrointestinal irritation. Calcium should not be taken with iron supplements because it decreases iron absorption.

Olive Oil or Gallbladder “Flush”

The gallbladder flush (or liver flush) is a common remedy that is said to cause gallstone passage. Several versions of the treatment exist, including combinations of olive oil, lemon juice, and apple juice. Proponents of this treatment claim that it causes the passage of gallstones. However, chemical analysis of subsequently passed “gallstones” has demonstrated them to be saponified complexes of olive oil, minerals, and lemon juice.⁴⁰ Monounsaturated fat in olive oil may stimulate the gallbladder to expel stones; however, these stones may then become lodged in the common bile duct. Ideally, this approach should be avoided until ultrasound evaluation has determined the size and number of stones.

Botanicals: Choleric Herbs

Herbal medicine has been used to treat gallbladder disease and is a good option for patients with small stones and mild symptoms. Choleric herbs can stimulate bile production, flow, and solubility.^{15,40} These effects can be enhanced by combination with peppermint oil to aid gallstone dissolution. The following list of choleric herbs may be used individually or mixed in combination as a tea by an herbologist.

Globe Artichoke (*Cynara scolymus*)

Dosage

The recommended dose of globe artichoke is 1 to 4 g of the leaf, stem, or root three times / day. This plant should not be confused with Jerusalem artichoke.

Precautions

If used topically, globe artichoke may cause contact dermatitis. Again, caution in those allergic to the *Asteraceae* / *Compositae* family (ragweed,

daisies, marigold).

Milk Thistle (*Silybum marianum*)

Dosage

Standardized 70% silymarin extract, starting at 150 mg twice daily and increasing to three times daily if needed

Precautions

Milk thistle may have a laxative effect and should be used with caution in patients allergic to plants in the *Asteraceae* / *Compositae* family (ragweed, daisies, marigolds).

Dandelion (*Taraxacum officinalis*)

Dosage

Give 4 to 10 g of dried leaf or 2 to 8 g of dried root three times / day. Dandelion tea is made by steeping the same amount in 150 mL of boiling water for 10 to 15 minutes and then straining. One cup of tea should be consumed three times / day. The most convenient dosing is a 1:5 tincture, 5 to 10 mL three times / day.

Precautions

Dandelion may cause gastric hyperacidity. If used topically, it may cause contact dermatitis and should be used with caution in patients allergic to plants in the *Asteraceae* / *Compositae* family (ragweed, daisies, marigolds). Dandelion may also have hypoglycemic effects.

Turmeric (*Curcuma longa*)

An animal study demonstrated that mice fed a lithogenic diet had a decreased incidence of gallstones of 73% when supplemented with curcumin. Curcumin also reduces biliary cholesterol concentration.⁴¹

Dosage

The recommended dose of turmeric is 450 mg of a curcumin capsule standardized extract or 1.5–3 g turmeric root daily in divided doses.

Precautions

Turmeric has blood thinning effects, so patients should be careful if taking other blood-thinning medications. Turmeric should be used with caution in patients allergic to yellow food colorings or plants belonging to the Zingiberaceae (ginger) family.

Botanicals: Gallstone-Dissolving Herbs

Monoterpenes are a class of hydrocarbon molecules found in the essential oils of many plants. These compounds have choleric properties and inhibit formation of cholesterol crystals.¹⁷ A combination of monoterpenes, predominantly consisting of menthol and pinene, has been shown to be effective for stone dissolution.⁴² A double-blind study concluded that the addition of menthol to ursodeoxycholic acid (UDCA) improved outcomes compared with UDCA alone and that menthol was equally effective as the monoterpene combination.⁴³ The addition of peppermint oil to choleric herbs should be considered in the treatment of minimal disease with small stones.

Peppermint Oil (*Mentha piperita*)

Dosage

One or two enteric-coated capsules (0.2 mL / capsule) three times / day between meals

Precautions

Peppermint oil relaxes the lower esophageal sphincter, and this may lead to reflux or heartburn (enteric-coated capsules may be used to avoid this effect.) Peppermint oil may also cause allergic reactions, flushing, and headache.

Pharmaceuticals

Treatment with bile acids can be used for gallstone dissolution. Bile acids work by inhibiting biliary secretion of cholesterol and increasing bile secretion from the liver. Bile acids may also improve gallbladder motility and are most effective when used in patients with small stones, mild symptoms, and good gallbladder function. Patients with calcified or pigment stones are usually poor candidates for bile acid therapy. Incomplete dissolution and stone recurrence are both significant limitations of bile acid therapy.

Ursodeoxycholic Acid (Ursodiol)

UDCA is a bile acid that lowers bile cholesterol saturation. Numerous studies have demonstrated the utility of UDCA in preventing the formation of gallstones in obese patients undergoing rapid weight loss, either through calorie-restricted diets or bariatric surgery.⁴⁴ Maintenance therapy may also be effective in reducing gallstone recurrence.⁴⁵

Dosage

The recommended dose of UDCA is 300 mg twice daily.

Precautions

Possible adverse effects include hepatic impairment, elevation of liver enzymes, and gastrointestinal upset.

Lifestyle is the key to treatment. Other than surgery, all treatments are associated with a high 5-year risk of recurrence if lifestyle modifications are not employed.

Surgery

Laparoscopic Cholecystectomy

Laparoscopic cholecystectomy is the recommended treatment for patients with symptomatic stones and gallbladder wall inflammation. However, laparoscopic cholecystectomy is not recommended for the majority of patients with asymptomatic gallstones unless they are at risk of gallbladder carcinoma. A major advantage of surgical treatment is the avoidance of recurrence; however, the potential benefits of surgery

should be weighed against the potential harms of surgery and anesthesia.

Therapies to Consider

Cholesterol-Lowering Medications

As supersaturation of bile with cholesterol is a key factor in gallstone formation, it has been hypothesized that gallbladder disease can be treated by lowering total cholesterol. Recent studies have indicated cholesterol-lowering medications may help reduce the incidence of cholesterol gallstones. Animal studies have shown that both statins and ezetimibe can prevent cholesterol gallstone formation in mice or prairie dogs^{46,47}; however, the limited number of clinical studies have reported conflicting results.⁴⁸ At this time, further research is warranted to determine appropriate role of these medications in the treatment of gallstone disease.

Fenugreek

Fenugreek has been shown to lower cholesterol, with animal studies demonstrating a marked reduction in gallstone formation with fenugreek supplementation.⁴⁹ Mice fed a lithogenic diet to induce cholesterol gallstones, and those that received fenugreek supplementation along with the lithogenic diet, had a 75% reduction in gallstones.⁵⁰ Unfortunately, specific recommendations for the use of fenugreek have yet to be determined due to a lack of clinical studies to support this data.

Piperine

Black pepper (*Piper nigrum* L.) is a very widely used spice, known for its pungent constituent, piperine. Based on the results of recent cellular, animal, and clinical studies, piperine has been found to have immunomodulatory, antioxidant, and antiinflammatory effects, among many others. Results from studies of mice fed a lithogenic diet indicate that piperine can reduce the incidence of cholesterol gallstone formation and reduce biliary cholesterol secretion, as well as have a positive influence on liver function.⁵¹

Homeopathy

Homeopathy has been used as a safe treatment for more than two

centuries despite a lack of scientific evidence. Homeopathy may provide benefit when other treatment options have failed. After consultation, a professional homeopath may recommend various remedies, including Chelidonium, Colocynthis, or Lycopodium.

Acupuncture

Acupuncture, as part of traditional Chinese medicine, can address energy flow through the liver and gallbladder. This technique may be helpful for gallbladder function, as well as for alleviating discomfort caused by gallbladder disease.

Osteopathy

Although manual therapy is effective for treating musculoskeletal complaints, it is also used to treat other body systems. Osteopathy can help to regulate physiology and aid the body in establishing homeostasis. Viscerosomatic reflexes are changes in the musculoskeletal system that reflect visceral disorders. These reflexes are mediated by afferent neurons of the sympathetic nervous system. The use of these reflexes can aid in diagnosis and provide treatment benefit by balancing the nervous system and influencing the viscera. Manual therapy will not cure or prevent gallstones but represent a useful adjunct to other therapies.

Prevention Prescription

Preventing gallstones is much easier than treating them. The same principles of prevention apply to many common chronic diseases (diabetes, heart disease).

- Maintain a healthy weight, with slow gradual weight loss if body mass index is elevated.
- Exercise. Get moving in a way that is enjoyable and sustainable for you, at least 30 minutes five times weekly.
- Find a stress-reducing practice.
- Encourage a diet high in fiber, vegetables, fruit, nuts, and omega-3 fatty acids.
- Maintain a low intake of saturated fats, refined sugars, and high-glycemic load foods.
- Remember hydration. Drink at least six to eight cups of clean water daily. Consider coffee if you enjoy it, two to three cups daily. A

moderate intake of alcohol may be suitable for some patients.

- Consider an elimination diet (see [Chapter 86](#)).
- Consider supplementation: vitamin C, 200 mg twice daily; magnesium, 300 mg/day; vitamin E, 400 units/day with meals; calcium, 1000 to 1500 mg/day; and curcumin 450 mg/day.
- Avoid medications associated with gallstone risk including estrogen, ceftriaxone, octreotide, and fibrates. Take precautionary measures if taking these medications, have excessive weight loss, or are receiving total parental nutrition (TPN).

Therapeutic Review

Immediate surgical referral is warranted in the setting of severe recurring symptoms or elevated liver enzymes, amylase, or white blood cell count. In asymptomatic patients or mild cases with normal liver function, the following therapies are recommended.

Lifestyle

- Maintain a healthy weight. 
- Exercise at least 30 minutes a day, five times a week. 
- Participate in stress-reducing activity. 

Nutrition

- Diet should be high in fiber, fruits, and vegetables. 
- Consider supplementing with fiber and flaxseed. 
- Recommend a diet low in saturated fat, rich in omega-3 fatty acids. 
- Drink six to eight cups of water daily. 
- Avoid refined sugars. 
- Avoid excess intake of legumes. 
- Consider an elimination diet. 

Supplements

- Vitamin C: 200 mg twice daily 
- Calcium: 1000 to 1500 mg/day 
- Magnesium: 300 mg/day 
- Vitamin E: 400 units/day 

Botanicals

- Milk thistle (*Silybum marianum*) standardized to 70% silymarin extract: starting at 150 mg twice a day and increasing to three times/day if needed 
- Artichoke (*Cynara scolymus*): 1 to 4 g of leaf, stem, or root three times/day 
- Turmeric (*Curcuma longa*): 450 mg curcumin capsule, or 3 g root daily 
- Peppermint oil (*Mentha piperita*): one to two enteric-coated capsules three times/day between meals 
- Dandelion (*Taraxacum officinalis*): 1:5 tincture, 5 to 10 mL three times/day 

Pharmaceuticals

- Ursodiol (ursodeoxycholic acid): 300 mg twice daily with meals 

Surgery

- Laparoscopic cholecystectomy 
- Patients with common bile duct obstruction (elevation of liver enzymes, lipase, and bilirubin, right upper quadrant pain, jaundice, and common bile duct dilation on ultrasound) may require either endoscopic retrograde cholangiopancreatography for stone removal or surgical exploration.

CHAPTER 45

Recurring Abdominal Pain in Pediatrics

Joy A. Weydert, MD

Pathophysiology

Recurrent abdominal pain (RAP) in children was first defined by Apley and Naish in 1958 as consisting of at least three episodes of pain over a 3-month period that are severe enough to interfere with normal activities. RAP is one of the most common reasons to seek medical attention.¹ RAP affects approximately 10% to 15% of all school-aged children and is responsible for 2% to 4% of all pediatric outpatient visits.² Fewer than 10% of children with RAP are ever found to have an organic cause for pain; however, substantial morbidity, such as depression, anxiety, lifetime psychiatric disorders, and social phobia, still occurs.³ Chronic abdominal pain rarely occurs in isolation and is often associated with other chronic pain syndromes, such as chronic headache, fibromyalgia, joint pain/hypermobility, and postural orthostatic tachycardia syndrome (POTS).⁴ In addition, RAP is associated with significant health care costs, not only from medical evaluations and medications, but also from missed work and productivity.⁵ On average, children with RAP miss 26 days per year of school compared with only 5 days in children who do not have abdominal pain,⁶ which has its own long-term consequences. Absenteeism has been identified as a precursor to undesirable outcomes, including poor academic performance, increased rates of school dropout, substance abuse, and violence in adolescents.⁷ Parents, teachers, and physicians frequently reinforce pain behavior by excusing children with RAP from chores and other responsibilities, allowing absences from school or providing medications.

The etiology and pathogenesis of RAP has traditionally been

considered multidimensional, with biological, psychological, and social factors all playing significant roles in the development of RAP in children. With advances in our understanding of pain physiology, further elucidation of the mechanism's underlying processes will help guide our approach to the treatment of this condition.

A phenomenon known as *central sensitization* is considered the core biological link and final common pathway that leads to chronic pain. Neuroanatomical, neurophysiological, and neurochemical changes occur within nerves of the peripheral (PNS) and central nervous systems (CNS), thereby altering the processing of sensory information. These changes trigger hyperarousal of CNS neurons to otherwise ordinary pain stimuli and leads to heightened experience of pain. Repetitive stimulation of neurons throughout the CNS (spinal column to the cerebral cortex) can lead to upregulation of excitatory receptors and death of the inhibitory interneurons that produce serotonin and endogenous opioids.⁸

The effects of the immune and endocrine systems on the nervous system have been demonstrated and are now widely accepted as part of normal physiology.⁹ In addition to the altered physiology of the PNS and CNS caused by trauma or disease, an imbalance in the immune or endocrine systems can promote dysregulation of the nervous system and increased pain through direct effects on neurotransmission ([Fig. 45.1](#)).

Immune system dysfunction in children with RAP may be a result of recent viral or bacterial intestinal infection,¹⁰ or from exposure to antibiotics, nonsteroidal antiinflammatory drugs (NSAIDs), steroids, chlorinated water, or a poor diet. These factors disrupt the natural balance of the intestinal microbiota necessary for optimal functioning of the gut. Bacteria interact with intestinal epithelial cells and generate inflammatory mediators that stimulate the sensory nerve endings lying in the gut mucosa. Bacteria also affect intestinal permeability, allowing chemicals and antigens access from the gut lumen into and between the cell walls.¹¹ Food sensitivity mediated by immunoglobulin G (IgG) antibodies has been identified as a further trigger for RAP. Rather than the classic IgE food allergy response, which is more immediate, IgG-mediated responses are delayed following exposure to a particular antigen,¹² the most common being wheat, dairy, eggs, corn, and soy. This type of food sensitivity creates a low-level, chronic inflammatory response that triggers gut neuronal sensitivity and pain. This response does not, however, trigger excessive levels of calprotectin, a cytosolic protein produced in high levels by granulocytes in inflammatory bowel

disease.¹³

Neurotransmitter imbalances, as a result of immune dysregulation, hormone imbalance, or nutritional deficiencies (such as magnesium, iron, zinc, or vitamin B, which are all cofactors in neurotransmitter production), may also contribute to RAP. In the brain–gut axis, which links the neuroendocrine, immune, and enteric nervous systems, the brain and the gut neurons share identical neurotransmitters as they originate from the same cells embryologically. Low levels of serotonin have been associated, not only with depression and headaches, but also with abdominal pain.¹⁴

Dysregulation of the autonomic nervous system, characterized by increased auditory startle reflex and low vagal tone, has been demonstrated in children with RAP.^{15,16}

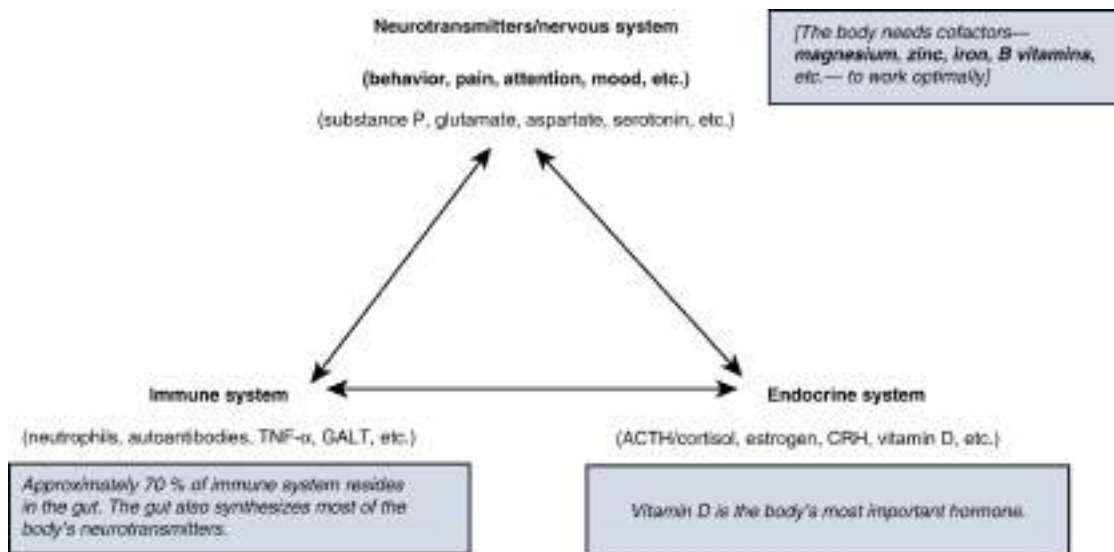

FIG. 45.1 Interactions Between Neuroendocrine Systems.

Fructose malabsorption, a condition that causes gas, bloating, and cramping, has been found to cause RAP in children found to have fructose intolerance on breath hydrogen testing.¹⁷ The same symptoms have been found in those with yeast overgrowth in the intestinal tract—intestinal candidiasis—typically as a result of oral antibiotic use. Yeast requires a source of carbohydrates to survive and releases carbon dioxide

gas during carbohydrate metabolism. Clinically, this process causes abdominal bloating, gas, pain, and intermittent diarrhea that may alternate with constipation.^{18,19}

Even obesity has been linked to a greater incidence of constipation, gastroesophageal reflux disease, irritable bowel syndrome (IBS), encopresis, and functional abdominal pain. This association may be related to food choices (processed foods versus whole fruits and vegetables and higher intake of soda with high-fructose corn syrup), physical activity levels, hormonal status, or emotional state.²⁰ A thorough diet history is important in identifying possible triggers for RAP.

In addition to the previous, other factors known to be associated with a greater incidence of RAP in children include the behavior profile of the patient and genetic vulnerability. A proportion of children may exhibit anxiety, mild depression, withdrawal, or low self-esteem. Investigators have postulated that this behavior profile is frequently fostered within a family structure characterized by parental depression, enmeshment, overprotectiveness, rigidity, and lack of conflict resolution. These factors may influence the way in which RAP is experienced and addressed.²¹ [Fig. 45.2](#) displays how each of these factors contribute to the clinical expression of chronic pain.²²

An understanding of the various pathways that may lead to or perpetuate abdominal pain in children will help approach treatment options in an integrative fashion to address any immune imbalances, food sensitivities, nutritional deficiencies, or nervous system dysregulation.

FIG. 45.2 Pathogenesis of visceral hyperalgesia and clinical expression of chronic pain. Primary hyperalgesia develops when sensory neurons with cell bodies in the dorsal root ganglia are recruited and sensitized after early or multiple pain experiences. Secondary hyperalgesia occurs when biochemical changes in pathways from the spinal cord to cerebral cortex result in increased pain perception. *Viscerosomatic convergence* refers to somatic and visceral afferent nerves terminating on the same spinal interneurons, such that the affected individual is unable to define a discrete pain location on the body. Psychological and developmental factors (within the brain) and psychosocial factors (arrows pointing to the brain) alter clinical expression of pain. (From Hyams JS, Hyman PE. Recurrent abdominal pain and

Children with RAP may demonstrate one of the classic presentations, as defined by the Rome Foundation's pediatric Rome III criteria, which may help guide clinical decision making and therapy.²³ To fulfill any of the criteria, the patient typically must experience pain at least once a week for over 2 months and have no evidence of inflammatory, anatomic, metabolic, or neoplastic processes as an underlying cause. Many of these patients may demonstrate evidence of autonomic nervous system imbalance, such as nausea, headaches, lightheadedness, dizziness, or pallor.

1. Functional abdominal pain or syndrome; must include all the following:
 - Episodic or continuous abdominal pain—usually periumbilical
 - Some loss of daily functioning
 - Additional somatic symptoms such as headache, limb pain, or difficulty sleeping
2. IBS; must include all the following:
 - Abdominal discomfort or pain associated with two or more of the following:
 - Improvement with defecation
 - Onset associated with a change in frequency or form of stool
3. Functional dyspepsia; must include all the following:
 - Persistent or recurrent pain or discomfort centered in the upper abdomen
 - Pain not relieved by defecation or associated with change or form of stool
4. Functional constipation; must include two or more of the following:
 - Two or fewer defecations per week
 - At least one episode of fecal incontinence per week
 - History of retentive posturing or excessive volitional stool retention
 - History of painful or hard bowel movements
 - Presence of a large fecal mass in the rectum
 - History of large-diameter stools that may obstruct the toilet
5. Abdominal migraine; must include all four of the following:
 - Paroxysmal episodes of intense, acute periumbilical pain that lasts more than 1 hour
 - Intervening periods of usual health lasting weeks to months
 - Pain interfering with normal activities
 - Pain associated with two or more of the following:

- Anorexia
 - Vomiting
 - Photophobia
 - Nausea
 - Headache
 - Pallor
6. Cyclic vomiting
- Two or more periods of intense nausea and unremitting vomiting or retching lasting hours to days
 - Return to usual state of health lasting weeks to months
7. Aerophagia; must include two of the following:
- Air swallowing
 - Abdominal distention because of intraluminal air
 - Repetitive belching or increased flatus

Serious organic disease can be ruled out by a thorough history, physical examination, and basic laboratory investigations. Pertinent positive results in this evaluation considered “red flags” include the following:

1. A family history of inflammatory bowel disease, ulcer disease, or significant psychosocial disorder
2. Pain that wakes the child from sleep
3. History of weight loss or growth delay
4. Blood in stool or bile-stained emesis
5. A history and physical examination revealing fevers, rashes, joint involvement, or perianal disease
6. Abnormal complete blood count, urinalysis, sedimentation rate, C-reactive protein, or stool for occult blood

If indicated by a positive history, the clinician may consider further testing (i.e., serologic testing for *Helicobacter pylori*, serum transaminases, amylase, lipase, stool for pathogens, and endoscopy).

Use of a comprehensive stool analysis, which assesses intestinal candidiasis, parasites, and the balance of microbiota, may also help direct therapy options. Results of this type of testing will identify the need for pharmaceuticals (i.e., nystatin, fluconazole, or metronidazole) or natural antimicrobial botanicals, such as grapefruit seed extract, olive leaf extract, or oregano oil. These tests may also help guide the choice of probiotics to rebalance the intestinal microbiota.²⁴

An evaluation for micronutrient deficiencies (zinc, iron, magnesium, B vitamins, etc.) may also be indicated because these factors play a role in neurotransmitter production and nervous system function.²⁵

Rather than a diagnosis of exclusion, recurrent abdominal pain should be presented as a positive diagnosis, identified as the most common cause of chronic abdominal pain in children. Parents can be reassured that serious disease is unlikely if the history and physical examination are normal.

Integrative Therapy

Nutrition

Diet manipulation has been trialed for years as a treatment for RAP, either through the elimination of certain foods (e.g., lactose-containing foods) or the addition of others (e.g., high-fiber foods). However, studies of dietary interventions have reported varying results.^{26,27}

Fiber

Although studies of fiber in the treatment of RAP have been small and the evidence is weak, some investigators have reported that additional fiber may be beneficial in a proportion of children, particularly those with constipation. Increased consumption of fiber goal can be accomplished by increasing the amounts of fruit, vegetables, legumes, and whole grains in the diet. Breakfast cereals can also be a good source of fiber, particularly cereals made with bran ([Table 45.1](#)). If a child has difficulty obtaining adequate fiber through the diet, one teaspoon (2 g) of psyllium powder in 8 oz of cool water or juice may be given up to three times a day. Increased water intake is strongly recommended with increased fiber consumption in order to prevent constipation.

TABLE 45.1

Fiber Content of Various Foods

Foods	Portion Size	Fiber (g)
High Fiber		
All-bran cereal	½ cup	10
Figs, dried	3	10
Kidney beans	½ cup cooked	9
Baked beans	½ cup cooked	8
Broccoli	¾ cup cooked	7
Spinach	½ cup cooked	7
Yam baked in skin	1 medium	7
Whole wheat bread	2 slices	6
Baked potato with skin	1 medium	5
Blackberries	½ cup	5
Apple with skin	1 medium	3.5
Raspberries	½ cup	3.5
Lentils	½ cup cooked	3.5
Whole wheat spaghetti	1 cup	3.5
Wheaties cereal	1 oz	2.5
Low Fiber		
Bagel	1	Less than 1
Cornflakes	1 oz	Less than 1
Grapes	20	Less than 1
Watermelon	1 cup	Less than 1
Lettuce	1 cup	Less than 1

The recommended minimum daily weight of dietary fiber in grams = age of the child + 5. Additional fiber can be added as required.

Food Elimination

Patients should avoid foods that appear to exacerbate pain. If symptoms are suggestive or if the patient has a family history of lactose intolerance, initiate a 2- to 4-week trial of cessation of all dairy products (milk, cheese, yogurt, ice cream, etc.). If no changes are noted after 2 weeks, then consumption of dairy products can be resumed. If improvement is noted, then the patient should slowly reintroduce dairy in small quantities as tolerated. The intake of highly processed foods should be reduced, particularly those with refined carbohydrates (e.g., snacks, candy, and cookies) because the fermentation of these sugars increases gas production. Studies have demonstrated that the ingestion of various sugars, such as lactose, fructose, sorbitol, and fructose plus sorbitol, increases breath hydrogen measurements and clinical symptoms in patients with RAP.^{28,29} Reduced consumption of these sugars caused a reduction in symptoms in 40% to 60% of the subjects studied. Fructose is readily available in sweetened soft drinks and juices, while sorbitol is the leading sweetener used in “sugar-free” foods.

Food allergy has been implicated in abdominal pain; however, testing for the presence of IgE-mediated antibody responses has not demonstrated benefit. However, one study evaluated the efficacy of food elimination based on the presence of IgG antibodies detected by enzyme-linked immunosorbent assay. IgG antibodies cause delayed sensitivity and irritation of the gastrointestinal tract. In a randomized controlled trial (RCT), compliant patients placed on a food elimination diet based on high levels of IgG antibodies had a 26% greater reduction of symptoms compared with patients receiving a sham elimination diet.³⁰ In a separate RCT, both migraine pain and symptoms of IBS were reduced with food elimination based on IgG food antibodies³¹ (see [Chapters 31](#) and [86](#)).

Behavior Modification

Pain behavior is frequently reinforced unknowingly but with good intentions toward the child. Help families recognize that special attention

or treatment during pain episodes (i.e., staying home from school, being dismissed from chores or responsibilities, having one-on-one attention from a parent) may foster ongoing pain behavior and diminish self-reliance. Encourage school attendance and completion of personal responsibilities. Physicians can also facilitate a return to a normal lifestyle by offering a thorough explanation of the diagnosis and pathophysiology, reassurance, and options for management and adaptation to the disorder.

Poor sleep can heighten the perception of pain; therefore, working on strategies to promote restorative sleep is important. Eliminate all stimulants in the evening before bedtime, including caffeine, decongestants, television, computer or video games, and arguments. Practice dusk simulation by dimming lights around the house 1 hour before bedtime and shifting to quieter activities. The child should take a warm bath with Epsom salt to relax tense muscles before bedtime. Make sure the bedroom environment is conducive to sleep, that is, dark, quiet, and cool. If the child has difficulty falling asleep, have them practice self-regulation techniques such as controlled breathing or self-hypnosis, discussed later. Also consider using calming herbs such as chamomile.

Botanicals

Chamomile (*Matricaria recutita*)

The active ingredients in chamomile include the volatile oils alpha-bisabolol and bisabolol oxide and the flavonoids apigenin, luteolin, and quercetin. These constituents have antiinflammatory effects that inhibit phospholipase A, cyclooxygenase, and lipoxygenase pathways.³² Bisabolol stimulates gastrointestinal tract receptors, thus causing smooth muscle relaxation. Apigenin acts on benzodiazepine receptors in the central nervous system, with anxiolytic effects similar to those of diazepam (Valium) and alprazolam (Xanax) but without the sedative effects.^{33,34} Chamomile can be administered as a tea, as an extract, or by capsule in standardized preparations. Glyceride extracts of chamomile can be found for use in children to offset concerns regarding preparations extracted with alcohol. A study in infants with colic used found an herbal tea preparation that included chamomile to be effective in reducing colic episodes.³⁵

Dosage

- Adults weighing approximately 150 lb: 3 g three to five times per day
- Children weighing approximately 75 lb: 1.5 g three to five times per day
- Children weighing approximately 35 lb: 0.75 g three to five times per day

One heaped teaspoon of chamomile flowers steeped in hot water yields approximately 3 g. Extracts are supplied as a 1 g/1 mL (1:1) dilution and a 1 g/4 mL (1:4) dilution. Use the following doses as a guide:

150 lb

- 1:1—3 mL three to five times per day
- 1:4—12 mL three to five times per day

75 lb

- 1:1—1.5 mL three to five times per day
- 1:4—6 mL three to five times per day

35 lb

- 1:1—0.75 mL three to five times per day
- 1:4—3 mL three to five times per day

Precautions

Chamomile is generally safe, although patients allergic to ragweed, asters, or chrysanthemums should take chamomile with caution. Chamomile is a member of the daisy family and has contributed to allergic reactions in rare cases.

Peppermint (*Mentha piperita*)

Analysis of peppermint oil typically shows more than 40 different compounds; however, the principal components are menthol, methone, and methyl acetate. Pharmacological studies on peppermint have focused almost entirely on menthol, which has carminative effects (elimination of intestinal gas), antispasmodic effects, and choleric effects (bile flow stimulant). The mechanism of action of peppermint is thought to be inhibition of smooth muscle contraction by blocking

calcium channels.³⁶ Many studies have been conducted using peppermint oil as a treatment for IBS, including one study in children.³⁷ Although peppermint did not alter symptoms associated with IBS, such as urgency of stool, stool patterns, or belching, peppermint was found to reduce associated pain. Peppermint is most widely used as a tea. Due to its calcium channel blockage effects, peppermint may cause relaxation of the lower esophageal sphincter and lead to an increase in heartburn symptoms in some patients. An enteric-coated capsule is available for use in the treatment of IBS. With its delayed release in the small intestine, peppermint has little effect on the lower esophageal sphincter; therefore, it is less likely to cause heartburn.

Dosage

- Tea: one to two teaspoons of dried leaves steeped in 8 oz of hot water as needed
- Enteric-coated capsules (200 mg or 0.2 mL):
 - Two capsules three times a day for children weighing more than 100 lb
 - One capsule three times a day for children weighing 60 to 100 lb

Precautions

Peppermint is generally regarded as safe; however, hypersensitivity reactions have been reported.

Due to its smooth muscle-relaxing properties, peppermint has the greatest effect on pain related to abdominal spasm.

Ginger (*Zingiber officinale*)

Ginger contains many volatile oils (sesquiterpenes) and aromatic ketones (gingerols). Gingerols are believed to be the more pharmacologically active constituents of ginger. Historically, ginger has been used as far back as the fourth century BC for stomach aches, nausea, and diarrhea. Ginger has also been used as a carminative, appetite stimulant, and choleric. Ginger can simultaneously improve gastric motility and exert antispasmodic effects.³⁸ Studies have shown that ginger's antispasmodic effects on visceral smooth muscle are likely attributable to antagonism of serotonin receptor sites. A double-blind, randomized crossover study reported a significant reduction in nausea and vomiting with the use of

ginger in women with hyperemesis gravidarum.³⁹ Due to its safety profile, ginger is regularly used in pregnancy with no untoward fetal effects.

Dosage

- Adults weighing approximately 150 lb: 1 to 2 g dry powdered ginger root per day (10 g fresh)
- Children weighing approximately 75 lb: 0.5 to 1 g dry powdered ginger root per day (5 g fresh)
- Children weighing approximately 35 lb: 0.25 to 0.5 g dry powdered ginger root per day (2.5 g fresh)

Ginger can improve gastric motility while also exerting an antispasmodic effect. The pharmacist can dissolve ginger capsules in an 8.4% bicarbonate suspension with good stability and bioavailability for use in children unable to swallow pills.

A one-fourth inch slice of fresh ginger root is approximately 10 g. This is equivalent to 1 to 2 g of a dry powder form of ginger that is a more concentrated form found in capsules. Fresh ginger can be brewed as a tea sweetened with honey or can be chopped and added to foods, soups, or salads.

A general rule of thumb for estimating the amount of fresh ginger to use in children is to use the child's "pinky" finger (fifth finger) as the guide to the size of ginger to chop up and steep for tea.

Precautions

Ginger is well tolerated when used in typical doses. At higher doses, side effects may include heartburn, abdominal discomfort, or diarrhea. Ginger may have antiplatelet effects and therefore may increase the risk of bleeding in some people.

Slippery Elm (*Ulmus fulva*)

Slippery elm has demulcent properties that can be used to protect the gastrointestinal tract from irritation. When used internally, slippery elm causes reflex stimulation of the nerve endings in the gastrointestinal tract that produces mucus secretion.⁴⁰ This effect may be particularly helpful in children with functional dyspepsia.

Dosage

A tea can be made with one cup of boiling water and one tablespoon of powdered bark. Use 2 to 5 mL three times a day.

Precautions

No contraindications are associated with slippery elm. Spontaneous abortions have been reported with the use of slippery elm; therefore, it should not be used during pregnancy.

Lemon Balm (*Melissa officinalis*)

Lemon balm contains volatile oils and constituents that relax muscles, particularly in the bladder, stomach, and uterus, thereby relieving cramps, gas, and nausea. Lemon balm is generally regarded as safe and is one of the components of the product Iberogast, used widely for gastrointestinal problems. A meta-analysis of double-blind, randomized controlled trials conducted on Iberogast found significant improvements compared with placebo in patients with functional dyspepsia.⁴¹

Dosage

- Capsules: 100 to 200 mg dried lemon balm three times daily or as needed.
- Tea: 0.5 to 1.5 g (one-fourth to one teaspoon) of dried lemon balm herb in hot water. Steep and drink up to four times daily.
- Tincture: 0.5 to 1 mL (15 to 30 drops) three times daily.

Precautions

Despite a lack of scientific evidence, lemon balm may interact with sedatives and thyroid medications.

Supplements

Probiotics

The human intestinal tract is populated with various microbial species that are nonpathogenic and necessary for normal digestive functioning.

Microorganisms, or probiotics, are now recognized as a way to fight disease and improve health. Studies in children have reported a significant reduction in diarrhea symptoms, both from rotavirus infection and antibiotic use, in children following the administration of probiotics.^{42,43} Probiotics increase the number of rotavirus-specific IgA-secreting cells and serum IgA levels. Probiotics are thought to help treat RAP by degrading dietary antigens, restoring normal intestinal permeability, and alleviating intestinal inflammation that can trigger pain.⁴⁴ Two double-blind, randomized, placebo-controlled trials found that *Lactobacillus* GG reduced the frequency and intensity of pain in children with RAP/IBS when this probiotic was administered over the course of 4 to 8 weeks.^{45,46} One of these studies also demonstrated a decrease in the number of patients with abnormal intestinal permeability test results after treatment with *Lactobacillus* GG but not with placebo.

Dosage

Use 10 to 100 billion colony-forming units (CFUs) per serving once or twice a day. These preparations can be of a single strain, such as *Lactobacillus* GG, or made of multiple strains, such as *Bifidobacterium bifidus*, *Lactobacillus acidophilus*, or *Lactobacillus reuteri*, to treat both the small and the large intestine.

Precautions

Probiotics are considered safe for use. *Lactobacillus* sepsis associated with probiotic therapy has been reported; however, this adverse effect occurred in children considered immunocompromised and at increased risk due to central line placement.

Pharmaceuticals

Despite a lack of controlled studies with established efficacy for many drugs used in functional bowel disorders,^{47,48} these agents continue to be prescribed. For this reason, as well as worrisome side effects (for metoclopramide, irritability, and dystonic reactions; for cisapride, arrhythmia, and adverse outcomes in prolonged QT syndrome; for anticholinergics, constipation, blurred vision, tachycardia, and sedation; for tricyclic antidepressants, sedation, agitation, acute mental

disturbance, and reduction in seizure threshold), these particular drugs cannot be safely recommended for use in children.

Histamine-2 (H₂) Receptor Antagonists and Proton Pump Inhibitors

For patients with dyspepsia as a primary symptom, histamine-2 (H₂) receptor antagonists and proton pump inhibitors can be used if other strategies are unsuccessful. Studies in children supporting such therapy are few; however, these drugs may be beneficial and are relatively safe in the short term (6 to 8 weeks).⁴⁹

Dosage

- Cimetidine (Tagamet): 10 mg/kg/dose given four times daily. Available as 100 mg over-the-counter (OTC), 200-, 300-, 400-, and 800-mg tablets and a 300-mg/5-mL suspension by prescription
- Ranitidine (Zantac): 2 to 4 mg/kg/dose given twice daily. Available as 75-mg OTC, 150-, and 300-mg tablets; 150-mg granules; and a 75-mg/5-mL suspension
- Famotidine (Pepcid): 0.5 to 3.5 mg/kg/day divided two times a day. Available as 10-mg OTC, 20-, and 40-mg tablets and a 40-mg/5-mL suspension
- Omeprazole (Prilosec): 0.2 to 3.5 mg/kg/day daily or divided twice a day. Available as 10-, 20-, and 40-mg capsules
- Lansoprazole (Prevacid): 1 to 2 mg/kg/day given daily. Available as 15- and 30-mg capsules

Precautions

Headaches, diarrhea, abdominal pain, and elevated liver function tests have been reported with the use of histamine-2 (H₂) receptor antagonists and proton pump inhibitors. Prolonged acid suppression can lead to malabsorption of key nutrients, including vitamin B₁₂, iron, magnesium, and calcium.

Cyproheptadine

Cyproheptadine (also known by the brand name Periactin) has

antihistamine effects and has been studied through a double-blind, randomized controlled trial conducted over 2 weeks in 29 children. The intensity and frequency of abdominal pain reported by children were significantly improved in the treatment group compared with the control group.⁵⁰ Cyproheptadine has historically been used as prophylactic treatment for migraine due to its effects on serotonin and histamine. These effects may have some benefit in children with abdominal migraines over a short period, although further studies are required.

Dosage

- Children 7 to 14 years of age: 4 mg two or three times daily (maximum, 16 mg/day)
- Children 2 to 6 years of age: 2 mg two or three times daily (maximum, 12 mg/day)

Precautions

The major reported side effects of cyproheptadine are increased appetite and weight gain. Sedation and sleepiness have also been reported.

Biomechanical Therapy

Massage

Massage can ease pain by calming sympathetic arousal, often observed in children with RAP. Decreased sympathetic drive improves gastrointestinal motility. Massage, either of the abdomen directly or indirectly by reflexology, is helpful in alleviating ileus and constipation and can be very comforting overall.^{51,52}

Osteopathic Manipulative Therapy

Understanding somatovisceral pathways has led to the treatment of RAP with osteopathic manipulative therapy. Trigger points along the spine and in the large muscles of the back and trunk (e.g., external and internal oblique, rectus abdominis, iliocostalis thoracis, and lumborum muscles) can cause referred pain to the abdominal region that mimics visceral disease. Release of these trigger points through manipulation decreases

this reflex effect and therefore lessens pain.⁵³

Surgery

Exploratory surgery is not warranted unless strong indications are revealed through history, physical examination, or laboratory investigations.

Bioenergetic Therapy

Traditional Chinese Medicine and Acupuncture

The philosophy of traditional Chinese medicine is that of restoring balance to the body through its flow of energy. Although large clinical trials of traditional Chinese medicine and acupuncture in children with RAP have yet to be reported, one study measured the effects of hand acupuncture in reducing intermittent abdominal pain in 40 children. Pain intensity and medication use were considerably lower in the treatment group.⁵⁴ In a randomized, double-blind, placebo-controlled study of Chinese herbs, patients receiving herbs noted significant improvement in bowel symptoms, global well-being, and return to normal life activities compared with the group receiving placebo.⁵⁵ Although children may be fearful of needles, many children have reported that acupuncture does not hurt when performed by an experienced professional. Acupressure or electroacupuncture may also be used as alternatives to needles.

Reiki and Healing Touch

As with traditional Chinese medicine, reiki and healing touch are based on the concept of restoring normal energy flow through the body. In patients with disease or pain, this energy may be blocked or stagnant, thus disrupting its normal flow. Through energy work, this energy flow can be restored. Many randomized controlled studies have indicated that energy healing can be effective for pain, anxiety, depression, wound healing, and other problems.⁵⁶ Although no specific studies have been conducted in children with RAP, this therapy has no serious side effects and is considered safe (see [Chapter 116](#)).

Mind-Body Therapy

It is clear that abdominal pain syndromes are disorders of bidirectional

mind-brain-gut interactions and neurobiological processes in the mind-brain-gut interactions lead to alterations in motility, sensation, and immune functions.⁵⁷

Because of our current knowledge of the brain-gut axis and associated interactions, it is logical that mind-body therapy be used for the treatment of RAP. Studies published primarily in psychiatric journals have supported the efficacy of interventions that teach stress management, progressive muscle relaxation, coping behaviors, or the use of cognitive-behavioral therapy.^{58,59} One study reported significant pain reduction with the addition of biofeedback, cognitive-behavioral therapy, or parental support to fiber therapy in the multimodal treatment of RAP.⁶⁰

Progressive Muscle Relaxation and Breathing Exercises

Both progressive muscle relaxation and breathing exercises, used alone or in combination, are forms of self-regulation that help decrease sympathetic arousal to promote comfort. Progressive muscle relaxation is a way for children to learn to feel the difference between tense and relaxed muscles, and to use this knowledge to cope with abdominal pain. Progressive relaxation reduces anxiety associated with pain by demonstrating the mind-body phenomenon and patient capacity for self-regulation. The benefits of these approaches are that they are easily taught, particularly to school-age children, and can be used anywhere. Scripts can be given to parents to use, or a tape can be made or purchased for home use (see [Chapters 94](#) and [95](#)).

Biofeedback

Biofeedback is a form of relaxation using physiological feedback instruments to reinforce behavior. As relaxation occurs, warmth can be brought to the fingertips, thus increasing distal temperature. Distal temperature can be monitored by sensors placed on the fingers and can reinforce the positive behavior of relaxation as the temperature rises. Biofeedback may be beneficial in patients who are skeptical regarding the ability of the mind to control body functions. Professionals trained in biofeedback with equipment readily available are best placed to teach this modality.

In a study of heart rate variability biofeedback, children with functional abdominal pain were able to significantly reduce their symptoms by significantly increasing their autonomic balance. The

investigators posited change in vagal tone was the potential mediator of this improvement.⁶¹

Hypnosis and Guided Imagery

Hypnosis and guided imagery allow a state of focused attention in which the mind is more receptive to suggestion. These techniques have been used successfully for all types of pain syndromes, including RAP, and are easily used in children older than 4 years of age (see [Chapters 95](#) and [97](#)).^{62,63}

A randomized controlled trial of the use of therapist-directed guided imagery with progressive muscle relaxation reported a significant decrease in the number of days with pain and missed activities compared with controls.⁶⁴ A similar study using audio-recorded guided imagery treatment also reported benefit, with treatment effects maintained for more than 6 months.⁶⁵ Gut-directed hypnosis therapy has been found to be superior to standard medical therapy in reducing pain scores in children with longstanding abdominal pain in other randomized controlled trials.^{66,67}

Psychotherapy

In children or families with significant psychosocial dysfunction, counseling by a child psychiatrist or clinical psychologist may be the best therapy. Cognitive-behavioral family intervention therapy, which often includes teaching specific coping skills, social skills, and relaxation, has been shown to be efficacious in studies of children with RAP.^{68,69}

Prevention Prescription

- Encourage liberal amounts of water and fiber in the form of natural fruits and vegetables to promote daily bowel movements.
- Promote probiotics if the patient has a history of antibiotic, steroid, or nonsteroidal antiinflammatory drug use.
- Ask the patient to practice breathing and relaxation exercises or other self-regulation techniques to reduce stress.
- Encourage healthy sleep habits to promote restorative sleep.
- Consider avoiding high amounts of processed foods and simple sugars, including sorbitol.
- Encourage regular movement and exercise.

Therapeutic Review

Once a child has been thoroughly evaluated and organic disease has been ruled out, any of these therapies can be used in an age-appropriate manner.

Nutrition

- Avoid foods that have sorbitol and high-fructose corn syrup or are a source of refined carbohydrate because these are poorly digested.
- Prescribe a 2- to 4-wk trial of cessation of all dairy products if the history suggests lactose intolerance (see [Chapters 31](#) and [86](#)).
- Increase fiber by at least 10 g/day through the addition of fruits, vegetables, legumes, and whole grains or with psyllium, one teaspoon/8-oz cool water one to three times daily.
- Increase water intake along with the increase of fiber.

Behavior Modification

- Encourage attendance at school and other usual activities.
- Offer strategies to overcome the reinforcement of illness behavior at school and at home.
- Improve restorative sleep.

Botanicals

Chamomile

- 3 g three to five times/day (150 lb patient)
- 1.5 g three to five times/day (75 lb patient)
- 0.75 g three to five times/day (35 lb patient)

Peppermint Tea

- One to two teaspoons dried leaves/8-oz hot water as needed
- Enteric-coated capsules (200 mg)
 - Two capsules three times/day (approximately 100-lb patient) 
 - One capsule three times/day (60- to 99-lb patient)

Ginger

- 10 g fresh (or 1 to 2 g dry powdered)/ day (150-lb patient)
- 5 g fresh (or 0.5 to 1 g dry powdered)/ day (75-lb patient)
- 2.5 g fresh (or 0.25 to 0.5 g dry powdered)/ day (35-lb patient)

Slippery Elm

- Make tea with one cup boiling water and one tablespoon powdered bark. Give 2 to 5 mL three times a day

Lemon Balm

- 100 to 200 mg capsules three times/ day
- 0.5 to 1.5 g tea three times/ day
- 0.5 to 1 mL (15 to 30 drops) tincture three times/ day

Supplements

- Probiotics: 10 to 100 billion CFUs once or twice/ day

Pharmaceuticals

- Histamine-2 (H₂) receptor antagonists or proton pump inhibitors for maximum of 6 to 8 weeks if dyspepsia is the primary complaint (see text for dosing)
- Cyproheptadine 2 to 4 mg two to three times/ day for abdominal migraine

Biomechanical Therapy

- Massage 
- Osteopathic manipulative therapy 

Bioenergetic Therapy

- Traditional Chinese medicine and acupuncture
- Reiki and healing touch

Mind-Body Therapies

- Progressive muscle relaxation and breathing exercises (see [Chapter 92](#))
- Biofeedback
- Hypnosis and guided imagery (see [Chapters 95](#) and [97](#))

- Psychotherapy

CHAPTER 46

Constipation

Tanmeet Sethi, MD

Pathophysiology

Constipation is estimated to affect up to 28% of the population of the United States, most commonly older adults, women, and children, and results in more than \$6.9 billion in medical costs.¹ Constipation is usually intermittent and self-limiting, although some patients require intervention to achieve resolution. [Table 46.1](#) presents the defining criteria for constipation,² but in practical clinical terms, the complaint of constipation and even the diagnosis are often made more subjectively. Asking what patients mean by the statement, “I am constipated,” may be the most important first step to management.³ The majority of patients complaining of constipation describe a perception of difficulty with bowel movements or a discomfort related to bowel movements. The most common terms used by young, healthy adults to define constipation are straining (52%), hard stools (44%), and the inability to have a bowel movement (34%).

Routine diagnostic testing is not recommended for patients with no alarm symptoms and no signs of organic disorder.⁴

Functional constipation is often classified into three distinct categories:

1. Normal-transit constipation: Also known as *functional constipation*, this is the most common type. In functional constipation, stool passes through the colon at a normal rate and bowel movement frequency is normal.⁵ In this group of patients, constipation is likely the result of a perceived difficulty with evacuation or the presence of hard stools.²
2. Slow-transit constipation: This type of constipation is characterized by

prolonged delay of transit of stool through the colon. Patients may complain of abdominal bloating and infrequent bowel movements.⁶ The causes are unclear.

3. Pelvic floor dysfunction: These patients have uncoordinated evacuation of stool through the rectum. They are more likely to complain of a feeling of incomplete evacuation, a sense of obstruction, or a need for digital manipulation.⁶

Physicians should keep secondary causes of constipation (the most common being hypothyroidism) in mind, as well as medications that can cause constipation. In one study of more than 20,000 patients, the use of certain drugs was found to be associated with a two- to three-fold increased risk of constipation.⁷ Although the list of drugs that can cause constipation is quite lengthy, [Table 46.2](#)^{7,8} provides some of the most common offenders.

Integrative Therapy

Physical Activity

The generally accepted view is that increasing the amount of physical activity can be a preventive measure for constipation. In fact, a subset of the Nurses' Health Study demonstrated that in more than 62,000 women, physical activity two to six times a week was associated with a 35% decrease in risk of constipation.⁹ A previous National Health and Nutrition Examination Survey reported a two-fold increased risk of constipation in persons with a low physical activity level. Despite these findings, data in support of exercise as a treatment for constipation have not been consistent. Nevertheless, many patients who comply with dietary and exercise recommendations have an improvement in symptoms.¹⁰

Nutrition

Fiber

Although dietary modification may not always succeed, all constipated patients should be initially advised to increase their dietary fiber intake as the simplest, most physiologic, and cheapest form of treatment.¹ Patients should be encouraged to ingest 20 to 25 g of fiber daily by eating whole grain breads, unrefined cereals, plenty of fruit and vegetables, or

flax meal or bran. A careful meta-analysis demonstrated that, in 18 of 20 studies, stool weight was increased by adequate fiber supplementation, with fecal transit found to be accelerated.^{11,12} Dietary fiber appears to be less effective in severe constipation, particularly the slow-transit variant, in evacuation disorders (fiber may actually worsen these two types), or in constipation secondary to medications.¹³⁻¹⁵ In one study, women who engaged in regular physical exercise and had a higher fiber intake (approximately 20 g/day) had a three-fold lower prevalence of constipation compared with women who rarely exercised and consumed approximately 7 g of fiber a day.⁹ If ensuring proper intake of fiber is difficult, a commercially packaged fiber supplement may also be used (discussed later under Supplements).

Increasing fiber intake too quickly can cause abdominal bloating or flatulence. To optimize compliance, increase fiber gradually over at least 2 to 3 weeks to 20 to 25 g/day and ensure increased fluid intake to avoid these symptoms.

An example of a 20 g fiber breakfast: half cup bran (10 g) and three dried figs (10 g). Make palatable with one cup soy or almond milk (1 g fiber), one tablespoon brown sugar for taste, and one tablespoon of cinnamon (slows absorption of sugar).

TABLE 46.1

Rome II Criteria for Functional Constipation

Adults*

Two or more of the following six must be present:

- Straining during at least 25% of defecations
- Lumpy or hard stools in at least 25% of defecations
- Sensation of incomplete evacuation for at least 25% of defecations
- Sensation of anorectal obstruction/blockage for at least 25% of defecations
- Manual maneuvers to facilitate at least 25% of defecations (e.g., digital evacuation, support of the pelvic floor)
- Fewer than three defecations/wk

Infants and Children

- Pebble-like, hard stools for a majority of stools for at least 2 consecutive wk
- Firm stools up to twice/wk for at least 2 wk
- No evidence of structural, endocrine, or metabolic disease

* Loose stools are rarely present without the use of laxatives; criteria for irritable bowel syndrome are not fulfilled.

From Lembo A, Camilleri M. Chronic constipation. *N Engl J Med*. 2003;349:1360-1368.

TABLE 46.2

Medications Associated With Constipation

- Aluminum-containing antacids
- Diuretics
- Antidepressants
- Antihistamines
- Anticholinergics
- Nonsteroidal antiinflammatory agents
- Iron supplements
- Opioids
- Anticonvulsants
- Calcium channel blockers
- Beta-blockers

Examples of other high-fiber foods include 1 large apple or pear (5 g), ½ cup raspberries (9 g), 1 cup Raisin Bran (5 g), 2 Brazil nuts (2.5 g), 23 almonds (3.5 g), 1 cup peas (16 g), 1 cup black beans (15 g), 1 artichoke

(10 g), and 1 cup cooked broccoli (5 g).

In pediatric populations, decreased fiber intake has been found to be a risk factor for chronic constipation.¹⁶ One safe and effective dietary fiber recommendation for many children is the *age + 5 = daily grams of fiber* guideline.¹⁷ According to this guideline, the amount of dietary fiber recommended daily is the sum of the child's age in years plus five.

In pregnant women, fiber supplements in the form of bran and wheat fiber have been shown to increase bowel frequency, soften stool, and be better tolerated than stimulant laxatives.¹⁸

Food Triggers

A large body of evidence indicates that cow's milk and dairy products may be risk factors for chronic constipation in some children.¹⁹⁻²¹

Evidence supports a 4- to 6-week trial of elimination of dairy products as a component of the integrative treatment of childhood constipation.

Fluids

Although the generally accepted approach is to increase fluids both as a preventive measure and as treatment for constipation, supporting data are conflicting.²² One study reported that increasing fluids with an increased fiber intake (25 g/day) led to greater stool frequency and decreased laxative use compared with increased fiber alone.²³ To date, no studies in children have demonstrated the benefits of increasing fluid intake in states other than severe dehydration.²⁴ However, carbohydrates and particularly sorbitol, found in some juices such as prune, pear, and apple, can cause increased frequency and water content of stools.²⁵

Supplements

Commercially Packaged Fiber Supplements

Commercially packaged fiber supplements include psyllium, methylcellulose, and polycarbophil as bulking laxatives. More

information, including dosing, is available in [Table 46.3](#) and is provided later under Pharmaceuticals. Psyllium has demonstrated efficacy in increasing stool frequency and weight and improving stool consistency in idiopathic constipation.²⁶

The American College of Gastroenterology Chronic Constipation Task Force systematically reviewed available clinical evidence regarding the use of fiber supplements in chronic constipation and concluded that psyllium was the only fiber supplement with sufficient clinical evidence to support a recommendation for the treatment of chronic constipation.²⁷

One double-blind, multicenter study reported psyllium (5.1 g twice daily) as superior to docusate sodium (100 mg twice daily) for softening stools by increasing stool water content with greater overall laxative efficacy in subjects with chronic idiopathic constipation.^{27a}

Probiotics

Lactobacillus reuteri, administered at a dose of 108 colony-forming units to infants older than 6 months, has been shown to increase bowel frequency.²⁸ A high-grade systematic review concluded that the use of probiotics in adults and children augments the number of stools and reduces the number of hard stools.²⁹ These results were statistically significant but clinically only modest. The most thoroughly studied strains for the treatment of constipation are *Bifidobacterium* and *Lactobacillus* (most specifically *Lactobacillus casei Shirota*). A separate prospective trial reported the efficacy of *Lactobacillus* in improving chronic constipation in nursing home residents.³⁰ Probiotics may be useful in relieving constipation; however, the effect may depend on the probiotic dose, the bacterial strain used, and the population studied.¹² Further studies are required to determine specific recommendations regarding dosing and strain type (see [Chapter 105](#)).

TABLE 46.3

Agents for Treatment of Constipation in Adults

Type	Generic Name	Dosage	ACG Grade	Comments
Bulking Laxatives	Psyllium (Metamucil)	Titrate up to 50 g/day in divided doses	B	Taken from the ground seed husk of the psyllium plant; needs to be taken with plenty of water to avoid fecal obstruction; undergoes bacterial degradation that may contribute to side effects of bloating and flatus; allergic reactions, such as anaphylaxis and asthma, are rare but have been reported
	Methylcellulose (Citrucel)	Titrate up to 6 g/day in divided doses	B	Semi-synthetic cellulose fiber relatively resistant to colonic bacterial degradation; tends to cause less bloating and flatus than psyllium
	Polycarbophil (FiberCap)	Titrate up to 4 g/day in divided doses	B	Synthetic polymer of acrylic acid that is resistant to bacterial degradation
Osmotic Laxatives	Magnesium hydroxide (milk of magnesia)	34–60 mL/day	B	Small percentage actively absorbed in the small intestine; remainder draws water into the intestine along an osmotic gradient
	Polyethylene glycol (MiraLax)	17–34 g once to twice/day	A	Organic polymer that is poorly absorbed and not metabolized by colonic bacteria
	Lactulose	15–30 mL once to twice/day	A	Synthetic disaccharide consisting of galactose and fructose linked by a bond resistant to lactase (and, therefore, not absorbed by the small intestine); undergoes bacterial fermentation in the colon resulting in formation of short-chain fatty acids; bacteria in the colon can metabolize up to 50 g of lactulose each day; gas and bloating common side effects
Stimulant Laxatives	Sennosides (senna)	8.6–30 mg once to twice/day	B	Anthraquinones are converted by colonic bacteria to their active form, which increases electrolyte transport into the lumen and stimulates intestinal motility; may cause melanosis coli, a benign condition usually reversible within 12 months; no definitive association established between sennosides and colon cancer or myenteric nerve damage
	Bisacodyl (Dulcolax)	10–35 mg/day orally 10 mg rectal suppository/day	B	Hydrolyzed by osogastric enzymes; stimulates secretion and motility of the small intestine and colon
Stool Softeners	Docusate sodium	50–200 mg once to twice/day	B	ionic detergents that soften the stool by allowing water to interact more effectively with solid stool; may have modest effects on fluid absorption and secretion; efficacy in constipation not well established
	Docusate calcium	5–45 mL orally slightly	B	Acts on stool by being emulsified into the stool mass and providing lubrication for passage of the stool; long-term use may cause malabsorption of fat-soluble vitamins, and cramps, and liquid stools in patients predisposed to separation of lipids
	Docusate potassium	5–45 mL orally slightly	B	Acts on stool by being emulsified into the stool mass and providing lubrication for passage of the stool; long-term use may cause malabsorption of fat-soluble vitamins, and cramps, and liquid stools in patients predisposed to separation of lipids
Chloride Channel Activator	Lubiprostone	8 mg twice/day for IBS-C; 24 mg twice/day for chronic constipation	Not graded	Activates CIC-2 in the intestine and causes fluid secretion and possible secondary effects on motility; wastes common; side effects include dry mouth and dizziness

ACG, American College of Gastroenterology; *bid*, twice daily; *CIC-2*, type-2 chloride channel; *IBS-C*, irritable bowel syndrome with constipation; *PEG*, polyethylene glycol; *po*, by mouth; *qd*, every day; *qhs*, every night.

From Eoff JC III, Lembo A. Optimal treatment of chronic constipation in managed care: review and roundtable discussion. *J Manag Care Pharm*. 2008;14(suppl A):1-15.

Mind-Body Therapy

Behavioral Training in Childhood Constipation

Education for parents and children is an important component of treatment for functional constipation.^{30a} The child's fear of a painful bowel movement is the most common motivating factor for fecal retention.

In childhood constipation, clinicians should explain the physiological changes that occur as a consequence of chronic constipation, including a diminished ability to recognize the need to stool or that soiling has occurred.³¹ Explain that this condition is common and is multifactorial in origin for most children and stress the need to avoid demeaning or embarrassing the child.

Biofeedback

In an instrument-based training program, patients receive auditory or visual feedback, or both, to help train the pelvic floor and relax the anal sphincter while simulating defecation. Biofeedback also improves rectal sensation to assist in proper evacuation.¹⁰ Biofeedback is the preferred treatment for pelvic floor dysfunction, with a reported success rate of 70% to 81% and to be superior to standard treatment (laxatives, fiber, and education).³²⁻³⁴ Randomized controlled trials (RCTs) have demonstrated that five biofeedback sessions are more effective than continuous polyethylene glycol (PEG) administration for treating pelvic floor dysfunction, with the benefits lasting at least 2 years.³⁵

Although biofeedback is not an effective treatment for slow-transit constipation, it should be considered as the first-line treatment for pelvic floor dysfunction. To evaluate for this, do a rectal exam with one hand while placing the other hand on the patient's lower abdomen and have them bear down. The perineum should relax and descend downward. If it does not, suspect pelvic floor dysfunction and remember to screen for a history of sexual abuse.

Hypnotherapy

Substantial evidence supports the use of hypnotherapy in constipation-dependent irritable bowel syndrome, which has considerable overlap with functional constipation.³⁶ However, there is a lack of specific data on hypnotherapy as a treatment for functional constipation. Until more evidence is available, it may, at times, be reasonable to try hypnotherapy, particularly in patients who have difficulty relaxing the pelvic musculature.

Botanicals

Aloe

Dried latex (aloe latex) from the lining of the inner leaf has historically been used as a laxative. One double-blind RCT of an herbal preparation of aloe, psyllium, and celandin reported a statistically significant advantage of the herbal preparation over placebo.³⁷ Which part of the preparation was most responsible for the effect was unclear, however, and this preparation is not available in the United States.³⁷ The anthraquinones in aloe act as a stimulant laxative.

Dosage

A typical dose of aloe is 50 mg aloe extract taken at bedtime.

Precautions

It is aloe latex, but not aloe gel, that has a laxative effect.

Traditional Chinese Medicine

Although numerous RCTs have evaluated the efficacy of various components of traditional Chinese medicine in the treatment of constipation, high-level systematic reviews have concluded that methodologic flaws limit their interpretation.³⁸⁻⁴⁰ At least two RCTs have reported the efficacy of a particular formula (yun-chang capsules; also known as the *hemp seed pill*) in treating the functional type of chronic constipation.^{41,42} Further studies are required before the use of these components, including Chinese herbs, moxibustion, and auriculotherapy, can be recommended for the treatment of constipation.

Abdominal Massage

There is some evidence to suggest that abdominal massage may be a helpful technique in the treatment of constipation. One small 8-week RCT demonstrated an increase in bowel movement frequency, but no decrease in laxative use, with the use of abdominal massage.^{42a} The study investigators concluded that this approach may have utility as an adjunctive therapy to the treatment of constipation. However, abdominal massage is considered a long-term treatment due to its delayed effect, which may first be noted after several weeks.

Acupuncture

A large randomized controlled trial of 1075 patients with severe constipation from 15 Chinese hospitals showed that 28 sessions of acupuncture over 8 weeks improved bowel frequency. Surprisingly, the acupuncture had a larger effect after treatment was completed. At 8 weeks, there was an increase in bowel movements by 31.3% compared to sham acupuncture control. And this increased to 37.7% during the 12 weeks of follow up. This improvement following treatment is rarely seen with medications. Often symptoms return after the medication is stopped unless underlying mechanisms have been addressed.^{42b}

Perineal Self-Acupressure

Investigators recruited 100 patients with functional constipation according to the Rome III criteria from the community. All patients received educational materials outlining standard treatment approaches, including increased dietary fiber intake, the use of stool softeners, and increased exercise. The patients were randomly assigned (allocation concealment unknown) to no further instruction or to receive a 3- to 5-minute instruction on how to perform perineal massage along with a sex-specific handout. Upon feeling the urge to defecate, patients were instructed to press the perineum, pulsing for 3 to 5 seconds with the goal of breaking up the stool before defecation begins. Clinically relevant improvements in quality of life ($p < 0.001$) and a bowel function index ($p < 0.01$) were noted with perineal massage.^{42c} Although this is the only RCT of perineal massage reported to date, it provides encouraging support for an intervention that has no toxicity and possible benefit.

Pharmaceuticals

A wide array of laxatives is available to patients. Clinicians must understand how to counsel patients regarding the appropriate use, risks, and optimal dosing of these agents. Dosing and further information on all agents for adults are provided in [Table 46.3](#),^{42d} and similar information for children is provided in [Table 46.4](#).⁴³

TABLE 46.4

Agents for Treatment of Constipation in Children

Type of Medication	Selected Medication	Recommended Dosage for Maintenance Therapy
Bulk-forming laxative (OTC)	Methylcellulose (Citrucel) powder	Older than 6 yr: 1–1.5 g/day Older than 12 yr: 4–6 g/day
Dietary Fiber (OTC) supplement (or synthetic absorption)	Psyllium (Metamucil, Fybion, Senasa, FiberL, Konyak)	6–11 yr: 1–1 rounded teaspoon (a 8-oz liquid one to three times/day) Older than 12 yr: 1–2 rounded teaspoons or one to two packets or one to two wafers one to four times/day or five capsules up to three times/day taken with 8-oz liquid
Osmotic laxative (OTC)	Magnesium hydroxide (Milk of Magnesia [MOM], liquid, tablets)	Younger than 2 yr: 0.5 mL/kg/day 2–5 yr: 5–15 mL/kg or in divided doses one to two tablets before bedtime 6–12 yr: 15–30 mL/kg in divided doses or three to four tablets before bedtime Older than 12 yr: 30–60 mL/kg or in divided doses six to eight tablets before bedtime
	Magnesium citrate	Younger than 6 yr: 3–4 mL/kg/day 6–12 yr: 100–150 mL/kg Older than 12 yr: 150–300 mL/kg, in single or divided doses
	Magnesium citrate	Use only for bowel cleanse
Lubricant	Mineral oil (OTC)	5–11 yr: 5–20 mL every day or in divided doses Older than 12 yr: 15–45 mL/kg every day or in divided doses or 1–4 mL/kg/day
Fiber supplement (OTC), powder, chewable tablets, capsules	BeneFiber (partially hydrolyzed guar gum): two teaspoons = 3 g soluble fiber	7–11 yr: 5–1 tablespoon one to three times/day 12 yr-adult: 1–2 tablespoon one to three times/day
Stool softener (osmotic)	Docusone (Colace); liquid, capsules, gel cap (OTC)	Infants and children younger than 3 yr: 10–40 mg/kg in one to four divided doses 3–6 yr: 20–60 mg/kg in one to four divided doses 6–12 yr: 40–150 mg/kg in one to four divided doses Older than 12 yr: 50–400 mg/day in one to four divided doses
Stimulant	Senna (Senna, Senna-Cin, Senalan, Ex-Lax); granules, (crisp, tablets) (OTC)	1–5 yr: 5–10 mL/kg 5–15 yr: 10–20 mL/kg One tablet = 3 mL/granules = 5 mL/syrup
Osmotic enema	Phosphate enema (OTC)	Younger than 2 yr: not recommended 2–11 yr: 2.25-oz pediatric enema Older than 11 yr: 4.5-oz adult enema
Osmotic laxative	Miralax (polyethylene glycol); liquid	12 yr or older: 17 g cap to containing line on cap in 8 oz of water Older than 2–11 yr: 8.5 g (a 1/2 way to measuring line on cap) in 4 oz of water

Type of Medication	Selected Medication	Recommended Dosage for Maintenance Therapy
Stimulant laxative	Bisacodyl (Dulcolax): 5-mg tablet, 10-mg suppository	Older than 2 yr: one half to one suppository or one to three tablets per dose; no liquid form Adequate: four tablets each week
Miscellaneous	Glycerin suppository	Children: one infant suppository one to two times/day Children >6 yr: one adult suppository
	Glycerin enema; Enemas: Mini Enema (ingredients: docusone, polyethylene glycol, glycerin)	5–10 mL glycerin in 200 mL normal saline solution 5-mL tube: one enema/day
Osmotic laxative	Lactulose (Constolac, Cholac, Chronulac, Constic, Dephac, Dulcolac, Lactulose), crystals, syrup	Infants: 2.5–30 mL/day individual doses Children: 8.6–0.6 mL/kg/day three to four times/day or 40–60 mL/kg in divided doses or 1–2 mL/kg/day in divided doses (maximum, 3 oz/day) Adults: 15–30 mL/day (maximum, 60 mL/day)
	Sorbitol	1–5 mL/kg/day in divided doses, 70% solution

OTC, over the counter.

Bulk-Forming Laxatives

Bulk-forming laxatives work naturally to add bulk and water to stools to allow stools to pass more easily through the intestines. These laxatives are safe to take every day and include oat bran, psyllium (e.g., Metamucil), polycarbophil (e.g., FiberCon), and methylcellulose (e.g., Citrucel). Bulk-forming laxatives are most useful in patients with normal-transit constipation, with one study reporting that 80% of this subgroup had resolution of symptoms compared with 35% of patients in the other subgroups.¹³

Stimulant Laxatives

Stimulant laxatives work by stimulating intestinal motility and secretion of water into the bowel. Stimulant laxatives generally take 6 to 12 hours to take effect and may cause abdominal cramping and diarrhea.⁵ Products in this class include senna and bisacodyl. Given the poor quality of study design, a lack of placebo-controlled trials, and inconclusive results, the American College of Gastroenterology Chronic Constipation Task Force stated that data were insufficient to make a recommendation regarding the efficacy of stimulant laxatives for the management of chronic constipation, with available data indicated a minimal benefit with these products.⁴⁴ Stimulant laxatives may also cause melanosis coli, be habit forming, and have unknown long-term effects on the colon.

Osmotic Laxatives

Saline or osmotic laxatives are hyperosmolar agents that cause secretion of water into the intestinal lumen by osmotic activity. Some of the most commonly used osmotic laxatives are oral magnesium hydroxide (milk of magnesia), oral magnesium citrate, sodium biphosphate (Phospho-Soda), PEG, and lactulose.⁵

Data on the commonly used osmotic laxative, magnesium, are sparse.⁴⁵ Despite a lack of evidence, patients and physicians find magnesium helpful and use it routinely.⁴⁶

Use magnesium citrate, 150-mg capsules, to help with constipation. Start with two capsules at bedtime and two in the morning. If no stool occurs the next morning after 4 days, add one capsule (total of three daily) at bedtime. Add one capsule to the evening dose every 4 days until a soft stool is produced each morning. One of the first side effects of magnesium is diarrhea. This helps prevent toxicity from taking too much magnesium. Stop at eight capsules (total of six at bedtime and two in the morning). Use magnesium-containing laxatives cautiously in patients with congestive heart failure and chronic renal insufficiency because of the potential for electrolyte imbalances.

PEG is superior to lactulose in terms of stool frequency per week, form of stool, relief of abdominal pain, and the need for additional products, both in children and adults.⁴⁷ Evidence is sufficient to support PEG as a first-line laxative treatment in children, both in terms of efficacy and

palatability.⁴⁸

Stool Softeners

These agents, which include docusate sodium, act by lowering surface tension, thus allowing water to enter the bowel more readily. Although stool softeners are generally well tolerated, their efficacy remains in question.⁴⁹

Emollient Laxatives

Mineral oil, the most common example in this category, works by coating and softening the stool. Scant evidence supports the use of mineral oil, which also may lead to depletion of fat-soluble vitamins and increased the risk of aspiration in older adults and children.⁵⁰

Chloride Channel Activators

Lubiprostone and linaclotide are the first agents in this class to be approved by the Food and Drug Administration for the treatment of chronic constipation and constipation-dominant irritable bowel syndrome. These agents work through chloride channels to increase intestinal fluid secretion. Because nausea is the most common complaint, lubiprostone should be taken orally with food and should be avoided in pregnant women and children. Linaclotide is contraindicated in those <6 years old. The safety of lubiprostone has been demonstrated for up to 48 weeks of use.

Prevention Prescription

- Eat high amounts of fiber-rich foods, including beans, vegetables, fruits, whole grain cereals, and bran.
- Minimize high-fat, low-fiber foods, such as processed foods, dairy products, and meat products.
- Drink an adequate amount of fluid each day to stay hydrated, and increase the amount of water if using higher doses of fiber.
- Engage in regular physical activity to avoid constipation.
- Adopt a good self-care and stress management program to avoid the impact of stress on gut function.
- Stay tuned to the body's natural signals to pass stool.

- Take advantage of the gastrocolic reflex and allow elimination to occur after meals.
- In young children, ensure adequate fiber as they transition to solid foods.

Therapeutic Review

In this summary of therapeutic options for the treatment of constipation, the interventions are presented in a ladder approach from the least to the most invasive options. Although patients with more moderate to severe constipation may travel up the ladder more quickly, the initial approaches are critical for all patients.

Adults

Removal of Exacerbating Factors

- Review the patient's medication list and eliminate any medications that may be causing or exacerbating the condition.

Behavioral Training

- If patients experience difficulty in expulsion of stool, they should be advised to place a support approximately 6 inches in height under their feet when they are sitting on a toilet seat, to flex the hips toward a squatting posture.

Nutrition

- Include a gradually increasing amount of fiber in the diet up to 20 to 25 g a day through fruits, vegetables, whole grain breads and unrefined cereals, flax, or bran.  A 1
- Encourage increased fluid intake, particularly with the introduction of increased fiber in the diet.  C 1

Movement

- Encourage regular physical activity.  B 1

Perineal Self-Massage

- Dr. Abbott (UCLA) explains the technique in a short video. See below

under [“Key Web Resources”](#). 

Supplements

- Consider adding a commercially packaged fiber supplement, such as psyllium (Metamucil) or methylcellulose (Citrucel). Be sure to take supplements with at least 8 to 12 oz of liquid. Using less fluid can worsen constipation (see [Table 46.3](#)). 
- Consider a probiotic strain of *Bifidobacterium* or *Lactobacillus* of at least 10^8 colony-forming units. 

Mind-Body Therapy

- Address stress management skills. 

Biofeedback

- In cases of pelvic floor dysfunction, this is a critical component of therapy. 

Pharmaceuticals

- If the foregoing interventions do not resolve symptoms, consider osmotic laxatives with polyethylene glycol (17 to 34 g once or twice daily) as first-line therapy. 
- For severe cases, a prescription chloride channel activator (lubiprostone, 8 to 24 mcg twice daily for adults; linaclotide, 145 mcg daily 30 minutes before breakfast for adults) may be necessary. 

Children

Behavioral Training

- Encourage daily sitting on the toilet, preferably after meals, and avoid embarrassing or punishing the child. Using a stool under the feet can also be used for children during toilet training.

Removal of Exacerbating Factors

- Consider a 4- to 6-week trial of a diet eliminating dairy products. 

Nutrition

- Ensure an adequate amount of fiber in the diet. Use the age + 5 = daily grams of fiber rule as a general guideline for dosing. 
- Increase fluid intake and, in particular, the amount of sorbitol-containing fruit juices (e.g., apple, pear) for osmotic effect. 

Movement

- Encourage regular physical activity. 

Supplements

- Consider adding a commercially-packaged fiber supplement if necessary. 
- Consider a probiotic strain of *Bifidobacterium* or *Lactobacillus* of at least 10⁸ colony-forming units. 

Pharmaceuticals

- If these interventions do not resolve symptoms, consider osmotic laxatives with polyethylene glycol (half to four teaspoons a day, depending on age) as first-line medical treatment (see [Table 46.4](#)). 

Therapies to Consider (or Emerging Therapies)

Fecal transplant therapy: Interest is growing rapidly worldwide regarding the use of fecal microbiota transplantation (FMT) as a “natural” therapy from both patients’ and physicians’ perspectives. FMT is popular among some patients because it is not associated with the adverse effects of regular medicinal therapy. Although evidence related to chronic constipation is limited to just one trial (n = 3) where chronic constipation was reversed in all patients, [51](#) it is a therapy to consider in the most refractory patients potentially before extensive surgery.

[Chapter 50. Inflammatory Bowel Disease](#)

CHAPTER 47

Fibromyalgia

Nancy J. Selfridge, MD

Pathophysiology

Fibromyalgia (FM) is a common cause of widespread pain, occurring in 2%–8% of the general population worldwide. Diagnostic criteria have been through modifications since the American College of Rheumatology (ACR) 1990 criteria were published. Wolfe (2010 and 2011) and Bennett (2013) have devised modified and alternative criteria, respectively, primarily for clinical and epidemiological research.^{1,2} Widespread pain of at least a 3-month duration remains a hallmark of the syndrome; however, both sets of criteria can be assessed by patient survey, and both eliminate the tender point count of the 1990 ACR criteria, which was challenging for clinicians to assess reliably. Both tools have high sensitivity and specificity, using the 1990 ACR criteria as the “gold standard.” More men meet diagnostic criteria with these newer tools compared to the 1990 ACR criteria.³ Bennett stresses that diagnostic criteria alone are insufficient for making an accurate diagnosis of FM.² Patients benefit from careful evaluation with a thorough medical history and physical examination, which also help establish the foundations of relationship-centered care. FM can coexist with and imitate various autoimmune diseases, hypothyroidism, and some chronic infections such as Lyme disease and hepatitis C. The identification of such disorders as the cause of pain is important to avoid treating these conditions as FM. For coexisting conditions, it is challenging but necessary to determine the contribution of FM to symptoms in order to avoid treating FM with escalating doses of immunosuppressive or disease modifying medications. Laboratory evaluation is guided by the history and physical examination and the evolving differential diagnosis. An exhaustive laboratory and imaging workup is seldom indicated.

Widespread pain for at least 3 months without an identifiable cause is the main diagnostic finding in fibromyalgia.

Central pain sensitization is now considered the primary pathology in FM and is supported by extensive translational neuroimaging research. Functional connectivity on MRI between areas of the brain involved in pain processing and interpretation (dorsolateral prefrontal cortex, anterior cingulate, amygdala, hippocampus, insula, and others) differs in FM patients compared to healthy controls, possibly mediated by altered glutamate and gamma-aminobutyric acid (GABA) levels, which will, in turn, affect other neurotransmitter levels.⁴⁻⁷ When an intervention appears to help reduce pain parameters, functional connectivity appears to normalize.^{4,6} Some evidence indicates that familial predisposition and gene polymorphisms may play a role in FM.⁸⁻¹⁰ Careful history taking often reveals a significant stressful trigger event or period, such as an accident, a flu-like illness, emotional stress, or overwork, preceding the onset of symptoms.³ The discovery of observable central nervous system (CNS) abnormalities in FM patients stimulates curiosity about the varied ways that the physiology of the stress response might change a brain to manifest as chronic pain and physical symptoms, given certain predisposing variables.

Autonomic dysfunction is present in patients with FM, a likely cause of a variety of symptoms that are occasionally reported as more problematic than pain.⁸ Increased sympathetic activity is correlated with increased pain intensity, explaining worsening of symptoms with stress.¹¹ Several neuroendocrine and immune function alterations have been well documented in FM.¹²⁻¹⁸ Although these immunological changes in FM do not meet criteria for immunodeficiency or autoimmune disease, they likely contribute to symptoms.

Research has shown that a subset of patients (approximately 20%) may have biopsy evidence of small fiber peripheral neuropathy.^{19,20} It is not yet currently recommended that patients undergo biopsy to detect this problem; however, clinicians should be on the alert for evolving clinical recommendations and guidelines.

Although the precise etiological and pathophysiological roles of the foregoing alterations in neurophysiological, immune, and neuroendocrine functions are unknown, their existence helps dispel any notion that FM is a purely psychosocial disorder. A list of pathological findings in FM patients from recent research is shown in [Fig. 47.1](#).

A sensitive temperament, characterized by high levels of empathy, and

a higher than normal sensitivity to environmental factors and emotional cues from others, appears to be a premorbid condition for many patients.^{21,22} In addition, FM patients have been shown to demonstrate alexithymia more than healthy controls, with difficulties both in identifying and describing feelings. Further, the degree of alexithymia is correlated with increased pain experience.^{23,24} The tension of experiencing stressful triggers and the consequence of living in a society that expects high productivity at the expense of self-care, superimposed on a natural sensitivity and inability to express feelings, may predispose the CNS of FM patients to abnormal sensory processing. High body mass index and reduced physical activity have also been found to be independent risk factors for FM.^{25,26}

- **Neurophysiological**
 - Reduced levels of hippocampal n-acetyl aspartate
 - Elevated levels of glutamate:
 - posterior insula
 - amygdala
 - posterior cingulate
 - ventral lateral prefrontal cortex
 - Reduced levels of GABA
 - Anterior insula
 - Altered functional connectivity between
 - Insula
 - DMN€
 - EAN§
 - Reduced resting connectivity within somatosensory cortex
 - Increased functional connectivity between
 - Somatosensory cortex
 - DMN€
 - Small fiber neuropathy (20%)
- **Neuroendocrine**
 - Elevated CSF substance P
 - Impaired growth hormone secretion in response to exercise
 - Excessive sympathetic autonomic tone
 - Reduced IGF-1 levels
- **Immunologic**
 - Elevated CFS Interleukin-8
 - Altered lymphocyte corticosteroid receptors
 - Decreased T cell activation marker expression

FIG. 47.1 Examples of pathological findings of recent translational research on fibromyalgia.^{3-8,12-20} €DMN (Default Mode Network) consists of the posterior cingulate, precuneus, medial prefrontal cortex, hippocampal formation, and lateral temporal cortex; it is believed to be engaged in self-referential cognition.³ §EAN (Executive Attention Network) consists of the dorsolateral prefrontal and posterior parietal cortices and is engaged in executive control over behavior.³

Despite the fact that the precise mechanism of the disorder remains obscure and is likely quite complex, great hope is contained in the fact that patients with FM can and do respond to a variety of nonpharmacological interventions. This fact may be a testament to the plasticity of the nervous system and its ability to change even in adults, although we cannot yet evoke reliable changes at will with any given intervention.

Integrative Therapy

General Considerations

Patients with FM are often viewed as difficult or burdensome in busy practices. Patients with other “algo-dysfunctional” syndromes (e.g., chronic chest wall pain, chronic abdominal pain of undetermined origin, irritable bowel syndrome, interstitial cystitis, chronic pelvic pain, dyspareunia, and vulvodynia) present similar challenges: symptoms that are not correlated with physical findings, poorly understood pathophysiology, significant impact on quality of life, and limited response to simple pharmaceutical interventions. Keeping abreast of translational research in FM is onerous in a busy, diverse medical practice. Consequently, well-meaning physicians often communicate invalidating messages to patients both verbally and nonverbally. This is a cognitive and clinical error on the part of the physician. First, evidence of altered neurophysiology and immune function in FM is strong. Second, research indicates that patients experience such invalidation as harmful; invalidation by and mistrust in the physician are correlated with lower quality of life among FM patients.²⁷ Providing generous listening and affirming the patient’s experiences of what often appear to be bizarre or exaggerated symptoms are important because most treatment interventions for FM have demonstrated limited efficacy. Patients experience affirmation as therapeutic, and it is something that all

clinicians can provide (see [Chapter 3](#)).

Citing current research that points to a change in the way that the brain processes sensory information, and explaining that FM is a disorder of central nervous system pain sensitization and augmentation associated with neuroendocrine and immune system abnormalities, can help patients move past unreasonable worry and concerns about misdiagnosis.

Promoting the concept that patients can leverage neuroplasticity by trying various integrative interventions and changes in behavior and thinking fosters self-efficacy and seems to support the fact that nonpharmacological therapies have better evidence of efficacy compared with that of medications.²⁸ Active listening to a patient, demonstrating empathy, and eliciting his/her perspectives may help favorably alter the physiology of the stress response and thus help reduce autonomic dysfunction, pain sensitivity, and other symptoms.²⁹

Nutrition

No specific diet has been shown to be effective for FM. However, obesity and being overweight contribute to lower quality of life scores.³⁰ Motivational interviewing techniques (see [Chapter 101](#)) are recommended to move overweight patients toward weight reduction. An increase in dietary antioxidant intake may be beneficial based on evidence of increased oxidative stress and reduced antioxidant enzyme activities in FM patients, although no specific supplements are currently supported by research.³⁰ An antiinflammatory diet, with increased consumption of whole plant based foods and avoidance of processed foods, may be helpful (see [Chapter 88](#)) and likely benefits patients' health in a more general way. Removal of excitotoxins such as MSG and aspartame from the diet may be rational in light of the CNS abnormalities in glutamate and GABA distribution and function observed in FM patients, though research support is mixed.³⁰ Strict avoidance of trans fats (partially hydrogenated oils, margarine, and shortening) and increased consumption of foods rich in omega-3 fatty acids, calcium, and antioxidants are strongly encouraged and address some of the common deficiencies in the standard U.S. diet.

Exercise

Poor physical fitness is associated with increased symptom severity in FM patients.²⁶ A 2014 systematic review concluded that diverse forms of exercise have a beneficial effect on physical function and help decrease some of the symptoms of FM.³¹ Adherence and attrition have been problematic in many research studies on exercise in FM. Postexercise fatigue and pain and tenderness are frequently severe and can lead to a cycle of muscle disuse.^{31,32} Thus, although exercise prescriptions are prudent for all patients with FM, clinicians must think flexibly about exercise and be willing to revise recommendations based on individual patient preferences and experiences. Aquatic exercise appears to provide as much symptom benefit and only slightly less improvement in muscle strength than land-based exercise.³³ Eastern movement practices (tai chi, yoga, qigong) have demonstrated some promise in improving FM symptoms in research; some patients find these forms of body movement easier and more acceptable than conventional exercise.³⁴⁻³⁶ Walking exercise can similarly be endorsed as helpful.³⁷

Even though activation of the patient through exercise is a most desirable treatment goal, many patients demonstrate resistance. Efforts should be aimed at helping patients both initiate and adhere to an exercise routine. Again, motivational interviewing techniques can be particularly effective in moving resistant patients toward a regular exercise habit. It can be useful to explore our patient's frame by asking, sometimes repeatedly over a long relationship, "What are you finding hard about starting or sticking with an exercise program?" Severe postexercise pain is often cited, but many patients are similar to our usual primary care patients in that they have never embraced an active, exercise-oriented lifestyle. Exploring the patient's present position in the stage of change continuum (precontemplation, contemplation, preparation, action, and maintenance) and focusing on moving to the next stage can help mitigate clinician frustration when patients find it hard to adhere to treatment plans. Current data supports such a broad range of exercise modalities that finding any kind of movement that patients can enjoy regularly and perceive as pleasurable is intuitively the key to success. Even a cumulative daily 30 minutes of self-selected lifestyle physical activity can provide improvement in FM symptoms³⁸ (see [Chapter 91](#)).

Evidence suggests that Eastern movement practices, such as tai chi, yoga, and qigong, which include meditative components, may reduce pain and improve function in patients with fibromyalgia.

Bodywork

A variety of bodywork interventions and massage seem to positively affect health-related quality of life for fibromyalgia patients, although pain and other symptoms are not a reliably improved.³⁹ Though the quality and quantity of evidence is still low, massage and body work interventions are low risk and accessible. Patients can be encouraged to try various modalities if they are so inclined.

Mind-Body Therapy

Meditation

Meditation has been reported to be helpful for a variety of FM symptoms.⁴⁰ Results from a recent experimental trial with a wait list control group and a randomized prospective trial supported the practice of mediation.^{41,42} Unfortunately, studies are plagued by poor design and methodological flaws. Some of the studies documenting FM symptom improvement with Eastern movement therapies include a strong meditation component, which may substantially contribute to the efficacy of this type of exercise.³⁴⁻³⁶ Meditation training increases body awareness and the ability to be comfortable in the present moment and thus can lessen fear of future pain and, with practice, help transform the sensation of pain. Meditation may have additional, as yet undetermined benefits by favorably altering neurophysiology in patients with FM. Meditation is also useful for personal growth, is quite safe, and is accessible in many communities and through online support (see [Chapter 100](#)).

Psychotherapeutic and Mind-Body Interventions

Cognitive behavioral therapy (CBT) appears to be somewhat better than pharmacotherapy at improving quality of life and other symptoms in FM patients and is more cost effective.^{43,44} Internet-based CBT is reportedly effective for several symptoms, a great advantage in increasing accessibility to this type of intervention.⁴⁵ Electromyographic

biofeedback, electroencephalographic biofeedback, and hypnotherapy have demonstrated benefit in controlled studies.⁴⁶⁻⁴⁸ Guided imagery may also be helpful⁴⁹ (see [Chapter 97](#)).

A randomized controlled study of an Affective Self-Awareness program involving a group intervention of emotional exploration through journaling and meditation demonstrated significant benefit for symptoms and perceived function in patients with FM⁵⁰ (see [Chapter 102](#)). Anecdotal evidence also supports increasing emotional awareness as a way to mitigate chronic pain.^{51,52} Known neurobiological associations between pain and emotion illuminate potential targets for mind-body interventions.⁵³ Although more research is needed on mind-body interventions, these generally low-risk and low-harm interventions should be part of every treatment plan for patients with FM because of their potential to alter the neurobiological associations between pain and emotion in ways that improve symptoms. When patients are either not receptive to these interventions, or when patients experience increasing disability, it may be helpful for the clinician to explore the following “four Rs” with the patient and encourage self-reflection in journaling if possible⁵⁴:

- **Roles:** The patient’s ability to maintain self-esteem through normal roles as spouse, parent, provider, and so on may be impaired. The work role requires careful evaluation and is often problematic for people who are becoming progressively more symptomatic and disabled. Focus on a simple question as a way of exploring where problems may exist: “In all your roles, are you living for your heart’s desires?”
- **Reactions:** Emotional reactions to events, such as the diagnosis of FM or events that trigger FM, often follow a grieving process.⁵⁵ Patients are often stuck in anger and depression and yet may not recognize or be able to easily express their distress.
- **Relationships:** The patient may often face seemingly insurmountable problems at home or in relationships at work that create repeated stress triggers for symptoms.
- **Resources:** Psychotherapy, ministers, community programs, self-help groups, and other sources of support and connection may help alter progressive decrease in ability to function. Isolation and alienation clearly make patients symptomatically worse.

Acupuncture

There is low to moderate level evidence that acupuncture and acupoint

stimulation temporarily help with some FM symptoms compared to standard treatment or no treatment.^{56,57} Electroacupuncture appears to be better than manual acupuncture for most FM symptoms. Studies have been handicapped by small sample sizes and methodological flaws; however, acupuncture has been shown to be safe and well tolerated, and it can be endorsed for patients who wish to try it.

Homeopathy

A 2015 review of complementary and alternative medicine (CAM) therapies for FM summarized three small randomized controlled studies on homeopathic treatments for FM.⁵⁸ In these studies, *Rhus toxicodendron*, *Arnica montana*, *Bryonia alba*, and individualized homeopathic remedies were all superior to placebo in treating several symptoms. Though evidence is limited and mechanisms of action remain obscure, homeopathy is considered safe. Patients should be referred to a homeopathic physician for optimum evaluation and treatment with the understanding that homeopathic remedies may not work well in the presence of certain pharmaceuticals (see [Chapter 115](#)).

Supplements

Low evidence of efficacy exists for supplements and natural medicines in the treatment of FM. Further, the use of some common supplements, such as calcium, selenium, and vitamin E, has come under scrutiny as possibly unsafe. Herbal and natural medicines potentially interact with one another and with prescription medications. Thus, a good peer-reviewed and frequently updated database (e.g., Natural Medicines Comprehensive Database; see [Key Web Resources](#)) should be used by integrative clinicians to assess available evidence regarding efficacy and harm before recommending supplements and natural medicine therapy. Currently, no natural medicines or supplements have sufficient evidence of efficacy specifically for FM symptoms to strongly recommend them for patients. However, some supplements may be beneficial in select patients for select symptoms based on known or proposed mechanisms of action and evidence of efficacy for other conditions.

Omega-3 Fatty Acids

Use of omega-3 fatty acid supplementation in the form of pharmaceutical grade fish oil, 2–4 g daily in a single dose, may have a modest pain-

modulating effect for some patients and may help treat depression in some patients. In general, supplementation with omega-3 fatty acids may also lower cardiovascular risk and help to balance the predominance of proinflammatory omega-6 fatty acids in the typical U.S. diet.

Dosage

The recommended dose is 2000 to 4000 mg once daily.

Precautions

Omega-3 fatty acids inhibit platelet function and should be discontinued 2 weeks before elective surgical procedures. Use with caution in patients receiving anticoagulant therapy. Choose a pharmaceutical grade product to avoid heavy metal contamination.

Vitamin D

Low vitamin D levels appear to be epidemic at northern latitudes. Although the link between low vitamin D and the pain of FM remains unclear, evidence indicates that low vitamin D levels can be associated with widespread pain.⁵⁹ Because of this association, it is not unreasonable to check 25-(OH) vitamin D levels in FM patients at risk for vitamin D insufficiency and supplement with vitamin D to maintain optimal blood levels (40–100 ng/mL) year round. As a general rule, 1000 units of vitamin D₃ (cholecalciferol) will raise serum 25-(OH) vitamin D levels in adults approximately 10 ng/mL. Although overdosing is unlikely, clinicians recommending vitamin D should be aware that vitamin D levels may be higher in patients in the summer if they have sufficient skin exposure to sunlight.

Dosage

Cholecalciferol (vitamin D₃) oral supplements in capsule or liquid form can be taken to attain a year round 25-(OH) vitamin D level of 40–100 ng/mL. Seasonal dosage adjustments may be necessary.

Precautions

Vitamin D is not to be used in patients who have primary

hyperparathyroidism or granulomatous disease, such as sarcoidosis, because of the increased risk of hypercalcemia.

Magnesium

Magnesium may be helpful for some patients with FM, possibly through its muscle-relaxing properties, and it is quite safe.

Dosage

The recommended dose is 400–750 mg once daily.

Precautions

At higher doses, magnesium may cause abdominal cramping and increased frequency of stools, helping patients recognize when they are taking too much.

S-Adenosylmethionine

S-adenosylmethionine (SAME) was demonstrated to be safe and effective in alleviating depression when administered to patients who failed to respond adequately to monotherapy with a selective serotonin reuptake inhibitor (SSRI).⁶⁰ Although SAME may have only a modest effect on other FM symptoms, this supplement can be helpful in patients to treat coexisting depressive symptoms.⁶¹

Dosage

The recommended dose is 400–800 mg twice daily.

Precautions

SAMe can act as a stimulant and should not be taken close to bedtime because it can cause insomnia. It is expensive.

Botanicals

No adequate controlled trials of botanical treatments have been conducted. In anecdotal reports, many treatments lead to a benefit that

wanes with time, a finding that may indicate a short-term placebo effect. Individual patients may benefit from trials of botanicals purported to be helpful for common symptoms of FM, such as low energy, insomnia, and depressed mood.

Turmeric and Ginger

The use of turmeric and ginger in cooking at culinary doses may provide benefit for some patients due to pain-modulating and antiinflammatory properties. At these doses, these spices are likely safe and can be encouraged. When these agents are used at supplement doses, potential side effects and interactions must be considered.

Dosage

Ginger may be taken as dried root, starting at 1 g total per day, divided into two or three doses, increasing to up to 4 g daily; or as tea, 1 g of dried root steeped in 150 mL of boiling water for 5 to 10 minutes and strained, one cup up to four times daily.

Turmeric may be taken as powdered root, 0.5–1 g two or three times daily.

Precautions

Because turmeric and ginger have platelet-inhibiting activities, they must be used with caution in patients taking anticoagulant therapy and should be discontinued 2 weeks before elective surgical procedures. Both cause gallbladder contraction and may be problematic in patients with gallstones. Ginger may lower blood glucose levels.

Boswellia

Boswellia is an ayurvedic herb that has some documented antiinflammatory and analgesic effects.

Dosage

The recommended dose is 500 mg of standardized product three times daily.

Precautions

Platelet inhibition and increased bleeding risk are possible with this plant substance. Discontinue 2 weeks before elective surgical procedures.

St. John's Wort

For patients who need treatment for depression and do not wish to use prescription pharmaceuticals, St. John's wort may be helpful.

Dosage

The recommended dose is 300 mg up to three times daily of a 0.3% hypericin standardized extract or as tea, steep 2–4 g of the dried herb in 150 mL of boiling water for 5 to 10 minutes and strain, one cup up to three times daily.

Precautions

Multiple potential interactions with other drugs occur through stimulation of the cytochrome P-450 enzymes of the liver. The result is lower serum levels of drugs that are cleared by this mechanism.

Pharmaceuticals

Medications can be helpful for FM, although improvement in symptoms is seldom dramatic. In recent reviews, 50% of patients will experience a 30% improvement in symptoms and 30% of patients will experience a 50% improvement, only slightly better than placebo.⁶² Side effects are common and interfere with adherence.

Antidepressants

Treating comorbid depression in patients with FM is in their best interest as depression worsens FM symptom severity and prognosis.^{63,64} Further, antidepressants can help improve sleep and have modulating effects on pain through norepinephrine and serotonin pathways. Tricyclic antidepressants (TCAs) have been the gold standard of treatment and remain inexpensive and widely available; although they are not FDA

approved for FM, amitriptyline is approved for chronic neuropathic pain and has been widely used for FM. Side effects are often prohibitive at higher antidepressant doses. Research on selective serotonin reuptake inhibitors (SSRIs) for the pain of FM has yielded mixed results.⁶⁵ The newer dual serotonin and norepinephrine reuptake inhibitors (SNRIs), duloxetine and milnacipran, have compared quite favorably with amitriptyline for the treatment of depression and are FDA approved for FM treatment. These two drugs have been better than placebo for mitigating FM pain and improving function; however, the effect size for these improvements is small, and the clinical significance remains questionable when weighed against common side effects.⁶² Clinicians must monitor patients closely and balance improvements in FM symptoms against adverse effects that often interfere with quality of life and functioning. Trazodone may help with sleep and measures of quality of life with a tolerable side effect profile. When combined with pregabalin, trazodone may be helpful in reducing pain as well.^{66,67} Although cyclobenzaprine is not an antidepressant, it is closely related to the TCAs, and reviews have supported its use in FM.^{62,68}

The clinician should develop a familiarity with several different antidepressants to feel comfortable managing the myriad of possible side effects and potential drug–drug and drug–botanical interactions. For example, patients sometimes add St. John’s wort to their prescribed regimens. Serotonin syndrome is a distinct risk when this natural medicine is taken with SSRIs or with SNRIs. Be sure to ask specifically about the use of St. John’s wort in patients who are taking these prescription antidepressants.

Tricyclics

Dosage

The recommended dose of amitriptyline is 5–10 mg at bedtime initially, titrating upward as needed.

Precautions

Excessive sedation, anticholinergic effects, and hypotension may occur.

Selective Serotonin Reuptake Inhibitors

Dosage

Fluoxetine is started at 5–20 mg daily and titrated upward as needed. Citalopram is started at 20 mg daily and may be titrated up to 40 mg daily. Escitalopram is started at 10 mg per day and may be titrated up to 20 mg daily.

SSRI Precautions

Activation or sedation, induction of mania, hot flushes and sweating, weight gain, sexual dysfunction, and multiple potential drug interactions are possible.

Serotonin and Norepinephrine Reuptake Inhibitors

Dosage

Duloxetine is started at 30 mg once daily for 1 week then increased to 60 mg daily. Milnacipran is started at 12.5 mg once daily on the first day, and increased by 12.5 to 25 mg daily for the first week until 50 mg twice daily dosing attained. A dose of 100 mg twice daily may ultimately be necessary for symptom relief.

Precautions

Precautions are potentially the same as for TCAs and SSRIs.

Trazodone

Dosage

Initiate therapy with 25–50 mg nightly, titrating upward to 300 mg or until the patient reports good sleep and no excess morning grogginess.

Precautions

Oversedation, orthostatic hypotension, morning grogginess, and vivid dreams may occur.

Cyclobenzaprine

Dosage

Start with 2.5–10 mg at bedtime and titrate up to 40 daily, in divided doses.

Precautions

Excessive sedation and an increase in “mental fogging” may occur.

Nonsteroidal Antiinflammatory Drugs

Nonsteroidal antiinflammatory drugs (NSAIDs) continue to be widely used despite evidence that chronic use is associated with health risks. Because of the limited evidence of efficacy and the potential for adverse effects, particularly with long-term use, it is wise to discourage NSAID use for FM and encourage other pain management strategies.

Anticonvulsants

Gabapentin has been used off-label for FM because of its indication for use in chronic neuropathic pain. This agent appears to be safe and efficacious for FM.⁶⁹ A similar pharmaceutical, pregabalin, appears to be effective compared with other newer FM drugs and is FDA approved.⁶² Both drugs often cause somnolence and dizziness. Significant weight gain with pregabalin is not uncommon and can interfere with adherence. Because significant weight gain can also increase the risk of other chronic diseases, such as hypertension, insulin resistance, and type 2 diabetes, this side effect cannot be considered trivial.

Dosage

Gabapentin is started at 300 mg once daily and increased by one tablet to twice per day, then three times per day as tolerated. The maximum dose is 3600 mg daily, although no therapeutic advantage has been shown for neuropathic pain in clinical trials for doses greater than 1800 mg daily. Pregabalin is started at 75 mg twice daily and may be titrated up to a maintenance dose of 450 mg daily, in two divided doses.

Precautions

Gabapentin may cause sedation, dizziness, cognitive impairment, and leukopenia, whereas pregabalin may cause sedation, dizziness, weight gain, and thrombocytopenia.

Analgesics

Tramadol

Tramadol is the only opioid that has been shown to have evidence of efficacy in FM.⁷⁰ It is a weak μ opioid receptor agonist and also inhibits reuptake of serotonin and norepinephrine. Although studies are limited, tramadol appears to improve pain and quality of life.⁶² Because of its mechanism of action, the use of tramadol with antidepressants or St. John's wort potentially causes serotonin syndrome. Tramadol can also cause excessive sedation, and abuse and addiction potential are real. Thus tramadol may be most useful as intermittent therapy for pain exacerbations, avoiding chronic use and dose escalation.^Z

Dosage

The recommended dose is 50–400 mg daily in divided doses.

Precautions

Sedation, habituation, and serotonin syndrome may occur when prescribed in combination with antidepressants or St. John's wort.

Opioids can induce hyperalgesia, a side effect that FM patients may be more susceptible to because of their baseline centralized pain sensitization. Opioids are not recommended for the treatment of FM.

Cannabinoids

A 2011 systematic review of research on cannabinoids for chronic noncancer pain reported that these drugs may be helpful both for pain and for improving sleep.⁷¹ Two small studies of nabilone have yielded positive outcomes for FM; however, side effects were common. These

drugs are not presently approved by the FDA for FM and carry some toxicity potential when they are abused. A cross-sectional survey of FM patients using cannabis compared to nonuser control patients reported some improvement in pain and psychological state, though not in quality of life measures.⁷² Patients may ask about the efficacy of cannabis and cannabinoids given the increasing number of states legalizing cannabis for medical and recreational use.

Other Therapies to Consider

Recent reviews of spa therapy and balneotherapy (bathing in hot mineral springs) suggest that these treatments are helpful for multiple symptoms and can have long-lasting effects.^{73,74} Patients with access to hot mineral springs and spas can be encouraged to try this modality. Repetitive transcranial magnetic stimulation (rTMS) appears to be promising for improving pain and quality of life for many types of chronic pain, though more research is needed to determine precise protocols for maximum efficacy in treating FM.^{75,76} It is expensive (\$6,000 to \$10,000 for a 4-week course of treatment). Traditional Chinese medicine (TCM) may be helpful for FM, though studies are limited by sample size and methodological flaws.⁷⁷ We can encourage and educate patients drawn to explore alternative healing traditions (e.g., TCM, Ayurveda, or shamanism) in a shared decision-making process. Patients may then choose to visit practitioners of the selected therapies to explore the approaches further. If the economic burden is not too great, the addition of this therapeutic modality may be in order.

Another area of potential benefit for patients with FM is emerging from the growing field of energy psychology and energy medicine (see [Chapters 103](#) and [116](#)). Though more research is needed to assess efficacy and to determine mechanism of action, these interventions are safe, and some of them can be learned by the patient and practiced at home.

Summary

Mainstays of a treatment plan for fibromyalgia include an exercise prescription, weight reduction when needed, mind-body types of interventions, treatment of comorbid depression and sleep problems, and judicious trials of other complementary and alternative medicine modalities and conventional pharmaceuticals. However, *every* treatment plan should be individualized and flexible. [Fig. 47.2](#) illustrates a rational

approach to an individualized integrative treatment plan for patients newly diagnosed with fibromyalgia.

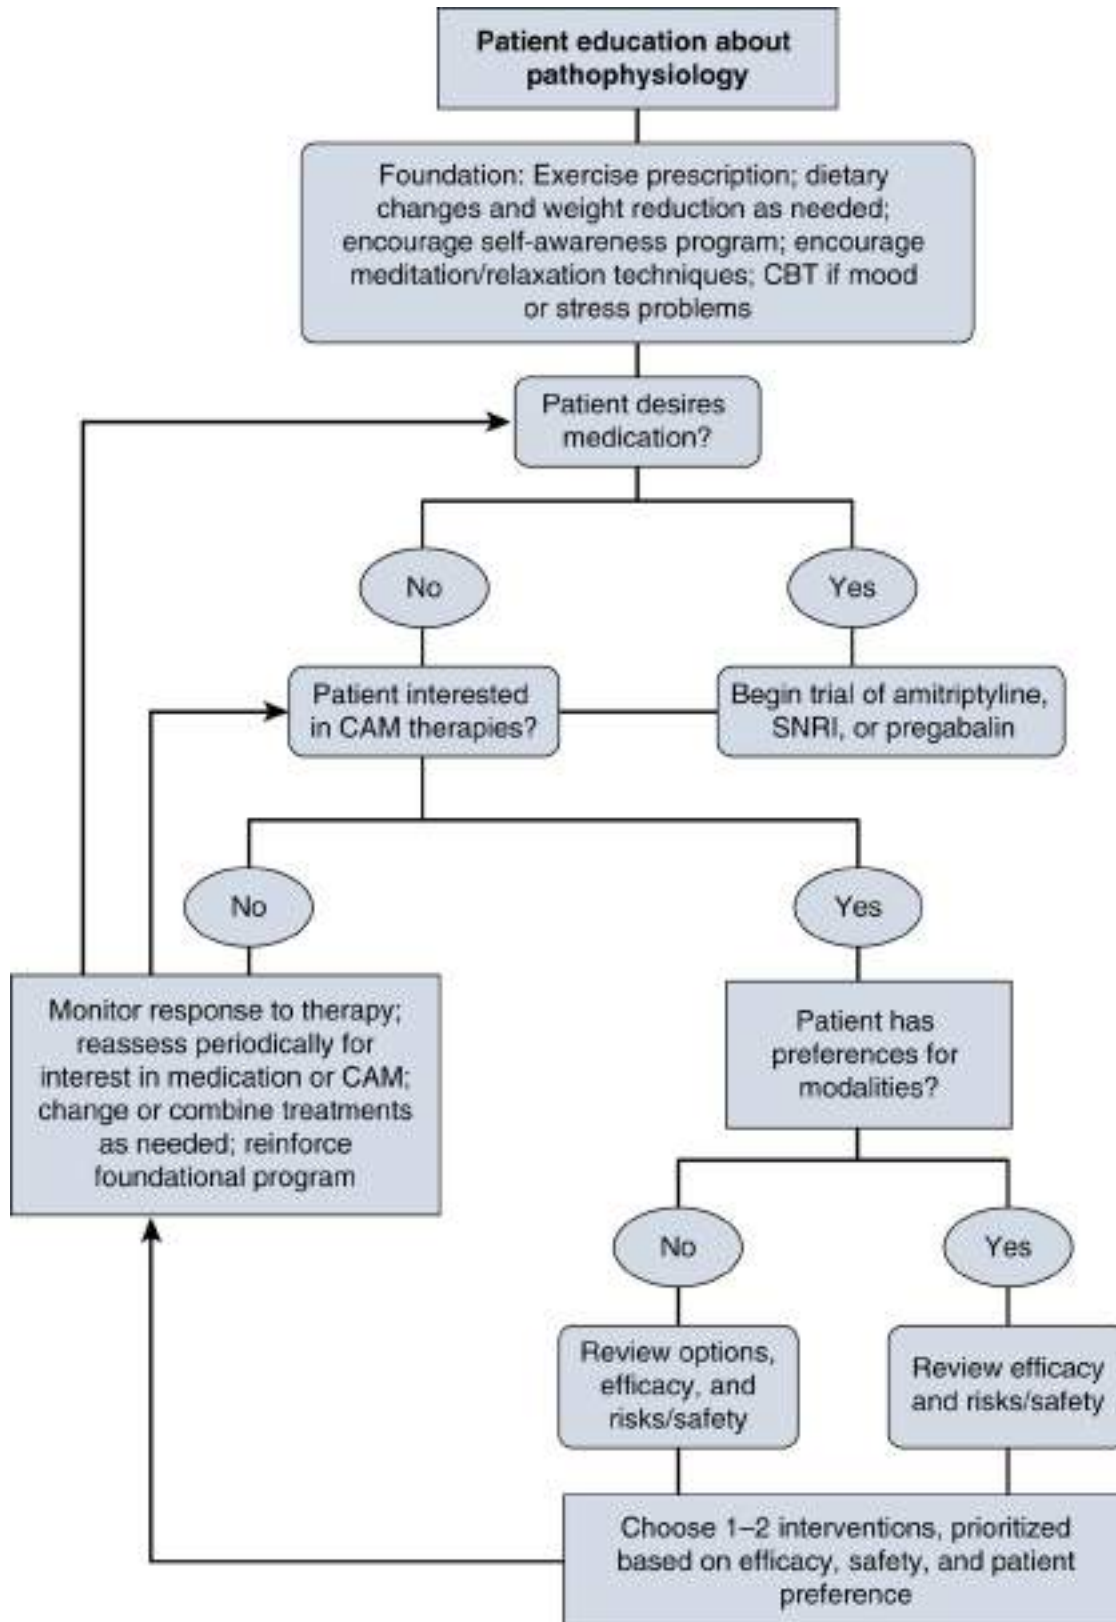

FIG. 47.2 A rational approach to an individualized integrative treatment plan for fibromyalgia.

Prevention Prescription

No proven preventive strategy exists for FM, but the following may help fortify a susceptible individual against the “slings and arrows of outrageous fortune”:

- Exercise and maintain a normal body weight. Combine aerobics, strength training, and stretching. Consider tai chi and yoga. Make exercise a time to play.
- Eat a healthy whole foods diet rich in plant sources of antioxidants. Avoid trans fats and excess caffeine, alcohol, sugars, MSG, and aspartame.
- Honor your temperament and sensitivity. Learn more about yourself and your unique needs and values in work and relationships.
- Journal to stay in touch with your inner feelings and to give voice to negative feelings and stressful events when they arise.
- Put yourself high on the list of things to take care of each day. Consider regular massage therapy or other bodywork to this end.
- Learn to meditate and practice daily. A mindfulness-based stress reduction course is recommended for the structure and support it offers.
- Allow yourself creative outlets such as art, music, dancing, or creative writing.
- Live for your own heart’s desires; give yourself permission to figure out what these are.
- If you get stuck in life, find a good psychotherapist.

Therapeutic Review

This summary provides the most helpful options for treating FM symptoms. FM has no documented “cure,” and few patients experience complete resolution of symptoms. Despite this dismal fact, the therapeutic benefit of generous listening and affirming the patient’s felt experience help. In clinical practice, most patients will report some relief of symptoms with attention and individualized treatment.

Nutrition

- Weight reduction toward a normal BMI 
- A whole foods antiinflammatory diet with ample plant antioxidants, omega-3 fatty acids, and minerals 
- Avoidance of trans fats and simple sugars 
- Avoidance of MSG and aspartame 

Exercise

- Exercise prescription tailored to patient preferences and fitness level 
- Land- or water-based aerobic exercise, strength training, and stretching 
- Encourage patients to try tai chi, yoga, and qigong 
- 30 minutes of daily cumulative lifestyle activity 

Mind-Body Therapy

- Mindfulness meditation training and daily practice 
- Mind-body self-awareness books and program 
- Journaling about emotions and stressors to help increase affective self-awareness 
- Cognitive-behavioral therapy for any identified psychological or life struggles 

Acupuncture

- A five-session trial of electro-acupuncture 

Bodywork

- Regular massage therapy or other bodywork 

Supplements

- Omega-3 fatty acids (fish oil): 2000–4000 mg daily 
- Magnesium: 400–750 mg daily 
- Vitamin D₃ (cholecalciferol) to maintain 25-(OH) vitamin D levels between 40–100 ng/mL year round 
- S-adenosylmethionine: 800 mg twice daily 

Botanicals

- Turmeric, ground root: 500–1000 mg two to three times daily 
- Ginger, ground root: 1–4 g total daily divided into two to three doses 
- Boswellia: 250–500 mg three times daily 
- St. John's wort: 300 mg three times daily 

Pharmaceuticals

Tricyclic Antidepressants and Similar

- Amitriptyline: 5–50 mg nightly as tolerated 
- Cyclobenzaprine: 2.5 mg daily, titrating to 40 mg daily in divided doses as needed 
- Trazodone: 25–300 mg nightly as needed 

SSRI

- Fluoxetine: 10–20 mg daily 
- Citalopram: 20–40 mg daily
- Escitalopram: 10–20 mg daily

SNRI

- Duloxetine: 30 mg for 1 week, increasing to 60 mg thereafter 
- Milnacipran: 12.5 mg daily, increasing to 50 mg twice daily by the end of the first week; 100 mg twice daily may be needed 

Anticonvulsants

- Gabapentin: 300 mg initially, increasing to a maximum of 1800 mg

daily as tolerated 

- Pregabalin: 50 mg three times daily, increasing to 450 mg per day over 7 days 

Analgesics

- Tramadol: 50–400 mg daily in divided doses

CHAPTER 48

Chronic Fatigue Syndrome

Sanford H. Levy, MD, FACP, ABIHM

Pathophysiology

The pathophysiology of chronic fatigue syndrome (CFS) is not well understood. Some experts believe that CFS and fibromyalgia are part of a single spectrum of disease; in this textbook, fibromyalgia is the subject of a separate chapter. Although this chapter is in the Autoimmune section of this textbook, it is uncertain as to whether CFS is an autoimmune disorder.

Infection is a common precipitant to CFS, based upon patient histories. A hypothesized mechanism is immune system dysfunction, such that interferon continues to be secreted in high amounts even after the resolution of acute infection. Excessive interferon can cause achiness, brain fog, and fatigue. In one 12-month prospective cohort study of 253 patients infected with Epstein-Barr Virus (EBV), Ross River virus, or *Coxiella burnetii*, 28 patients met criteria for CFS at 6 months after onset of infection, with the severity of initial infection found to be a predictor of progression to CFS.¹

Oxidative stress is a factor, but may well be a consequence rather than an underlying cause. Preliminary research in those with obstructive sleep apnea shows that sleep deprivation increases inflammatory cytokines by 40%.² Hypercoagulability is also a factor; researchers performing a variety of assays on 54 patients with CFS/fibromyalgia concluded that 50 of the 54 (92%) had evidence of a hypercoagulable state.³

Richard A. Van Konynenburg, PhD, has hypothesized that a methylation cycle block causes depletion of glutathione in some who suffer from CFS. This hypothesis predicts that the key to treatment is to interrupt this vicious cycle by stimulating the enzyme, methionine synthase. This theory was presented in a poster presentation⁴ and also in

an article published in the *Townsend Letter*,⁵ a nonpeer-reviewed medical journal. A search of Medline citations for this author fails to reveal any publications in the peer-reviewed medical literature.

Etiology

The etiology of many cases of CFS is believed to be hypothalamic dysfunction.^{6,7} A hypothesis, advocated by Jacob Teitelbaum, MD, is that the energy demands of the body are more than it can meet, so it “blows a fuse” in the hypothalamus and the ensuing fatigue protects the body from harm.⁸ Mitochondrial dysfunction is hypothesized to contribute to this imbalance between energy supply and energy demand. Nutritional deficiencies or insufficiencies may contribute to this imbalance. In addition, personality type may also contribute to this imbalance.

The hypothalamic dysfunction is hypothesized to cause disturbances of sleep, hormonal balance, and autonomic control. A vicious cycle is established whereby the sleep disturbance can cause immune dysfunction and further hormonal imbalances.

Stress and exposure to environmental toxins, including pesticides, herbicides, persistent organic pollutants (POPs), and toxic metals (such as mercury, lead, cadmium, and arsenic), are hypothesized to contribute to the development of CFS; 53%–67% of patients with CFS have reported at least one episode of symptom flare after specific chemical exposure.⁹ A survey completed 10 years after the Gulf War comparing the health of 1061 deployed veterans to 1128 nondeployed veterans found that their physical health was similar, but deployed veterans had an adjusted odds ratio of chronic fatigue syndrome of 40.6.¹⁰ Hypothesized explanations for this very high odds ratio include stress and exposure to toxins.

Historically, some have proposed that a viral infection is the cause of CFS. In the 1980s, chronic EBV was hypothesized to be the cause of CFS. In the 1990s, HSV 6 was hypothesized as the cause of CFS. However, ongoing research suggests that high viral titers for viruses such as EBV and HSV 6 are a consequence of immune system dysfunction in those with CFS. More recently, researchers have hypothesized xenotropic murine leukemia virus (XMRV) was a cause of CFS. However, methodological issues were identified with the initial positive study, and additional studies seem to rule out a causal link between XMRV and CFS.¹¹

Diagnosis

Historically, CFS was defined as more than 6 months of fatigue not relieved by rest and severe enough to interfere with daily activities, not due to another diagnosable cause, and often associated with fever, sore throat, lymphadenopathy, achiness, trouble concentrating, and/or sleep disturbance.¹²

The Institute of Medicine (IOM), in a February 2015 expert committee report, proposed the following diagnostic criteria¹³

- A substantial reduction or impairment in the ability to engage in preillness levels of occupational, educational, social, or personal activities, that persists for more than 6 months and is accompanied by fatigue, which is often profound, is of new or definite onset (not lifelong), is not the result of ongoing excessive exertion, and is not substantially alleviated by rest, and
- Postexertional malaise, after physical, cognitive, or emotional activity, at least half the time of moderate, substantial or severe intensity, and
- Unrefreshing sleep, at least half the time of moderate, substantial or severe intensity, and
- At least one of the following:
 - Cognitive impairment, at least half the time of moderate, substantial or severe intensity, and
 - Orthostatic intolerance

In this same February 2015 report, the IOM proposed renaming CFS as “systemic exertion intolerance disease,” stating that this name provides a more accurate description of the condition.

The Institute of Medicine, in a February 2015 report, proposed new diagnostic criteria for CFS and renaming of CFS as “systemic exertional intolerance disease (SEID).”

Impact

Chronic fatigue syndrome affects between 836,000 and 2.5 million individuals in the United States,¹⁴ with an estimated total economic cost of \$17 to \$24 billion.¹⁵ As many as 25% of those with CFS are homebound or bedridden, sometimes for extended periods.¹⁶

Integrative Therapy

Conventional Treatment

For decades, the standard of care for CFS has been cognitive behavioral therapy (CBT) and graded exercise therapy (GET). Historically, this standard of care was based on small studies. More recently, the large, multi-arm PACE trial, described in the following text, has been completed.

A 2008 Cochrane review of 15 studies (n = 1043) of CBT concluded, “CBT is effective in reducing the symptoms of fatigue at posttreatment compared with usual care and may be more effective in reducing fatigue symptoms compared with other psychological therapies. The evidence base at follow-up is limited to a small group of studies with inconsistent findings.”¹⁷ While there is strong evidence for the efficacy of CBT, with improvement often sustained for months, various studies have shown that only approximately 30% of people with chronic fatigue syndrome (CFS) recover after cognitive behavior therapy. There is abundant published literature on CBT for treating CFS, with published studies including topics of internet-based CBT; telephone-based CBT; and predictors of a positive response to CBT as a function of practitioner characteristics, patient characteristics, and / or the therapeutic relationship. One study examined outcomes as a function neuropsychological test performance and found that neuropsychological test performance was not related to the change in fatigue, functional impairments, and physical limitations following CBT for CFS, but that underperforming patients did drop out more often.¹⁸ Level of depression may be the most important factor of the cognitive-behavioral model predicting posttreatment fatigue in CFS.¹⁹ Of note, low cortisol levels, as assessed by measurement of 24-hour urinary free cortisol (UFC), are associated with a poorer response to CBT, based on a study of 84 patients.²⁰

The PACE trial is a large, multicenter, four-arm randomized trial of adaptive pacing therapy (APT), cognitive behavior therapy (CBT), graded exercise therapy (GET), and specialist medical care (SMC) for chronic fatigue syndrome, with the first participant randomized on March 18, 2005, and a total of 641 participants. Adaptive pacing therapy involves planning daily activity so as not to overwhelm capacity and worsen fatigue. Preliminary results were published in 2011.²¹ A statistical analysis plan for analyzing the results of this trial was published in

2013.²² A publication reporting on rates of clinical recovery 52 weeks after randomization found that the percentages of participants meeting trial criteria for recovery were 22% (32/143) after CBT, 22% (32/143) after GET, 8% (12/149) after APT, and 7% (11/150) after SMC. This study confirms that recovery from CFS is possible, and that CBT and GET are the therapies most frequently associated with recovery.²³ A publication examining adverse events in the trial, as recorded on three occasions over 1 year in the 641 participants, found that the numbers of adverse events did not differ significantly between trial treatments, but physical deterioration occurred most often after adaptive pacing therapy (APT).²⁴ Thus, based on a lack of efficacy combined with associated adverse effects, APT is not indicated as a treatment for CFS.

In a 12-week open label trial of 26 patients with CFS, graded exercise therapy had a positive effect on both physical and psychological state.²⁵ In regard to exercise, a challenge is that overly vigorous exercise is associated with a transient worsening of symptomatology. Thus, the challenge for the practitioner is to incorporate strategies to assist patients to self-monitor and self-regulate energy expenditures, thus maintaining appropriate energy expenditures in coordination with available energy reserves can help improve functioning over time.²⁶

Cognitive behavioral therapy (CBT) and graded exercise therapy (GET) are the conventional standard of care for treatment of CFS.

General Considerations

SHINE Protocol

SHINE is an acronym that can be used as a mnemonic for guiding treatment of CFS—*t*reat the sleep disturbance, *h*ormonal imbalances, *i*nfections/immune system dysfunction, *n*utritional deficiencies and insufficiencies, and *e*xercise to tolerance. This acronym was created by Dr. Jacob Teitelbaum to summarize his treatment approach. The details of treatment guided by this approach are outlined in Dr. Teitelbaum's book, *From Fatigued to Fantastic!*²⁷

There is published evidence of the efficacy of treatment guided by the SHINE approach. The first publication was a report of a case series.²⁸ The second, an RCT,²⁹ showed that at a median follow-up of 101 days, 16 patients in the active treatment group were “much better,” 14 “better,” 2

“same,” 0 “worse,” and 1 “much worse.” In comparison, at a median follow-up of 98 days, 3 patients in the placebo group were “much better,” 9 “better,” 11 “same,” 6 “worse,” and 4 “much worse” ($p < 0.0001$ Cochran-Mantel-Haenszel trend test).

Many patients with CFS also have symptoms consistent with fibromyalgia. Indeed, some experts consider these two conditions part of the same spectrum of disease. The number of published trials examining interventions for CFS is far fewer than the number of published trials examining interventions for fibromyalgia. Some of the interventions with published evidence of benefit in fibromyalgia may also be of benefit to some who suffer with CFS; I am not citing these published studies in this chapter, as a separate chapter in this textbook devoted to fibromyalgia (see [Chapter 47](#)).

There is a growing body of published studies of a variety of unconventional approaches to the treatment of CFS. A systematic review identified a total of 26 RCTs, including 3273 participants, which met the following inclusion criteria: RCTs of any type of CAM therapy used for treating CFS were included, with the exception of acupuncture and complex herbal medicines; studies were included regardless of blinding. Controlled clinical trials, uncontrolled observational studies, and case studies were excluded. The 26 RCTs included study of the following modalities: mind-body medicine, distant healing, massage, tuina and tai chi, homeopathy, ginseng, and dietary supplementation. The authors of this review concluded that studies of qigong, massage, and tuina demonstrated positive effects, whereas distant healing failed to do so. Compared with placebo, homeopathy also had insufficient evidence of symptom improvement in CFS. Seventeen studies tested supplements for CFS. Most of the supplements failed to show beneficial effects for CFS, with the exception of NADH and magnesium.³⁰ Of the 26 RCTs in this citation, the findings of several are included in this overview chapter; a comprehensive discussion of each of these studies is outside of the scope of this chapter.

While published data is sparse, some patients subjectively feel better after completing a metabolic detoxification regimen. Those with a body burden of toxic metals (lead, mercury, etc.), as measured with a 6-hour urine collection post-provocation with a chelating agent such as DMSA, sometimes subjectively feel better after treatment for the systemic burden of these toxic metals (see [Chapter 106](#)).

SHINE is an acronym that is useful as a general guide to treatment. In addition, some individuals feel better after a course of metabolic detoxification.

Nutrition

Anecdotally, and based upon general principles, an antiinflammatory, low glycemic load, alkaline diet accompanied by plentiful water intake is optimal for those with CFS.

Exercise

Graded exercise therapy (GET) is considered a conventional treatment for CFS—see the section on [conventional treatment](#) previously.

Supplements

Supplements to Treat the Presumed Mitochondrial Dysfunction

Acetyl-L-Carnitine

Carnitine: L-carnitine, acetyl-L-carnitine, or propionyl-L-carnitine may be beneficial and, anecdotally, may also facilitate weight loss in patients who are overweight. The rationale for treatment is that carnitine is essential for mitochondrial energy production; patients with CFS have significantly lower levels of acetyl-L-carnitine, total carnitine, and free carnitine; and those with the lowest levels have the worst functional capacity.³¹ In an 8-week crossover trial of 30 CFS patients comparing amantadine with L-carnitine, amantadine was ineffective, but L-carnitine 3 grams per day was beneficial and well tolerated, with the authors reporting a statistically significant clinical improvement in 12 of the 18 studied parameters.³² In a small, open-label, 24-week study, the clinical global impression of change scale improved significantly in 59% of patients taking acetyl-L-carnitine 2 grams per day and 63% of patients taking propionyl-L-carnitine 2 grams per day.³³

Dosage

500–1000 mg two to three times per day, typically for an 8-week trial, with gradual tapering of the dose if subjectively effective; discontinue if ineffective.

Precautions

Carnitine supplements are generally very well tolerated and safe. If one experiences diarrhea, anxiety, agitation, or insomnia, the dose should be decreased.

Coenzyme Q10

There are several published studies showing that Co Q10 supplementation is beneficial in fibromyalgia, but no published trials of Co Q10 supplementation specifically for CFS. In a survey of patients with unexplained chronic fatigue, 69% of 13 subjects reported that Co Q10 was beneficial.³⁴ Co Q10 is available in supplement form as either ubiquinol, the reduced form, or ubiquinone, the oxidized form. There are divergent opinions amongst experts as to whether one form versus the other is superior.

Dosage

100–300 mg daily. Outcomes of supplementation with Co Q10 may be best if dosing is guided by results of serum measurements. Based on the anecdotal experience of Dr. Steven Sinatra, with a focus on treatment of congestive heart failure, an optimal serum level of Co Q10 is considered to be 2.5–3.5 mcg/mL.³⁵ This blood test is available through commercial labs, such as Quest, but it is expensive and may not be covered by insurance. Note that absorption varies as a function of formulation of Co Q10, and thus the optimal dosage may also vary as a function of the formulation. Data shows that softgels that contain solubilized formulations of soy bean oil or emulsifying agents are more absorbable than powder-based capsules or tablets.³⁷ Furthermore, Q-Gel, a patented soft gel in which the particle size is reduced from 25–50 microns to 0.4 microns, is more highly absorbable than softgels, as demonstrated by a pharmacokinetic study which showed that the area

under the curve was more than twice as high for Q-Gel as compared with softgel capsules with an oil suspension, powder filled hard-shell capsules, or regular tablets.³⁷ All-Q is a solubilized tablet form of Co Q10 with better bioavailability than Q-SorB (Nature's Bounty) and bioequivalence with Q gel.³⁸ VESIsorb uses a colloidal delivery system. A study in 20 healthy men and women reported that the area under the curve with this preparation was greater than that for three other oil-based preparations (brand names not specified).³⁹

Precautions

Generally very well tolerated and safe; however, there are case reports of hypoglycemia and hypotension and of a decrease in the INR in patients on warfarin.

Creatine

Creatine monohydrate is a source of ATP and thus theoretically beneficial in treating the presumed mitochondrial dysfunction in CFS.

Dosage

5 g four times a day for 5 days, then 2 g daily for 8 weeks on an empty stomach with a bit of honey. Gradually taper the dose if subjectively effective; discontinue if ineffective.

Precautions

Avoid in those with renal failure.

NADH

NADH (also known as *Coenzyme I*) 10 mg daily was reported to be beneficial in a 4-week crossover RCT of 26 patients with CFS.⁴⁰

Dosage

10 mg/day for at least 2 months, first thing in the morning, on an empty stomach, half an hour before any food. If no benefit, consider a

trial of 20 mg/day. If dose is subjectively effective, gradually taper; if ineffective, discontinue.

Precautions

Due to its activating mechanism, it can cause agitation with a caffeine-like effect.

NT Factor Energy Lipids

NT Factor Energy Lipids is a proprietary lipid blend (soy lecithin extract), which contains phosphatidic acid, phosphatidyl-choline (PC), phosphatidyl-ethanolamine (PE), phosphatidyl-glycerol (PG), phosphatidyl-inositol (PI), phosphatidyl-serine (PS), digalactosyldiacylglyceride (DGDG), and monogalactosyldiacylglyceride (MGDG). Benefit was reported in a 12-week clinical trial of elderly patients with severe fatigue.⁴¹

Dosage

¼ teaspoon twice a day for 8 weeks. Treatment can be repeated every 6–12 months.

Precautions

None.

Potassium/Magnesium Aspartate

Aspartate is a nonessential amino acid that is converted to oxaloacetate, which is a Krebs cycle substrate. There is published evidence that this compound is effective in fatigue states, with 70%–85% responding to this compound compared, often within 10 days, as compared with a 25% response to placebo.^{42,43} The quality of product is important—as presentations by Jacob Teitelbaum, MD, indicate, it must be fully reacted. Dr. Teitelbaum also suggests taking aspartate with malic acid.

Dosage

500 mg qid or 1 g bid for 12 weeks, with gradual tapering of the dose if

subjectively effective; discontinue if ineffective.

Precautions

Caution should be used in those with renal failure.

Ribose (D-ribose)

Significant improvement was reported in an uncontrolled study in 41 patients with CFS or fibromyalgia.⁴⁴ Significant (statistical and clinical) improvement was also reported in a 3-week open-label, multicenter trial in 203 patients, examining endpoints of energy, well-being, sleep, mental clarity, and pain.⁴⁵

Dosage

One scoop (5 g) tid for 4 weeks, with gradual tapering of the dose if subjectively effective; discontinue if ineffective.

Precautions

Very safe. If patients feel overenergized or hyperactive when they take ribose, take it with a meal or lower the dose. Anecdotally, this response also suggests the need for adrenal support.

Antioxidants

Because mitochondrial dysfunction increases oxidative stress, this provides a theoretical rationale for supplementation with broad spectrum antioxidants. Anecdotally, some patients report subjective improvement in association with antioxidant supplementation. Consider a whole food antioxidant supplement, such as Fruit 4 Life and Veggies 4 Life, available online or via mail order from Swanson Health Products. Be wary of recommending high-dose individual antioxidants, such as vitamin E in the form of alpha tocopherol or beta-carotene, as high supplemental doses of a single antioxidant may be associated with depletion of other antioxidants, such as gamma tocopherol or alpha carotene.

Supplements to boost mitochondrial function include carnitine, Co

Q10, NADH, potassium/magnesium aspartate, and ribose.

Supplements to Treat the Sleep Disturbance

Anecdotally, the multiingredient product from Integrative Therapeutics, End Fatigue Revitalizing Sleep Formula, may be of benefit. This product is a blend of valerian root extract, passionflower leaf and flower extract, hops flower extract, wild lettuce leaf and leaf extract, Jamaica dogwood root extract, and L-theanine. The recommended dosage is one to four capsules 30 minutes before bedtime.

Additional supplements that may be of benefit in the treatment of insomnia include adenosine, casein tryptic hydroxylate, GABA, glycine, kava kava, L-tryptophan, lavender oil, lemon balm, melatonin, and 5-HTP. For more information on supplements for the sleep disturbance of CFS, see [Chapter 9](#).

Supplements to Treat Hormonal Imbalances

Thyroid

If hypothyroid, consider iodine supplementation and selenium 200 mcg to support conversion of T4 to T3. Note that some multivitamins contain as much as 200 mcg of selenium in the suggested daily dose. Brazil nuts, with approximately 100-mcg selenium per nut, are an alternative to a selenium supplement.

Adrenal

Supplements for adrenal gland support include the amino acid, L-tyrosine 500–1500 mg bid, betaine (TMG) 500–1000 mg/day, pantothenic acid (vitamin B5) 500–1000 mg/day, vitamin B6 100–200 mg/day, and vitamin C 1–2 g tid. In addition to the above supplements, the hormones DHEA and pregnenolone are available over-the-counter in the United States and thus categorized as supplements. Anecdotally, some individuals with CFS report symptom improvement in conjunction with supplementation with these hormones.

Dehydroepiandrosterone (DHEA)

In a survey of those with unexplained chronic fatigue, 65% of 17 subjects reported that DHEA was beneficial.⁴⁶ It is advisable to measure serum levels of DHEA-sulfate and to supplement only if these levels are

suboptimal.

Dosage

Jacob Teitelbaum suggests treating if DHEA-S < 150–180 mcg/dL in females and < 350–480 mcg/dL in males, using the following dosing guidelines (doses are once daily):

- Men: 50 mg if level is 0–100 mcg/dL, 40 mg if level is 101–200, 25 mg if level is 201–280, and 10 mg if level is 281–320. The usual supplemental dose in men is 25–50 mg/day.
- Women: 25 mg if level is 0–30 mcg/dL, 15 mg if level is 31–80, 10 mg if level is 81–110, and 5 mg if level is 111–114. The usual supplemental dose in women is 5–25 mg/day.

Precautions

Too high a dose in women can cause elevated testosterone levels and can result in acne, darkening of facial hair, and insulin resistance. DHEA supplementation theoretically may increase the risk of breast cancer in women and prostate cancer in men.

Pregnenolone

It is advisable to measure serum levels of pregnenolone and to supplement only if these levels are suboptimal. Sometimes levels are very low, presumably due to high interferon levels (endogenous antiviral) suppressing cholesterol and thus pregnenolone synthesis.

Dosage

Dr. Teitelbaum suggests 100–200 mg/day to achieve levels in the upper third of normal; Dr. David Brownstein anecdotally reports success with a lower dose of 10–25 mg daily.

Precautions

Supplementation theoretically may increase the risk of breast cancer in women and prostate cancer in men.

Many CFS patients subjectively derive benefit from adrenal and

thyroid support, even if measurements of glandular function are within the normal range.

Supplements to Treat the Immune System Imbalance and Infections

Probiotics modulate immune system function, along with many additional mechanisms of action. In a small, open-label study involving 15 patients diagnosed with chronic fatigue syndrome, supplementation with *Lactobacillus paracasei* ssp. *paracasei* F19, *Lactobacillus acidophilus* NCFB 1748, and *Bifidobacterium lactis* Bb12 for a period of 4 weeks was found to improve neurocognitive functions, with a trend toward improvement in general symptoms and quality of life.⁴⁷

Chronic candidiasis (yeast overgrowth) is a condition recognized by many integrative practitioners; however, conventional medicine practitioners do not consider this as a true entity. For integrative practitioners, diagnosis is based either on symptom questionnaire scores or on biomarkers in the stool, as measured by specialized laboratories, such as Genova, Metametrix, or Doctors Data. Natural remedies for yeast overgrowth include caprylic acid, garlic, grapefruit seed extract, olive leaf extract, oregano oil, probiotics, and undecylenic acid. Yeast overgrowth that is refractory to treatment may be due to the yeast existing in a biofilm; Interfase has been demonstrated to have efficacy in treating the biofilm.

Supplements to Treat Nutritional Imbalances

Multivitamins

A multivitamin is recommended, at the least for a 2-month trial, with indefinite continuation if effective. The multi, End Fatigue Energy Revitalization System, formulated by Dr. Jacob Teitelbaum and marketed by Integrative Therapeutics, is one option. Dr. Teitelbaum selected the ingredients and the milligram or microgram doses of each ingredient based on his extensive clinical and research experience treating those with CFS.

Amino Acids (Free-Form)

Amino acids may be of benefit based on anecdotes. Amino acids may be administered as a customized blend based on the results of laboratory

testing to measure amino acid levels, or alternatively administered empirically as a full spectrum free-form amino acid formulation. There are several full spectrum formulations available, including AMINOpowerplus and Total Amino Acid solution.

Iron

Consider supplementing with iron if ferritin levels are < 60 ng/mL. Anecdotally, many individuals with low normal iron stores, as well as those with frankly low iron stores, experience improved energy and improved cognition in association with a ferritin level > 60 . In a 12-week RCT of 198 women, aged 18–53, with fatigue, a serum ferritin level < 50 mcg/L (low normal), and a hemoglobin level > 12.0 g/dL (not anemic), those randomized to prolonged release ferrous sulfate 80 mg/day showed a 48% improvement in scores on the Current and Past Psychological Scale for Fatigue, as compared with a 28.8% improvement in the placebo group ($p = 0.02$). Compared with placebo, iron increased hemoglobin by 0.32 g/dL ($p = 0.002$) and ferritin by 11.4 mcg/L ($p < 0.001$).⁴⁸ For those who cannot tolerate ferrous sulfate due to gastrointestinal side effects, other OTC forms, such as ferrous bisglycinate or ferrous fumarate, may be better tolerated. For those who cannot tolerate various forms of oral iron, intravenous iron (administered at an infusion center) is safe and effective, and generally covered by insurance.

Methylation Protocol

This is the treatment protocol to address a methylation cycle block if homocysteine levels are elevated. The positive results with this protocol have been presented in a poster,⁴⁹ an article in a nonpeer-reviewed medical journal,⁵⁰ and in a book.⁵¹

The protocol includes the following brand name supplements:

1. Activated B12 Guard (hydroxocobalamin) one sublingual lozenge (2 mg) daily.
2. FolaPro (5-methyltetrahydrofolate) $\frac{1}{4}$ tablet (2 mg) daily.
3. Intrinsi B12/folate (combination of folic acid, 5-methyltetrahydrofolate, folinic acid, cyanocobalamin, calcium, phosphorous, and intrinsic factor) $\frac{1}{4}$ tablet daily.
4. General Vitamin Neurological Health Formula (a multi with a high ratio of magnesium to calcium, ingredients to support sulfur metabolism, and no iron or copper), $\frac{1}{4}$ tablet daily, with dose gradually increased to

two tablets daily.

5. Phosphatidyl Serine Complex (phospholipids and fatty acids) one soft gel capsule daily.

PUFA (Long Chain Polyunsaturated Fatty Acids)

The published data is mixed. In one 3-month RCT, 63 adults with a diagnosis of postviral fatigue, each ill for 1–3 years, were treated with 4 g per day of a blend of linoleic acid, gamma-linolenic acid (GLA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). At 3 months, 85% of those in the active treatment group assessed themselves as improved over the baseline as compared with 17% in the placebo group ($p < 0.0001$). Essential fatty acid (EFA) levels were abnormal at the baseline and corrected by active treatment. There were no adverse events.⁵² However, a second 3-month trial of 50 patients, using entry criteria of a diagnosis of CFS, and using the same dose and same product (Efamol Marine) as in the previously described trial in patients with postviral fatigue failed to show benefit of treatment. Furthermore, in contrast to the findings in the study of patients with postviral fatigue in which EFA levels were abnormal at baseline, in this study pretreatment red-cell membrane (RBC) EFA of patients showed no significant differences, as compared with those of age-and sex-matched normal controls.⁵³ Essential fatty acid administration was reported beneficial in a case series of four patients with CFS. These patients consumed a range of 10–18 capsules daily of a supplement (eye qTM), for which two capsules provide 186 mg EPA, 58 mg DHA, 20 mg GLA, and 3.2-mg natural vitamin E (in the form of D alpha tocopheryl acetate).⁵⁴

Vitamin B12

Dr. Teitelbaum recommends supplementing with vitamin B12 if the vitamin B12 level is < 540 pg/mL. Hydroxocobalamin and methylcobalamin are activated forms of vitamin B12, and some individuals derive greater subjective benefit from one of these forms as compared with cyanocobalamin. Furthermore, some individuals derive greater subjective benefit from intramuscular or subcutaneous vitamin B12 (cyanocobalamin, hydroxocobalamin, or methylcobalamin) as often as three times a week for 15 weeks, as compared with oral vitamin B12. Dr. Alan Gaby suggests a trial of hydroxocobalamin 1 mg intramuscularly every 4 days for all individuals who suffer from fatigue, independent of baseline vitamin B12 levels, as some individuals may

have a defect in transport of B12 across the blood–brain barrier.

Vitamin D

Supplementation with vitamin D3 is recommended at a dose of 1000–2000 IU per day if the 25 hydroxy vitamin D level is < 30 ng/mL. Vitamin D is a fat soluble vitamin, and while the therapeutic window for dosing is wide, high doses of > 10,000 IU daily are potentially toxic. Furthermore, the long-term safety of doses > 2000 IU daily is unknown.

Zinc

There is a theoretical rationale for the use of zinc for treating CFS as some of the symptoms of CFS/FM are similar to symptoms associated with low zinc levels. The typical dose is zinc citrate 30 mg daily or zinc sulfate 220 mg daily. High doses long term can suppress HDL cholesterol and lead to copper deficiency, as zinc and copper compete for absorption in the small bowel.

Botanicals

Myelophil, an extract of a mix of *Astragalus membranaceus* and *Salvia miltiorrhiza*, appears to have a pharmacological effect against fatigue based on results of a pilot 4-week RCT of 36 adults who complained of chronic fatigue. Note the entry criteria for this particular study was chronic fatigue rather than a diagnosis of CFS.⁵⁵

Adaptogens are herbs that support and balance adrenal gland function. Common adaptogens include *Eleutherococcus senticosus*, *Ginkgo biloba*, *Ocimum sanctum* (Holy basil), Maca, *Panax ginseng*, *Rhodiola rosea*, and *Withania somnifera* (Ashwagandha). The medicinal mushroom, *Cordyceps sinensis*, also has adaptogenic properties. Adaptogens may be of benefit in the treatment of CFS; however, there are no published trials.

Medicinal mushrooms that modulate immune system function include *Agaricus blazei*, *Coriolus versicolor*, *Grifola frondosa*, Lion's mane (*Hericium erinaceus*), maitake, reishi (*Ganoderma lucidum*), and shiitake (*Lentinula edodes*). Medicinal mushrooms may be of benefit in the treatment of CFS; however, there are no published trials.

Physical Modalities

Hyperbaric Oxygen

Hyperbaric oxygen therapy may be beneficial in the treatment of CFS based on preliminary data from 16 patients.⁵⁶

Massage Therapy

Intelligent-turtle massage, a traditional Chinese medicine modality, is an effective therapy for relieving the physical symptoms of CFS, based on a RCT of 182 patients.⁵⁷

Mind-Body Therapy

Cognitive Behavioral Therapy

As mentioned in the “conventional treatments” section of this chapter, cognitive behavior therapy (CBT), a form of mind-body therapy, is a conventional treatment for CFS. Mindfulness-based cognitive therapy (MBCT) may offer additional benefits based on the results of a pilot study of a mindfulness-based cognitive therapy (MBCT) intervention adapted for people with CFS who were still experiencing excessive fatigue after CBT. This pilot study included 16 MBCT participants and 19 waiting-list participants; there were significant group differences in fatigue at the 2-month follow-up, and these improvement were maintained up to 6 months posttreatment. The authors of this pilot study concluded that MBCT is a promising and acceptable additional intervention for individuals still experiencing excessive fatigue after CBT for CFS.⁵⁸

Breathing Training

Breathing retraining may offer symptomatic benefit for a subset of patients with CFS who are identified with an asynchronous breathing pattern. In a preclinical study, 5 of 20 patients with CFS were identified with an asynchronous breathing pattern; the session of breathing retraining resulted in an acute decrease in respiratory rate ($p < 0.001$) and an increase in tidal volume ($p < 0.001$).⁵⁹ It is unknown from this study whether these physiological changes will translate into clinical improvement in symptoms (see [Chapter 96](#)).

Guided Imagery

A literature review of 24 articles, of which 8 met criteria, concluded that while guided imagery is a simple, economic intervention with the

potential to effectively treat fatigue, findings from the studies to date were inconsistent regarding the effectiveness of guided imagery in treating fatigue.⁶⁰

Self-Management

Brief fatigue self-management training may be beneficial based on the results of a RCT of 111 patients with unexplained chronic fatigue or chronic fatigue syndrome. In the group assigned to two sessions of brief self-management, at 12-month postintervention follow-up, scores on the Fatigue Severity Scale were statistically better than the scores in the attention control group and the usual care group. The limitation of this trial was the high dropout rate (42%–53%).⁶¹

Counseling

Dr. Jacob Teitelbaum, MD, who has treated hundreds of patients with CFS, has observed that a common psychological profile is one of low self-esteem in childhood, and subsequently a perfectionist and overachiever as an adult. Counseling may be beneficial in this regard, both in terms of assisting the individual in recognizing these traits and guiding the individual as to how to say “no” and achieve adequate rest.⁶²

Energy Medicine

Acupuncture

A systematic review of acupuncture and moxibustion treatment for chronic fatigue syndrome in China found that all studies concluded the treatments were effective, with response rates ranging from 78.95% to 100%; however, the qualities of the studies were generally poor, and none of them used a RCT design.⁶³ In a small, open-label trial of Bo’s abdominal acupuncture once a day for 2 weeks in 40 patients with CFS, the authors reported statistically significant improvement in a variety of clinical symptoms.⁶⁴ More recently, a two-arm, randomized, controlled, single-blinded trial of acupuncture in 127 individuals with CFS was conducted in China. Sham acupuncture was used in the control group. The treatment regime was two sessions/week for 4 consecutive weeks. Despite considerable positive effects in the control group (sham acupuncture), the experimental group demonstrated significant net-effect sizes at a moderate magnitude in physical and mental fatigue and in the physical component of health-related quality of life.⁶⁵

Qigong

An RCT in which 64 participants were randomly assigned to either an intervention group or a wait-list control group reported that fatigue symptoms and mental functioning were significantly improved in the qigong group compared to controls. Furthermore, telomerase activity increased in the qigong group from 0.102 to 0.178 arbitrary units ($p < 0.05$), and this change was statistically significant when compared to the control group ($p < 0.05$). Thus qigong offers a promising intervention for CFS.⁶⁶

Systems Approaches

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) is widely used in the treatment of CFS in China. The authors of a systematic review of randomized clinical trials identified 23 RCTs involving 1776 participants. The risk of bias of the included studies was high. The types of TCM interventions varied, including Chinese herbal medicine, acupuncture, qigong, moxibustion, and acupoint application. The authors concluded that TCM appears to be effective in alleviating fatigue symptoms in patients with CFS; however, these results are preliminary due to the high risk of bias in the included studies and small study size.⁶⁷

NOTE: See the previous section on [energy medicine](#) for citations of studies of acupuncture and qigong.

Pharmaceuticals

There are no FDA-approved pharmaceutical treatments for CFS. Nonetheless, practitioners may prescribe off-label. In a study, which included a survey, 94 CFS patients recruited into an Australian study investigating immunological biomarkers filled out a questionnaire assessing the medicines they were taking. The 94 CFS patients used 474 different medicines and supplements. The most commonly used medicines were antidepressants, analgesics, sedatives, and B vitamins.⁶⁸ While RCT evidence of efficacy is lacking for these categories of medications and supplements used to treat CFS, some individuals may nonetheless derive significant symptomatic benefit from an off-label prescription.

Many patients with CFS have generalized achiness (overlap of CFS

and FM) and may be treated with one of the FDA-approved pharmaceuticals for fibromyalgia: pregabalin (Lyrica), duloxetine (Cymbalta), or milnacipran (Savella) (see [Chapter 47](#)).

Pharmaceutical formulations may be used to treat hormonal imbalances.

Thyroid

Dr. Jacob Teitelbaum recommends a trial of treatment for all individuals with a free T4 < 1.3 ng/dL (below the 50th percentile of the range of normal). Options include the prescription porcine glandular, Armour Thyroid, levothyroxine (synthetic T4), and compounded T4/T3. If CFS is due to hypothalamic dysfunction, as outlined in the etiology section of this chapter, thyroid-stimulating hormone (TSH) is not a valid measure of thyroid function, as in secondary hypothyroidism due to hypothalamic dysfunction, TSH will be low in the hypothyroid individual.

Adrenal

Dr. Jacob Teitelbaum recommends consideration of a trial of low-dose prescription hydrocortisone if the 8 a.m. serum cortisol level is < 16 mcg/dL (below the 50th percentile of the range of normal). Anecdotally, Dr. Teitelbaum reports dramatic responses to hydrocortisone in some patients, and this author too has observed a few dramatic responses. Low-dose hydrocortisone at < 20 mg/day (in two to three divided doses) represents a physiological dose (similar to treating an individual with low normal thyroid function with physiological doses of thyroid medication), and this unconventional approach to treatment is safe.⁶⁹

Gonads

Some practitioners treat with bioidentical testosterone, estrogen, and progesterone when serum levels are below the 50th percentile for a young adult, with anecdotes of positive responses.

Pharmaceuticals may be used to treat coexisting viral infections and parasites; further discussion is outside of the scope of this chapter.

Low-Dose Naltrexone

Giving 1.5–4.5 mg at bedtime, prepared by a compounding pharmacist, may be used to treat immune system dysfunction. The proposed

mechanism of action is prolonged upregulation of immune system function, triggered by brief blockade of opioid receptors between 2 a.m. and 4 a.m., and mediated by an increase in endorphin and enkephalin production (www.lowdosenaltrexone.org). There are anecdotes of benefit in those with CFS, and two published trials of benefit in those with fibromyalgia. Low-dose naltrexone is occasionally associated with insomnia during the first week of treatment and may affect thyroid function in those with Hashimoto's thyroiditis.

Prevention Prescription

- Nutrition: Avoid excess sugar and artificial sweeteners. Consume a low glycemic load diet.
- Sleep: Get 7–8 h of sleep a night.
- Exercise: Choose a physical activity that is fun and feels good.
- Pursue those things that give life meaning and purpose. Follow your bliss!⁷⁰

Therapeutic Review

Nutrition

- Antiinflammatory, low glycemic load, alkaline diet, accompanied by plentiful water intake 

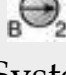

Exercise

- Graded exercise therapy (GET). Go slow and gradually increase. Consider referral to exercise physiologist or trainer who has experience in working with those with fatigue (see [Chapter 91](#)) 

Mind-Body

- Cognitive behavioral therapy 
- Mindfulness-based cognitive therapy (MBCT) 

Supplements

- Carnitine 500–1000 mg 2–3 times per day 
- Coenzyme Q 10 100–300 mg daily 
- NADH 10–20 mg daily 
- Potassium/magnesium aspartate 1 g bid 
- Ribose 5 g tid for 1 month, then bid 
- End Fatigue Energy Revitalization System multivitamin one scoop daily 
- DHEA 5–10 mg daily in females, 25–50 mg daily in males, if serum DHEA-S levels are suboptimal, with continuation only if subjective benefit and if repeat measurement shows normal level on supplementation 
- Iron: If ferritin levels are < 60 ng/mL, with monitoring of level to avoid a level > 150 ng/mL 
- Vitamin B12 1 mg as a therapeutic trial, either orally daily or intramuscular twice a week 
- Vitamin D: 1000–2000 IU per day of vitamin D3; discontinue in summer months if moderate sun exposure without sunscreen 

Pharmaceuticals

- Thyroid medication (Armour, levothyroxine, or compounded T4/T3) to achieve a free T4 > 50th percentile; continue only if subjective benefit 
- Hydrocortisone, maximum dose of 20 mg daily in divided doses, to achieve serum cortisol > 50th percentile; continue only if subjective benefit 
- Naltrexone 1.5–4.5 mg at bedtime, as a therapeutic trial; continue only if subjective benefit

CHAPTER 49

Rheumatoid Arthritis

Daniel Muller, MD, PhD

Pathophysiology

Rheumatoid arthritis (RA) is likely caused by a pathological immune response in genetically predisposed individuals to an environmental challenge, probably a viral or bacterial infection.¹ Epidemiological studies have shown that genes encoding the class II major histocompatibility antigens are linked to clinical features of RA. The HLA-DR4 and DR1 proteins present foreign and self-antigens to T cells. These molecules are presumed to play a direct role in the etiology of this autoimmune disease by presenting an “arthritogenic” viral or bacterial antigen to T cells. However, no organism has been definitively linked to the etiology of RA. Recent evidence points to the gut microbiome as playing important roles in health and susceptibility to autoimmune disease.¹ Antibiotic therapy with minocycline is helpful in mild cases of rheumatoid arthritis, although minocycline may act through direct immunomodulatory or antiinflammatory effects rather than through antibacterial activity. Other genes of the immune, endocrine, and neural systems may contribute to the pathogenesis of RA; however, the precise pathophysiological cascade has yet to be defined. RA is an autoimmune inflammatory disease in which immunosuppressive drugs constitute the mainstay of therapy. Certain cytokines, such as tumor necrosis factor (TNF), interleukin (IL)-1, and IL-6, appear to play important roles because inhibitors of these molecules have been shown to decrease disease activity.²⁻⁴ Tofacitinib is a new oral Janus kinase (JAK) inhibitor that acts upstream on intracellular signals to inhibit cytokine production.⁵ Similarly, the importance of the roles of cell surface molecules on B and T cells can be shown when these molecules are used as targets for immunomodulatory therapy.^{6,7}

Nonsteroidal antiinflammatory drugs (NSAIDs) act to inhibit the enzymes that produce inflammatory prostaglandins, particularly thromboxanes and leukotrienes. The newer NSAIDs preferentially inhibit the cyclooxygenase (COX)-2 enzyme that produces certain of these inflammatory molecules. Unfortunately, these COX-2 inhibitors have increased thrombotic and hence cardiovascular risks, and they may not offer any increased gastroprotection.^{8,9} Celecoxib (Celebrex) is still on the market, albeit with increased warnings, while other COX-2 inhibitors have been withdrawn from the market. Omega-3 fatty acids and certain botanicals, such as ginger and turmeric, may also act through decreasing the production or activity of inflammatory prostaglandins.¹⁰⁻¹⁴

The neural, endocrine, and immune systems all share communication molecules that interact extensively. Molecules from the hypothalamic-pituitary-adrenal axis, particularly cortisol and corticotropin-releasing factor, and from the sympathetic-adrenal-medullary system are linked to disease activity in RA.¹⁵ Corticosteroid drugs have powerful disease-suppressing activity, with equally powerful adverse side effects, such as osteoporosis.^{16,17} Prolactin and the estrogenic and androgenic sex hormones have been postulated to play roles as well. Other environmental factors, such as nutrition, coffee, and tobacco, may also contribute to increased risk of RA.^{18,19}

Stress and psychological factors have been linked to the etiology of RA and to disease exacerbations.²⁰ In one study, psychological factors and depression accounted for at least 20% of disability in patients with RA, greater than the 14% attributable to articular signs and symptoms.²¹ In another study, helplessness had a direct effect on disease activity.²²

Study data indicate an increased risk of cardiovascular diseases in patients with inflammatory and autoimmune diseases. Current recommendations include controlling underlying disease, monitoring the ratio of total cholesterol to high-density lipoprotein, the use of statins and angiotensin-converting enzyme inhibitors for antiinflammatory activity, and caution with the use of COX-2 inhibitors and steroids.²³

Diagnosis

In 2010, new criteria for diagnosing RA were approved by the American College of Rheumatology and the European League against Rheumatism (ACR/EULAR) (Fig. 49.1).²⁴ Definite RA is confirmed by the presence of synovitis in at least one joint, the absence of a better alternative diagnosis, and a score of 6 or greater (out of a possible 10) from four

domains: number and site of involved joints (0–5); rheumatoid factor or anticyclic citrullinated peptide (0–3); elevated sedimentation rate or C-reactive protein (0–1); and duration greater than 6 weeks (0–1). Prior criteria had been criticized for insensitivity to early RA disease. The newer criteria are directed toward instituting more aggressive therapy sooner. Official diagnostic criteria are used for inclusion into studies and do not always reflect diagnoses made in the clinic. In practice, a diagnosis of RA may include earlier diagnostic criteria, such as duration of morning stiffness greater than 1 hour, subcutaneous nodules, x-ray changes, and histological changes in biopsies of synovial tissue. Further, these ACR/EULAR diagnostic criteria do not include newer methods of diagnosis, such as ultrasound and magnetic resonance imaging. Earlier treatment of RA results in better long-term outcomes. These criteria will be used to test whether more aggressive treatment will be helpful in disease in which joint damage has not yet taken place.

Joint involvement (0–5)	
1 med/large joint	0
2–10 med/large joints	1
1–3 small joints	2
4–10 small joints	3
>10 joints (at least 1 small)	5
Serology (0–3)	
Neither Rf nor ACPA positive	0
At least one test low positive	2
At least one test high positive	3
Duration of synovitis (0–1)	
<6 weeks	0
>6 weeks	1
Acute phase reactants (0–1)	
Neither CRP nor ESR abnormal	0
Abnormal CRP or abnormal ESR	1

FIG. 49.1 American College of Rheumatology and European League against Rheumatism (ACR/EULAR) diagnostic criteria for rheumatoid arthritis (RA): 6 out of 10 points or more suggest the diagnosis of RA. *ACPA*, anticyclic citrullinated peptide; *CRP*, C-reactive protein; *ESR*, erythrocyte sedimentation rate; *Rf*, rheumatoid factor. (From Aletaha D, Neogi T, Silman AJ,

et al. 2010 Rheumatoid arthritis classification criteria: an American College of

Integrative Therapy

Exercise

Joint pain can inhibit activity and lead to muscle disuse and atrophy. In turn, muscle atrophy can lead to decreased stability of joints. Light weight training can maintain or even increase muscle strength around joints and can lead to increased joint stability. Stretching muscles can help decrease flexion contractures. Aerobic exercise improves mood, decreases fatigue, and helps control weight gain. Water exercise can be helpful because it is less stressful on joints; however, weight training and walking work better to decrease bone loss (osteoporosis). The Arthritis Foundation provides information on exercise programs (see [Key Web Resources](#)). Asian exercise disciplines such as tai chi and yoga can also be beneficial. A form of tai chi called the *range-of-motion (ROM) dance* is particularly suited to persons with disabilities (see [Key Web Resources](#)).

Physical and Occupational Therapy

Physical therapy and occupational therapy programs can be invaluable in the treatment of RA. Goals are to improve range of motion and strengthen muscles. Joint protection from deformities can be aided by education and the use of splints, orthotics, ambulatory aids, and other devices. Massage and local heat and cold applications can decrease inflammation, increase circulation, and relax muscles.

Mind-Body Therapy

Self-help courses given through the Arthritis Foundation provide information about diseases and medication and can help in developing coping skills. Simply writing in a journal about positive and negative emotions for 15 minutes a day can be a powerful therapy that relieves symptoms by 25% or more (see [Chapter 98](#)).²⁵

The benefit of psychological interventions for RA was reviewed in a meta-analysis of 27 studies. Comparisons showed benefit in increasing physical activity and in decreasing pain, disability, depression, and

anxiety. Self-regulation techniques, such as goal setting, planning, self-monitoring, feedback, and relapse prevention, were particularly helpful in reducing depression and anxiety.²⁶

Meditation and breath awareness are central to yoga practice, and a recent review has documented benefits in RA.²⁷ A study of meditation in psoriasis, an autoimmune inflammatory skin disease, showed decreased time to clearing the skin disease.²⁸ Two studies investigated the role of meditation in RA. Pradhan et al.²⁹ found reductions in psychological stress and increases in measures of well-being at 6 months, but no effects on the progression or activity of RA disease. Zatura et al.³⁰ reported that both cognitive therapy and meditation were helpful in RA, with better responses in subjects with depression. I continue to recommend this modality for RA (see [Chapter 100](#)). The effects of mind-body therapies on depression are important because depression is correlated with pain levels and measures of inflammatory markers.³¹

Nutrition

Food Triggers

Fasting clearly decreases symptoms in RA; however, symptoms rapidly recur with the resumption of food intake.³² A few people with RA appear to have a food intolerance that exacerbates their disease. Many more people believe that certain foods exacerbate symptoms, but this effect has not been observed in blind trials of food exposure. The offending foods are usually dairy products, wheat, citrus, or nuts. An elimination diet for 2 weeks with the reintroduction of the suspected food can be done with or without the supervision of a physician or a nutritionist (see [Chapter 86](#)).

Omega-3 and Omega-9 Fatty Acids

Increased intake of omega-3 fatty acids from cold-water fish, such as salmon, and from nuts, such as walnuts, as well as from flaxseed or hempseed, can provide modest improvement in the control of RA.^{10-12,32} The role of saturated fatty acids and trans fats in increasing symptoms is currently unproven. In view of the association of these saturated and trans fats with cardiovascular disease, however, reduction in intake is worthwhile (see [Chapter 88](#)).

Cooked vegetables and olive oil have been found to be independently protective against the development of RA. Omega-9 fatty acids in olive

oil may confer anti-RA activity.³³

Coffee

A high intake of coffee (four or more cups a day) has been linked to an increased risk of RA.^{18,19} Intake should be decreased to less than this level, or the patient can switch to green tea, for the possible benefit from its antioxidant polyphenols.

Elimination of Tobacco Use

Smoking causes oxidant stress in connective tissues, as evident from the increased wrinkles seen in long-term smokers. One study demonstrated a clear association between smoking and increased risk of RA. In this Swedish population, more than 50% of RA cases could be attributable to smoking in association with certain HLA-DR genes.³⁴ Patients with RA should be counseled to avoid tobacco.

Supplements

Essential Fatty Acids

Omega-3 fatty acids can be increased by dietary means or through supplementation. Approximate doses for supplementation are eicosapentaenoic acid, 30 mg/kg/day, and docosahexaenoic acid, 50 mg/kg/day.^{10-12,32}

Gamma-linolenic acid, 1.4–2.8 g/day, the equivalent of 6–11 g of borage oil daily, has also been shown to be helpful.¹¹ Effects may not be felt for 6 weeks or more, and continued improvement may occur after many months.

Conjugated Linoleic Acids

One study reported that 3-month supplementation with conjugated linoleic acids (CLAs) led to reductions in standard measures of RA activity (DAS28), morning stiffness, and erythrocyte sedimentation rate. This study provided 2.5 g CLA daily in two capsules containing equal amounts of *cis*-9, *trans*-11 CLA, *cis*-12, and *trans*-10 CLA.³⁵

Antioxidants

Antioxidant vitamins may be helpful in RA, as they seem to be in osteoarthritis. Vitamin E should be taken at 800 units daily as mixed

tocopherols, and vitamin C at 250 mg twice per day. Selenium can be found in many foods, including nuts; intake should be at least 100 mcg daily, not to exceed 400 mcg daily.

The recommended intake of calcium to prevent osteoporosis is 1000–1200 mg daily. Adding magnesium, at 400–750 mg daily, and a vitamin D supplement, at 2000 units per day, is probably a prudent approach.³⁶

Echinacea should be avoided by patients with rheumatoid arthritis because of anecdotal reports of increased symptoms in persons with autoimmune disease.

Botanicals

Ginger

Ginger (*Zingiber officinale*) may have efficacy in treating RA by inhibiting inflammatory prostaglandins.¹³

Dosage

As the dried root, 1 g of ginger two or three times per day to start, increase up to 4 g daily. As tea, 1 g of dried root steeped in 150 mL of boiling water for 5–10 minutes and strained, one cup up to four times daily. Ginger can also be taken in 500-mg capsules at a dose of 1 g two or three times a day.

Precautions

Stimulation of increased bile flow can cause pain in the presence of cholelithiasis. Other risks include bleeding, hypertension or hypotension, and hypoglycemia.

Turmeric

Turmeric (curcumin) was shown to have an efficacy similar to that of NSAIDs in an open trial.¹³

Dosage

As powdered root, turmeric 0.5–1 g two or three times daily.

Precautions

Risks include bleeding, gastrointestinal intolerance, and impaired fertility.

Pharmaceuticals

Nonsteroidal Antiinflammatory Drugs

NSAIDs can be used on a short-term basis with minor risk of gastrointestinal toxicity. The long-term use of NSAIDs, particularly in older adults, poses significant risks for gastrointestinal bleeding. Many NSAIDs are available, with many of the newer ones restricted on some formularies. The classic NSAIDs are ibuprofen (Motrin), at a dose of 800 mg three times daily, and naproxen (Naprosyn), at a dose of 500 mg twice daily. Both have antiplatelet activity. The advantage of using the COX-2 inhibitor, celecoxib, for possible decreased gastrointestinal toxicity has been called into question.⁹ Celecoxib shares a lack of antiplatelet effects with other newer NSAIDs. These drugs also have the potential for renal toxicity and are no more effective than older NSAIDs. Data point to the risk of increased thrombosis in patients taking COX-2 inhibitors who have a preexisting increased risk of thrombosis or cardiovascular disease.⁸ Two other COX-2 inhibitors have been withdrawn from the market. Celecoxib is used at a dose of 200 mg twice daily.

Corticosteroids

Corticosteroids can rapidly decrease RA symptoms, often within a few hours at high doses. However, both short-term and long-term toxic effects are well known. High and even moderate doses can lead to avascular necrosis of joints, such as the hip, knee, or shoulder; fortunately, this is a rare occurrence. With proper care and early diagnosis of avascular necrosis, disability and joint replacement may be avoided. With long-term corticosteroid use, osteoporosis is a significant risk when doses of prednisone or equivalent are higher than 7.5 mg daily. Other risks include atherosclerosis, diabetes mellitus, cushingoid

features, acne, and infection. A minor disease flare can often be treated with a moderately high dose, such as 30–40 mg of prednisone orally and a rapid taper over the course of 1–2 weeks. In some patients, a low dose of corticosteroids appears necessary for optional function; prednisone, 5–7.5 mg daily, is often used for this purpose.^{16,17} A common method of treating a flare is to give a long-acting depot preparation such as triamcinolone acetonide (Kenalog), 80 mg intramuscularly. This approach can often control disease for 1–2 months, long enough for the slower-acting disease-modifying antirheumatic drugs (DMARDs) to start working. For disease flares in isolated joints, once infection is ruled out, an intraarticular injection of triamcinolone, 2.5–40 mg, can be given to control local disease.

A single joint with severely decreased range of motion and increased pain is presumed to be infected until proven otherwise. The patient should be hospitalized overnight for joint aspiration to obtain culture specimens. Blood should also be drawn for cultures, followed by administration of intravenous antibiotics until results of culture are known.

Antibiotics

Antibiotics, particularly minocycline (Minocin) at a twice-daily dose of 100 mg, may be useful in patients with less severe disease.³⁷ Side effects include gastrointestinal intolerance; dizziness; photosensitivity rash; vaginitis; skin and gingival discoloration; and, rarely, hepatic, lung, and kidney injury. The salutary effects of these agents may not be caused by their antibacterial activity because the tetracyclines also show immunomodulatory and antiinflammatory activities.

Disease-Modifying Antirheumatic Drugs: Overview

DMARDs are also referred to as slow-acting antirheumatic drugs (SAARDs) because they usually take 6 weeks–3 months to show activity. The use of most U.S. Food and Drug Administration (FDA)–approved DMARDs is supported by Cochrane Reviews, including low-dose steroids, hydroxychloroquine, sulfasalazine, methotrexate (with folic acid), azathioprine, leflunomide, cyclophosphamide, etanercept, adalimumab, and infliximab ([Fig. 49.2](#)).

Hydroxychloroquine and Sulfasalazine

Hydroxychloroquine (Plaquenil) and sulfasalazine (Azulfidine-EN) are used early in disease when a diagnosis may not be clear or in patients with no characteristic erosive disease. Both drugs have little short-term and long-term toxicity.

Dosage

The current accepted dose of hydroxychloroquine is 200 mg twice daily, which carries little risk of toxicity; nevertheless, an ophthalmological examination to test for retinal toxicity is recommended every 6–12 months. To reduce gastrointestinal intolerance, sulfasalazine is usually used in an enteric-coated form; dosing is started at 500 mg a day and raised by one tablet every few days until a dose of 1 g twice daily is reached.

Precautions

When used in high doses, hydroxychloroquine carries a risk of retinal toxicity resulting from deposition of the drug into the retina. Sulfasalazine can uncommonly cause rash, hepatotoxicity, and leukopenia.

Methotrexate

Of all of the DMARDs, methotrexate (Rheumatrex) has been shown to be tolerated for longer periods of treatment than any other drug.^{3,38}

Methotrexate is a folate antagonist and has a multitude of immunomodulatory activities, but its exact mechanism of action in RA is unknown. Doses of methotrexate for RA are usually between 5 and 25 mg given once a week. The dose is usually given orally in tablet form; however, the liquid form can be used orally and is sometimes less expensive. A common practice is to start with 7.5 mg orally once per week, although many practitioners, including myself, recommend starting at higher doses such as 15 mg/week. With the use of higher doses of 20 mg and more, patients are often taught to self-administer the dose subcutaneously once per week to avoid possible problems with gastrointestinal absorption. To decrease side effects, I always prescribe folic acid, 1–2 mg, to be taken each day. A decision to start methotrexate

therapy or to raise or decrease the dose should be taken by a practitioner with extensive experience. Methotrexate is the standard by which all other drugs are judged, yet few patients achieve remission and less than a majority will achieve a 50% improvement on composite scores.

Contraindications to use of methotrexate include the following: preexisting hepatic, renal, or pulmonary disease; unwillingness to discontinue alcoholic beverages; and recent malignant disease.

Methotrexate has many side effects, the most prominent being hepatitis, bone marrow suppression, pneumonitis, mouth sores, nausea, and headache. A complete blood count, platelet count, and determination of aspartate transaminase, albumin, and creatinine levels are performed initially and then every 2 weeks for 6 weeks after methotrexate therapy is begun. Thereafter, monitoring can be performed every 8–12 weeks. A baseline hepatitis screen and chest radiography are recommended. Tuberculosis skin testing is reserved for patients with strong risk factors or an abnormal appearance on chest radiograph.

Other Immunosuppressive Drugs

Many other immunosuppressive drugs are used in RA. Leflunomide (Arava) is a newer drug that is similar in efficacy to methotrexate.³⁹ Leflunomide interferes with pyrimidine synthesis, whereas methotrexate interferes with purine synthesis. Leflunomide has fewer hepatotoxic effects and possibly little bone marrow toxicity, but is much more likely to cause diarrhea. Azathioprine (Imuran) is metabolized to 6-mercaptopurine and interferes with inosinic acid synthesis. Azathioprine is often substituted for methotrexate; however, its use is associated with gastrointestinal and bone marrow toxicity. Other immunosuppressive drugs less commonly used are mycophenolate mofetil (CellCept), cyclosporine (Neoral), tacrolimus (Prograf), and chlorambucil (Leukeran). Cyclophosphamide (Cytosan) is often used to treat rheumatoid vasculitis.

FIG. 49.2 Treatment algorithm for rheumatoid arthritis (RA) in adults.

*When starting methotrexate (MTX), add 1 mg of folic acid by mouth daily to decrease side effects, warn patients to avoid alcohol, and schedule laboratory studies (complete blood count, differential, platelets, aspartate aminotransaminase, albumin, creatinine) before starting, then every 2 weeks for 6 weeks, then every 2 months if results are normal. †When adding another disease-modifying antirheumatic drug (DMARD) to MTX, decrease the dose of MTX to 10–15 mg once per week. *Ca*, calcium; *FA*, fatty acid; *HCCQ*, hydroxychloroquine; *IM*, intramuscular; *Mg*, magnesium; *Se*, selenium; *SQ*, subcutaneous; *SSZ*, sulfasalazine; *TB*, tuberculosis; *vits*, vitamins.

Recombinant Biologics

Advances in the therapy of RA have targeted cytokines and cell surface molecules used to communicate between cells of the immune system.³⁻⁷ Etanercept (Enbrel), adalimumab (Humira), and infliximab (Remicade) are TNF inhibitors.⁴⁰⁻⁴² Etanercept is given subcutaneously once or twice per week, adalimumab is given subcutaneously once every 2 weeks, whereas infliximab is usually given intravenously once every 2 months. Two newer TNF inhibitors, certolizumab (Cimzia) and golimumab (Simponi), can be given subcutaneously once per month.^{3,4} These drugs are most often used with another DMARD, usually methotrexate, to reduce the development of autoantibodies. Short-term safety is very high, with little toxicity. As many as 30% of patients may show almost complete remission of symptoms with the combination of methotrexate and an anti-TNF agent. Currently, approximately 15 years of data are available on long-term safety and efficacy.^{3,4} Use of these agents carries a risk of life-threatening exacerbations of severe infections, especially sepsis. Patients should temporarily discontinue the anti-TNF therapy during presumed infections and restart the therapy when the infection has resolved. All patients must be tested for latent tuberculosis with the purified protein derivative (PPD) skin test before the initiation of therapy. These drugs also may exacerbate demyelinating disorders; therefore they should be avoided in patients with suspected or proven multiple sclerosis or optic neuritis.

An IL-1 receptor antagonist, anakinra (Kineret), is approved for the treatment of RA. It is given subcutaneously daily and also increases the risk of serious infection. Anakinra is generally thought to have lower efficacy in RA than other biologics. Agents directed toward a cell surface molecule on B cells (rituximab [Rituxan])⁶ and a costimulatory molecule

on T cells (abatacept [Orencia])² have been approved for use in RA. Tocilizumab (Actemra) is directed toward another cytokine, IL-6, and has been approved for use in RA, but is associated with increased risk of neutropenia and increased cholesterol and liver function values. Tofacitinib (Xeljanz) is a new oral Janus kinase (JAK) inhibitor that acts to inhibit cytokine production. Tofacitinib is not a true biologic, but rather a new class of oral medication that acts similarly to a biologic with similar risks to tocilizumab.⁵

It should be noted that these very expensive biologics may not be needed in all cases of methotrexate failure. A recent study documented that triple therapy with sulfasalazine and hydroxychloroquine, added to methotrexate, was not inferior to etanercept added to methotrexate in active RA disease.⁴³

Acupuncture

Several small controlled trials of acupuncture in RA have demonstrated decreased knee pain for an average of 1–3 months.⁴⁴

Low-Level Laser Therapy

Low-level laser therapy uses a single-wavelength laser source that likely has photochemical, not thermal, effects on cells. A Cochrane Review suggests that this therapy may be considered for short-term relief of pain and morning stiffness for patients with RA, particularly because it has few side effects.⁴⁵

Surgery

Loss of joint function and intractable pain may be indications for surgical intervention. Synovectomy can be helpful when systemic therapy and intraarticular corticosteroids are ineffective. Joint replacement can help restore function and increase independent activity. Patients with RA have an increased risk of surgical and postoperative complications. Cervical spine disease can lead to spinal instability and risk of neurological injury. Replacement of one joint can result in increased stress on other joints during recovery and rehabilitation. Long-term corticosteroid use can cause fragility of vessels and connective tissue and thus increase the risks of surgery.

Therapies to Consider

The roles of traditional Chinese medicine or Ayurvedic, homeopathy, or spiritual therapies in the management of RA have not been adequately studied.⁴⁶ Patients should learn about several different modalities and then record their feelings about these approaches in a journal. They may then choose to visit a practitioner of a selected modality for a trial of the techniques. If the economic burden is not too great, further exploration of therapeutic techniques may be appropriate.

Prevention Prescription

No proven methods of preventing rheumatoid arthritis exist. However, the following can be recommended:

- Laugh as much as possible. Watch funny movies, read funny books, get up every morning and force yourself to laugh. You'll find it is awkward at first, but it works anyway!
- Journal about stressful events. Make a list of 25 things for which you are grateful.
- Be creative. Do art, dance, play an instrument, beat a drum, write poetry or prose.
- Meditate; I recommend mindfulness meditation.
- Find meaning in life. Ask what gives you the energy to get up in the morning.
- Investigate your personality.⁴⁷ Try new things that you are afraid to do.
- If you feel stuck, find a good psychotherapist.
- Exercise. Combine aerobics, strength training, and stretching. Make it a time to play!
- Love people. Hang out with "positive people"; make sure they outweigh the "negative" people in your life. Find "positive" support groups.
- Eat well. Try a vegetarian diet. Make sure to balance your protein intake, and make sure you have adequate vitamin intake.
- Eliminate coffee, smoking, and alcohol. Make high-sugar desserts a small, rare treat.

Therapeutic Review

Evidence is accumulating that current allopathic treatments are successful in slowing joint destruction and in decreasing the mortality associated with rheumatoid arthritis (RA).^{3,4,38,43,48} In addition, the rates of extraarticular manifestations of RA, such as Felty syndrome and rheumatoid vasculitis, seem to be decreasing. Therefore, in any but the mildest cases of RA, an integrated approach should include the disease-modifying antirheumatic drugs (DMARDs), usually starting with methotrexate.

Exercise

- Muscle strengthening and stretching can be invaluable for maintaining function. Physical therapy can be used initially for instruction; modified yoga or tai chi in the form of the range-of-motion dance can be helpful.

Mind-Body Techniques

- Meditation is highly recommended for patients with RA who are willing to devote the daily time to looking more closely at the connections among body, mind, and spirit. Also recommended are relaxation exercises and the development of methods to cope with stress. Tai chi and yoga also may include a meditative component to the training.
- Journaling should be encouraged (see [Chapter 98](#)).

Removal of Exacerbating Factors

- Use of coffee, tobacco, and alcohol should be eliminated. 
- If intolerance to dairy products, wheat, citrus, or nuts is suspected, a trial of an elimination diet for 2 weeks with the reintroduction of the suspected food can be undertaken (see [Chapter 86](#)). 

Nutrition

- A diet rich in omega-3 fatty acids is achieved by increasing intake of cold-water fish or adding flaxseed meal or flaxseed oil. Olive oil should also be increased in the diet. An antiinflammatory diet is also

recommended (see [Chapter 88](#)).

Supplements

- Omega-3 fatty acids are recommended; doses for supplementation are eicosapentaenoic acid, 30 mg/kg/day and docosahexaenoic acid, 50 mg/kg/day, along with gamma-linolenic acid, 1.4–2.8 g/day, the equivalent of 6–11 g of borage oil daily. 
- Conjugated linoleic acid (borage oil, evening primrose oil) can be trialed at 2.5 g/day. 
- Vitamin E should be taken at a dose of 800 units daily as mixed tocopherols, and vitamin C can be taken at a dose of 250 mg twice daily. Selenium intake, as nuts or supplements, should be at least 100 mcg daily, not to exceed 400 mcg daily. Recommended intake of calcium is 1.5 g daily; magnesium, 400–750 mg daily, and a vitamin D supplement of 2000 units/day are also recommended. 

Botanicals

- Start with ginger, at 1 g twice daily to a maximum of 4 g daily. 
- If no effect is seen after 6–8 weeks, the addition of turmeric 0.5–1 g two to three times daily can be trialed. 

Pharmaceuticals

- NSAIDs are used as little as possible owing to gastrointestinal toxicity. The classic NSAIDs are ibuprofen, 800 mg three times daily, and naproxen, 500 mg twice daily. 
- The COX-2 inhibitors decrease but do not eliminate the risk of gastrointestinal bleeding. The dose of celecoxib is 200 mg twice daily. 
- Most patients with RA are receiving combinations of drugs. Most patients are given methotrexate therapy unless they have contraindications or side effects. 
- A common combination is methotrexate and hydroxychloroquine; sulfasalazine can be added for triple therapy. Corticosteroids in moderately high doses with a rapid taper are often used for

exacerbations. 

- Commonly, a TNF inhibitor such as etanercept, adalimumab, infliximab, certolizumab, or golimumab is added if methotrexate is only partially effective. If one to two TNF inhibitors are unsuccessful, try rituximab, abatacept, or tocilizumab. 
- Leflunomide or azathioprine is often substituted for methotrexate if side effects of methotrexate are intolerable. 
- Methotrexate and leflunomide can be used together with only a modest increase in risk of side effects. The DMARDs and the recombinant biologics have many varied side effects, some of which are only now being defined. New biologics are being developed, including oral formulations. Immunosuppressive pharmaceuticals should be used only with input from a subspecialist rheumatologist.

Acupuncture

- Acupuncture can be tried for any patient with RA. This modality may be less effective in patients taking corticosteroids. 

Low-Level Laser Therapy

- Low-level laser therapy can be trialed with little risk of side effects.

Surgery

- Loss of joint function and intractable pain may be indications for surgical intervention. Synovectomy can be helpful when systemic therapy and intraarticular corticosteroids are ineffective. Joint replacement can help restore function and increase independent activity.

Caution

Studies have not been conducted on the possible additive effects of ginger, turmeric, vitamin E, and an NSAID for increased risk of hemorrhage. Other commonly used supplements or botanicals such as ginkgo may add further risk. Particular care must be used in patients taking other antiplatelet agents or warfarin sodium (Coumadin). In addition, the interactions of supplements and botanicals with allopathic

pharmaceuticals are not fully understood. All health care professionals involved in patient care must be aware of all therapies being used. The addition of any new treatment should prompt increased laboratory monitoring for patients receiving immunosuppressive pharmaceuticals.

CHAPTER 50

Inflammatory Bowel Disease

Alyssa M. Parian, MD, Gerard E. Mullin, MD, Jost Langhorst, MD, and Amy C. Brown, PhD

Introduction and Pathophysiology

Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are autoimmune-based chronic inflammatory diseases that follow a relapsing and remitting course. The pathogenesis of IBD has yet to be fully elucidated; however, studies suggest a multifactorial process involving genetics, environmental exposures, the gut microbiome, and immune dysregulation among others. One accepted theory is that IBD develops due to an exaggerated, uncontrolled immune response to an environmental trigger in the gut microbiota. There has been a rising incidence of IBD worldwide, and experts believe a "westernized diet" is at least partially to blame. A diet high in refined sugars, animal fat, and complex carbohydrates is associated with higher rates of IBD, whereas diets rich in omega-3 fatty acids and fiber protect against development of IBD.¹⁻⁵ Alterations in the gut microbiome such as decreased bacterial diversity and an overgrowth of *Bacteroides* species are commonly found in patients with IBD compared to the general population. Aside from diet, gastrointestinal infections^{6,7} and antibiotics⁸ are known to disrupt the microbiome and have both been recognized as triggers for IBD flares. Aberrations in the mucosal immune system have been implicated in the pathogenesis of IBD. Patients with IBD commonly have increased intestinal permeability, which increases exposure of the intestinal immune system to luminal antigens, triggering further inflammation ([Fig. 50.1](#)).⁹

Integrative Therapies for Inflammatory Bowel Disease

IBD is a highly complex chronic inflammatory disease that is amenable to successful modulation by the combination of conventional allopathic medicine and complementary and alternative modalities (CAM). There are many facets of CAM that are highlighted in this text that can mitigate the chronic inflammation of IBD and address the root causation by modifying the triggers for this autoimmune condition. We will utilize a functional medicine approach towards achieving this goal for patients and practitioners. The first goal is to identify preventative risks and to eliminate harmful triggers and mediators of disease. Once the body is in a reboot mode, proper nutrition and lifestyle interventions can help to rebalance the gut ecosystem and mucosal immunity as well as restore vitality and quality of life (QOL).

Nutrition

The gut serves as the body's principle interface between the outside world and immune system. Disruptions in gut integrity and overall function are distorted in autoimmune diseases such as IBD. Orally ingested medications and or nutrients may play a number of roles in propelling or improving symptoms and the course of disease by influencing gut health and mucosal immunity. A number of studies have disclosed the following identifiable and modifiable risks: genetic susceptibility, antibiotic use,¹⁰ hygiene status, diet, infective agent(s) transferred through foods or beverages, recall of bacterial intestinal infections,¹⁰ appendectomy, pollution, smoking, stress,¹¹ food additives, oral contraceptive use, NSAIDS, and or other environmental factors.¹² However, the relative contributions of individuals factors have yet to be defined. Tetracycline class antibiotics, particularly doxycycline, which is used for acne or other conditions, may be associated with the development of IBD, particularly CD.¹³ Overall, disruptions in the delicate balance of gut mucosal and microbial health portend to autoimmunity, but also provide targets to mitigate the onset and course of disease.

Diet is the primary modality that patients use to help modify symptoms. Surveys reveal that a large percentage of IBD patients not

only alter their diets but also ask clinicians for dietary advice.¹⁴ Researchers reported that 90% of CD and 71% of UC patients changed their diets following diagnosis.¹⁵ Among patients altering their diets, 73% reportedly experienced improved symptoms of abdominal pain, flatulence, and diarrhea. Despite patient demand for dietary guidance, no diet is currently recommended for IBD in clinical practice guidelines and the online Nutrition Care Manual, which is used by many hospitals, as their diet manual (www.eatright.org) requires extensive updating for IBD.¹⁶

Enteral nutrition may influence the course of IBD via a number of mechanisms, as illustrated in [Fig. 50.2](#).¹⁵ A systematic review concluded that IBD rates have increased with the spread of the Western diet, specifically a higher intake of total fats, total PUFAs, omega-6 fatty acids, and meat. High-fiber and fruit intakes were shown to be associated with a decreased risk of CD, while high-vegetable intakes were found to be protective against UC.¹⁷ A high fiber diet was revealed in the NHANES study to be associated with a lower risk of CD, but not UC.⁵ Only fruit and vegetable fiber (soluble) was associated with this decreased risk, not fiber from insoluble fiber from cereals, whole grains, or legumes. Dixon et al. discuss the possible mechanisms behind the hypothesized link between IBD and carbohydrate, protein, and fat.¹⁸ Alcohol consumption increases IBD risk, perhaps through disruption of the intestinal epithelial barrier resulting in an increased intestinal permeability and associated endotoxemia perpetuating inflammation.¹⁹ Researchers suggest that a semi-vegetarian diet may also help because CD patients maintained clinical remission 94% of the time compared to 33% of the time with an omnivorous diet.²⁰ Coconut-derived medium-chain triglycerides (MCT) oil has been shown to improve bowel damage in animal models and modulate immunity.²¹

FIG. 50.1 Pathophysiology of Inflammatory Bowel Disease.

The exact pathophysiology of inflammatory bowel disease remains unknown; however, an interplay of diet, genetics, environmental exposures, the immune system, and the microbiome is believed to contribute. These factors are believed to interact collectively in the pathogenesis of this chronic disease.

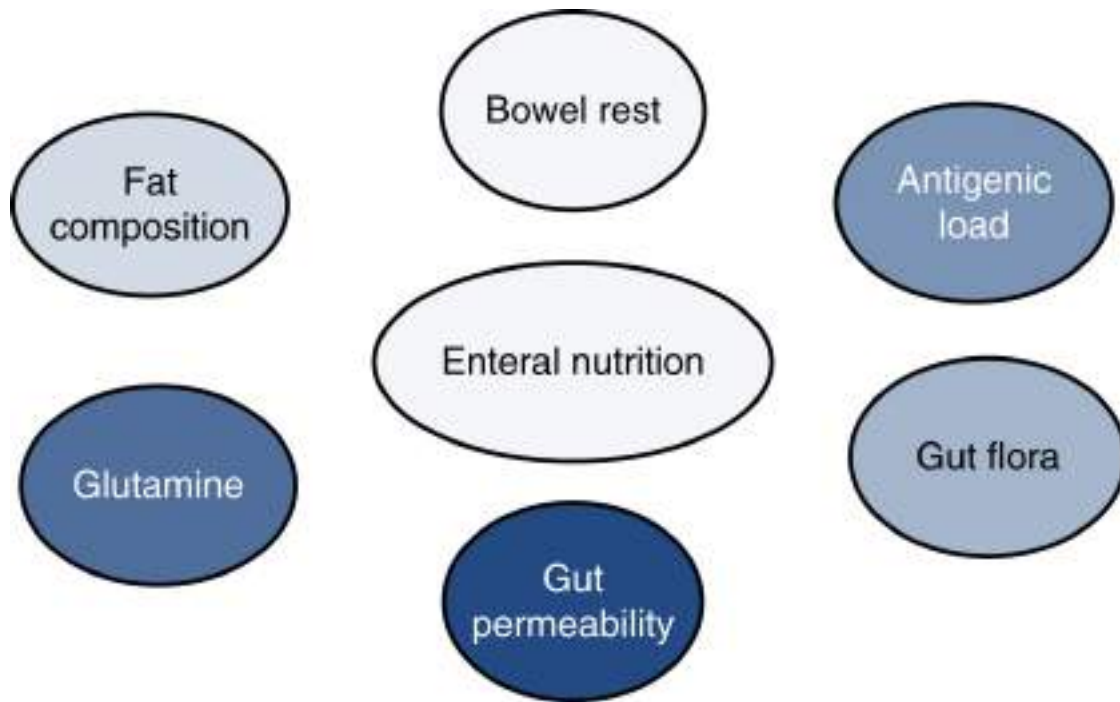

FIG. 50.2 Mechanisms of Enteral Nutrition for the Induction of Remission of Crohn's Disease (CD).

Enteral nutrition has been shown to induce remission in children and adults with Crohn's disease. The possible mechanisms for the benefit of enteral nutrition for CD include its glutamine content, which has trophic effects upon the small intestine, promotes healing, and improves gut permeability, which decreases the translocation of enteric toxins and food-derived antigens, resulting in the attenuation of inflammation. The presence of prebiotic nutrients in enteric formulations enhances the biodiversity of the gut microbiome and decreases the growth of enteric pathogens, thereby promoting immune regulation. Bowel rest for severe disease, elimination diets, and elemental and polymeric formulations all decrease the antigenic load present in the small intestine, thereby diminishing the translocation of immune-enhancing antigens. Finally, diets that are high in saturated fat content, such as the Western diet, drive inflammation and promote IBD in animal models. In contrast, oral nutritional supplements containing omega-3 fatty acids have been shown to induce clinical remission. In Japan, oral nutrition continues to serve as first-line therapy for CD in children and adults.

Enteral nutrition involves a liquid diet containing nutrients broken down into their small or smallest absorbable units. These liquid formulas are provided to the patient via enteral (gut) or parenteral (vein) routes to provide a partial or exclusive source of nutrients. Three types of enteral formulas are available that vary in their degree of hydrolyzation, palatability, and cost:

1. Polymeric—intact nutrients (carbohydrates, proteins, and lipids) are the most palatable and affordable

2. Semi-elemental—partially hydrolyzed nutrients (peptides, starch polymers, simple sugars, glucose, and fats [primarily MCT; medium-chain triglycerides])
3. Elemental—completely hydrolyzed nutrients (amino acids, monosaccharides, fatty acids, vitamins and minerals), not palatable, and costly.^{22,23}

Enteral formulas have a high success rate of inducing remission and ameliorating symptoms without the toxicity seen with pharmaceutical medications. Enteral nutrition is effective for inducing clinical remission in both small and large bowel CD inflammation²³ but not for UC patients.²⁴ A Cochrane meta-analysis of ten trials involving CD patients found no difference in efficacy between polymeric, semi-elemental diets (n = 146) and elemental diets (n = 188) in obtaining clinical remission.²⁵ Unlike corticosteroids, enteral therapy may enhance mucosal healing.²⁶ Researchers have reported improved lactulose/L-rhamnose permeability ratios and cytokine levels²⁷ with enteral therapy. Additionally, 74% (14/19) of pediatric CD patients on oral polymeric formula experienced endoscopic improvement compared to 33% (6/18) treated with corticosteroid.^{28,29} Mucosal healing may be influenced by enteral formulas through lower fecal bacterial concentrations or a lower antigen load crossing the intestinal barrier and triggering inflammation.³⁰ In a study of 61 CD patients who were induced into remission with drugs, 94% in the home elemental enteral hyperalimentation (HEEH) group (n = 22) maintained remission for 1 year, 63% for 2 years, and 63% at 4 years. Enteral nutrition is the recommended treatment in the United States for children with active CD and for adults suffering from corticosteroid complications or malnutrition.³¹

There is a discrepancy between clinical practice guidelines and practice because a survey of 326 of the 1162 North American Society for Pediatric Gastroenterology, Hepatology and Nutrition members found that 55% used exclusive enteral therapy sparingly, 31% never used it, and 12% used it regularly.³² Practice guidelines published in the *American Journal of Gastroenterology* for CD state that “corticosteroids are more effective than enteral nutrition to induce remission in active CD patients”³³ based on a Cochrane meta-analysis of only six trials despite identifying 15 eligible trials.²⁵ However, a PubMed review found that 86% (30/35) of studies supported beneficial results of enteral therapy in CD patients.³⁴

In Japan, enteral nutrition is the first line of therapy for both adults and children, and it is also covered by health insurance.³⁵ After clinical remission with enteral therapy, nightly nasogastric tube feeding followed

by a low-fat diet in the day (20–30 g) reportedly resulted in fewer hospitalizations, surgeries, and complications; longer remissions; and lower mortality rates compared to those not receiving enteral therapy.^{36,35} The benefits of enteral therapy include improved nutritional status and mucosal healing, higher remission rates, and decreased rates of relapse, hospitalizations, and mortality. CD patients need to be informed of enteral therapy as an available treatment choice because it may be necessary in CD patients with strictures or obstructions and may be particularly useful in managing flares that may precede a recommendation for surgery. Enteral nutrition, as with many other dietary changes, may favorably alter gut microbial balance.³⁷

The suggested diet for IBD has a bimodal approach: (1) an elimination diet for symptom control and (2) an antiinflammatory diet for long-term disease control and optimum health. Both of these dietary approaches are covered in depth in [Chapters 86](#) and [88](#). Popular diets that patients have anecdotally reported to be useful for symptom control and improved quality of life (QOL) in IBD include, but are not limited to, the specific carbohydrate diet (SCD), low-carbohydrate diets, the gluten-free diet, and the yeast-free diet, among others. Essentially, these are all different forms of an elimination diet designed to remove potentially sensitizing foods that trigger symptoms. The SCD and low carbohydrate diets have received the most attention and acclaim from patients and have some research to support their use. The SCD eliminates certain carbohydrates, lactose, and some gluten. It was developed in the 1920s by a pediatrician, Dr. Haas, for celiac disease and published in his 1951 book, *Management of Celiac Disease*.³⁸ The diet was so successful in reducing Elaine Gottschall's daughter's UC symptoms that she later popularized the SCD in her book, *Breaking the Vicious Cycle: Intestinal Health Through Diet*, and accompanying websites. The current SCD is low gluten because breads are not allowed, and it eliminates disaccharides (lactose, sucrose, maltose, and isomaltose) and digestible saccharides (starches); however, monosaccharides such as glucose, fructose, and galactose are allowed. Foods to avoid include cereal grains, legumes (beans, peas, and lentils), potatoes, and sweeteners. Allowed foods include meat, poultry, fish, eggs, nut flour, peeled vegetables and low-carbohydrate fruits, aged cheese, homemade yogurt, and honey.³⁴ Essentially, the SCD is an elimination diet that restricts gluten and dairy (lactose-containing foods), two of the highest food offenders in CD. Only two clinical and two case studies have specifically evaluated the SCD in patients. A retrospective study of seven children using the SCD reported that Pediatric Crohn's

Disease Activity Index (PCDAI) levels decreased to zero at 3 and 6 months. Each patient's laboratory values, including C-reactive protein, hematocrit, and stool calprotectin, either normalized or significantly improved when measured.³⁹ Cohen et al.⁴⁰ reported the first prospective study evaluating the SCD in nine CD pediatric patients. Six (60%) patients achieved clinical remission by 12 weeks (PCDAI < 10), with improved symptom indices and capsule endoscopy revealing mucosal healing of intestinal lesions in four (44%) of the subjects at 12 weeks. Two case reports documented improved clinical and endoscopic remission in two adults after 1–2 years on the SCD.⁴¹ In addition to SCD studies, four clinical trials, with weak methodology, have evaluated low-carbohydrate diets in CD. They all support that lower carbohydrate diets (not a SCD) reduce gastrointestinal symptoms in CD.⁴²⁻⁴⁵

Dietary suggestions based on clinical practice guidelines include, but are not limited to, eating smaller meals, decreasing fiber during active disease and slowly reintroducing it, avoiding dairy products if not tolerate, and avoiding fatty foods (especially fatty meats), beans, peas, nuts, and “scrappy” foods such as raw fruits, vegetables, seeds, and popcorn.¹⁶ During bouts of diarrhea and abdominal pain, a softer diet and sufficient fluids are recommended, whereas high sugar drinks, juices, caffeine, alcohol, and sugar alcohols should be avoided. Obstruction may require a liquid diet or nothing by mouth. Retrospective studies have reported that the top two dietary offenders in a subgroup of CD patients are gluten and casein/lactose⁴⁶; however, wheat (34%; 34/199), milk (31%; 35/144), and yeast (19%; 22/119) were reported to be the foods most likely to cause problems for CD subjects.⁴⁷ A cohort survey of 1647 Crohn's and Colitis Foundation Association (CCFA) members (Herfarth, Martin, Sandler, Kappelman, & Long, 2014) revealed that 19% (314) had tried a gluten-free diet, with 66% of them reporting improved symptoms of bloating, diarrhea, abdominal pain, and/or nausea.⁴⁸ Such varied responses to diet among IBD patients made it difficult to suggest one type of diet, so IBD patients would appear to benefit from an individualized diet eliminating their particular aggravating foods. Accordingly, the best diet to achieve this aim would be a comprehensive elimination diet as discussed in [Chapter 86](#).

There is no one particular recommended diet to help alleviate the symptoms and inflammation caused by IBD. Each patient's nutrition plan should be individualized based on disease activity, extent, and

phenotype. However, celiac disease and lactose intolerance commonly co-occur with IBD and should be ruled out.

Vitamin-Mineral Supplements in IBD

Patients suffering with IBD frequently have vitamin and mineral deficiencies due to decreased intake or poor absorption secondary to inflamed mucosa. Some vitamins and minerals are believed to have antiinflammatory, immunogenic, and antineoplastic properties. However, serious toxicities are possible with excessive intake of certain nutrients, and caution should be taken regarding interactions between medications and supplements.

Vitamin A

Vitamin A (retinol) is a fat-soluble vitamin important for wound healing⁴⁹ and is found to be deficient in up to 44% of IBD patients.⁵⁰⁻⁵² Vitamin A requires an intact enterohepatic biliary circulation to be adequately absorbed, which is altered in patients with large ileal resections or extensive ileal disease as is commonly seen in Crohn's Disease (CD), which involves the ileum in 80% of cases. Two studies failed to demonstrate a benefit of high-dose vitamin A for maintaining remission in CD, although both studies comprised patients without acute inflammation.^{53,54} Supplementation is only recommended to sufficiency in patients with vitamin A deficiency.

Vitamin B₁₂

Vitamin B12 (cobalamin) deficiency is common in IBD patients and has been reported in up to 50% of Crohn's patients.⁵⁵⁻⁵⁸ Vitamin B12 deficiency can manifest clinically with a variety of signs and symptoms, including nervous system dysfunction or megaloblastic anemia.^{57,59,60} The absorption of B12 requires the secretion of intrinsic factor by the stomach, which is essential for the absorption of vitamin B12 in the ileum. Because the ileum is the most frequent location affected in Crohn's disease, there is a significantly increased risk of B12 deficiency and insufficiency among this patient population.⁶⁰

True cobalamin deficiency leads to elevated serum levels of methylmalonic acid (MMA) and homocysteine, which have both been linked to higher risks of cardiovascular disease and stroke. The

sensitivity and specificity of serum B12 levels in the diagnosis of B12 deficiency is poor⁶¹⁻⁶⁴ and some experts, including NHANES, have recommended that an elevated MMA or homocysteine level be required for an accurate diagnosis of cobalamin deficiency.^{61,65} The daily requirement of B12 is 2.4 mcg in the general population.⁶⁶ Higher doses are needed if a patient is deficient according to the severity of symptoms. Supplementation via the subcutaneous route is best in patients with ileal inflammation or resection due to poor absorption. However, the malabsorption can be overcome with high doses of oral cobalamin (1000–2000 mcg daily), which are absorbed through passive diffusion or the sublingual route.^{66,67}

Vitamin D

Vitamin D has been shown to regulate cell growth and is a key cofactor in the immune system.⁶⁸⁻⁷⁰ Vitamin D may act as an antiinflammatory and immune regulatory agent. Between 22% and 70% of Crohn's patients and up to 45% of UC patients have been reported to have vitamin D deficiency.⁷¹⁻⁷⁴ The Nurses' Health Study has demonstrated two important findings: a lower risk of UC in those with the highest intake of vitamin D supplementation and a lower risk of CD in those with higher vitamin D levels.⁷⁵ Patients with CD appear to have less frequent flares and improved disease activity scores with vitamin D supplementation.^{76,77} A prospective study showed that CD patients supplemented with vitamin D to sufficiency (30–50 ng/mL) had a decreased risk of hospitalization and surgery.⁷⁸ A subsequent prospective, randomized, placebo-controlled study found that daily supplementation with 1200 IU of vitamin D3 decreased the rate of relapse ($P = 0.06$) in 108 CD patients in remission.⁷⁶ Vitamin D levels (25 hydroxy-D) should be assessed on at least an annual basis in IBD patients and repleted to maintain levels > 30 ng/mL.

Vitamin K

Vitamin K has been shown to play a role in bone health along with magnesium, calcium, and vitamin D. IBD patients with ileitis or those treated with sulfasalazine or antibiotics are at risk of vitamin K deficiency.^{78a} Dietary intake of vitamin K has been shown to be lower in IBD patients in several studies. Currently, there is insufficient evidence to support daily vitamin K supplementation. Patients should instead be encouraged to consume green leafy vegetables to obtain vitamin K

naturally through the diet.⁷⁹

Vitamin E

Vitamin E has been shown to significantly reduce oxidative stress by preventing the production of reactive oxygen species and terminating chain reactions in cell membranes.^{52,80,81} IBD patients have been found to have decreased levels of vitamin E (tocopherol).⁸² Several rodent studies and a small human study have shown promise in the treatment of colitis with vitamin E enemas.⁸³⁻⁸⁵ Vitamin E is another fat-soluble vitamin; therefore, large doses can lead to toxicity, and caution needs to be taken with this therapy. Large population-based studies have actually found increased rates of all-cause mortality with high doses of vitamin E supplementation.^{86,87}

Vitamin C

Vitamin C or ascorbic acid is an essential water-soluble vitamin that has been found to be low in IBD patients, at least partially due to inadequate intake.^{50,52,56} More than 50% of Crohn's patients have been reported to be vitamin C deficient.⁵⁶ The wound-healing effects of vitamin C are particularly important.⁸⁸ Although excess vitamin C is not life threatening because it is water soluble, high levels may cause diarrhea, nausea, vomiting, abdominal pain, and oxalate kidney stones. Excessive repletion of vitamin C (i.e., intravenous infusions) has not been shown to have any proven health benefits and is not recommended.

Folate

Folate deficiency is observed in up to 26% of CD patients.^{50,58} Mesalamines, particularly sulfasalazine and methotrexate, inhibit folate absorption. Folate supplement of 1 mg daily is therefore advised.⁸⁹ Folic acid deficiency is associated with elevated homocysteine levels⁹⁰ and thromboembolism.⁹¹ Additionally, low folic acid levels are associated with an increased risk of colorectal dysplasia or cancer in IBD patients⁹²⁻⁹⁴ as well as the general population.⁹⁵⁻⁹⁸ Folate supplementation beyond sufficiency has not been shown to prevent colorectal neoplasia or dysplasia.⁹⁹⁻¹⁰² Red cell folate levels are more accurate than serum levels and should be monitored at least annually in patients on the aforementioned medications that predispose to folate deficiency. Low folate levels may also reflect an inherited posttranslational modification

of the enzyme methylene tetrahydrofolate reductase (MTHFR), requiring supplementation with folinic acid to sufficiency to bypass the defective metabolic process. Genetic testing for MTHFR mutation is therefore recommended and offered by most commercial laboratories and covered by insurance carriers.

Calcium

Calcium is an essential macronutrient and requires vitamin D for adequate absorption from the intestines. It has been reported that 80% of IBD patients have inadequate calcium intake^{50,56} and up to 50% have osteopenia.^{103,104} Low magnesium levels, commonly caused by diarrhea, also cause calcium malabsorption. Corticosteroids used to treat IBD are known to inhibit calcium absorption. Calcium deficiency leads to an inability to maintain bone health that eventually causes osteoporosis. Glucocorticoids are also known to accelerate the development of osteoporosis.⁷⁹

The majority of IBD patients likely should be on standard daily calcium supplementation (1000–1500 mg). Because calcium requires vitamin D to be absorbed, IBD patients should be on both calcium and vitamin D supplementation to maintain bone health and prevent osteoporosis, particularly those currently on steroids.⁷⁹

Monitoring of bone health is essential in all patients with IBD because they are at high risk for osteoporosis and bone fractures. To maintain adequate bone health, IBD patients should not smoke cigarettes and should limit or avoid corticosteroid use. Bone homeostasis requires adequate calcium, vitamin D, magnesium, and vitamin K.

Chromium

Chromium deficiency can occur in patients on long-term central parenteral nutrition (CPN),¹⁰⁵ and 10–15 mcg should be added to the daily mix to prevent it. Glucocorticoids have been shown to increase urinary excretion of chromium. Signs of chromium deficiency include a hypochromic microcytic anemia and poor glucose control. Supplementation with chromium up to 600 mcg daily may reverse steroid-induced diabetes.¹⁰⁶

Iron

Iron is the most commonly deficient nutrient in IBD patients, with a prevalence of approximately 30%.¹⁰⁷ Repletion of iron is clinically challenging in IBD patients. Cholestyramine and antacids impair absorption of iron, whereas ascorbic acid facilitates absorption. Oral iron can be harsh on the GI tract, causing nausea, gastritis, and constipation. There is some evidence that oral iron may increase oxidative stress in the intestines by increasing superoxide anion generation according to Fenton chemistry analysis in animal models.¹⁰⁸ Intravenous iron repletion may be the most effective approach despite a risk of anaphylaxis, particularly in patients with severe deficiency.¹⁰⁹ Ferric carboxymaltose is a new formulation of iron that can be safely administered at higher doses (1000 mg) to achieve normal levels more rapidly while decreasing the required number of infusions. Due to the decreased number of infusions, patients are more compliant with this therapy. Additionally, ferric carboxymaltose (1000 mg) has been shown to be more effective than standard iron sucrose (200 mg) in improving hemoglobin levels.¹¹⁰

Magnesium

Magnesium plays a role in maintaining adequate bone health, parathyroid function, and calcium absorption. Magnesium deficiencies have been reported in patients with diarrhea, high fistula output, malabsorption, or inadequate oral intake. To most accurately measure the body stores of magnesium, a 24-hour urine is required.^{111,112} Red blood cell (RBC) magnesium levels also provide an additional measure of intracellular magnesium status. Decreased levels of magnesium in the urine increase the risk of urolithiasis, for which CD patients are already at risk.¹¹³ Magnesium formulations, such as heptogluconate and magnesium pyroglutamate, may have less association with diarrhea than citrate.

Selenium

Selenium is a mineral that plays a vital role in antioxidant functioning by acting as a cofactor for glutathione peroxidase and reducing vitamin E regeneration. Selenium deficiency is associated with cardiomyopathy, hypothyroidism, and cartilage degeneration.⁷⁹ The long-term use of CPN and small bowel resection can lead to selenium deficiency.¹¹⁴ Several studies have confirmed lower levels of selenium in both UC and CD patients compared with the general population.¹¹⁵⁻¹²⁰

Zinc

Zinc deficiency can develop in patients with severe diarrhea, high output ostomies, and long-term corticosteroid or CPN use.¹²¹ Zinc is required for the metabolism of vitamin A, including the oxidative conversion of retinol to retinal and vitamin A transport.¹²² Measuring the overall zinc status in the body is challenging; however, many use the levels of zinc in RBCs to reflect intracellular status.⁷⁹ Supplementation with 220 mg of zinc sulfate once or twice daily is recommended in patients with draining fistulae, recent surgery, or active and severe diarrhea.⁷⁹ Zinc repletion should be provided with vigilance because excess zinc interferes with the absorption of iron and copper.⁸⁸ Copper deficiency with profound neurological manifestations has been described with high-dose supplementation of zinc because these two micronutrients compete for binding to metallothioneine.

Non-Vitamin-Mineral Supplements

Fish Oils or Fatty Acids

There are two major types of essential fatty acids (EFAs): omega-3 and omega-6 polyunsaturated fatty acids (PUFA). These are considered essential because the body is unable to synthesize them, thereby necessitating dietary intake. Omega-3 has been shown to have beneficial health effects, including antiinflammatory properties, whereas excess omega-6 has been associated with proinflammatory and prothrombotic states. The ratio of omega-6 to omega-3 consumed should be approximately 4:1, but a Western diet has a ratio closer to 10:1 and some experts believe this imbalance contributes, in part, to the development of IBD and or its recalcitrance to medical therapy.¹²³ Omega-3 supplementation decreases inflammatory cytokines, including TNF- α , IL-1 β , and NF- κ B, as well as improves the functioning of the immune system.^{124,125} Fish oil is an excellent source of omega-3 fats. Up to a quarter of IBD patients have some level of EFA deficiency.¹²⁶ Diets high in omega-3 fatty acids are associated with a reduced risk of ulcerative colitis.¹²⁷ Several animal studies have suggested a benefit to dietary fish oil supplementation and rectal fish oil treatment in chemically-induced colitis.¹²⁸⁻¹³³ There are no randomized trials investigating omega-3 fatty acids for the induction of remission in Crohn's patients, but maintenance studies have been reported. The Epanova Program in Crohn's study (EPIC) 1 and 2 was a randomized, controlled, multicenter, parallel design

study that reported no benefit of fish oil in the maintenance of CD.¹³⁴ Subsequently, a second Cochrane review of six studies investigating the role of fish oil on Crohn's disease maintenance found high heterogeneity with slightly improved outcomes in patients on fish oil (RR = 0.77, 95% CI 0.61–0.98). When the studies with high risk of bias and heterogeneity were excluded, there was no longer a benefit to fish oil over placebo.¹³⁵ A smaller study reported a benefit of fish oil with concomitant mesalamine use.¹³⁶ Another study suggested that fish oil may be more efficacious in Crohn's colitis than in small bowel enteritis.⁴⁵

In contrast to CD, studies on the role of fish oil in the treatment of active ulcerative colitis have shown more promising results.¹³⁷⁻¹³⁹ Supplementation with fish oil in active UC has been shown to improve clinical disease activity scores,¹³⁷ decrease the need for prescription therapy,¹³⁷ promote weight gain,¹³⁸ and reduce proinflammatory leukotriene B4 levels.¹³⁸ A novel nutritional approach using fish oil in a nutrition supplement was consumed by patients with active UC who were corticosteroid dependent. UC patients who consumed a solution containing fish oil, fructooligosaccharides, gum arabic, and antioxidants were more likely to taper prednisone over 6 months compared to placebo (P < 0.001).¹⁴⁰ Interestingly, the same principal investigator conducted a similar study in CD and reported a benefit of this solution in lowering the CD activity index and improving vitamin D status.¹⁴¹ Only one study has compared mesalamine (sulfasalazine 2 g daily) to omega-3 fatty acids (5.4 g daily) in patients with active UC, with sulfasalazine treatment found to be superior to treatment with omega-3 fatty acids.¹⁴² Therefore, fish oil should be considered as an adjuvant therapy to standard therapies. Of note, a case report has described a woman with distal UC who was brought into clinical and endoscopic remission with daily enemas of 3 g of omega-3 fatty acid.¹⁴³ This is of particular interest given the aforementioned animal studies whereby rectal instillation of fish oils prevented and mitigated chemically induced colitis.

Glutamine

Glutamine is a nonessential amino acid but can be conditionally essential in catabolic conditions. It is the main energy source for small intestine enterocytes.^{144,145} Animals provided a glutamine-deficient diet developed increased gut permeability and decreased functioning of the mucosa.^{146,147} Supplementation of glutamine is beneficial in patients on TPN as it preserves villous health and prevents disruptions in intestinal

permeability.^{148,149} A small study investigating the role of glutamine on intestinal permeability in CD found no improvement following supplementation with 7-g glutamine three times daily.¹⁵⁰ The majority of alternative practitioners provide a dose escalating program starting with 5 g tid to a maximum of 30 g daily. In a pediatric CD study, 18 children with active CD were provided either a glutamine-enriched diet or a low-glutamine diet, and no differences were found in the remission rate, weight, or lab values.¹⁵¹ Two rodent studies have reported harmful effects, with the use of glutamine causing worsening colitis or increased oxidative stress.¹⁵² Currently, glutamine is contraindicated in colitis until further studies can shed light on the efficacy of glutamine in IBD. Glutamine has been recently reported to have favorable effects on the gut microbiome, which may be one reason why many practitioners continue to use this supplement for IBD patients. There is a theoretical concern that glutamine could be converted to glutamate, which is an excitatory neurotransmitter.¹⁵³

N-Acetylcysteine

Glutathione is considered one of the most important antioxidant defenses in the body. N-acetylcysteine (NAC) replenishes glutathione rendered inactive by oxidation within the liver and has been shown to have antiinflammatory effects.¹⁵⁴ Animal models have demonstrated promise in using NAC as a treatment for colitis.¹⁵⁵⁻¹⁵⁸ Only one human study of UC demonstrated clinical improvement with the use of NAC; however, rates of remission did not reach clinical significance ($P = 0.19$).¹⁵⁹

Phosphatidylcholine

Phosphatidylcholine (PC) is an important component of the mucosal layer of the colon and acts as a surfactant within the mucus to create a hydrophobic surface to prevent bacterial penetrance. PC levels have been found to be reduced in the colon of UC patients compared to controls.^{160,161} Without adequate PC in the mucosa, the intestinal barrier is permeable to colonic bacteria, leading to chronic intestinal inflammation and barrier defects.¹⁶¹⁻¹⁶⁴ Four human trials have been performed to determine the efficacy of PC in the treatment of UC. Two studies on patients with chronic active UC have reported clinical, endoscopic, and histological improvements.^{165,166} Steroid-refractory UC patients were more successful in weaning off steroids when treated with PC compared to placebo ($P < 0.01$).¹⁶⁷ A double-blinded, randomized, placebo-

controlled, multicenter study found that 3.2 g daily of PC improved clinical activity scores, histological remission, and relapse rates without any significant adverse events.¹⁶⁸

Melatonin

Melatonin is synthesized from the amino acid tryptophan and is important for the circadian rhythm. It is known to induce Th1 lymphocytes and worsen the clinical course of UC and CD. As such, this supplement is contraindicated in IBD patients.¹⁶⁹⁻¹⁷¹

Dehydroepiandrosterone

Dehydroepiandrosterone (DHEA) is one of the most abundant endogenous circulating steroid hormones produced mainly within the adrenal cortex. DHEA may inhibit the activation of NF- κ B and secretion of IL-6 and IL-12.¹⁷² One study found lower levels of DHEA-S (the sulfated form) in the blood and intestines of IBD patients,¹⁷³ although this may have been secondary to the use of corticosteroids.¹⁷⁴ A pilot trial by Andus et al. demonstrated an improvement in clinical activity indices in 20 IBD patients treated with 200 mg of DHEA orally for 8 weeks.¹⁷² A case report suggests that DHEA may also be useful in the treatment of pouchitis.¹⁷⁵

Probiotic and Prebiotic Supplements in IBD

Probiotics are defined as “live microorganisms which, when administered in adequate amounts, confer a health benefit on the host.” To be labeled a probiotic, a number of criteria must be met.¹⁷⁶ Each probiotic must be strictly specified at the genus, species, and strain levels. Probiotics, by definition, contain live cultures when administered and should be shown to be viable prior to consumption, during intestinal transit, and be able to successfully colonize the intestines. There should be human-controlled trials evaluating the health benefits of probiotics. Probiotics are considered safe for their intended use.¹⁷⁷

VSL#3

VSL #3 is a commercial product containing three genera of bacteria and a total of eight different species: Lactobacilli (*L. casei*, *L. plantarum*, *L. acidophilus*, and *L. delbrueckii*), Bifidobacteria (*B. longum*, *B. breve*, and *B.*

infantis), and *Streptococcus* (*S. salivarius*). VSL#3 has been shown to restore the gut flora, attenuate inflammation, and decrease bacterial translocation.¹⁷⁸⁻¹⁸² It has been studied for CD, UC, and pouchitis, with the most compelling evidence for treatment of pouchitis. Regarding CD, several meta-analyses have failed to demonstrate a benefit of probiotics, although these trials were all quite heterogeneous.¹⁸³⁻¹⁸⁶ Several studies have demonstrated a benefit of VSL#3 in the treatment of active UC.¹⁸⁷⁻¹⁹¹ A systematic review with meta-analysis concluded that VSL#3 at a dose of 3.6×10^{12} CFU/day is superior when added to standard therapy compared to standard therapy alone in achieving response and remission in mild to moderate UC. This report noted that VSL#3 appears to be an adjuvant therapy and not a therapy that has been shown to be efficacious as monotherapy for active UC. Two trials^{192,193} have provided evidence for the use of VSL#3 in the maintenance of remission of UC, and the American recommendations for probiotic use from 2011 strongly recommend VSL #3 for UC maintenance.¹⁹⁴ The most common side effect noted was symptomatic bloating without any serious adverse events reported.¹⁹⁵ The best data for VSL#3 is in UC patients who have undergone ileal pouch anal anastomosis with pouchitis, which is a common complication of total colectomy with ileal pouch anal anastomosis in these patients. Although exact mechanisms are still unknown, mucosal ischemia, genetic factors, and bacteria dysbiosis are thought to contribute to the pathogenesis of UC. Antibiotics temporarily alleviate the symptoms, but they rapidly return after treatment cessation due to gut microbial dysbiosis.¹⁷⁶ Clinical guidelines suggest the use of VSL#3 for the maintenance of remission of pouchitis and prevention of recurrent pouchitis; however, there is insufficient evidence to recommend VSL#3 for the treatment of acute pouchitis.¹⁹⁶

Lactobacillus GG

Lactobacillus rhamnosus GG (LGG) was first isolated in 1983 and is known to have a strong avidity for human intestinal cells and can survive acid and bile environments. It is considered one of the most studied probiotics, with research showing that it could alleviate rotavirus diarrhea in children,¹⁹⁷ prevent atopic dermatitis,¹⁹⁸ protect against urinary tract infections,^{199,200} and improve symptoms of irritable bowel syndrome.²⁰¹⁻²⁰³ LGG appears to be safe and effective in prolonging remission in UC patients.²⁰⁴⁻²⁰⁷ LGG has also been studied in CD, but found to be no better than placebo.^{208,209}

Saccharomyces boulardii

Saccharomyces boulardii (SBC) is a tropical, nonpathogenic strain of yeast, which has been successfully used as a probiotic for alleviating traveler's diarrhea,²¹⁰ HIV-induced diarrhea,²¹¹ antibiotic-associated diarrhea,²¹² and even in the prevention of *Clostridium difficile* relapses.²¹³ Animal models have shown hope for the use of SBC in the treatment of IBD.²¹⁴⁻²¹⁷ A pilot study has demonstrated the efficacy of SBC in treatment of mild to moderate UC.²¹⁸ A case series of six patients with left-sided UC who were intolerant to mesalamine reported that patients responded to *S. boulardii* 500 mg plus rifaximin 400 mg.²¹⁹ In CD, SBC has been shown to decrease the frequency of bowel movements.²²⁰ The addition of *S. boulardii* to mesalamine has demonstrated utility in maintaining remission of CD.²²¹ Interestingly, in one study, SBC has been shown to improve intestinal permeability among patients with CD.²²² The largest prospective, randomized, placebo-controlled trial of 165 Crohn's patients in remission who were followed for 1 year found that SBC was no better than placebo in preventing relapse.

Prebiotics

Prebiotics are defined as nondigestible fibrous products that selectively promote the growth or activity of beneficial bacteria and improve the well-being of the host. Prebiotics generally are not digested and absorbed into the intestines and instead provide nutrition to the beneficial bacteria (*Lactobacillus* and *Bifidobacterium*) in the distal small bowel and colon. Some examples of prebiotics include bran, psyllium husk, inulin, fructooligosaccharides (FOS), and galactooligosaccharides (GOS). Prebiotics are commonly used to regulate the bowels both in constipation, where they increase fecal water content, and diarrhea, where they add bulk to the stool. *Plantago ovata*, also known as psyllium, has been studied in the treatment of ulcerative colitis. One small study reported that a 4-month treatment with *Plantago ovata* improved symptoms in UC patients in remission.²²³ An open-label trial in 105 patients with quiescent UC who were randomized to one of three groups: 10 g twice daily of *Plantago ovata*, 500 mg three times daily of mesalamine, or *Plantago ovata* plus mesalamine reported similar rates of continued remission.²²⁴ Inulin (12 g daily) has been shown to decrease levels of fecal calprotectin in active UC patients and to be well tolerated.²²⁵ In a mouse model of UC, inulin decreased the amount of nitric oxide in the colon and the severity of the colitis, indicating that

inulin may be helpful in the treatment of active UC.²²⁶ Inulin has also shown promise in the treatment of pouchitis.²²⁷ An open-label trial of fructooligosaccharides (FOS, 15 g daily for three weeks) was performed in 10 active CD patients with active ileocolonic disease with clinical improvement.²²⁸ In contrast, a controlled trial of 103 patients found no difference in clinical response, but patients treated with FOS had higher drop-out rates. There are several rodent studies demonstrating a decrease in intestinal inflammation and improvement in colonic bacterial composition after FOS treatment²²⁹⁻²³¹; therefore, further studies are required to investigate the potential efficacy of FOS in IBD.

Germinated barley foodstuff (GBF) was initially discovered to attenuate colitis in animal models by increasing luminal short-chain fatty acid production.^{232,233} In a pilot study, 10 patients with active UC received 30 g of GBF for 4 weeks and were found to have an improvement in clinical activity and endoscopic scores and an increase in stool butyrate levels.²³⁴ A study by Kanauchi et al. of 18 UC patients found that 20–30 g daily of GBF improved clinical scores and increased *Bifidobacterium* numbers.²³⁵ A follow-up, open label study of 21 UC patients by Kanauchi et al. again demonstrated improved symptomatic scores, a decrease in rectal bleeding, and lower rates of nocturnal diarrhea.²³⁶ To investigate the efficacy of GBF in maintaining remission in UC, 59 patients were administered either GBF (20 g daily) plus standard therapy or placebo plus standard therapy for 12 months. Improved clinical activity index scores were observed in the GBF group at each time point with lower recurrence rates.²³⁷ In a study investigating the mechanism of action of GBF, Faghfoori et al. demonstrated that GBF reduced levels of serum TNF- α , IL-6, and IL-8. The most recent clinical study of GBF reported a reduction in CRP levels, abdominal pain, and cramping compared to placebo.²³⁸ A rodent model has also shown GBF may prevent the development of colitis-associated neoplasia,²³⁹ although this decreased risk of neoplasia may simply be due to the decrease in inflammation and not necessarily a chemopreventive effect.

Prebiotics must be used with caution in CD patients with stricturing disease because high fiber loads can lead to obstruction. Additionally, prebiotics are known to cause gas and bloating when commenced, and starting at lower doses may help alleviate these GI effects.

Synbiotics

Synbiotics are a combination of prebiotics and probiotics that are believed to have a synergistic effect by inhibiting the growth of pathogenic bacteria and enhancing the growth of beneficial organisms.^{240,241} One study found that synbiotic therapy (*Bifidobacterium longum* plus psyllium) was superior to either therapy alone in improving IBD questionnaire scores and C-reactive protein (CRP) levels.²⁴² The synbiotic Synergy 1 (FOS/inulin mix) and *Bifidobacterium longum* reportedly improved active UC according to sigmoidoscopy scores and inflammatory markers.²⁴³ A synbiotic containing 10^9 CFU of the *Bifidobacterium breve* strain Yakult and 5.5 g of galactooligosaccharide (GOS) was shown to improve colonoscopic findings and fecal concentrations of *Bacteroidaceae*.²⁴⁴ In a small study, 10 patients with active CD refractory to mesalamine and steroids were administered a synbiotic containing 75 billion CFU of either *Bifidobacterium* or *Lactobacillus* and 9.9 g of psyllium and were allowed to adjust the consumption of prebiotic and probiotic as needed. Six patients were able to decrease or stop other therapies for CD, including prednisone. Despite the clinical improvement, no improvements were observed in serum inflammatory markers.²⁴⁵ A randomized, double-blind, placebo-controlled trial of 35 CD patients found that the synbiotic Synergy 1 plus *B. longum* improved CDAI scores ($P = 0.02$) and histological scores ($P = 0.018$).²⁴⁶ In a study investigating the role of synbiotics in the prevention of postoperative recurrence in CD, 30 patients were randomized to either Synbiotic 2000 or placebo in a 2:1 ratio. Synbiotic 2000 consists of four lactic acid bacteria and four fermentable fibers. After 24 months of postoperative follow-up, no effect of Synbiotic 2000 on postoperative recurrence was observed based on symptomatic, endoscopic, laboratory, and histological criteria.²⁴⁷

Bovine Colostrum

Colostrum is a form of milk produced in the mammary glands just before giving birth. It contains high levels of antibodies and protein as well as growth factors and antimicrobial factors that help provide passive immunity and stimulate development of the GI tract in newborns.²⁴⁸⁻²⁵⁰ Several animal studies have found colostrum prevents or alleviates colitis.²⁵¹⁻²⁵³ A study of 14 patients with distal colitis reported improvements in symptoms and histology after 100 mL of 10% bovine colostrum solution enema was given for 4 weeks.²⁵⁴

Herbal Therapies in IBD

Aloe Vera

Aloe vera has been shown to have dose-dependent antiinflammatory properties in vitro by inhibiting the production of reactive oxygen metabolites, eicosanoids, and IL-8.²⁵⁵ A double-blind, randomized, placebo-controlled trial of 44 patients with active UC found that 100 mg of oral aloe vera was superior to placebo in improving clinical and histological disease activity. Additionally, no significant adverse events were observed, indicating that aloe vera may be a safe and efficacious treatment for active UC.²⁵⁶ To date, there are no trials evaluating the effects of aloe vera on CD.

Andrographis paniculata Extract (HMPL-004)

Herbal treatment with *Andrographis paniculata* has been used in Asian countries to treat inflammatory diseases. An extract of *A. paniculata*, HMPL-004, was found to inhibit the development of chronic colitis in rodent models.²⁵⁷ HMPL-004 1200 mg/day was found to have equivalent efficacy to mesalamine 4500 mg/day in terms of clinical remission, response, and endoscopic remission in 125 patients from China with active UC.²⁵⁸ In a larger placebo-controlled trial of 224 patients with mild to moderate active UC, patients were randomized to HMPL-004 at a dose of 1800 mg/day, and a significantly higher rate of clinical response was observed compared to placebo.²⁵⁹

Boswellia serrata

Boswellia serrata has been used for hundreds of years in Indian herbal treatments for multiple inflammatory conditions. *Boswellia* is believed to act via inhibition of 5-lipoxygenase, thereby decreasing leukotriene biosynthesis and resulting in diminished proinflammatory cytokine release.²⁶⁰ A small trial of active UC patients found that *Boswellia* 350 mg three times a day was as effective as sulfasalazine 1000 mg three times a day in decreasing symptoms and laboratory indicators.²⁶¹ A second similar study of 30 active UC patients again found *Boswellia* to be as effective as sulfasalazine, with remission rates of 82% and 75%, respectively.²⁶² *Boswellia* has also been tested in Crohn patients for initiating²⁶³ and maintaining remission.²⁶⁴ Gerhardt et al. performed a randomized, double-blinded study of 102 patients comparing H15, a proprietary *Boswellia serrata* extract, to mesalazine and found a similar

decrease in CDAI in both groups, showing that *Boswellia* is noninferior to mesalamine for treatment of CD.²⁶³ Holtmeier et al. evaluated *Boswellia* versus placebo for maintenance of remission in CD and found no significant difference, but did confirm excellent tolerability and minimal adverse effects.²⁶⁴

Bromelain

Bromelain is a concentrate of proteolytic enzymes derived from the stem of the pineapple fruit and is believed to have antiinflammatory properties. Rodent models of colitis reportedly improved after treatment with bromelain.²⁶⁵ A case series described two chronic UC patients who achieved clinical and endoscopic remission after treatment with bromelain supplementation.²⁶⁶ Larger trials are required to further explore the potential for this novel therapy.

Cannabis sativa

Cannabis sativa, or marijuana, is frequently used for both recreation due to its psychoactive properties and medicinal use due to its effects on pain, nausea, and perhaps inflammation. Cannabis contains more than 60 cannabinoid compounds, with tetrahydrocannabinol (THC) being one of the main active components that act on CB1 and CB2 receptors in the body.²⁶⁷ New findings show that there are endogenous endocannabinoids that also act on these receptors and may play a role in limiting intestinal inflammation.^{268,269} Numerous basic and clinical studies have shown that cannabis use has positive effects on pain, specifically that originating within the GI tract, and inflammation.²⁶⁹⁻²⁷⁶ Cannabinoids have also been shown to prevent or ameliorate colitis in animal models.²⁷⁷⁻²⁸¹

A retrospective observational study reported that 21 of 30 patients improved clinically after cannabis treatment. Additionally, the need for other CD therapies and the number of surgeries both decreased.²⁸² A prospective, placebo-controlled study of cannabis in the treatment of refractory CD showed benefit ($P = 0.028$), with clinical remission (CDAI < 150) achieved in 45% in cannabis group versus 10% in placebo group ($P = 0.43$).²⁸³ A recent study investigating the effects of cannabis on IBD reported an association between more severe disease and higher risk of surgery among cannabis users, although causality could not be determined based on this study design.²⁸⁴

Marijuana use is most common amongst IBD patients with a history of abdominal surgery and worse symptom scores.²⁸⁵ Cannabinoids have

been shown to inhibit intestinal secretion and may help with diarrheal symptoms.^{268,269,286} Severe IBD patients also suffer with a loss of appetite, and cannabis is known to enhance appetite.²⁸⁷ Notably, cannabis is not without side effects. Almost a third of patients reported paranoia and anxiety,²⁸⁵ and there are known long-term mental health consequences of chronic cannabis use.²⁸⁸ Palpitations and cardiac effects have been reported in cannabis users.²⁸⁹

Curcumin and Turmeric (*Curcuma longa*)

Curcumin is a naturally occurring substance from the plant *Curcuma longa* and is an active phytochemical contained within turmeric.²⁹⁰ Curcumin has been shown to possess antioxidant, antiinflammatory, and anticarcinogenic properties.²⁹¹⁻²⁹³ By inhibiting the synthesis of IL-2, TNF- α , and IFN- γ , curcumin also acts as an immunosuppressant.^{292,294} The antiinflammatory effects of curcumin on the colonic tissue have been shown to be at least in part due to inhibition of chemokine expression and direct inhibition of neutrophil chemotaxis and chemokinesis.²⁹⁵ The poor systemic absorption of curcumin maintains the active compound within the intestines, where it has antiinflammatory properties.²⁹⁴ Preliminary studies in rodents have reported that curcumin is able to prevent and treat chemically induced colitis.²⁹⁶⁻³⁰⁰

Several human studies have reported promising results and an excellent safety profile for the use of curcumin in IBD patients. An initial open-label study of 10 IBD patients (5 UC, 5 CD) found symptomatic improvement in 90% of patients.³⁰¹ Hanai et al. conducted a randomized, double-blind, placebo-controlled trial of 89 UC patients with quiescent disease on stable doses of baseline mesalamine therapy. Two grams daily of oral curcumin was associated with reduced symptoms, UC flares, and endoscopic inflammation compared to placebo.³⁰² A recent multicenter, randomized, double-blind, placebo-controlled study by Lang et al. reported that the combination of mesalamine and curcumin may have a synergistic effect in mild to moderately active UC. Oral curcumin at a dose of 3 g daily was administered to 26 UC patients on optimized mesalamine therapy and compared to placebo plus mesalamine administered to 24 patients. Clinical remission was achieved in 54% of patients receiving curcumin compare to 0% of patients receiving placebo. Additionally, clinical improvement, endoscopic remission, and endoscopic improvement were significantly improved in the curcumin group compared to the placebo group. Importantly, no difference in rates

of adverse events were observed between the two groups, again demonstrating curcumin as a safe and well-tolerated treatment in UC.³⁰³ Curcumin has also been shown to be antineoplastic and has proven to decrease polyp growth in familial polyposis syndrome.²⁹³ Due to these known chemopreventive effects against colon cancer, curcumin may be an excellent choice for IBD patients who have a known increased risk of colorectal cancer. Curcumin definitely appears to have promise in the treatment of UC and possibly CD, although further studies are required.

Wormwood (*Artemisia absinthium*)

Wormwood is a fragrant herb traditionally used to treat various digestive disorders with favorable effects on the gut microbiome, leading to resolution of gut microbial dysbiosis.³⁰⁴ Two human studies have evaluated the efficacy of wormwood in CD. In an initial study of 40 patients with CD receiving 40 mg of prednisone daily, participants were administered 1500 mg of wormwood or placebo daily for 10 weeks. More patients receiving wormwood compared to placebo were able to successfully taper the steroids.³⁰⁵ The second study of 20 CD patients administered either 2250 mg of wormwood or placebo daily. Patients receiving wormwood had a decrease in serum TNF- α levels after 6 weeks. Additionally, patients treated with wormwood had reduced CDAI and overall mood scores (Hamilton's Depression Scale).³⁰⁶

Wheat grass juice (*Triticum aestivum*/Poaceae)

Wheat grass juice is made from the pulp of the common wheat plant *Triticum aestivum*, which is a subspecies of the family Poaceae. Antioxidant properties have been exhibited by wheat grass extracts due to radical scavenging and antiinflammatory activity.^{307,308} In a study of 23 patients with UC, patients were administered either 100 cc of wheat grass juice or placebo daily for 1 month. Those who received active treatment had significantly reduced overall disease activity ($P = 0.031$) and rectal bleeding severity ($P = 0.025$) without any serious side effects.³⁰⁹ Due to the concurrence of IBD and celiac disease, patients should be certain they do not have celiac disease before using wheat grass juice.

Xilei-san

Xilei-san (XLS) is a mixture of herbs used in Chinese medicine for inflammatory or ulcerative diseases, such as oral ulcers, gastritis, and peptic ulcer disease.³¹⁰ XLS consists of a fixed combination of eight

natural herbs/minerals.³¹⁰ Animals treated with XLS enemas were shown to have less severe colitis.³¹⁰ XLS suppositories 0.1 g daily were used for refractory ulcerative proctitis patients who improved clinically and endoscopically compared to placebo.³¹¹ A second human study was performed on 35 patients with ulcerative proctitis where the researchers compared XLS to dexamethasone enemas. After 12 weeks, XLS was found to be equivalent to dexamethasone in terms of clinical, endoscopic, and histological grading scores. No adverse events were noted with XLS, and it was found to be well tolerated overall. XLS may be considered as an adjuvant or alternative therapy for patients with ulcerative proctitis.

Pharmaceuticals and Helminths

Antimicrobial Drugs

Because studies have suggested that infectious agents may be the cause or exacerbating factor in IBD, antibiotics have been frequently used in the treatment of IBD. The data is sparse, and there is no clear benefit in UC, a small benefit in CD, and the most benefit in pouchitis.³¹²⁻³¹⁵ Antibiotics are mainly used to treat the complications of IBD, such as abscesses, perforations, or wound infections. Antibiotics have common side effects that limit their use, and the most significant risk is *Clostridium difficile* infection, to which IBD patients are more susceptible.³¹⁶⁻³¹⁹ Additionally, antibiotics are only effective in the short term, with no long-term data currently available. The available evidence indicates a moderate benefit with the use of metronidazole 10–20 mg/kg/day or the combination metronidazole plus ciprofloxacin 500 mg twice daily for colonic CD, but not isolated small bowel CD.³²⁰ A meta-analysis from 2011 reported that antibiotics were superior to placebo in inducing and maintaining remission in CD and reducing fistula drainage.³²¹ There is some emerging data on the benefits of rifaximin, a nonabsorbable antibiotic, in the treatment of CD³²²⁻³²⁴; however, further studies are required.

Metronidazole is a frequently used antibiotic for IBD patients but has significant adverse effects, including irreversible peripheral neuropathy, which should be discussed with the patient prior to prescribing. Metronidazole causes severe GI upset in some patients leading to nausea, vomiting, abdominal cramping, and diarrhea, which can be difficult to discern between a disease flare or medication side

effect.

Naltrexone

Naltrexone is a nonselective opioid receptor antagonist that acts on the three opioid receptor subtypes μ , κ , and δ . Endogenous opioids are believed to play a role in immune system modulation.^{325,326} Narcotics are considered to be proinflammatory, with several studies reporting an association between narcotic use and worsened IBD.^{327,328} Opioid antagonists appear to promote tissue growth, repair, and healing. Naltrexone has been shown to reverse chemically induced rodent colitis by reducing levels of the proinflammatory cytokines IL-6 and IL-12. Naltrexone has predominantly been studied for the treatment of CD in humans. In an open label study, 17 patients with active CD were treated with 4.5 mg of naltrexone daily. After 12 weeks, 89% had a clinical response, and 67% achieved clinical remission.³²⁹ A case report noted a child with duodenal CD that was treated successfully with low dose naltrexone.³³⁰ The first double-blind, placebo-controlled study of 40 active CD patients treated with 4.5 mg of naltrexone demonstrated a significant response clinically ($P = 0.009$) and endoscopically ($P = 0.008$) compared to placebo.³³¹ The most recent study evaluated naltrexone (0.1 mg/kg) use in children with active CD in an open label trial. There were no serious adverse outcomes. Remission was achieved in 25% of patients treated with naltrexone, and 67% had clinical improvement based on disease activity indices.³³²

Helminths

Industrialization and improved sanitation have led to the eradication of many infectious parasites. The prevalence of helminth infections in developed Western countries has significantly decreased to less than 2%.³³³ Based on the hygiene hypothesis contributing to the development of IBD, the disappearance of helminth infections may predispose developed nations to an increased risk of developing IBD³³⁴ and other autoimmune diseases. In response to helminthic infections, the Th2 immune response is invoked, leading to suppression of Th1 and Th17 effector cells, which promote chronic inflammation in IBD.³³⁵⁻³⁴² A number of IBD animal models have indicated that helminth infection may be a promising treatment for colitis.³⁴³⁻³⁴⁶ Summers et al. conducted three clinical studies investigating the pig whipworm, *Trichuris suis* (*T. suis*), as a treatment for IBD. An open label trial in seven IBD patients

showed significant clinical improvement, although patients required repeated doses to maintain efficacy.³⁴⁷ In the second study, 29 CD patients were administered 2500 *T. suis* orally every 3 weeks for 24 weeks, resulting in remission and response in 72% and 79% of patients, respectively.³⁴⁸ A randomized, double-blind, placebo-controlled study of 54 UC patients administered 2500 *T. suis* every 2 weeks for 12 weeks reported improvement in 43% of treated patients compared to 17% in the placebo group (P = 0.04).³⁴⁹ The most recent study investigated the safety and tolerability of *T. suis* at three doses (500, 2500, or 7500 parasites) compared to placebo. There were no significant differences in patient-reported symptoms, and there were no dose-dependent side effects.³⁵⁰ A small study investigating the hookworm *Necator americanus* in nine CD patients observed an improvement in CDAI scores.³⁵¹ The data thus far show that helminths do attenuate chronic inflammation in IBD and other autoimmune diseases, but long-term safety still has to be evaluated as the potential for migration of the helminths is a possibility. This treatment is only available through clinical trials that are ongoing.

5-Aminosalicylic Acid (Mesalamine)

There are multiple formulations of mesalamines currently on the market, including sulfasalazine, asacol, delzicol, lialda, pentasa, and apriso. Mesalamines are also available in suppositories and enemas to treat distal colitis. Mesalamines are effective for inducing and maintaining remission in ulcerative colitis patients with mild to moderate colitis. The exact mechanism is still unknown, but they act topically on the colonic mucosa as antiinflammatory agents. Sulfasalazine is a prodrug composed of 5-aminosalicylic acid (5-ASA) and sulfapyridine. 5-ASA is the active drug, whereas sulfapyridine can cause allergic reactions in patients with sulfa allergies, folate deficiency, agranulocytosis, and anemia and azoospermia in men. Other mesalamine products only contain 5-ASA, which is poorly absorbed and has a low risk of side effects. A paradoxical reaction with mesalamines may cause worsening of colitis in approximately 3% of patients. This is considered an allergy, and other mesalamines should not be used. Mesalamines are the mainstay of therapy for mild to moderate ulcerative colitis. In left-sided only colitis, enemas alone may be effective, although oral plus rectal therapy is recommended. Proctitis, inflammation confined to the rectum, can be managed with suppositories and/or enemas. Pancolitis is best managed with oral and rectal mesalamine therapy. Because CD is characterized by transmural inflammation, mesalamines are not as effective. There is some

evidence to suggest that mesalamine therapy may provide some benefit in mild Crohn colitis, although typically, immunosuppressive medications may be required. Mesalamines have the least toxic side effect profile of the pharmaceutical agents approved for IBD.

Glucocorticoids

Steroids were previously the only therapy available for IBD patients. They are potent antiinflammatory agents and reduce intestinal inflammation rapidly and effectively. Steroids have been shown to bring both UC and CD into remission, although there is no benefit of maintaining remission for either disease. The use of steroids has tremendous risks, including the development of diabetes, hypertension, weight gain, gastritis, growth failure, osteoporosis, poor wound healing, and severe infections. Aseptic necrosis of the femoral head is a commonly feared adverse effect. Steroids have been shown to decrease intestinal absorption of calcium, phosphorus, and zinc.⁷⁹ The use of steroids in CD has become more controversial, and data are emerging that the risks of steroids in CD far outweigh the benefits. Expert opinions currently suggest that steroids can increase the risk of abscesses, fistulas, and need for surgery. Therefore, CD therapy is shying away from the use of steroids if possible, especially in children.³⁵²

Immunosuppressants

6-mercaptopurine and its prodrug azathioprine (thiopurines) are immunosuppressant medications that have shown benefit in the maintenance of remission in both CD and UC. These drugs do not induce remission and can take up to 3 months to have their full effect. Multiple studies have shown excellent efficacy of thiopurines in maintaining steroid-free remission in IBD.^{353,354} Thiopurines may help heal Crohn fistulas and prevent postoperative recurrence of CD.³⁵⁵ Once thiopurine treatment is discontinued, the risk of CD flare is high.³⁵⁶ The major risk of thiopurines is bone marrow suppression, which can lead to life-threatening cytopenias. It is therefore recommended to monitor blood counts frequently. There is an increased risk of lymphoma and nonmelanoma skin cancers with the use of thiopurines. Yearly dermatology visits are recommended for full skin exams. Cyclosporine is another immunosuppressant agent previously used in the treatment of UC. Although it has fallen out of favor with the advent of tumor necrosis factor blockers (described in the subsequent text), it is still occasionally

used for the induction of remission of steroid refractory UC. Cyclosporine is a fast-acting immunosuppressant that decreases T-cell activity and the subsequent immune response. Cyclosporine has a narrow therapeutic window, with elevated levels resulting in nephrotoxicities, neurotoxicities, seizures, and GI upset.

Patients receiving thiopurine medication are required to undergo frequent blood monitoring of white and red blood cell counts because life-threatening pancytopenia uncommonly may occur. Liver function tests should also be performed as there is a potential for hepatotoxicity.

Tumor Necrosis Factor- α Blockade

The first tumor necrosis factor- α (TNF- α) inhibitor, infliximab, was approved for use in CD and UC in 1998. Since that time, adalimumab, certolizumab pegol, and golimumab have been approved as TNF- α inhibitors for the treatment of IBD. Infliximab is administered as an intravenous infusion, while the others are self-injectables. TNF inhibitors have revolutionized the treatment of IBD because they are fast-acting and potent inhibitors of proinflammatory cytokines. They have been shown to be effective in inducing and maintaining remission in CD and UC. TNF inhibitors can heal fistulas in CD patients, decrease relapse rates of IBD, and promote mucosal healing. These are steroid-sparing agents and are used as first-line agents in severe UC and moderate to severe CD. As immunosuppressants, TNF inhibitors increase the risk of serious infections, such as reactive hepatitis B and latent tuberculosis (TB). Prior to initiating therapy with these agents, a purified protein derivative (PPD) or Quantiferon Gold serum test is required to confirm a negative TB status. Hepatitis B serologies should be performed to ensure that hepatitis B is not present, and vaccination should be offered. There is a possible increased risk of lymphoma and skin cancers with the use of TNF inhibitors, although this may only occur in combination with thiopurine therapy.

Surgery

The goal of medical therapy in IBD is to prevent the need for surgery. In UC, severe colitis refractory to medical therapy can develop and require a complete colectomy. After the initial operation, there are two options: a

permanent ileostomy or an ileal pouch anal anastomosis (IPAA). A total colectomy is seen as a “cure” for ulcerative colitis and, after struggling with refractory colitis for many years, patients typically feel significantly better. Although there is no further colitis, the ileostomy can be difficult to manage, can leak, and may develop a hernia around the stoma. If an ileal pouch is created, patients should anticipate having six to seven loose BMs daily, including possible nocturnal BMs and chance of seepage. There is also the risk of pouchitis, inflammation of the pouch, requiring antibiotic therapy. VSL#3 has shown to be protective against the development of pouchitis and recurring pouchitis. IPAA can cause infertility in females. More-so than in ulcerative colitis, surgery is strongly avoided in CD. As CD can affect the entire GI tract from mouth to anus, frequent surgeries can lead to short gut syndrome and severe malabsorption. CD is also known to recur at the site of previous surgical anastomosis. Surgery for CD is required when stricturing disease occurs that causes bowel obstruction and inability to tolerate oral intake. There are ongoing studies investigating endoscopic dilation and stent placement of Crohn strictures in an attempt to delay if not avoid surgery.

Mind-Body Medicine

Inflammatory Bowel Disease and Stress

Perceived stress is a significant predictor for flaring in ulcerative colitis (UC), and the risk of experiencing exacerbation is multiplied by prolonged exposure to stress.³⁵⁷ Up to 70% of patients with inflammatory bowel disease (IBD) regard stress as a modifying factor for their disease, and 85% regard stress coping as having a positive impact on their course of disease.³⁵⁸ A number of studies ([Table 50.1](#)) have evaluated the effects of different interventions targeting stress and psychological well-being on the course of IBD.

TABLE 50.1

Randomized Trials of Stress-Reducing Therapies in IBD

Authors	Disease	Patients	Design	Intervention	Control	Duration	Outcomes
Herrill et al. ³⁵⁸	IBD	66, 2 groups	RCT	Multiconvergent Therapy (MCT): 6 × 40-min sessions over 16 weeks	Standard care (SC)	4, 8, 12 months	No difference in outcomes (IBQ), perceived stress, coping)
Langhorne et al. ³⁵⁹	UC	63, 2 groups	RCT	Lifestyle modification (MBSR)	Wait list control (WL)	3, 12 months	Improved SF-36 (3 months in MBSR—improvement in HRSA anxiety (3 months in MBSR) compared with WL
Mitsuda et al. ³⁶⁰	IBD	50, 2 groups	RCT	Relaxation training (RT)	WL, SC	5 weeks	Stress, mood, pain, anxiety, QOL, depression improved by RT
Milos et al. ³⁶¹	IBD	66, 2 groups	RCT	Stress management techniques	SC	4, 8, 12 months	Improvement within the treatment group, but not control group for all time points, CDAI
Keefe et al. ³⁶²	UC	55, 2 groups	RCT	Gut-directed hypnotherapy	Attention control (AC)	12 weeks	More patients in remission in hypnotherapy vs. control, more days in clinical relapse in hypnotherapy
Jedrej et al. ³⁶³	UC	55, 2 groups	RCT	MBSR	AC	3, 6, 12 months	Big group difference in bowel subscale and systemic subscale
Ellenbroek et al. ³⁶⁴	UC	55, 2 groups	RCT	MBSR	WL	2, 4, 6, 8, 10 weeks	Improved SF-36 mental health scale, Psychological Health Scale Score and IBDQ after 10 weeks in MBSR vs. WL

Lifestyle Modification

Two studies investigated the effect of lifestyle modification programs on disease activity, quality of life, psychological parameters, and laboratory profiles in 30³⁵⁹ and 60³⁶⁰ patients with UC. Both studies applied a randomized wait-list controlled study design. Results showed significant improvements in psychological quality of life after 10 weeks³⁵⁹ and 3 months³⁶⁰ as well as significant reduction of anxiety after 3 months.³⁶⁰ Neither medication nor laboratory profiles showed any change. The risk of bias was low in both studies.

Mindfulness-Based Interventions

There are two studies which have investigated the effects of mindfulness-based interventions on IBD. The first involved 66 patients with inactive IBD,³⁶¹ which compared one-to-one multiconvergent therapy (MCT) plus standard care (SC) to standard care alone. The other study involved 55 patients with inactive UC and compared mindfulness-based stress reduction (MBSR) courses to time/attention control courses.³⁶² Neither study showed significant group differences regarding disease activity, relapse, or psychological variables in the main analysis. However, significant improvements in quality of life (QOL) were observed in inactive IBD patients with additional irritable bowel syndrome-type symptoms.³⁶¹ The risk of bias was low.³⁶¹ MBSR was found to mitigate the effects of stress and C-reactive protein in UC patients who flared during the course of the study, which was noted to have a high risk of bias.³⁶²

Hypnotherapy

Keefe et al.³⁶³ investigated the effects of gut-directed hypnotherapy, a program that was developed for irritable bowel syndrome. Patients received seven weekly sessions of hypnotherapy compared to an

attention control (AC) group. After 52 weeks, patients were significantly better regarding the probability to flare; however, no effects were found on quality of life or other psychological measures. The risk of bias of the trial was low.

Relaxation Training

A study by Mizrahi et al. involving 56 subjects investigated the effects of relaxation training in patients with IBD in general.³⁶⁵ Study subjects were randomized into three sessions and subsequent home practice of relaxation or a usual care group. The authors found significant improvements in pain, anxiety, depression, mood, stress, and quality of life, including bowel symptoms within the relaxation group, but not the usual care group. Risk of bias was high in this study as it failed to report a random allocation procedure and no attempt was made to blind patients or outcome assessors.

Traditional Chinese Medicine (TCM)

Acupuncture is an ancient tradition of healing that prevents and mitigates illness by balancing the flow of energy (chi) in energy circuits (meridians). Acupuncture can modulate neuroenteric circuits, inflammation, and many physiological processes that influence the gastrointestinal tract.³⁶⁶ There are studies to support the use of acupuncture for treating gastrointestinal pain and other symptoms. Acupuncture has been shown to benefit patients with gastroparesis, nausea (postoperative, chemotherapy), irritable bowel syndrome, constipation, functional dyspepsia, gastroparesis, and possibly more.³⁶⁷⁻³⁷⁰ Joos et al. evaluated the potential role of acupuncture in the management of IBD and were the first to report a therapeutic effect upon IBD with regard to disease activity scores, but not to quality of life questionnaires or symptom scores, in active CD as well as UC.^{371,372} A recent meta-analysis by Ji et al. included 43 studies of which 37 are in the Chinese literature.³⁷³ Among the 43 included trials, 10 trials compared oral sulphasalazine (SASP) with acupuncture and/or moxibustion treatments for induction of remission and demonstrated the superiority of acupuncture and moxibustion therapy.³⁷³ However, use of the Jadad scale to assess the methodological quality of these studies demonstrated a score of 1 or 2 (scale of 1–5 in ascending order of quality) in a total of 39 studies, demonstrating low methodical standards including insufficient description of endpoints and randomization process, and missing power

calculations. Lee et al. conducted a meta-analysis of the effect of moxibustion/acupuncture on ulcerative colitis including five RCTs published in the Chinese literature.³⁷⁴ The studies compared the effects of moxibustion/acupuncture with conventional IBD drug therapy (sulfasalazine alone or with other drugs). The results showed favorable effects of moxibustion on response rates compared to conventional drug therapy but with a high-risk bias (n = 407; risk ratio = 1.24, 95% CI = 1.11 to 1.38; P < 0.0001; heterogeneity: I² = 16%). The authors concluded that there is insufficient evidence to show that moxibustion/acupuncture is an effective treatment of UC. Further high-quality research is mandatory to provide higher levels of evidence in the field of acupuncture and TCM.

The pathogenesis of IBD involves a multifactorial process, which includes genetic predisposition, immune dysregulation, barrier dysfunction, and altered microbial flora as well as environmental and lifestyle factors. Thus, it seems plausible that subgroups of patients may benefit from a tailored therapy with emphasis on individually different modalities. In particular, mind-body medicine widens the spectrum and adds a resource-orientated salutogenetic dimension to introduce a multimodal integrative treatment program. Future high-quality designs in health research are warranted.

Prevention Prescription

Primary Prevention

- Minimize exposure to antibiotics in childhood and beyond, particularly the tetracycline family of antibiotics.
- Eating a diet high in fiber-rich fruits and vegetables while minimizing Western-based diets (red meats, fried foods, refined sugars, and grains).
- Encourage probiotic and prebiotic foods to promote gut microbial diversity.

Secondary Prevention

- Curcumin 1000 mg twice daily (UC).
- Fish oils 4000–5000 mg daily (CD).
- Mind-body relaxation techniques.
- Germinated barley foodstuff (GBF) 20 g daily (UC).
- VSL#3 three sachets daily (UC, pouchitis).

Therapeutic Review

Inflammatory bowel disease (IBD) is a chronic autoimmune disease without a “cure” that has the potential for numerous complications, including gastrointestinal cancer. Thus all patients should be under the care of a gastroenterologist for regular screening colonoscopy and ongoing medical therapy. The integrative practitioner can provide personalized lifestyle and dietary guidance to achieve improved quality of life.

Laboratory Tests

A number of laboratory tests are available for disease monitoring and nutritional guidance. Patients with IBD should have annual testing with a complete blood count, complete metabolic profile, and C-reactive protein. Nutritional markers for IBD patients with chronic diarrhea should include red blood cell (RBC), zinc, serum homocysteine, RBC magnesium, serum iron, and 25-OH vitamin D. In steroid-treated patients with refractory disease, serum dehydroepiandrosterone sulfate (DHEA-S), 25-OH vitamin D, and an essential acid profile may be useful. Patients with recent onset, relapse, or exacerbation of IBD—especially those with diarrhea—should undergo stool testing for parasites, pathogenic bacteria, *Clostridium difficile* toxins, and yeast. The potential role of more advanced stool testing using genetic analysis and metabolomics for stool pathogens is controversial; however, integrative gut experts and functional medicine practitioners have anecdotally reported intriguing benefits.

Self-Management

Patients are oftentimes in need of health coaching to manage their medical care, which can become overwhelming and interfere with QOL and productivity at work. Encouraging a support network to help maintain good mental health and resources in the midst of a flare are helpful adjuncts to good integrative care.

Nutrition

- Overarching recommendation is to maintain a balanced macro and micronutrient rich diet with ample antiinflammatory nutrients, minimize fiber for fibrostenosing CD, and limit sucrose and

- symptom-provoking foods. 
- Lactose intolerance is common in patients with IBD and should be avoided only in those who are intolerant because dairy contains calcium which is important for bone health. 
- Provide prebiotic soluble fiber-rich foods for ulcerative colitis (UC) to maintain remission. 
- Consider an elimination diet for symptoms relief and control. 
- The specific carbohydrate diet has some evidence to suggest benefit for symptom control but is no substitute for recommended medical therapy. 
- An enteral formula diet may help improve symptoms and may help induce or maintain remission in children with CD. 

Supplements

- Patients taking mesalamine (5-ASA) medications or sulfasalazine, or those who have high homocysteine not due to low B12 status, should consider taking folate 1 mg/day and should get tested to confirm sufficiency. Consider genetic testing for methylene tetrahydrofolate reductase (MTHFR) homozygosity if sufficient serum folate levels are difficult to achieve. 
- Vitamin B₁₂: 1 mg/month for patients with ileitis or previous ileal resection  receiving folic acid, or with high homocysteine. 
- Vitamin B₆: 10 to 20 mg/day, especially for patients with high homocysteine or taking high-dose folic acid or with urolithiasis. 
- Vitamin D₃: 1000 units/day or more to maintain levels of 25-OH vitamin D at 40 ng/mL 
- Calcium: 1000 mg/day for patients taking steroids or with low dietary calcium 
- Chromium: Up to 600 mcg/day for patients with steroid-induced glycemia or as part of micronutrient mix on central parenteral nutrition 

- Zinc sulfate: 220–440 mg/day recommended in patients with draining fistula, recent surgery, or active, severe diarrhea. 
- Fish oils supplying 4000 to 5000 mg/day of omega-3 fatty acids (eicosapentaenoic acid and docosahexaenoic acid) for patients with active UC and to maintain remission for CD , more effective in Crohn colitis than enteritis. Fish oils may cause burping and bloating.
- Prebiotic oligosaccharides: approximately 10 g/day for UC.  They can cause distention and flatulence.
- Germinated barley foodstuff: 20–30 g/day has been shown to maintain remission in UC patients when added to standard medical therapy.  Side effects include bloating and flatulence.
- HMPL-004: 1200–1800 mg/day improves clinical scores in active UC patients.  A higher incidence of rash was reported compared to placebo.

Biological Agents

- VSL-3: one sachet twice to three times a day for patients with mild-to-moderate UC who are not sensitive to corn, the growth medium used as an adjunct to medical care, to maintain remission for pouchitis or to maintain remission for UC . Any probiotic may aggravate bowel symptoms in patients with IBD.
- DHEA: 200 mg/day for patients with refractory disease and low DHEA-S .

Botanicals

- *Boswellia serrata* gum resin: 350 mg three times daily for patients with UC who are intolerant of 5-ASA derivatives.  No adverse effects reported to date.
- Curcumin: 1000 mg twice daily with meals to maintain remission in UC as an adjunct with mesalamines .

Pharmaceuticals

- 5-ASA derivatives for induction of remission in mild-to-moderate

colitis and for maintenance of remission. 

- Antibiotics for acute exacerbations of CD or perianal disease. 
- Glucocorticoids for induction of remission in severe disease. 
- 6-Mercaptopurine or azathioprine for steroid-dependent IBD or for maintenance of remission when 5-ASA derivatives fail.  Consult GI.
- TNF- α blockers. For patients with severe CD, initiating pharmaceutical therapy with immunosuppressants and TNF- α blockers (step-down therapy) produces superior long-term results to initiating therapy with steroids and 5-ASA derivatives (step-up therapy). None of these studies included dietary interventions, which are of proven value in CD.  Consult GI.

Surgical Resection

- For patients with colonic dysplasia or for those who fail to respond to medical management. 
- Postsurgical recurrence is high for CD, and pouchitis is a frequent complication of ileal pouch–anal anastomosis for UC.

Therapies to Consider

- Phosphatidylcholine: 3.2 g daily improved clinical activity scores, histological remission, and relapse rates in UC patients without any significant adverse events.
- Inulin may be efficacious in treating active UC.
- Fructooligosaccharides 15 g daily improves clinical active CD.
- Aloe vera gel: 100 mL bid for patients with UC. Aloe may cause diarrhea. Use latex-free inner leaf extract formulations.
- Cannabis may have beneficial effects in the treatment of IBD with appetite stimulation and modulation of pain; however, due to its effects on the central nervous system, further studies are needed.
- Woodworm has been shown to improve active CD in small studies.
- Xilei-san was found to improve ulcerative proctitis in two studies.
- Antibiotics may have a role in the maintenance of CD in a subset of patients that have yet to be well defined.
- Naltrexone has shown promising results in Crohn's patients, but

further studies are needed.

- Helminth therapy decreases mucosal inflammation, but long-term effects are still unknown.

CHAPTER 51

Preconception Counseling and Fertility

Victoria Maizes, MD

Overview

From childhood, we play with dolls and imagine becoming parents. Our ability to conceive and bear a child is often assumed; when it does not occur with ease, or at all, it can be a source of great suffering. Most religions consider bearing children a blessing, and traditional societies often embrace elaborate preparations for conception. In our society, up to 50% of pregnancies are unplanned. Simultaneously, we are faced with increasing numbers of children who suffer from chronic diseases, such as autism and ADHD, obesity, and diabetes, some of which might be prevented through preparation for pregnancy and the adoption of healthier lifestyles. Sadly, we are not doing a good job at preconception counseling. Only 7% of primary care physicians prescribe preconception folic acid, and only 20% of obstetricians query their pregnant patients about environmental chemical exposures.¹ Given the fetal origins hypothesis, which suggests that the seeds of both childhood and adult diseases are planted in the womb, preconception counseling may be the most important preventive care we provide. This chapter outlines preconception advice that enhances the likelihood of conception as well as giving birth to a healthy child.

Introduction

The 1960s brought reliable contraception and, for the first time in human history, the ability to reliably control reproduction. It conferred new

freedoms and increased the average age of first childbirth in the United States from 21 to 26 years. Within conventional medicine, tremendous advances in assisted reproductive technologies (ART) have helped couples that struggle to become pregnant. The best-known treatment, in vitro fertilization (IVF), has made it possible for couples who may never have conceived to become parents. Recognizing this fact, the 2010 Nobel Prize was awarded to Sir Robert Edwards, PhD, who developed IVF.

The success of high-tech solutions, including IVF, has reduced the emphasis in our culture on the simpler, more natural, less invasive, lower cost, and lower risk strategies that are the strength of integrative medicine. While assisted reproductive technologies can be miraculous, the cost and higher risks to mother and baby should make them a second-line approach except under special circumstances.

Causes of Infertility

Approximately 15% of couples in the United States struggle to conceive. Infertility is defined, somewhat arbitrarily, as an inability to conceive despite 12 months of unprotected intercourse. Of the couples deemed infertile, 43%–63% of women younger than 40 years will conceive naturally within the second year of trying.²

Male Infertility

Male infertility can be due to a variety of diseases (diabetes, cystic fibrosis, and varicoceles), behaviors (smoking, use of marijuana, testosterone or other anabolic steroid supplementation, alcoholism, and hot tub use), trauma, infection, chemotherapy, or radiation therapy. Infertility may also result from environmental exposures, such as pesticides, lead, and electromagnetic fields. It has been postulated that decreasing male sperm counts may be due to environmental toxins. Male infertility is usually evaluated with a semen analysis during which the number, movement, and morphology of the sperm are evaluated.

Female Infertility

Women need functional ovaries, fallopian tubes, and uterus as well as a perfectly tuned endocrine system to conceive. The most common reason women struggle to become pregnant is advanced age. All the oocytes a woman will ever have are formed when she is a fetus. As women age, so

do their oocytes, thereby reducing the likelihood of conception somewhat after 30 and significantly after 40 years of age. Yet, media portrayals of celebrities conceiving and bearing children in their late 40s has created a cultural message that modern medicine has all but obliterated the significance of women's biological clocks. This prevalent myth suggests that women can wait until they are ready, and then if they need help, ART will fix the problem. As will be explained later in the chapter, this is a false message that integrative clinicians can help dispel.

Ovulatory infertility is the next most common cause of female infertility and includes polycystic ovarian syndrome, luteal phase dysfunction, hypothalamic problems, and stress-induced infertility. Anatomical causes of infertility include blocked tubes (often due to infection), endometriosis, and congenital or acquired uterine anomalies. Trauma, infection, chemotherapy, or radiation therapy may also cause infertility in women.

Integrative Therapy

Lifestyle

Nutrition

Abundant research supports the role of a healthy diet in conception.³ An optimal fertility diet is made up of freshly prepared whole food and includes substantial vegetables and fruits, sufficient omega-3 fatty acids, and vegetable sources of protein. The diet should also be low in processed foods, meats, and rapidly digesting, high-glycemic load carbohydrates.

Mediterranean diet has been studied and is associated with a 44% lower risk of infertility in women attempting to conceive naturally and a 40% greater likelihood of conception in couples using IVF to conceive.^{4,5}

The Nurse's Health Study II (NHS II) used food frequency questionnaires to examine the macro and micronutrients that impact ovulatory infertility. The researchers found that carbohydrates, protein, and fats, as well as micronutrient intake, all influenced female fertility.

Increased ovulatory infertility occurred in women who ate high

glycemic index (GI) carbohydrates: breakfast cereals nearly doubled the risk.⁶ Flour, a high GI carbohydrate, is the first ingredient in most breakfast cereals; it is rapidly metabolized, elevating blood sugar, which leads to spikes in insulin levels and subsequent inflammation. Higher levels of insulin reduce sex-hormone-binding globulin (SHBG) and increase free testosterone, which can reduce fertility. Soda, another high GI carbohydrate, has also been associated with a longer time to conception^{7,8} (see [Chapter 87](#)).

The type of protein the nurses ate was also related to the risk of ovulatory infertility in the NHS II.⁹ Women aged more than 32 years were most affected, with each additional daily serving of red meat, chicken, or turkey increasing the risk of ovulatory infertility by nearly one-third. Fish and eggs had no effect, and vegetable protein reduced the risk by 50%.

With respect to fat, trans fats were found to increase the risk of ovulatory infertility by 73%.¹⁰ More surprising was the NHS II finding that full fat dairy was associated with enhanced fertility as compared with nonfat or low fat dairy foods.¹¹ Women who ate two or more daily servings of low fat dairy had almost double the risk of ovulatory infertility when compared with women who ate one or less servings per week. A 27% reduction in risk was found when women ate one or more servings of full fat dairy per day compared to less than one per week. Milk is centrifuged to create varying fat concentrations; an unintended consequence is differing hormonal concentrations. Estrogens are lipophilic and are found in higher proportions in full fat than reduced fat dairy products. In contrast, prolactin and insulin-like growth factor 1, both of which reduce fertility, are lipophobic and are proportionally more abundant in lower fat dairy products.

In 2014, the FDA/EPA revised their recommendations to pregnant women and women of childbearing age regarding fish consumption.¹² Evidence had shown that in response to the 2004 warning, 90% of women were consuming less than the FDA-recommended amount of fish, placing themselves and their babies at risk of insufficient levels of omega-3 fatty acids. The new draft guidelines recommend that women eat a minimum of 8–12 ounces of low mercury fish each week.¹³ The agencies continued to advise against eating high-mercury containing fish (shark, swordfish, king mackerel, and tilefish) and advise limiting albacore tuna to six ounces or less per week.

Male fertility is also impacted by diet. While fewer studies exist, we know that a father's diet plays an important role in the health of his

sperm and his offspring. Oxidative stress is a leading cause of male subfertility, yet 80% of men in the United States do not consume the recommended five servings of fruits and vegetables per day that are the source of dietary antioxidants.

Fat intake impacts sperm quality and quantity. A study of military recruits in Denmark found that men who ate the most saturated fats had a 38% lower sperm concentration and 41% lower sperm counts than those who ate the least fat.¹⁴ A similar result was found in semen analyses of men attending a U.S. infertility clinic.¹⁵

Eating more monounsaturated fat may protect sperm health; when 2.5 ounces a day of walnuts were added to the Western-style diet of healthy young men, sperm vitality, motility, and morphology were increased.¹⁶

Some women will do well to experiment with an elimination diet (see [Chapter 86](#)). Common food sensitivities that can cause inflammation and in turn reduce fertility include gluten, dairy, soy, corn, eggs, and citrus. One prospective trial found previously undiagnosed celiac disease to be the root cause of unexplained infertility in 5.9% of women.¹⁷

Physical Activity

As health professionals, we generally counsel people to be more physically active. During preconception counseling, however, we sometimes find ourselves asking women to cut back on their activity. Up to 44% of athletic women experience intermittent or regular amenorrhea; an even higher percentage will have intermittent luteal phase dysfunction.¹⁸ Vigorous exercise, more frequent exercise, or exercising to exhaustion significantly increased time to conception in a prospective Norwegian population study of 3887 women.¹⁹ The exception is overweight or obese women in whom exercise reduces the time required to conceive.²⁰ Limiting exercise to less than 4 hours per week may be prudent advice for women of normal weight who struggle to conceive, as is encouraging walking and gentle forms of yoga in place of running, cycling, and vigorous yoga.

Spirituality

The mystical perspective holds that it takes three parties to create a new

life: a woman, a man, and God. Some adults will resonate with this spiritual point of view and may seek out religious or secular preconception ceremonies. Indeed, every religion has special prayers that are used to beseech God's intervention to be blessed with a child. Both Judaism and Hinduism advise a period of abstinence prior to conception; the former then advises immersion in the waters of the Mikveh, and the latter meditation practices, special foods, and adaptogens. Ceremonies can be created to help women prepare to become a vessel that bears a newly forming life. They may also be designed to help women and men acknowledge their longing for a child, their frustration at not conceiving with ease, the loss of a child to miscarriage, or the loss of the dream of bearing children.

Struggling to conceive can lead to a crisis of spirit. Couples may wrestle with existential questions and the inherent unfairness of life. "Why is this happening to me?" may be the unspoken question in the exam room. Religious traditions can be of great help to some couples grappling with these questions and can pose conflicts for others when infertility is experienced as a punishment from God or when reproductive treatments are prohibited. Examples of practices forbidden by some religious traditions include IVF, use of a third party donor or surrogate, and embryo wastage.

Environmental Chemicals

The environmental chemical exposures we face as individuals and as a society are unprecedented. Yearly, we release more and more industrial chemicals into the environment while rarely testing their risks. A fetus or young child is uniquely susceptible because its neurological and immune systems are still developing and its detoxification systems have not fully matured, thereby rendering them less able to metabolize harmful chemicals.

Shockingly, studies of umbilical cord blood reveal that babies have an average of 232 chemicals in their bodies at the time of birth.²¹ These environmental chemicals can potentially increase a child's risk of ADHD, autism spectrum disorders (ASD), and leukemia; later in life they increase the risk of diabetes and heart disease.²² A 2014 review of 37 trials of environmental toxicant exposure and ASD in preconception, pregnancy, or early childhood found a positive association in 34 of the studies. The strongest evidence was found for air pollutants and pesticides, and phthalates, polychlorinated biphenyls (PCBs), solvents, and toxic waste sites were also implicated.²³

Studies of umbilical cord blood have revealed that babies have an average of 232 chemicals in their bodies at the time of birth.²⁴

Awareness is the first important step towards behavior change. Lifestyle modification can reduce exposures to toxic chemicals in parents, thereby reducing the risk to the fetus.^{25,31} For example, exposure to air pollution can be reduced by avoiding idling one's car or standing near a vehicle's exhaust, and by turning on the "recirculate" function when driving in traffic. Purchasing organic food can minimize pesticide levels. Indeed for most people, food and beverages are the most significant source of environmental toxin exposure. Choosing organic meat, poultry, pork, and produce, whenever possible, is the best way to avoid pesticides and genetically modified organisms (GMO). When the cost of organic food is prohibitive, shoppers can selectively purchase the least contaminated conventionally grown vegetables and fruits by using the Environmental Working Group's updated list (www.ewg.org). The EWG has calculated that you can reduce your pesticide exposure by 92% when you eat from the "clean fifteen" rather than the "dirty dozen."²⁷ Packaging introduces other forms of industrial chemicals. Frozen vegetables are a better choice than canned as the liners of most cans contain bisphenol A (BPA). Avoiding storing and microwaving food in plastic containers reduces BPA and phthalate exposure.

Many excellent online resources are available to help guide choice of food, water, cleaning, and personal care products.²⁸ The fish with the least amount of mercury, PCBs, and other environmental toxins can be identified by using the Monterey Bay Aquarium website (www.montereybayaquarium.org/cr/seafoodwatch). Skin deep (www.cosmeticsdatabase.com) reviews personal care products for carcinogenic, reproductive toxicant, and allergenic ingredients. Flame retardant exposure from mattresses, computers, TVs, carpeting, and furniture can be minimized by exploring and purchasing products listed at www.saferproducts.gov. Websites such as www.treehugger.com list companies that package in BPA free cans. In response to consumers' desire for green products, newer packaging made from glass or cardboard is increasingly available.

Adopting new behaviors can significantly reduce the body burden of many, but not all, environmental toxins. For example, a 2011 San Francisco study revealed that adults dropped their urinary BPA levels by two-thirds in 3 days when they were provided with fresh, catered meals that avoided canned foods and the use of plastic containers²⁹⁻³¹ (see

[Chapter 108](#)).

In response to the pervasive presence of environmental chemicals, the Royal College of Obstetricians and Gynecologists published a scientific impact paper titled “Chemical Exposures During Pregnancy: Dealing with Potential, but Unproven, Risks to Child Health.” Specifically, the following recommendations were made for pregnant and lactating women³²:

- Use fresh food rather than processed foods whenever possible
- Reduce the use of foods and beverages in cans and /or plastic containers, including their use for food storage
- Minimize the use of personal care products, such as moisturizers, cosmetics, shower gels, and fragrances
- Minimize the purchase of newly produced household furniture, fabrics, nonstick frying pans, and cars whilst pregnant or nursing
- Avoid the use of garden, household, pet, pesticides, or fungicides (such as fly sprays or strips, rose sprays, flea powders) and avoid paint fumes
- Only take over-the-counter analgesics or painkillers when necessary
- Do not assume the safety of products based on the absence of “harmful” chemicals in their ingredients list or the presence of a tag “natural” (herbal or otherwise)

Micronutrients

Vitamins

The American Academy of Pediatrics, the American College of Obstetrics and Gynecology, the American Academy of Family Physicians, and the United States Preventive Services Task Force all recommend that women of childbearing age take a multivitamin with folic acid. When taken prior to conception and throughout the first trimester of pregnancy, these supplements reduce the risk of neural tube defects, heart defects, musculoskeletal defects, and orofacial defects.³³ Multivitamins and folic acid have benefits beyond reducing birth defects. The NHS II found that multivitamins made it easier for women to conceive and decreased the risk of miscarriage.³⁴ Three large studies have revealed a 40% lower risk of autism in women who took folic acid in the 3 months prior to conception and the first trimester of pregnancy.³⁵⁻³⁷

Yet, the 2011 National Health and Nutrition Examination Survey (NHANES) revealed that only 34% of women between the ages of 20 and 39 consume the recommended amount of supplemental folic acid. One

study revealed that women who received preconception counseling from their primary care physician were five times more likely to take folic acid before conception.³⁸ However, data from the CDC's National Ambulatory Medical Care Survey and the National Hospital Ambulatory Medical Care Survey reveal that folic acid or a multivitamin with folic acid is prescribed at only 7.2% of primary care visits in women of reproductive age.³⁹

Prenatal multivitamins can contain very different ingredients. Iodine, for example, is only present in 51% of prenatal multivitamins.⁴⁰ In the UK, where salt is not routinely iodized, mild iodine insufficiency is thought to contribute to lower cognitive function in children.⁴¹ Some women require higher doses than the 400–800 mcg of folic acid found in most prenatal vitamins. This includes women with inflammatory bowel disease, diabetes, a body mass index > 35, or a personal or family history of having a child with a neural tube defect. Higher doses are also indicated for women who take anticonvulsant medications, folate antagonists, (e.g., methotrexate, sulfonamides), smoke cigarettes, or belong to higher-risk ethnic groups (Sikh, Celtic, Northern Chinese).⁴² While some advocate the use of 5-methyltetrahydrofolate to address single nucleotide polymorphisms (SNPs), to date, no studies have been carried out.⁴³

Preconception Multivitamin Ingredients

- Vitamin A: the current recommended dietary allowance (RDA) of preformed vitamin A is 700 retinol activity equivalents (RAEs) or 2300 IU per day, with a tolerable upper intake level for pregnancy of 3000 RAEs/day or 10,000 IU/day.⁴⁴ Most experts recommend no more than 5000 IU per day should be preformed since we also get vitamin A in our food and through food fortification. (The RDA during pregnancy is 2567 IU/day preformed vitamin A and 4300 IU/day for lactating women.)
- Iron: 18 mg (once pregnant, 27 mg and 9 mg when lactating).⁴⁵
- Iodine: 150 mcg (once pregnant, the iodine RDA is 220 mcg/day from all sources and 290 mcg/day for lactating women).⁴⁶
- Folic acid: 400 mcg or more (once pregnant 600 mcg or more).⁴⁷
- Vitamin D: 600 IU⁴⁸ (or more depending on vitamin D level). Both vitamins D2 and D3 are effective.

- Vitamin B12: 2.4 mcg (once pregnant, 2.6 mcg).
- Vitamin E: the RDA is 22.4 IU/day for women aged more than 14 years including while pregnant and 28.4 while lactating.⁴⁹
- Calcium: the Food and Nutrition Board at the Institute of Medicine recommends total calcium from food and supplements of 1000 mg for women aged more than 19 years and 1300 mg a day for girls aged 9–18 years.⁵⁰
- Trace minerals: small amounts of copper, zinc, magnesium, and potassium.

Subfertile men also benefit from taking multivitamins. A Cochrane review of 34 studies found that men who received supplements were four times more likely to impregnate their partner and almost five times as likely to have a live birth.⁵¹ A wide variety of antioxidant supplements were used across the 34 studies including vitamins C and E, folate, zinc, selenium, omega-3, and N-acetylcysteine.

Supplements

Omega-3

Women who consume less than the recommended 12 ounces of fish per week may benefit from supplementation with omega-3 fatty acids.

Dosage

A consensus statement from the World Association of Perinatal Medicine recommends a dose of at least 200 mg of DHA during pregnancy.⁵² A consensus was not formed for the dose of EPA; however, the group noted that intakes of up to 1 g/day of DHA or 2.7 g/day of total omega-3 have been safely used in randomized clinical trials.⁵³ Subfertile men may benefit from omega-3 supplementation as well. One study reported higher sperm counts and more normal morphology in men who received 1.1 g of EPA and 700 mg of DHA.⁵⁴

Fertility Blend

Two randomized controlled studies of Fertility Blend (a supplement formula containing chaste tree berry; green tea extracts; L-arginine;

vitamins E, B6, B12, and folate; iron; magnesium; zinc; and selenium) were conducted in women. The first pilot study followed 30 women who had been unsuccessful conceiving for 6–36 months. Participants were administered Fertility Blend or a placebo for three cycles. Five women in the treatment group conceived compared with zero in the control group.⁵⁵ The second study randomized 93 women; at 6 months, 17 women in the treatment group had conceived compared with 10 women in the control group.⁵⁶ A male Fertility Blend formulation has also been developed but has not been clinically studied.

Vitamin C

Vitamin C has also been shown to enhance fertility in women with luteal phase dysfunction. In a randomized controlled trial of 150 women, vitamin C supplementation was associated with significantly higher progesterone levels and higher pregnancy rates after 6 months (25% vs. 11%; $p = .045$).

Dosage

The dose used was 750 mg/day.⁵⁷

Precautions

High doses of vitamin C may cause diarrhea.

Herbal medicine

Chasteberry (*Vitex agnus-castus*)

Herbal medicines have a long tradition of use in women's health, including for supporting fertility. One of the best-known herbs, *Vitex agnus-castus* has been studied for premenstrual syndrome, cyclic mastalgia, and infertility as part of a mixed herbal formulation called Mastodynon. Vitex has been shown to reduce levels of follicle-stimulating hormone and increase luteinizing hormone, thereby reducing estrogen and increasing progesterone levels. At higher doses, Vitex inhibits prolactin production. Thus, it can be particularly helpful in women who have luteal phase disorders.⁵⁸

Dosage

The dose is Mastodynon 60 drops / day (32.4 mg of chasteberry extract).

Shatavari root (*Asparagus racemosus*) and Damiana (*Turnera aphrodisiaca*)

Less well studied, but highly esteemed for their use in fertility, are the Indian adaptogenic herb, Shatavari root (*Asparagus racemosus*), and the southwestern herb, damiana (*Turnera aphrodisiaca*).

Dosage

Damiana can be prepared by steeping 2–4 g of the dried leaf in one cup of boiling water, straining, and drinking three times daily. A traditional Shatavari dose is 1–2 g / day.

Detoxifying Prior to Conception

Herbs are also used at times to help women cleanse or detoxify before pregnancy. Schisandra (*Schisandra chinensis*) fruit is said to tonify and strengthen the hypothalamus, pituitary gland, ovaries, and adrenals.⁵⁹ Milk thistle (*Silybum marianum*) is another safe choice; it is thought to maximize the ability of the liver to detoxify chemical pollutants. The dose of Schisandra is variable depending on the strength of the extract. Milk thistle is commonly prescribed as an extract containing 70%–80% silymarin at a dose of 140 mg three times daily.

Herbal medicines can also act as abortifacients and should be prescribed by knowledgeable practitioners. In addition to western herbal preparations, Chinese medicine, Ayurveda, and other traditional systems have their favored herbal preparations.

Mind-Body Therapies

Our ability to conceive can be affected by stress. Elevated cortisol levels signal receptors on the ovaries, testes, pituitary, and hypothalamus to tone down reproductive capacity. From an evolutionary biology perspective this makes perfect sense. Our body's clear message is, "Bad timing! Focus on survival, not reproduction."

Infertility can take a huge toll on our well-being. A survey of 121

couples with infertility revealed depression in 32% of the women (19% moderate depression and 13% severe depression). In addition, 26% were at high risk for sexual dysfunction.⁶⁰

Mind-body therapies have been found to help normalize reproductive function and reduce the stress of infertility. One small study examined the use of hypnosis in twelve women with functional hypothalamic amenorrhea; each woman had one hypnotherapy session and was followed for 12 weeks. Nine of the twelve participants resumed menstruating and all twelve described improvements in well-being and confidence. While this was a very small sample, it is notable that one hypnotherapy session led to three-fourths of women resuming menstruation, with broad salutogenic effects observed in all participants⁶¹ (see [Chapter 95](#)).

Another small study evaluated cognitive behavioral therapy (CBT) for functional hypothalamic amenorrhea. Fifteen women were enrolled and followed for 20 weeks. Six of the eight women randomized to CBT resumed ovulating; the remaining two women had partial recovery of ovarian function. In contrast, only two of the women in the control group experienced renewed ovarian activity.⁶²

Mind-body groups are commonly designed as multiple-session, skill-building classes. They typically include a wide range of practices including yoga, guided imagery, breath work, mindfulness, journaling, body scanning, and cognitive restructuring.⁶³ The goal is for participants to find one or more practices that resonate and that they will continue to use once the class ends. A meta-analysis of psychological interventions for infertility showed that skill-building groups are more effective than educational programs or individual therapy.⁶⁴ A second meta-analysis showed that mind-body groups lasting six or more sessions were more effective than those with fewer sessions⁶⁵ (see [Chapter 94](#)).

Acupuncture

Traditional Chinese medicine (TCM) includes acupuncture, herbs, tui na, moxibustion, dietary advice, and more. A retrospective chart review of 1069 fresh, nondonor IVF cycles was recently conducted. This study evaluated whole systems TCM compared with acupuncture at the time of IVF or routine IVF (without acupuncture) and revealed live birth rates of 61.3% in the whole systems TCM compared to 50.8% in the acupuncture at embryo transfer and 48.3% in the routine IVF group.⁶⁶

Acupuncture is the modality most commonly studied for its impact on fertility. Most studies examine the impact of acupuncture before and

after embryo transfer during IVF. While many individual trials have demonstrated benefit, eight meta-analyses have been published with contradictory findings. It has been suggested that this discrepancy may be attributed to the use of a nonvalidated acupuncture protocol (the Craig protocol.)⁶⁷ Another possible reason lies with the challenge of finding an appropriate sham for acupuncture. Some researchers have suggested that noninsertive needling at true acupoints is an active treatment. Acupuncture has also been studied in subfertile men and shown to significantly increase the fertility index of sperm.⁶⁸

Ayurveda

Ayurveda has even fewer studies than TCM examining its impact on fertility. Ayurveda has a rich set of traditional practices including panchakarma (detoxification practices), abstinence before attempting conception, meditation practices, herbs, and specific foods. The most commonly recommended herb for female fertility is Shatavari (*Asparagus racemosus*). In Sanskrit, Shatavari means “she who possesses a hundred husbands,” suggesting its ability to promote fertility and vitality. Male fertility is often enhanced with the adaptogenic herb Ashwagandha (*Withania somnifera*).

Conventional Medicine

Conventional medicine has a wide range of recommendations in the preconception period. A healthy diet and discontinuation of hazardous behaviors, including the use of alcohol, cigarette smoking, and illicit drugs, are universally recommended. A review of prescribed and over-the-counter medications that may pose harm to a fetus is suggested for men and women. Assessment of immunization status is recommended for measles, mumps, rubella, varicella, and, for high-risk women, hepatitis B. Prenatal supplementation with multivitamin containing folic acid is recommended.

Inquiring about future interest in childbearing during regular well-women visits can serve to educate and address misconceptions regarding the relationship between age and fertility. Egg freezing is the newest option available to preserve fertility in women. Accordingly, it is especially important to discuss in women of childbearing age who have a cancer diagnoses for which treatment may impede future fertility. While it is being suggested as insurance policy for women in their early thirties who are delaying childbearing, egg freezing may provide “insufficient

coverage.” Current statistics suggest that egg freezing resulted in successful pregnancies in 18.8% of women who were less than 30 years of age when their eggs were frozen and only 10.3% of women who were more than 40.⁶⁹

Clomid and N-Acetylcysteine

For women who struggle with infertility, conventional medicine provides more options than ever. Clomid is frequently used for ovulation induction, sometimes in combination with metformin, in women with polycystic ovarian disorder (PCOS). Several studies suggest that integrative medicine approaches can enhance the effectiveness of conventional treatment alone. N-acetylcysteine (NAC) has been studied in combination with Clomid in women aged 18–39 years with Clomid-resistant PCOS. Women who took the combination reportedly had a 49% ovulation rate and a 21% pregnancy rate compared with 1% ovulation and 0% pregnancy with Clomid alone. The dose used was 1200 mg of NAC plus 100 mg Clomid.⁷⁰ A prospective study randomized 56 subfertile women receiving Clomid for ovulation induction to receive either folic acid alone or a multivitamin multimineral supplement. The women who received the multivitamin had statistically significant higher pregnancy rates (67% vs. 39%; $p = .013$) and became pregnant more quickly.⁷¹

In Vitro Fertilization

In vitro fertilization has become an important option for women who cannot conceive naturally. Overriding a woman’s normal cycle with gonadotropins leads to the production of multiple eggs that are removed in an office-based surgical procedure. The eggs are fertilized and used fresh or frozen. Fifteen states require insurance coverage for IVF, while the remainder do not require insurance coverage.⁷² The procedure is costly and less likely to be successful than many women imagine. According to the CDC, the overall success rate of IVF using fresh nondonated embryos in 2012 was 36%.⁷³ Success rates of IVF are significantly higher for women under the age of 35 (42% live birth rate) than women aged 41–42 years (26% live birth rate).⁷⁴ Particularly surprising to many is that women aged more than 44 years have a 2% live birth rate when using IVF with their own eggs.⁷⁵

In vitro fertilization also poses potential risks to mother and baby. A

rare but serious risk is ovarian hyperstimulation syndrome. There is some research that links IVF to an increased risk of ovarian and breast cancer,^{76,77} and IVF is associated with a higher rate of twins and multiple births, which poses risk to both mother and child. Finally, there is evidence of a higher rate of birth defects in children born as a result of IVF.⁷⁸

Natural Procreative Technologies

Natural procreative technologies (NPT) are based on the Creighton Model FertilityCare System, which helps women identify ovulation through daily observations of cervical fluid. It was developed in response to the Catholic Church's prohibition against IVF. Pre- and postovulatory estradiol and progesterone levels are sometimes assessed to diagnose hormonal deficiencies and, when needed, medications are prescribed to enhance cervical mucus production (such as vitamin B6, guaifenesin, or antibiotics) or to increase luteal hormones (oral, vaginal, or transbuccal progesterone or human chorionic gonadotropin injections). NPT has been studied in Ireland and Canada and has been shown to significantly increase birthrates over a 2-year period.^{79,80}

Prevention Prescription

While living a healthy lifestyle is always of value, evidence points most strongly to the 3- to 4-month window prior to conception; this is the time it takes both the oocyte and sperm to fully mature. This interval can be used for physical, emotional, mental, and spiritual preparation. Changes in lifestyle, environmental chemical avoidance, and detoxification can be practiced. The fetal origins theory affirms the critical importance of the uterine environment and its influence on an individual's health over the course of a lifetime.⁸¹ It is a compelling reason to follow a healthy lifestyle when trying to conceive as well as during pregnancy.

Preconception Counseling

- Counsel all women about the impact of age on fertility. Explain that IVF success rates are markedly affected by age.
- Discuss the physical signs of fertility and set appropriate expectations

for the time it will take to conceive.

- Consider the need for genetic counseling and refer as needed.
- Discuss discontinuation of dangerous behaviors (e.g., smoking, illicit drugs, and alcohol).
- Discuss a healthy fertility diet.
- Discuss avoidance of environmental toxin exposures.
- Assess immunizations: recommended vaccines include MMR, varicella, DPT, and influenza.
- Recommend an appropriate multivitamin with 400–800 mcg of folic acid.
- Review prescribed and OTC medications and supplements carefully and make a plan to discontinue any that present risk or are not absolutely necessary.

Therapeutic Review

Nutrition

- Encourage a Mediterranean-type diet that is rich in vegetables, fruit, and essential fatty acids in the form of nuts and 8–12 oz of low mercury fish per week. Encourage a low-glycemic index diet. Avoid trans fats and soda. 

Exercise

- Maintain moderate physical activity. Aim for 4 hours or less of physical activity per week unless you are overweight or obese. 

Mind-Body

- Recommend mind-body groups that build skills and last six or more sessions. 

Toxic Exposure

- Avoid environmental toxins to the extent you are able. Avoid canned beverages and foods that contain bisphenol A; avoid exhaust fumes; and choose to eat organic foods or those with minimal pesticides. 

Supplements

- Take a multivitamin with at least 400 mcg of folic acid daily. 
- If unable to eat low mercury fish, consider supplementing with 1 g of fish oil that contains 200 mg of DHA. Do not exceed 2.7 g/day of total EPA + DHA. 

Acupuncture

- Consider acupuncture for infertility. 

Spirituality

- Consider recommending a ceremony based on patients' beliefs to create positive expectation in preparation for a healthy conception. 
- Refer to spiritual counselor if there is anger or angst towards a higher power in relation to infertility.

Pharmaceuticals

- Clomid (dose to be selected and monitored by OBGYN or reproductive endocrinologist). 
- Clomid and N-acetyl cysteine for those with polycystic ovarian syndrome. 1200 mg of NAC plus 100 mg Clomid. 

Surgery

- In vitro fertilization

CHAPTER 52

Labor Pain Management

Michelle J. Mertz, MD, and Connie J. Earl, DO, ABIHM

After a period of heavily medicated birth in the United States during the midtwentieth century, a backlash against the medical model arose, and women began to demand the right to choose their own childbirth experience. Today, women are much more at liberty to influence these experiences. This chapter explores the birthing woman's many options for pain management.

Physiology

Labor is separated into three stages. The first stage involves dilation of the cervix and the beginning descent of the fetus into the pelvis. The second stage is full dilation and birthing of the fetus, and the third stage is passage of the placenta.

Pain in the first stage is primarily visceral, resulting from the mechanical dilation of the cervix and lower uterus. Nociceptive information is carried back on sympathetic fibers to the posterior nerve root ganglia at T10 through L1, as well as on parasympathetic fibers from the pelvic splanchnic nerves (S2 through S4).² The T10–L1 segmental levels also receive nociceptive information from the skin of the back.² This last mechanism may explain why many women feel contractions in their back. Pressure on the pelvic nerves may explain why labor pain can radiate to the thighs or buttocks as well. In some cases of fetal malposition, such as occiput posterior or occiput transverse, the woman may experience more severe back labor resulting from a relative increase in diameter of the head passing through the pelvis in these positions. However, back labor is not isolated to the occiput posterior or occiput transverse position.

During the second stage of labor, pain primarily stems from

mechanical stretching and distention of the perineum and pelvic floor musculature. This is somatic pain, carried to the central nervous system on the pudendal nerve fibers (S2 through S4).² It is often described as being sharp. Many women report a sensation of rectal pressure during descent of the fetus. As the presenting part begins to stretch the perineum, many women describe a classic “ring of fire” sensation.

Pain Relief in Labor

Any acute pain, including labor pain, has two main physiological components: the transmission of the physical pain stimulus to the brain and the interpretation of the information that is filtered through the hypothalamic and limbic systems. Thus, the experience of pain is influenced by emotions and memories.³ Whereas pharmaceutical agents are typically geared toward relief of physical pain, many of the nonpharmacological methods do not attempt to remove the sensation, but instead target the perception of the pain stimulus. One mechanism proposed for many of the therapies discussed in this chapter is the *gate control theory*: sensations such as pressure, vibration, pain, or temperature stimulate superficial tactile nerve endings, and this stimulation leads to inhibition of the pain signal transmission from the organs and deeper tissues at that segmental level.⁴

Integrative Therapy

Continuous Labor Support or Doula

Historically, women have long provided continuous labor support to other women in labor. In the twentieth century, a break in that tradition occurred as birth moved from an out-of-hospital midwifery model of care to a more institutionalized model. Since the 1980s, resurgence in labor support has attempted to integrate the two models. Research in this area typically focuses on the labor “doula,” a person present solely to support the birthing woman and her family.⁵ Doulas have no medical role in the labor or birth and are often hired in the second or third trimester of pregnancy to form a relationship with the birthing family before labor begins.

A large Cochrane Review demonstrated a significant decrease in pain medication required, length of labor, and incidence of cesarean delivery and operative delivery with continuous labor support by a doula.⁶ This

benefit was most pronounced when doula support was initiated in early labor.⁶ The most important factor appears to be the continuous presence of labor support.⁷ An earlier study demonstrated that even the continuous presence of a silent female observer had a positive effect on the foregoing outcomes, although the greatest benefit was observed when a trained doula was present.⁸ Continuous support is most efficacious when the provider is not a member of the hospital staff.^{9,10} Given the benefits, all women in labor should be offered a doula. Several states in the United States are exploring Medicaid reimbursement for doula care in an effort to reduce medical costs. Indeed, a study in Minnesota, which demonstrated a decreased incidence of Cesarean births in Medicaid patients supported by doulas, used multivariate regression to estimate impacts of doula care nationwide and predicted significant obstetrical cost savings with provision of a paid doula support to Medicaid recipients.¹¹

Childbirth Preparation

Half of the women in the United States are estimated to attend some sort of childbirth education class during pregnancy.¹² Many approaches are used, but most classes aim to prepare women and their partners for childbirth and parenthood. Some of these classes introduce women and their partners to various pain relief techniques reviewed in this chapter. Data on pain during labor in relation to childbirth education are sparse. Although individual studies have demonstrated benefits of prenatal education besides pain relief, a systematic review of the literature found the study methods too diverse to clearly comment on the benefits.^{13,14} A large randomized controlled trial (RCT) found no difference in the epidural rate or pain level rated retrospectively with one form of childbirth education.¹⁵ Given the popularity of antenatal education, more research is needed to determine its best use.

Lifestyle

Exercise

Research suggests that regular aerobic exercise during pregnancy is associated with decreased pain scores in labor.^{16,17} Moderate-intensity exercise in labor has also been observed to lower pain scores, even after the exercise ends.¹⁸ No known risks to the fetus are associated with

moderate exercise, though some increased uterine activity occurs with exercise at term.^{18,19} Women should be encouraged to exercise regularly during pregnancy.

Biomechanical Therapy

Positions During Labor and Ambulation

Western medicine long ago adopted the lithotomy position as the position of choice for childbirth, mostly for ease of the practitioner. In contrast, historically around the world, women have employed an upright position in the first and second stages of labor.²⁰

Ambulation, use of a birth ball, and an upright position during the first stage of labor are associated with a decreased length of the first stage, a decreased use of epidural anesthesia, and no difference in adverse maternal or neonatal outcomes.²¹⁻²³ Additionally, in women with a fetal malpresentation associated with back labor, the hand and knees position during labor appears to decrease back pain.²⁴

The use of an upright or side-lying position in the second stage of labor is associated with a decreased length of the second stage. It was also associated with a decreased report of severe pain in a systematic review of 23 RCTs.²⁵ A small but significant increase in the incidence of blood loss greater than 500 mL was reported, but without adverse maternal or fetal outcomes. Unless medically contraindicated, all women should be allowed to ambulate and choose the positions they assume in labor and birth.

Water Immersion

Originally relegated to home birth and out-of-hospital birthing centers, water birth and water immersion in labor are now options in many hospital labor and delivery units. Laboring in water has many purported advantages, including ease of position change with the decreased effects of gravity, relaxation, decreased sensation of pain, and greater control for the laboring woman over her personal space.

A Cochrane Review of water immersion demonstrated a significant reduction in use of pain medication with water immersion in the first stage of labor and no difference in adverse maternal or neonatal outcomes.²⁶ Two of these RCTs also demonstrated increased maternal satisfaction with water immersion in the second stage of labor,²⁶ with no difference in mode of delivery or adverse maternal or neonatal

outcomes.^{26,27} A small RCT found an increased incidence of normal vaginal delivery in water birth compared with land birth.²⁸

In 2014, the American College of Obstetrics and Gynecology (ACOG) released a committee opinion on immersion in water during labor and birth, questioning its safety as a result of one small study, excluded from the previously mentioned Cochrane Review,⁶ that reported increased NICU admission of newborns following water immersion in labor.^{29,30} Of note, this study was designed to investigate water immersion and expectant management versus pitocin augmentation in nulliparous women diagnosed with labor dystocia; the multiple variables in these study groups complicates analysis for causality.³⁰ While most research has demonstrated maternal and fetal safety for water immersion in labor, perhaps more research on its use in protracted labor would yield different results.

More research is needed to evaluate water immersion in labor and birth. Water immersion in labor does not appear to increase the risk of chorioamnionitis or endometritis, even in women with ruptured membranes.³¹

The temperature of the water should be no more than 99°F to avoid raising maternal core temperature in labor.²⁶

Chiropractic, Osteopathic, and Manual Therapy

Back pain is a common phenomenon in pregnancy because the body changes shape, joints relax from hormonal effects, and the spine and frame are required to support added weight. Some data suggest that back pain in pregnancy may be associated with increased back pain in labor.³² One small retrospective study demonstrated that women who received prenatal chiropractic manual therapy reported less pain in labor than those who did not.³² Manual therapy is an option for the management of musculoskeletal back pain in pregnancy, and it may lead to less pain in labor for women who receive regular treatments during pregnancy. Further study in this area is needed. No adverse events have been reported with the use of manual therapy in pregnancy.³³

Massage

Although research is limited, intrapartum massage has been shown to reduce pain perception³⁴⁻³⁸ and decrease anxiety³⁴⁻³⁶ in the first stage of

labor.³⁹ No evidence indicates that it decreases the use of pain medication in labor. Regardless of the paucity of research on this topic, clinicians generally accept that massage can promote relaxation and enhance the quality of women's birth experiences.

Sterile Water Injections

Nearly 30% of women have severe continuous back pain in labor that persists between contractions. Sterile water injections in the low back can be used to relieve this pain. In contrast to isotonic saline, the salt-free water causes irritation as well as physical distention of the skin. The underlying mechanism of pain inhibition is not fully understood. Many investigators refer to the process of counterirritation,^{40,41} in which one type of pain masks another, or to the gate control theory.

Several studies demonstrated that intracutaneous or subcutaneous sterile water injections provided good pain relief in the first stage of labor, particularly for low back pain.⁴²⁻⁴⁸ The effect lasted for up to 2 hours.⁴²⁻⁴⁷ These injections are simple to administer, inexpensive, and carry no known risks. They were not shown to reduce the use of pain medication in these studies. Administration can be quite painful, but the pain is transient, and subcutaneous injection may be less painful than the intracutaneous route.⁴⁹ The precise location of the points does not appear critical to the success of the procedure.⁵⁰

Technique

Palpate the posterior superior iliac spines, and mark them with a pen. From these sites, measure 3 cm inferiorly and 2 cm medially. Mark these two spots, and swab all four spots (two on the left and two on the right) with alcohol.⁵⁰ During a contraction, inject 0.1–0.5 mL of sterile water subcutaneously or intracutaneously with a fine needle, thus forming a small white bleb, as during a tuberculin skin test. Repeat at the remaining three sites as quickly as possible. It may help for two providers to inject simultaneously. Repeat as necessary.

Bioenergetics

Transcutaneous Electrical Nerve Stimulation

Transcutaneous electrical nerve stimulation (TENS) emits low-voltage

electrical impulses through electrodes, with operator-controlled variation in frequency and intensity. TENS units are portable, battery operated, and relatively inexpensive. TENS has typically been used to treat musculoskeletal and neuropathic pain, although its efficacy is controversial. The mechanism of action most often proposed is the gate control theory. Application of the electrodes is not standardized in labor. Although electrodes are typically applied paraspinally at T10 and S2, many studies also describe acupoints and cranial placement.⁵¹

A Cochrane Review of studies with notably heterogeneous methods demonstrated little evidence of significant pain relief in labor from the use of TENS. Despite this finding, fewer women reported severe pain with the use of TENS, and women who had true TENS were more likely to want to use it in a future labor than those who received sham TENS.⁵¹ The trials that applied TENS to known acupoints more consistently demonstrated pain relief.^{52,53} Application can be intermittent or continuous, although continuous TENS may be more effective in active labor.⁵³

FIG. 52.1 Acupressure to SP6.

The application of transcutaneous electrical nerve stimulation may interfere with electronic fetal monitoring.

Acupuncture

In obstetrics, acupuncture has been used to promote version in a breech presentation, decrease nausea, induce or augment contractions, and provide pain relief.⁵⁴ It has also been used for pain management during perineal suture repair. Spleen 6 (SP6) and large intestine 4 (LI4) are the most commonly used acupoints in labor (Figs. [52.1](#) and [52.2](#)).

The considerable heterogeneity among the study designs, treatment protocols, and outcome measures of studies in the literature make it challenging to comfortably draw conclusions about the effect of acupuncture on labor pain. Early data of a systematic review drawing from three trials of acupuncture for labor pain was quite hopeful,⁵⁵ and newer data is still optimistic, but the studies draw conflicting conclusions. One recent study⁵⁶ of 303 women concluded that acupuncture does not reduce women's experience of labor pain; however, fewer women in the electroacupuncture group used epidural analgesia compared with those receiving standard treatment. Another recent trial⁵⁷ found that electroacupuncture reduced pain and shortened the active phase of labor. The most recent Cochrane systematic review⁵⁸ included nine trials of acupuncture. Pain scores were not significantly reduced overall using acupuncture; however, there was a significant reduction in the use of pharmacological analgesia in the acupuncture group compared with placebo and standard care. Length of labor was reduced and satisfaction with pain relief was increased when compared with placebo. Compared with standard care, women receiving acupuncture reported greater relaxation. When acupuncture was compared with no treatment for pain, there was reduced pain intensity reported by the acupuncture group. An earlier review⁵⁹ of 10 trials and 2038 women (some overlapping with the previously mentioned review) did not support the use of acupuncture for controlling labor pain, but the acupuncture group showed a significant reduction in the requirement for all forms of analgesia, including epidural. Women in the acupuncture group had a significantly shorter duration of labor, were more satisfied

with their pain relief, and were more relaxed.

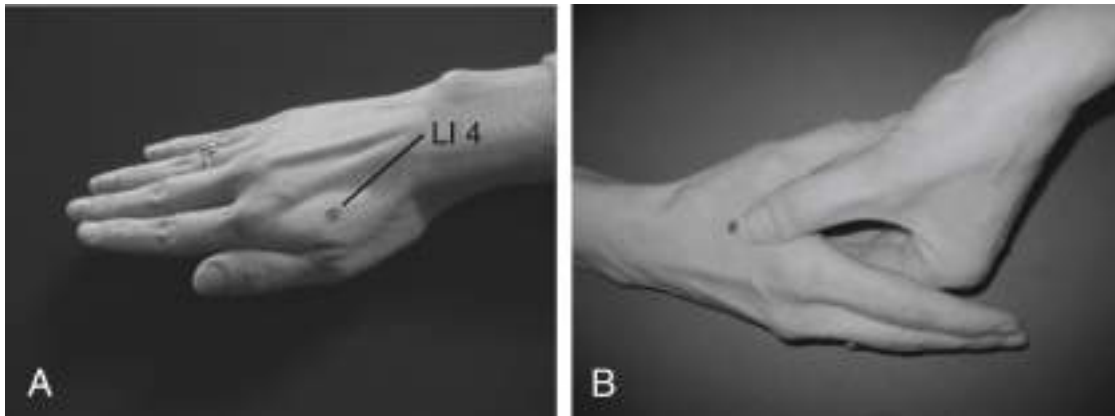

FIG. 52.2 A and B, Acupressure to LI4.

When reviewing the literature, we acknowledge that the heterogeneity among the studies may have contributed to conflicting conclusions. An additional consideration is that a nonsignificant or equal score among those receiving acupuncture and those receiving conventional analgesia may actually suggest that acupuncture is equivalent to conventional analgesia. We agree with the authors of a recent narrative literature review⁶⁰ who concluded that the benefit of acupuncture may lie largely in the capacity to help women avoid pharmacological medication.

SP6 and LI4 are purported to cause uterine contractions and should therefore not be used if labor is not desired.⁶¹

Acupressure

Acupressure is a variation of acupuncture involving the application of a constant pressure on specific acupoints. Like acupuncture, it is frequently used to enhance labor, manage labor pain, and shorten the time to delivery.⁶² Because the needles are replaced by pressure, this technique is noninvasive, requires no equipment, and can easily be taught to partners or support staff. Two recent relatively small trials^{63,64} measured the effect of acupressure on pain scores at several intervals during labor and found that the women in the control group perceived pain as more severe at nearly each phase of labor compared with the acupressure group. These

results are consistent with a prior study.⁶⁵ Additionally, labor duration has been shown to be shorter in the acupressure group.⁶⁴ A 2011 Cochrane Database Review⁵⁸ included four separate studies looking at acupressure with more than 400 women. It revealed a significant reduction in pain scores, reduced length of labor, and decrease in anxiety among women using acupressure during labor compared with controls. The authors ultimately concluded that acupressure may be beneficial in reducing pain, but stated that the risk of bias was high in the studies, and there was need for more research.

Find SP6: Located one handbreadth (four finger widths based on the proximal interphalangeal joints) above the prominence of the medial malleus, in a depression just medial to the border of the tibia (see [Fig. 52.1](#)).⁶¹

Find LI4: Ask the patient to squeeze the thumb against the base of the index finger (see [Fig. 52.2A](#)). LI4 is on the dorsum of the hand, at the height of the muscle bulge, level with the end of the crease. It is between the first and second metacarpal bones (see [Fig. 52.2B](#)).⁶¹

Mind-Body Therapy

Hypnotherapy

Hypnosis is a state of focused concentration in which the patient is relatively unaware, but not completely blind to her surroundings.⁵⁴ *Hypnotherapy* refers to the clinical use of suggestions under hypnosis to achieve specific therapeutic goals.⁶⁶ During labor, these suggestions focus on the diminished awareness of pain, fear, and anxiety, thus leading to a decreased perception of each. Generally, this technique requires practice before the onset of labor.

Multiple small, heterogeneous studies have demonstrated decreased use of pain medications,⁶⁷ higher pain thresholds,⁶⁷ shorter hospital stays,⁶⁸ less surgical intervention,⁶⁸ fewer complications,⁶⁸ and a more satisfying birth experience⁶⁶ in hypnotized women. A 2012 systematic review⁶⁹ of seven studies, including many of the above, concluded that while there is a positive trend for pain relief in labor using hypnosis techniques, the difference is not statistically significant. Further research with more consistent study design is needed to truly assess its efficacy.

Yoga

Yoga uses the breath to focus on the interconnectedness between the mind and the body. It is thought to bring the individual toward a state of greater relaxation, increased self-awareness, and increased emotional well-being. Yoga also promotes muscle strength and flexibility.⁷⁰ Although yoga has been linked to improved birth weight^{71,72} and decrease in labor duration,⁷¹ preterm labor, intrauterine growth restriction, and emergency cesarean rate,⁷² few studies have focused on maternal comfort in labor. While two of these studies failed to demonstrate a decrease in the use of pain medication in labor, both demonstrated that regular yoga practice in pregnancy was associated with higher levels of maternal comfort during labor and 2 hours afterward and a shorter duration of first stage and total time of labor.^{70,73} In addition, investigators noted that the yoga group remained “in control” despite intensifying labor. One small RCT demonstrated a significant decrease in the visual analog scale-rated pain during labor with a regular prenatal yoga practice in women who became pregnant by in vitro fertilization.⁷⁴ A nonrandomized controlled trial demonstrated⁶⁶ that women who participated in a prenatal yoga program had significantly fewer pregnancy discomforts and increased childbirth self-efficacy. Participants also felt more in control and had lower pain levels that allowed them to be more active in their childbirth experience. Yoga is considered safe in pregnancy because all poses can be modified for the pregnant woman.

Music and Audioanalgesia

The use of music as adjunct therapy has been shown to reduce pain significantly in patients with chronic, postoperative, and cancer pain. Music has also been shown to decrease anxiety during colposcopy and in cardiac patients.⁷⁵⁻⁷⁷ Many people have extrapolated the analgesic effects of music to labor as well. In the limited available studies, music therapy indeed appears to be mildly effective in reducing both labor pain and distress from that pain.^{78,79} Music should be offered to women in labor if they desire.

Biofeedback

With biofeedback, physiological information such as pulse or blood pressure is recorded through electrodes and shown in real time on a monitor while the patient adjusts her behavior or thoughts to control

physiological functions that were previously considered involuntary. Patients like biofeedback because it puts them in control and allows them to learn by trial and error.⁵⁴ Results are equivocal regarding the efficacy of biofeedback in labor.⁸⁰⁻⁸³ The technique is risk free; however, it does require practice to master during pregnancy.

Biochemical Therapy: Aromatherapy

Aromatherapy is a natural healing art that uses essential oils extracted from aromatic botanical sources. These oils can also be used in the bath water, rubbed on clothing or towels for use as a compress, mixed with oil and applied, or kept available in small vials to open and smell. Examples of essential oils used in labor are lavender, chamomile, mandarin, clary sage, ginger, frankincense, eucalyptus, jasmine, lemon, and peppermint. In one large observational study, women consistently reported aromatherapy to be a helpful adjunct to their labor experience. Incidentally, a substantial overall reduction was noted in the use of systemic opioids in the hospital during the 8 years of the study. Frankincense was rated most highly for pain relief, followed by lavender. Rose and lavender were rated most highly for anxiety reduction. One percent of patients noted mild adverse reactions, such as nausea, itchy rash, and headache.⁸⁴ One small underpowered RCT demonstrated a positive trend for decreased pain perception with aromatherapy,⁸⁵ and a retrospective study of aromatherapy and massage together demonstrated a decreased use of intrapartum anesthesia.⁸⁶ A systematic review⁸⁷ of aromatherapy use in labor identified only two studies that met their criteria, and the authors were unable to include any of the data related to pain management because of the way the data was reported. Although more research is required, aromatherapy shows promise for pain relief in labor.

Botanicals

Raspberry Leaf

Raspberry leaf is commonly used as a uterine tonic.⁸⁸ As many as 25% of women in the United States use raspberry leaf in pregnancy,^{89,90} and up to one-third of U.S. nurse midwives use raspberry leaf to stimulate labor.⁹⁰ A review of the existing studies demonstrated a positive trend toward decreases in the length of first and second stage of labor and

operative vaginal delivery.⁹¹ No data are available on pain in labor with prenatal raspberry leaf. None of the studies have evaluated raspberry leaf in the form of tea, although this is typically how it is used.

Dosage

The dose is 1.2 g orally twice daily,⁹² starting in the third trimester.

Motherwort, Cramp Bark, and Black Cohosh

These botanicals are used by some herbalists to relieve back pain and spastic uterine contractions during labor.⁸⁸ No human studies have evaluated the efficacy of these botanicals. Black cohosh may be linked to hepatotoxicity and should be used with caution until more data on its use are available.⁸⁸

Pharmaceuticals

Maternal discomfort in labor is multifactorial. A few common combinations of pharmaceuticals are often given together in labor to address the pain, nausea, anxiety, and extreme fatigue that often accompany this process. Pharmaceuticals can be divided into two main categories: systemic and regional.

Systemic Agents

Essentially all analgesic agents cross the placenta.⁹⁵⁻⁹⁸ Because of the complexity of fetal circulation, only a small percentage of the drug may reach the fetal brain.⁹⁹ Therefore the mother may be affected by a certain concentration of drug without affecting the fetus. Providers should anticipate that beat-to-beat variability of the fetal heart rate may be reduced markedly with the use of these agents, but this may not necessarily affect the clinical status of the newborn. Systemic agents can be divided into three types: opioids, inhaled analgesics, sedatives, and antiemetics (the last two are not completely discussed here).

Opioid Analgesia

Parenteral opioids are frequently used for pain relief in labor, although a large meta-analysis demonstrated that the efficacy is mild to moderate at

best, and maternal satisfaction is moderate as well.¹⁰⁰ Whether one opioid is superior to the others remains unclear.¹⁰⁰ Institutional preference often dictates the choice. All opioids are associated with maternal and neonatal respiratory depression, delayed gastric emptying, and nausea and vomiting, which may increase the risk of aspiration if general anesthesia becomes necessary. Some centers use patient-controlled intravenous infusion pumps programmed to give a predetermined amount of drug at the patient's request. Please see [Table 52.1](#) for a comprehensive list of parenteral opioids and their profiles.

Inhaled Analgesics

Inhaled analgesia was introduced in the mid-1800s as one of the first forms of systemic pain control for labor, and is still used widely around the world, although not often in the United States. It can be self-administered after simple instruction, and therefore requires less effort by labor attendants than that required for other forms of analgesia/anesthesia. The agents used primarily for labor pain are nitrous oxide and fluorine derivatives, selected because of their rapid uptake/washout rate, which allows rapid onset of the analgesia. It can be used only during contractions or continuously in labor. There has been some controversy about the risks of nitrous oxide, as it has been associated with decreased fertility and increased spontaneous abortions in maternity professionals, possibly via inactivation of methionine synthase.¹⁰¹ The precise mechanism of action is unknown, but a systematic review of inhaled analgesia for labor pain in the first stage of labor⁸⁷ revealed that there were fewer reports of pain, as well as decreased pain intensity, with the use of inhaled analgesia using fluorine derivatives or nitrous oxide. Both analgesic agents were associated with side effects such as nausea, vomiting, drowsiness, and dizziness. There was no evidence of short-term harm to the neonate, but because of the significant heterogeneity of this research, more research is required to assess the efficacy and safety of inhaled analgesia in labor.

TABLE 52.1

Parenteral and Inhaled Analgesia

Drug	Dose	Pros	Cons	Comments
Morphine Opioid	2-5 mg IV Onset less than 5 min Lasts 1.5-2 h 10 mg IM Onset 10-20 min Lasts 2.5-4 h	Long-acting when given IM	Nausea and vomiting ⁹⁵ Urinary retention ⁹⁵ Orthostatic hypotension ⁹⁵	Used primarily for therapeutic rest during early prodromal labor ⁹⁵
Meperidine (Demerol) Opioid agonist	25-30 mg IV every 1-2 h Onset 5 min 75-100 mg IM every 2-4 h Onset 10-45 min	Less respiratory depression than with morphine ⁹⁵ Slightly less urinary retention than with morphine ⁹⁵	Active metabolites accumulate in fetal tissue after first hour ⁹⁵ Active metabolites may cause dose-dependent neuroleptic depression demonstrated up to 3 days ⁹⁵ Neonatal risk of delirium occurs within 1-4 h Nausea and vomiting ⁹⁵ Delay in gastric emptying	Laning favor in pain management
Fentanyl Opioid	50-100 mcg IV every 1 h Onset 1 min Can lead up to 200 mcg	Rapid pharmacokinetics No active metabolites Less neonatal neurobehavioral depression ⁹⁵	Highly lipophilic and potent May cause transient benign sinusoidal fetal heart tracing ⁹⁵	
Buprenorphine (Stadol) Opioid agonist-antagonist	1-2 mg IV every 4 h Onset 1-2 min 1-2 mg IM every 4 h Onset 10-30 min	Ceiling effect for respiratory depression ⁹⁵ Nausea and vomiting less common ⁹⁵	Somnolence ⁹⁵ Dysphoria ⁹⁵ Dizziness ⁹⁵	May cause increased blood pressure, avoided in hypertension or preeclampsia ⁹⁵ Opioid antagonist effect may promote opioid withdrawal in opioid-dependent women ⁹⁵
Nalbuphine (Nubain) Opioid agonist-antagonist	10 mg IV Onset 2-3 min 10 mg IM every 3 h Onset 15 min Maximum dose 160 mg over 24 h	Ceiling effect for respiratory depression ⁹⁵ Nausea and vomiting less common than with meperidine ⁹⁵	Maternal sedation ⁹⁵ Dizziness ⁹⁵ May cause benign transient sinusoidal fetal heart tracing ⁹⁵	Primary similar to morphine ⁹⁵ Opioid antagonist effect may promote opioid withdrawal in opioid-dependent women ⁹⁵
Inhaled nitrous oxide ⁹⁵	50% nitrous oxide (N ₂ O) and 50% oxygen ⁹⁵	Safety not fully assessed with single instruction Decreased effectiveness ⁹⁵	Increased nausea, vomiting ⁹⁵	Most commonly used inhaled analgesia
Inhaled Nitric Oxide ⁹⁵	Dosed by protocol inhalation	Decreased nausea vs nitrous oxide Increased pain relief vs nitrous oxide ⁹⁵	Increased effectiveness ⁹⁵ Requires medical provider to prescribe	Typically delivered by anesthesia technicians due to risk of over-sedation

75 mg meperidine = 10 mg morphine = 0.1 mg fentanyl = 10 mg nalbuphine. ⁹⁵

IM, intramuscularly; IV, intravenously.

Sedatives

Sedatives do not possess any analgesic qualities. They are often used in early labor to reduce anxiety, augment the analgesic effects of narcotics, and decrease the nausea often associated with narcotics. Barbiturates, phenothiazines, and benzodiazepines are examples. The last two classes are not commonly used because of their many maternal and neonatal risks. ¹⁰²⁻¹⁰⁴ Promethazine (Phenergan) is an antiemetic and is the most widely used sedative in labor. It rapidly crosses the placenta and has no known antagonist. In large or small doses combined with opioids, promethazine can depress the fetus for long periods of time. When used carefully with an opioid such as morphine in prodromal labor, however, promethazine may promote therapeutic rest for the patient. In some institutions, zolpidem, a sleep aid, is alternately given for therapeutic rest.

Local and Regional Anesthesia

Because local and regional analgesia methods do not depress the central nervous system, the birthing woman remains awake and able to participate actively, and the neonate is alert on delivery. Regional anesthesia provides the most effective form of pain relief in obstetrics, and the term refers to partial or complete loss of sensation below the T8-

T10 level.¹⁰⁴ Depending on the agent used, motor blockade may also be present. Examples of regional anesthesia include spinal anesthesia and epidural anesthesia. Several options for more localized anesthesia also are available, such as the pudendal block, paracervical block, and perineal block. Please refer to Tables [52.2](#) and [52.3](#) for detailed information regarding local and regional blocks, respectively.^{105,106}

Therapies to Consider

Hot or Cold Application

Although the use of hot or cold application for pain relief in labor is common practice among doulas and labor support staff, no RCTs have evaluated this therapy. Easy to initiate, the use of heat or ice should depend on the desires of the laboring woman. Typically, heat is applied to the back, neck, shoulders, or abdomen by using warm compresses, microwaveable rice-filled pillows, or electric heating pads. Caution should be taken to avoid burns; the heat should never be painful. Cold is typically applied to the forehead, back, or neck using a cool washcloth, ice-filled sacs, a glove, or ice pack. Cold soda cans, which can double as massage tools on the lower back, can also be used. One study demonstrated a decrease in pain scores with ice massage to the acupoint LI4 during contractions.¹⁰⁷

Homeopathy

Although many birth attendants administer homeopathy for pain, anxiety, and labor management, the use of these remedies is largely driven by traditional homeopathic literature. Currently, no data are available on homeopathy in labor and birth; however, research indicates that homeopathy is a very safe form of therapy with minimal side effects.¹⁰⁸ If a woman is interested in using homeopathy, consult a homeopath or homeopathic literature to find appropriate remedies.

Reflexology

Reflexology focuses on zones in the hands and feet that are believed to correspond to specific areas of the body.¹⁰⁹ The practitioner applies manual pressure in these zones to achieve therapeutic benefits in the target organ, gland, or body part. One small RCT in Iran¹¹⁰ demonstrated a significant decrease in reported pain throughout the entire first stage of labor after reflexology treatment in early labor, compared to either

routine care or routine care plus labor support. The session addressed the areas associated with the pituitary gland, diaphragm, uterus, and genital area, as well as lumbar and sacral spine. The mechanism for reflexology is unclear and has been controversial. Further study is required to assess its efficacy on labor pain, but this study showed promise.

TABLE 52.2
Other Analgesia

Type	Description	Precautions	Indications	Technique
Local perineal analgesia	Direct perineal infiltration with rapidly acting agent Local analgesia lasting 20–40 min ⁹⁷	Intravascular injection can rarely cause sciatica, hypotension, and cardiac arrhythmias. Avoid injecting into the fetal scalp.	Used before episiotomy, outlet forceps, and breech repair.	Use 1%–2% lidocaine without epinephrine at 2–3 cm spacing. Aspirate for blood before injecting. Use as little as possible to avoid toxicity.
Pessurement block	Simple, effective Duration of analgesia dependent on type of anesthetic used.	Fetal brachyplexia, which can be associated with fetal acidosis. ⁹⁸ Do not use in mothers with fetuses with acute or chronic distress. ⁹⁹	Pain relief for cervical dilation Administration is usual to first stage of labor.	Inject 2–6 mL of local anesthetic without epinephrine into lateral foramina of cervix (4 and 8 o'clock or 3 and 9 o'clock).
Pudendal nerve block	Safe Variably effective	Risk of injecting directly into large vessels that lie in close proximity to injection site. Hematomas ⁹⁹ Infection ⁹⁹	Pain relief in second stage Spontaneous vaginal delivery, spontaneous, forceps outlet and low forceps, or to supplement epidural block.	Inject 2–10 mL of local anesthetic slightly below the ischial spine bilaterally. Aspirate before injection to reduce the risk of local anesthetic toxicity.

TABLE 52.3
Regional Blocks

Type	Description	Indications/Effects	Precautions
Spinal block	A single-shot, long-acting local anesthetic is often used with or without an opioid agent.	This is used for the second stage of labor and short procedures such as cesarean delivery.	Hypotension, which may lead to decreased uterine perfusion. ¹⁰⁰ Pruritus (when opioids are added) ¹⁰¹ Blunting of the pressure sensation during the second stage of labor Impaired ability to push if the motor block is too dense Increased risk for operative vaginal delivery ¹⁰² Prolongation of labor ¹⁰³ Fever, ¹⁰⁴ periodically leading to suspicion of infection and subsequent interventions Transient fetal heart rate deceleration ¹⁰⁵ Increased need for oxytocin (Pitocin augmentation) ¹⁰⁶ Unstable ¹⁰⁷ Transient painful sensation in legs or buttocks (with spinal) ¹⁰⁸ Epidural or spinal hematoma (rare) ¹⁰⁹ Abscess (rare) ¹¹⁰ High spinal anesthesia, resulting in paralysis of the respiratory muscles (rare) ¹¹¹ Neurotoxicity (rare) ¹¹²
Combined spinal–epidural block	This combines the rapid onset of spinal analgesia with the ability for continuous infusion of analgesia through the epidural catheter.	This widely used block provides immediate pain relief during the second stage of labor. It can convert to anesthetic adequate for cesarean section if continues to provide postoperative pain relief.	
Epidural anesthesia	Local anesthetic and opioid are injected through a catheter into epidural space, to allow for continuous infusion. The dose can be titrated over the course of labor.	The same catheter can be used for labor, vaginal delivery, and cesarean section. The block is usually not initiated until active labor is established.	
“Walking” epidural anesthesia	This epidural block preserves motor strength for manual effective pushing. Most women are not able to walk or support their weight.		

^a Maternal satisfaction, obstetric outcomes, and neonatal outcomes do not appear to differ between the combined spinal–epidural block and the epidural block.¹⁰⁶

Prevention Prescription

- Cultivate the patient-provider relationship prenatally when possible.
- Discuss the woman's expectations about labor prenatally.
- Discuss preferences for labor pain management before labor begins.
- Involve the laboring woman in decision making.
- Recommend that women arrange for continuous labor support.
- Recommend regular moderate exercise or yoga practice during pregnancy.

Therapeutic Review

A laboring woman has many options for pain control. Individually, many of these therapies are quite effective in reducing pain, but nearly all may be used in combination. No research has evaluated the synergistic effect, but we recommend offering multiple options to women.

- Plan for continuous labor support. Consider hiring a trained doula.

- Consider childbirth education classes to prepare for labor and birth.

Lifestyle

- Regular prenatal exercise 
- Moderate exercise or movement during labor 

Biomechanical Therapy

- Ambulation or upright position during first stage of labor 
- Upright or side-lying position during second stage of labor 
- Hands and knees position for back labor 
- Water immersion,
 - First stage 
 - Second stage 
- Massage during labor 

- Regular chiropractic, osteopathic, or manual treatment in pregnancy

- Sterile water injections for back labor

- Hot or cold application

- Reflexology

Bioenergetics

- Transcutaneous electrical nerve stimulation in labor, with possible focus on acupoints

- Acupuncture during labor

- Acupressure during labor

- Homeopathy

Mind-Body Therapy

- Regular yoga practice in pregnancy

- Hypnotherapy techniques prenatally to prepare for labor

- Music/audioanalgesia during labor

- Biofeedback techniques during pregnancy to prepare for labor

Biochemical: Aromatherapy

- Aromatherapy during labor (e.g., frankincense, lavender, rose)

Botanicals

- Raspberry leaf to shorten labor: 1.2 mg twice daily in the last trimester

- Motherwort or skullcap may have a calming effect for anxiety

- Black cohosh

Pharmaceuticals

- Parenteral opioids for mild to moderate pain relief

medication and dose is often institutionally driven

- See [Table 52.1](#) for options and doses
- Promethazine: 12.5–25 mg, orally or intravenously, every 4–6 hours as needed for sedation and nausea 
- Local anesthesia 
 - See [Table 52.2](#) for technique and details
- Regional anesthesia or epidural anesthesia 
 - See [Table 52.3](#) for options and details

CHAPTER 53

Postdates Pregnancy

D. Jill Mallory, MD

Pathophysiology

Postdates or postterm pregnancy is defined as a pregnancy that extends to or beyond 42 weeks of gestation (294 days or estimated date of delivery [EDD] plus 14 days). A normal pregnancy lasts approximately 40 weeks from the start of a woman's last menstrual period, but any pregnancy that lasts between 37 and 42 weeks is considered normal. Approximately 4%–7% of all singleton pregnancies extend to 42 weeks or 14 days beyond the EDD.¹

Postterm pregnancy is associated with a higher perinatal mortality rate (stillbirth and newborn death within the first week) and a higher risk for complications during delivery, such as an emergency cesarean delivery, shoulder dystocia, postpartum hemorrhage, birth asphyxia, meconium aspiration syndrome, and neonatal birth injury.² Current research suggests that the lowest infant mortality rate is achieved when pregnant women have completed at least 41 weeks of gestation before labor is induced and when induction occurs before or at 42 weeks of gestation, although the absolute risk for problems from delivering beyond 42 weeks is low.² The overall risk for perinatal death is estimated at 0.4% in women who deliver beyond 42 weeks of gestation and 0.3% for women who deliver between 37 and 42 weeks of gestation.³

Because of this small increase in perinatal mortality, the induction of labor is widely practiced at or before 42 weeks of gestation, and postterm pregnancy has become the most common reason for induction.⁴ Unfortunately, labor induction itself is not without risks. Obstetric problems associated with induction of labor in postterm pregnancy include cesarean section, prolonged labor, postpartum hemorrhage, and traumatic birth. These problems are more likely to result from induction

when the uterus and cervix are not ready for labor.² Furthermore, induction of labor brings with it increased risks of uterine rupture, uterine hyperstimulation, fetal distress, and instrumentation.⁵

Very few studies have considered women's experiences and opinions when it comes to the timing of inducing labor, and for women seeking a natural, unmedicated labor and birth, induction poses many philosophical challenges. Accurate dating is obviously important for reducing the need of induction, and studies have shown that early ultrasound is associated with a reduced incidence of pregnancies misclassified as postterm.⁶ When women have accurate pregnancy dating and are approaching 41 weeks of gestation, many may seek nonpharmaceutical measures of cervical ripening and labor induction. One small study of 50 women showed that many were opposed to medical induction of labor, yet they used self-help measures to stimulate labor at home.⁷ More research is needed in the realm of nonpharmaceutical cervical ripening and labor induction options for women who have postdate pregnancies.

Integrative Therapy

Nutrition

Pineapple

Pineapple (*Ananas comosus*), which contains the compound bromelain, has historical medicinal use both as a whole food and in extract form. Bromelain has been proposed as the active ingredient, and it is present only in the fresh fruit because the canning process destroys it. Bromelain has been used to elicit uterine contractions as a means of shortening labor. Some animal model research suggests that instead of increasing cervical prostaglandins, bromelain may actually inhibit them.⁸ No research is available on the possible effectiveness of bromelain for induction of human uterine contractions, although this use is widely suggested in lay pregnancy resources. Some investigators suggest that pineapple's effects on labor may result from gastrointestinal stimulation by fiber and sugar, thus affecting local neural pathways.⁹ No known risks are associated with pineapple use in pregnancy.

Supplements

Castor Oil

Castor oil, derived from the bean of the castor plant (*Ricinus communis*), has a very rich history of use for labor stimulation that dates back to ancient Egypt. One survey completed in 1999 found that 93% of U.S. midwives reported using castor oil to induce labor.¹⁰ Despite this prevalence, research into the use of castor oil has been limited. A recent study in mice found that the castor oil metabolite ricinoleic acid activated intestinal and uterine smooth muscle cells via prostaglandin E2 receptor 3 (EP3) prostanoid receptors.¹¹ This may explain its mechanism of action in humans. Three trials were included in a recent Cochrane review looking at castor oil for labor induction.¹² It included 233 women at term and compared ingestion of castor oil with no treatment/placebo. Outcomes evaluated included cesarean section rate, meconium staining of amniotic fluid, instrumental delivery, and Apgar scores. All women who ingested castor oil had nausea; otherwise, outcomes were not significantly different from those in women who did not ingest castor oil. A retrospective observational study done in Thailand of 612 women looked at the timing of delivery, fetal distress, meconium-stained amniotic fluid, tachysystole of the uterus, uterine rupture, abnormal maternal blood pressure during labor, Apgar scores, neonatal resuscitation, stillbirth, postpartum hemorrhage, severe diarrhea, and maternal death.¹³ No differences were seen in outcomes between the women who ingested castor oil and the women who did not. This finding suggests that castor oil is safe to use but may not be helpful. Prospective randomized controlled trials are needed.

Evening Primrose Oil

Evening primrose oil (*Oenothera biennis*) is often used for several health conditions of women, including breast pain (mastalgia), menopausal and premenstrual symptoms, and labor induction or augmentation. It contains the amino acid tryptophan and an unusually high content of essential fatty acids, especially cis-linoleic acid (CLA) and gamma-linoleic acid (GLA).¹⁰ These fatty acids are prostaglandin precursors, which may explain traditional use of the oil for stimulating cervical ripening.¹⁰ This supplement is used widely during the last month of pregnancy by midwives in the United States both for cervical ripening and to decrease the incidence of postdates pregnancy.¹⁰ Evening primrose oil is traditionally administered as one to two capsules intravaginally at bedtime, starting after 37 completed weeks of

pregnancy. There has been one case report of an infant born with petechiae and ecchymosis after its mother took primrose oil a week before giving birth.¹⁴ One study investigated oral administration and showed that this route was not effective.¹⁵ Furthermore, the oral use of evening primrose oil during pregnancy may also be associated with more prolonged labor and an increased risk for premature rupture of membranes, arrest of descent, oxytocin use, and vacuum extraction.¹⁵ This finding is not surprising because oral administration during pregnancy was never a traditional use. Larger trials assessing the efficacy of vaginal administration are needed.

Homeopathy

Homeopathy is a safe choice for pregnant women and babies because the remedies used in this system of healing have no pharmacological action.¹⁶ In the United States, the use of homeopathic remedies has increased, and a survey among nurse-midwives in North Carolina reported that 30% recommend homeopathic substances for use during pregnancy.

The two most common homeopathic remedies used for labor induction are *cimicifuga* (homeopathic black cohosh) and *caulophyllum* (homeopathic blue cohosh), which are believed to act directly on the uterus and cervix. These remedies have a long history of use around the world for labor stimulation, especially in Europe and India.¹⁷ *Caulophyllum* is used either to induce labor or augment labor if uterine contractions are short and irregular or when uterine contractions stop. *Caulophyllum* and *cimicifuga* are both indicated for dysfunctional uterine contractions and are thought to help initiate a coordinated and effective contraction pattern. *Cimicifuga* is used specifically to ease the fear of labor and delivery in women who have a history of traumatic childbirth, miscarriage, or abortion.¹⁸ *Cimicifuga* alone is administered as a single dose of 30 C or 200 C potency every 30 minutes for at least 2 hours or together with *caulophyllum* 200 C, alternating doses of the two remedies for a total of six doses in 24 hours. Other remedies that are commonly used for labor induction include aconite, arsenicum, gelsemium, phosphorus, and pulsatilla. These are all given in 200 C potency as a single dose (two pellets).¹⁹

A 2003 Cochrane review examined the use of *caulophyllum*, *cimicifuga*, and some of these other homeopathic remedies.¹⁶ The review assessed only two studies comparing homeopathy and placebo for

cervical ripening or labor induction and found that small sample sizes and insufficient detail in the research made it impossible to draw any meaningful clinical conclusions. More research needs to be conducted to determine whether homeopathy is a potentially viable alternative to oxytocin and prostaglandins for labor induction. Furthermore, studies should be designed to incorporate individualized homeopathic treatments, prescribed by a trained homeopath, to account for the individualized nature of this modality.

For labor induction, caulophyllum and cimicifuga homeopathic remedies are as follows: 30 C or 200 C given every 30 minutes, 1 pellet of each remedy, for a total of six doses in 24 hours. No remedy is given the next day. Repeat the same protocol on day 3 if needed. Other remedies to consider are gelsemium for fear of birth and pulsatilla when contractions come and go, but labor never becomes established.

Botanicals

Red Raspberry Leaf

Red raspberry leaf (*Rubus idaeus*, *Rubus occidentalis*) has been used as a uterine tonic and general pregnancy tea for at least two centuries. Although this botanical is often mistakenly recommended to induce labor, its actual role is to increase blood flow to the uterus and aid the uterine muscle fibers in more organized contraction. Studies indicate that some of the plant components, such as frangine, an alkaloid, do act directly on smooth muscle.²⁰ Animal studies show conflicting data in terms of the herb's effect on uterine muscle. Some studies show a contractile effect, whereas others show a relaxing effect. Historical uses include prevention of miscarriage, prevention of postdates pregnancy, decrease of discomfort in prodromal labor, and decrease of morning sickness. Red raspberry leaf was also probably consumed for nutritional support because the plant contains many nutrients, including vitamins A, C, and E, as well as calcium, iron, and potassium. Overall, the herb does seem to reduce the risk for postdates pregnancy and appears safe for general use.²¹ One randomized controlled trial of 192 women showed no adverse effects to mother or baby, a shorter second stage of labor (a mean difference of 10 minutes), and a lower rate of forceps use.¹⁹ One retrospective, observational study of more than 150 women also found

that red raspberry leaf reduced the risk for postdates pregnancy, but more conclusive data are needed.¹⁶

Dosage

It is most commonly consumed as a tea, taken as 1–3 cups daily.

Precautions

Generally regarded as safe

Black Cohosh

This herb (*Actaea racemosa*) also has a long history of use. Native Americans mixed it with chamomile, ginger, and raspberry tea to induce menses and labor. The active compounds in black cohosh include terpene glycoside fractions, such as actein and cimifugoside, which have been associated with an estrogenic effect and are thought to reduce levels of pituitary luteinizing hormone, thus decreasing ovarian production of progesterone.¹⁸ This effect may contribute to the initiation of uterine contractions because the relaxing effect of the high levels of progesterone on the uterine muscle decreases before the initiation of labor. However, a systematic review on the use of black cohosh in labor found no evidence of efficacy.²²

One of its alkaloids, caulosaponin, causes coronary blood vessel constriction and direct myocardial toxicity in a dose-dependent manner. This poses challenges to practitioners because the doses present in over-the-counter products may be difficult to verify. At least one case report has been published of toxicity in an infant whose mother was given an unknown dose of black cohosh at term.²³ At this time, the German Commission E, an expert committee established by the German Ministry of Health that evaluates herbal products, does not recommend the use of black cohosh in pregnancy.²⁴

Blue Cohosh

The herb blue cohosh (*Caulophyllum thalictroides*) also has a long tradition of use as a uterine tonic. It was traditionally used by Native Americans during 2–3 weeks before the onset of labor.²² Between 1882 and 1905, blue cohosh was listed in the *United States Pharmacopoeia* for labor induction.²² Over-the-counter preparations of blue cohosh contain varying amounts

of triterpene glycosides, which have documented oxytocic effects.²⁵ No studies are available on efficacy.

Three case reports are available that demonstrate possible adverse neonatal effects, such as fetal hypoxia, myocardial infarction, and congestive cardiac failure.²⁶ Whether these effects resulted from the herb itself is not known, given that herbs are often used in combination with other plants, and adulteration and contamination problems can occur. Until further research on this plant is done, it is best avoided for labor induction.

At this time, the use of blue and black cohosh is best avoided in pregnant women because of safety concerns.

Biomechanical Therapy

Breast Stimulation

Breast stimulation has historically been used to induce or augment labor since as early as the eighteenth century.²⁷ Stimulation of the breast is thought to increase the production of endogenous oxytocin in pregnant and nonpregnant women. The most commonly used protocol for breast stimulation involves using either a manual or electric breast pump, manual massage around the areola of the nipple, or rolling the base of the nipple. Typical hospital protocols recommend stimulating each breast individually for 10 minutes each, with a 10-minute rest period following, for a total of four cycles.

The Cochrane Collaboration performed a systematic review of six trials with a total of 719 participants that compared breast stimulation with no intervention to induce labor in women at term.²⁸ The review found that compared with no intervention, breast stimulation significantly reduced the number of women who had not gone into labor at 72 hours.²⁸ This difference was not significant in women with an unfavorable cervix. Breast stimulation also reduced the risk for postpartum hemorrhage by 84%.²⁸ It did not seem to have an effect on cesarean section rates. No incidences of uterine hyperstimulation were noted.

Breast stimulation for labor induction allows women's participation in the induction process and has the advantage of being a low-cost and nonpharmaceutical means of labor induction. Observational studies, however, have shown a link between bilateral breast stimulation and

uterine hyperstimulation.²⁹ For this reason, unilateral stimulation is typically recommended. Concerns have been raised regarding possible adverse effects on placental perfusion; however, the incidences of abnormal fetal heart rate tracings are similar to those found with oxytocin use.³⁰ Continuous electronic fetal monitoring is typically used with breast stimulation in the hospital setting. A common protocol used by women in their homes at term is unilateral breast stimulation done for 1 hour per day for 3 consecutive days. Until safety issues have been more thoroughly evaluated, this technique should not be used in high-risk populations.

Shiatsu

Shiatsu is an ancient form of massage based on Chinese acupuncture theory that often includes the use of breathing and stretching. Shiatsu can be done through the clothes or on bare skin and uses static pressure, which can vary from light holding to deep physical pressure applied with the palm of the hand or thumb. Shiatsu lends itself well to maternity settings because specific shiatsu techniques can be taught to birth partners or practitioners. It has historically been used in midwifery practices to induce or augment labor.³¹

One small pilot study evaluated shiatsu for induction and augmentation of postterm labor.³² Sixty-six women with postterm pregnancies were studied in a hospital-based midwifery practice. Pregnant women were taught to massage three acupuncture points in conjunction with breathing techniques and exercises. The controls attended the same clinic, but they were not taught the techniques. The investigators found that the women with postterm pregnancies who used shiatsu were significantly more likely to have spontaneous labor than were the study participants who did not use shiatsu.

Bioenergetics

Acupuncture

As part of the ancient system of medicine, known as traditional Chinese medicine, acupuncture has been used in pregnancy for thousands of years. Modern studies have evaluated the insertion of fine needles into specific points on the body, as well as the use of mild electrical currents through these needles, known as electroacupuncture. A 2013 Cochrane Systematic Review evaluated acupuncture for inducing labor.³³ The

investigators identified 14 trials that included 2220 women for review. Acupuncture was compared with sham acupuncture or usual cases. Most of the trials were undertaken in Western countries. No trial reported on the achievement of vaginal delivery in 24 hours or uterine hyperstimulation. The use of acupuncture did not seem to affect cesarean section rates or neonatal seizure rates. Acupuncture did seem to increase cervical ripening; however, it did not seem to shorten labor. There were no other statistically significant differences between the groups, including no differences in neonatal morbidity or maternal mortality. Overall, the limited studies to date suggest that acupuncture appears safe for inducing labor, has no known adverse effects on the fetus, and may be effective. The inherent difficulties in blinding for acupuncture treatment make the study of this technique challenging. Given its safety profile, it may be worth trying in patients who wish to avoid pharmaceutical induction of labor. [Table 53.1](#) provides acupuncture points that patients can massage at home to stimulate labor.

Lifestyle

Sexual Intercourse

Unprotected sexual intercourse is thought to encourage the onset of labor by two means. One is the release of endogenous oxytocin in the mother, and the other is cervical ripening caused by seminal prostaglandins. A Cochrane review looked at an observational study of 28 women at term. Unprotected intercourse for three consecutive nights neither significantly changed Bishop scores (1.0 with coitus vs. 0.5 controls; $P > .05$) nor increased the number of women who went into labor at the end of 3 days (relative risk, 0.99; 95% confidence interval, 0.45–2.20).³⁴ Sexual intercourse in pregnancy is considered safe, provided the absence of placenta previa, rupture of membranes, or active genital infection.³⁰ Larger studies are needed to determine whether sexual intercourse has any significant effect on reducing the risk for postdates pregnancy.

TABLE 53.1

Acupressure Points for Induction of Labor

1. Midway along the top of the trapezius muscles, if you were to draw a line from the acromion to C7
2. The motion sickness point at the angle between the first

- and second metacarpals
3. In the semicircle around the distal medial and lateral malleoli
 4. The little toe, all over
- Massage these points for at least 2–3 minutes each.

Pharmaceuticals

Misoprostol

Misoprostol is a prostaglandin E₁ analog widely used for off-label indications such as induction of labor in postdates pregnancy. This hormone is given by insertion through the vagina or rectum or by mouth to ripen the cervix and elicit uterine contractions. A Cochrane review looked at 121 trials and found that small doses (25 mcg every 4 hours) of misoprostol vaginally were as effective as other methods of labor induction.³⁵ Larger doses of misoprostol were found to be more effective than prostaglandins for labor induction, and larger doses also reduced the need for additional oxytocin. Another Cochrane review found that the oral route of administration may be preferable to the vaginal route.³⁶ Compared with the vaginal route, oral route of administration was associated with a lower rate of babies born with low Apgar scores and a lower rate of postpartum hemorrhage but with a higher rate of meconium-stained amniotic fluid. A third Cochrane review has looked at buccal or sublingual administration.³⁷ Data on these routes of administration are more limited; however, there was a trend toward a lower cesarean section rate, a reduced need for oxytocin augmentation, and an increased rate of vaginal delivery in 24 hours. More studies are needed to establish the optimal buccal/sublingual dosage. The main risk for misoprostol use is hyperstimulation of the uterus, and this risk seems to increase with increasing dose. At this time, misoprostol is not approved by the Food and Drug Administration (FDA) for induction of labor.

Dosage

The most common dose used in the United States is 25 mcg intravaginally every 4 hours (maximum, 50 mcg). Wait for more than 4 hours after the last dose before adding oxytocin. The most common oral dose used is 50 mcg. Misoprostol comes in 100- and 200-mcg tablet formulations.

Precautions

Uterine hyperstimulation, uterine rupture, diarrhea, nausea, vomiting, headache

Although misoprostol is commonly used for labor induction in the United States, it has not been approved by the FDA for this use.

Oxytocin

Oxytocin is the most common induction agent used worldwide. It is used alone, in combination with amniotomy, or following cervical ripening with other pharmacological or nonpharmacological methods. Oxytocin is a synthetic analog of the natural labor hormone by the same name. It binds to oxytocin receptors in the uterine myometrium, increases intracellular calcium, and stimulates uterine contractions. A Cochrane review of more than 61 studies concluded that it is safe and effective.³⁸ A black box warning placed on the drug by the FDA states that oxytocin is not to be used for elective labor induction.

Dosage

Start with 0.5–2 milliunits/minute and increase by 1–2 milliunits/minute every 15–40 minutes until the uterine contraction pattern is established. The maximum for induction is 40 milliunits/minute. Oxytocin is available in intravenous and intramuscular preparations.

Precautions

Increased use of epidural anesthesia, uterine hyperstimulation, uterine rupture, abruptio placentae, fetal distress, nausea, vomiting

Vaginal Prostaglandins (PGE₂ and PGF_{2α})

Prostaglandins have been used for the induction of labor since the 1960s. These drugs are synthetic analogs of the body's naturally occurring prostaglandins, which function to ripen the cervix and bring about contractions. A Cochrane review looked at 70 randomized controlled studies of various forms of prostaglandins and found them to be a safe and effective means of labor induction.³⁹ Prostaglandin E₂ is the most commonly used type, and it increases the likelihood of vaginal birth in 24 hours and may reduce the risk for cesarean section by 10%.³⁹

Dosage

The dose is one 10-mg pessary intravaginally. The insert releases 0.3 mg/hour over 12 hours. Remove at 12 hours, at the onset of active labor, or if uterine hyperstimulation occurs. The agent is available as a 10-mg sustained-release insert. It is also available as an intravaginal tablet or gel.

Precautions

Uterine hyperstimulation, fetal distress, uterine rupture, bronchospasm, abdominal cramps, headache, nausea, diarrhea

Mechanical Methods

Potential advantages of mechanical methods, compared with pharmacological methods, for the induction of labor in postdates pregnancy include simplicity of use, lower cost, and reduction of side effects, such as uterine hyperstimulation and fetal distress. However, special attention should be paid to contraindications such as a low-lying placenta, risk for infection, and maternal discomfort.

Amniotomy

The deliberate rupture of membranes may be sufficient to bring about labor without the use of pharmaceuticals. This approach has the advantage of being cheap, but it may be uncomfortable for some women. If the time between amniotomy and delivery of the baby is long, infection may occur. The risk for umbilical cord prolapse is also increased,

especially if the fetal head is ballotable at the time of membrane rupture. Anecdotal reports note that amniotomy may be less beneficial in nulliparous women. More evidence is needed regarding effectiveness compared with placebo or compared with other methods of induction of labor.⁴⁰

Membrane Sweeping

Sweeping of the membranes, also known as *membrane stripping*, is a simple manual technique usually done in the outpatient setting. The technique involves inserting a finger into the cervical os during a sterile vaginal examination and sweeping the finger in a circular motion to detach the membranes from the lower uterine segment. This method sometimes works to initiate labor by increasing the local production of prostaglandins. A Cochrane review of 72 studies found that sweeping of the membranes performed routinely for women at term was associated with a reduced frequency of pregnancy extending beyond 41 weeks.⁴¹ This method is considered safe and reduces the need for pharmaceutical means of induction of labor in postdates pregnancy.⁴¹ There was no increased risk for cesarean section or maternal or neonatal infection. Adverse effects include maternal discomfort, vaginal bleeding, and irregular contractions.

Transcervical Foley Catheter or Cook Catheter Insertion

This approach involves placing a 30-mL Foley catheter bulb or an inflatable Cook catheter transcervically, inflating it with sterile saline solution, and applying maintenance traction or simply leaving it in place ([Fig. 53.1](#)). A Cochrane review looked at 71 studies and concluded that induction of labor with mechanical methods resulted in a similar rate of cesarean section as prostaglandins with equal efficacy of achieving vaginal delivery in 24 hours and a lower risk for uterine hyperstimulation.⁴² When compared with oxytocin alone, the rate of cesarean section is lower with mechanical methods. Complications include acute febrile reaction, pain, vaginal bleeding, and altered fetal presentation.

Prevention Prescription

- Women can be encouraged in the preconception period to track their menstrual cycles and sexual activity closely to aid in accurate pregnancy dating. When women are unsure of their pregnancy dates, first-trimester ultrasound reduces the number of women later incorrectly classified as having postdates pregnancies.
- Good self-care in pregnancy, including aromatherapy, good nutrition, massage, sexual intercourse, spiritual practices, chiropractic, and yoga during the latter weeks of pregnancy may serve to relax the mother and allow the natural rise of oxytocin and reduction of stress

hormones, thus resulting in a greater likelihood of spontaneous onset of labor.⁴³⁻⁴⁵

- Membrane sweeping, done routinely at 39 weeks, may also reduce the risk for a pregnancy that continues beyond 41 weeks.

Therapeutic Review

These therapeutic options for prevention of postdates pregnancy and induction of labor in postdates pregnancy may be considered in the healthy, term patient with no medical complications that would make delivery urgent.

Nutrition

- Pineapple consumption is commonly recommended for labor induction. Although pineapple has no proven benefit, the risks of this intervention are low. 

Supplements

- Castor oil has a long history of use for labor induction. It is considered safe, but it has not been proven effective. Side effects include nausea. Doses are not standardized. 
- Evening primrose oil use lacks data on efficacy. The dose is two capsules intravaginally at bedtime, starting at 38 weeks of pregnancy. This supplement should not be used orally in pregnancy. 
- The homeopathic remedies caulophyllum and cimicifuga can be dosed at 200 C potency by alternating 1 pellet of each remedy every 30 minutes for a total of six doses in 24 hours to help stimulate labor. The benefit is unknown, and risks are minimal. 

Botanicals

- Red raspberry leaf, taken as 1–3 cups of tea daily during the third trimester, may reduce the risk for postdates pregnancy. 
- Despite a strong history of use, black cohosh and blue cohosh should be avoided in pregnancy because of safety concerns until more data

are available. 

Biomechanical Therapy

- Unilateral breast stimulation can be done for 1 hour per day for 3 consecutive days to induce labor at term. 
- Shiatsu may reduce the risk for postdates pregnancy. 

Acupuncture

- Evidence is mixed on the effectiveness of acupuncture to reduce the risk for postdates pregnancy, for cervical ripening, and for labor induction. Acupuncture is considered safe. 

Lifestyle

- Sexual intercourse may not be effective for reducing the risk for postdates pregnancy. 

Pharmaceuticals

- Misoprostol is commonly used for cervical ripening and labor induction, despite a lack of approval by the FDA for this indication. See the doses and precautions discussed in the text. 
- Oxytocin may be used to induce uterine contractions in postdates pregnancy when cervical conditions are favorable. See the doses and precautions discussed in the text. 
- Vaginal prostaglandins may be used for cervical ripening and labor induction, and they are a good choice for postdates pregnancy in patients with unfavorable cervical conditions. See the doses and precautions discussed in the text. 

Mechanical Therapy

- Amniotomy may be used to induce or augment labor, and it may be more beneficial in multiparous women. 
- Membrane sweeping can be considered routinely at 39 weeks to reduce the risk for postdates pregnancy. 

- Transcervical Foley catheter insertion or Cook catheter insertion can be done for cervical ripening in postdates pregnancy, and it may have lower risks than pharmaceutical ripening agents.

CHAPTER 54

Nausea and Vomiting in Pregnancy

Andrea Gordon, MD, and Abigail Love, MD, MPH

Pathophysiology

Nausea and vomiting in pregnancy (NVP) represent a conundrum for the pregnant woman. On the positive side, NVP are correlated with better fetal outcomes than the absence of these symptoms,¹ but at the other extreme, NVP can interfere with nutrition and hydration for the mother and developing fetus. Symptoms may range from occasional mild nausea to multiple episodes of daily vomiting resulting in weight loss and electrolyte abnormalities. This severe manifestation is often referred to as hyperemesis gravidarum. Definitions of hyperemesis gravidarum vary, but commonly accepted criteria include weight loss (often more than 5% of prepregnancy weight), electrolyte disturbances, and ketonuria.

Usually appearing before the ninth week of pregnancy, NVP will affect up to 85% of normal pregnancies, with symptoms generally remitting by the fourteenth week. Initial presentation of symptoms after the ninth week should prompt a workup to determine an alternative cause. NVP may be mild, but up to 20% of women find their symptoms so significant that they cannot continue to work.² The reported incidence of hyperemesis gravidarum, the most severe end of the spectrum, varies from 0.5% to 2%. This severely debilitating condition is the most common reason for hospital admission in the first trimester and the second most common problem for which pregnant women are admitted to the hospital, after preterm labor.³

Even at the milder end of the symptom continuum, NVP can lead to a decreased quality of life and missed time from work. The aptly named Motherisk Pregnancy-Unique Quantification of Emesis and Nausea (PUQE) index has been shown to demonstrate a significant correlation

between the presence and severity of NVP and poorer quality of life.^{4,5} This effect on quality of life and the economic impact of missed work emphasize the need to control these symptoms. Mild or moderate vomiting does not appear to have any significant effects on the fetus. Among women with severe hyperemesis, the reported incidence of low birth weight is higher, but increased reporting of birth defects has not been noted.⁶ In fact, several investigators suggested that NVP represent an evolutionary adaptation that helps protect the developing fetus from exposure to foods that may contain potential toxins.^{7,8}

The cause of NVP is unknown. Both biological and psychological factors have been proposed. Human chorionic gonadotropin (HCG) and estrogen have been studied as triggers for these symptoms. Suggestive evidence includes the finding that pregnant women with higher levels of HCG, which occur in molar pregnancies and multiple gestations, have significantly more episodes of vomiting and higher rates of hyperemesis gravidarum. This theory is also supported by the observations that nonpregnant women who experience nausea and vomiting after exposure to estrogens are more likely to experience NVP. Cigarette smoking is known to reduce both estrogen and HCG levels, and pregnant smokers are less likely to experience hyperemesis gravidarum.⁹

No controlled studies support the theory that NVP comprise a conversion disorder or an inability to respond to life stress.^{10,11} The association of high levels of HCG and estradiol with increasingly severe episodes of vomiting in pregnancy indicates a physiological origin, as do epidemiological factors. Daughters and sisters of women who had hyperemesis are more likely to have NVP as well. Other risk factors include a previous pregnancy affected by hyperemesis, a female fetus, and a history of motion sickness or migraines.¹²

Integrative Therapy

When treatment is considered, risks and benefits must be clearly explained to the pregnant woman. Minimizing the risks of any treatment is desirable, but the presence of a developing fetus makes it more urgent to decrease any unnecessary exposures. This is an ideal time to use integrative approaches because drugs generally represent more risk than other modalities. In addition, some of the behavior modifications such as exercise are beneficial in and of themselves.

Lifestyle

Although the efficacy of lifestyle modifications has not been studied, these interventions are safe and have been anecdotally reported to be useful.¹³

Avoid Odors

Some women report that NVP are triggered by strong odors such as foods, cigarette smoke, or perfume. This is supported by a small study showing that women with congenital anosmia were less likely to develop NVP.¹⁴

Avoiding these stimuli may be helpful. Women should be supported in doing so, for example, by passing off cooking duties to someone else, avoiding tasks with strong odors such as feeding the dog, or politely asking coworkers not to wear perfume for a few weeks.

Increase Rest

Sleep requirements increase in early pregnancy.¹⁵ Women frequently report nausea in association with feelings of exhaustion. Caregivers should educate pregnant patients that fatigue is common and support them in trying to obtain the additional rest they need.

Exercise

Light to moderate aerobic exercise is associated with fewer NVP symptoms. Women who exercised at least three times a week for 20 minutes or more reported fewer symptoms of pregnancy, including nausea.¹⁶ Women who have already been exercising can remain active during uncomplicated pregnancies. Previously inactive women may benefit from gentle exercise but should be evaluated on an individual basis before recommendations for physical activity are made.¹⁷

Nutrition

Low blood glucose levels seem to trigger nausea and subsequently vomiting in many women; thus small, frequent, high-protein, high-fiber meals are often recommended.¹⁸ A potentially helpful approach is to decrease simple carbohydrates that rapidly raise blood glucose and thus stimulate insulin secretion, which can cause rapidly falling blood glucose (see [Chapter 87](#)). However, this includes foods such as pasta, white rice,

potatoes, and white bread, whose blandness seems desirable when patients are nauseated, so education is key. Some patients find that eating something as soon as they wake up and then every 2 hours can suppress nausea. Each pregnant woman may have specific foods she avoids because of a taste or smell that triggers nausea, but it may also be necessary to avoid spicy or fatty foods because they can exacerbate symptoms. Little published evidence exists on the efficacy of dietary changes, but benefit clearly outweighs harm. In one international survey, dietary interventions seemed to help 22% of women with hyperemesis gravidarum.¹⁹

Two studies found that taking a multivitamin before pregnancy or before 6 weeks of gestation was associated with a decreased incidence of NVP. Although this approach would not help a woman already suffering with symptoms, it could be helpful for women at risk for symptoms in their next pregnancy.^{20,21}

Botanicals

Ginger Root (*Zingiber officinale*)

Historically, ginger has been effectively and safely used to treat nausea, including that of pregnancy. Randomized controlled trials have shown that ginger is effective for treating NVP,²² and it is the most thoroughly studied herb for this indication. Some trials have shown ginger to be not only more effective than placebo²³ but also comparable to or better than vitamin B6^{24,25} and comparable to dimenhydrinate.²⁶ It will reduce overall nausea symptoms but not the number of vomiting episodes significantly.²⁷

Patients should be advised that it may take longer for ginger to work: up to 3 days, rather than 1 day for dimenhydrinate. The U.S. Food and Drug Administration (FDA) has listed ginger as a food supplement that is generally recognized as safe,²⁸ and studies have not shown any increased incidence of malformations in children of mothers using ginger.²⁹

Ginger seems to work primarily in the gastrointestinal tract on serotonin receptors in the ileum, the same receptors affected by some antiemetics, such as ondansetron. Some evidence indicates that ginger constituents may also have some action in the central nervous system.³⁰ No toxicity has been demonstrated, although ginger can cause abdominal discomfort or heartburn when it is taken in large doses, especially on an

empty stomach.

Dosage

Most of the studies have used 1000 mg daily, in two or four divided doses.^{23,26,28,31} A higher dose of 650 mg three times daily has also been used,³² but total doses of less than 1500 mg a day are more effective.³⁴ Ginger is available in a variety of forms, and an evaluation of products purchased in pharmacies and health food stores found a wide variation in the amount of active ingredients and suggested serving sizes.³⁵ Women may prefer one form over another, so approximate equivalents can be calculated. In general, 1 g of standardized extract is equivalent to 1 teaspoon of fresh grated ginger root, two droppers (2 mL) of liquid extract, four 8-oz cups of prepackaged ginger tea, four 8-oz cups of tea made with 0.5 teaspoon of grated ginger steeped for 5–10 minutes, 8 oz of ginger ale (made with real ginger—most commercial ginger ales are not effective), two pieces of crystallized ginger (1 inch square, 0.25 inches thick), or two teaspoons (10 mL) of ginger syrup.³⁶ Capsules of ginger come in various dosages, ranging from 100 to 1000 mg, and chewable tablets may contain 67 to 500 mg, so attention to the dosing of the product used is advisable, with the goal a total of less than 1500 mg a day.

Using ginger throughout the day is also helpful. Patients can incorporate ginger into their diet by sprinkling dried or candied ginger in oatmeal, having some ginger tea, and adding fresh ginger to soup or stir-fries.

Precautions

There is a theoretical risk for bleeding as ginger inhibits thromboxane synthetase and may inhibit platelet function. This has not been demonstrated, but precaution should be taken when ginger is used concomitantly with anticoagulants.

Chamomile (*Matricaria chamomilla*)

Chamomile is a flowering plant that is often used for various types of gastrointestinal upset, including travel sickness, colic, and inflammatory

diseases of the bowel. It is commonly used for NVP,³⁷⁻³⁹ although no research on this application has been published. Chamomile appears to be safe and well tolerated, however, and the FDA labels it as safe.⁴⁰

Dosage

Prepare it as a tea, allowing it to steep for 5–7 minutes while covered, so it will retain the volatile active constituents, and sip as needed.

Precautions

Chamomile should be used with caution in patients who are allergic to the Asteraceae/Compositae family, which includes ragweed, daisies, and many other flowers. Some erroneous concern exists about teratogenicity, but that concern is based on a study with alpha-bisabolol at high doses that could not be achieved by someone drinking tea.⁴¹

Peppermint Leaf (*Mentha piperita*)

Peppermint is another herb often used in pregnancy.^{42,43} The active parts are the stems, leaves, and flowers, as well as the peppermint oil that is distilled from these plant parts. Studies have shown peppermint oil to be effective for reducing bowel spasms in irritable bowel syndrome and for patients receiving barium enemas, but peppermint oil has not been studied in pregnancy.⁴⁴ Its mechanism of action is reduction of spasm in smooth muscle, and it may help with NVP by reducing esophageal dysmotility. However, this effect can also reduce lower esophageal sphincter pressure, resulting in reflux. Theoretical concerns exist with using the essential oil in pregnancy because it may cross the placental barrier, but the amount of peppermint ingested in tea or food seems to be safe.⁴¹ Peppermint has been rated as safe by the FDA.⁴⁰

Dosage

The dose is two to three cups of tea daily. Many women find peppermint candies or gum to be effective in squelching nausea. A dose of 0.2 mL in 2 mL of isotonic saline solution used as aromatherapy has been used for postoperative nausea and can be tried if teas or foods

containing peppermint are not tolerated.⁴⁵

Precautions

Peppermint can aggravate reflux by decreasing the lower esophageal sphincter tone.

Bioenergetics

Acupressure: Stimulation of the P6 Neiguan Point

Acupressure of the pericardium 6 (P6) Neiguan (meridian) point, which is located on the inner wrist, may be beneficial. Several small studies have found this to be effective, including a Korean trial, which found significantly less NVP in a group of women with hyperemesis gravidarum,⁴⁶ and another that demonstrated self-administered nerve stimulation therapy over using a commercial device.⁴⁷ However, a 2014 Cochrane analysis did not find P6 acupuncture or acupressure wristbands to be significantly more effective than placebo. Other studies using a crossover design, which were not included in the Cochrane analysis, also showed benefit to using acupressure at the P6 point,^{46,48} and another trial revealed decreased nausea with P6 stimulation, but no change in the frequency of vomiting.⁴⁹ Patients should be made aware of this mixed evidence; patients are willing to try acupressure because it is inexpensive and has no significant side effects.

Patients can be taught to find the P6 point and treat themselves with either manual pressure or the application of “Sea-Bands” ([Fig. 54.1](#)). These elastic bands with attached plastic disks were originally used for motion sickness. Patients can create their own version of such bands by placing a small, round object such as a bead over the point and securing it with tape and then massaging the bead. This therapy has no known negative side effects.

To have a patient accurately locate the P6 point, have her lay one hand palm up, with the other hand placed palm down at right angles to the upturned arm. The first three fingers of the palm-down hand are held close together, and the edge of the ring finger is placed at the crease of the wrist closest to the palm in alignment with the middle finger of the upturned hand. The P6 point, between the palmaris longus and flexor radialis tendons, is now readily palpable under the tip of the index finger of the examining hand (see [Fig. 54.1A](#)). This point is often tender, a characteristic that aids in its location. Many patients use this acupressure

in conjunction with other interventions because it has no known side effects or interactions.

Patients can stimulate the P6 point at any time, but they should be cautioned against using any other acupressure points without consulting a trained practitioner. Some commonly used points, such as the Ho-Ku point that is located between first and second metacarpals (often used for headaches), can stimulate contractions.

Patients must be instructed to press on the point when feeling nausea, as just wearing the bands may not provide significant relief.

Mind-Body Therapy

Hypnosis

Hypnosis has been studied as a treatment for hyperemesis gravidarum. A review of six studies showed encouraging effects, but methodological problems did not allow a definitive recommendation.⁵⁰ This intervention is safe, however, and some women may want to try it for all levels of NVP. One approach has been to suggest to a woman that the “nausea center” in her brain is very sensitive to the hormones of pregnancy and that she is able to “turn down” that sensitivity as one would a thermostat.⁵¹ Another approach is to link the muscle tension in the stomach and throat or the nausea as a hypnotic cue to pleasant imagery.⁵² This imagery may be helpful for patients to use when nausea strikes.

NVP may have an element of conditioned response, as noted with chemotherapy-associated vomiting. Some uncontrolled studies showed that hypnosis can reduce vomiting and anticipatory vomiting in patients undergoing chemotherapy,¹⁰ so the potential exists for hypnosis to work for NVP. Because this treatment may require several sessions of training, the time and expense may be prohibitive for some patients.

FIG. 54.1 A, The P6 Neiguan acupressure point is located on the volar aspect of the forearm by placing the examining hand three fingerbreadths below the wrist crease. The patient's finger widths should be used for measurement. The P6 point is essentially in the midline between the tendons of the palmaris longus and flexor radialis muscles. B, Location of this point. *PC*, pericardium

Counseling and Psychotherapy

Although the general consensus is that NVP does not represent a conversion disorder and is not caused by emotional responses to the pregnancy,¹⁰ evidence indicates that women with NVP may be under more stress. Two investigators stated that NVP "could subject any normal expectant mother to stress sufficient to trigger adjustment disorders, generalized anxiety, or even depressive episodes."¹⁰ In recognition of this extraordinary stress, counseling or psychotherapy may be helpful in coping with the symptoms and their effects on a woman's life.

Supplements

Vitamin B6 (Pyridoxine)

Vitamin B6 is a water-soluble vitamin that is an effective treatment for nausea in pregnancy. The benefit in reducing vomiting episodes is less

clear.^{53,54} The mechanism of action of pyridoxine remains unknown, but extensive analysis for teratogenicity has shown no negative effects on pregnancy outcome.⁵⁵

Patients can expect a significant reduction of nausea with few side effects if they take vitamin B6, so this should be used as a first-line treatment of NVP.⁵⁶

A popular medication for nausea and vomiting, known as Bendectin in the United States and Diclectin in Canada, contained pyridoxine and doxylamine. Bendectin was withdrawn from the United States market in 1983 out of safety concerns about teratogenicity, but no studies validated this possibility. Diclectin remains available in Canada and is one of the most widely studied and used medications in pregnancy today. Following removal of Bendectin from the market, no reduction in birth defects was reported, but hospitalization rates for NVP doubled.⁵⁷

Diclectin, a combination of doxylamine 10 mg and pyridoxine 10 mg, is available in Canada and can be purchased online (www.canadadrugs.com). It is expensive, at more than a dollar a pill. A recommended and less expensive alternative is to combine Unisom (contains 25 mg doxylamine), one-half tablet at bedtime, with 25 mg of pyridoxine, as the combination reduces symptoms by 70%.⁵⁶ [Category C]

Dosage

The most effective dosage of B6 appears to be 30–75 mg daily in three divided doses. Studies performed with the higher end of the dosing range have shown effectiveness against vomiting as well as nausea.^{53,54} When vitamin B₆ alone is not effective, it may be combined with doxylamine to obtain relief from NVP.

Precautions

Pyridoxine can cause sensory neuropathy, which is related to the daily dose and duration of intake. Doses exceeding 1000 mg daily or total doses of 1000 g or more pose the most risk, so the doses that have been used for NVP appear generally to be safe.⁵⁸

Pharmaceuticals

Antihistamines

Several histamine (H1) receptor antagonists have been studied for the treatment of NVP. The most frequently studied and used is doxylamine (Unisom, an over-the-counter sleep aid). An extensive review of safety data revealed no adverse pregnancy outcomes from the use of doxylamine alone or in combination with pyridoxine.⁵⁹ Other drugs in this group, which all have shown some evidence of efficacy and safety for controlling NVP, are dimenhydrinate (Dramamine), cetirizine (Zyrtec), meclizine (Antivert), hydroxyzine (Vistaril), and diphenhydramine (Benadryl).⁶⁰

Dosage

Most patients should use 12.5 mg of doxylamine, the amount in one-half of a scored tablet. This is the amount of doxylamine that was present in Bendectin. Indeed, many women try to “make” a form of Bendectin by combining doxylamine with vitamin B6. This safe option can be suggested if vitamin B6 alone or with ginger or P6 point stimulation is not working adequately. Diphenhydramine, given in 25- to 50-mg doses up to every 6 hours, is also safe and easily obtained.

Precautions

All antihistamines can cause drowsiness.

Phenothiazines

The phenothiazines used to treat NVP include promethazine (Phenergan), prochlorperazine (Compazine), chlorpromazine (Thorazine), and perphenazine (Trilafon). Only promethazine has randomized controlled study data supporting its efficacy and safety.^{60,61} However, some evidence indicates that all medications in this group have some efficacy in the treatment of NVP.⁵⁵ These medications may be used in the outpatient setting, but therapy is often not started until hospital admission for treatment of dehydration or intractable vomiting. The variable dosing forms are advantageous for NVP: these drugs can be self-administered orally or rectally or given intramuscularly by medical personnel if needed.

Dosage

For promethazine, begin with 12.5 mg per rectum or by mouth and progress to 25 mg every 4 hours as needed.

Precautions

Side effects of promethazine include sedation, hypotension, dystonia, and extrapyramidal symptoms. If needed, diphenhydramine 25 mg can be given orally every 6 hours to treat dystonia or extrapyramidal side effects.

Dopamine Antagonists

Two dopamine antagonists have been studied for the treatment of NVP: trimethobenzamide (Tigan) and metoclopramide (Reglan).

Trimethobenzamide has been shown to be safe,⁶² but it has been largely studied for nausea in other settings such as chemotherapy.⁶³ Only one double-blind trial focused on the effectiveness of trimethobenzamide in treating NVP.⁶⁴ This study showed that trimethobenzamide, alone or in combination with pyridoxine, significantly improved symptoms of nausea and vomiting compared with placebo.⁶⁴

Metoclopramide is not associated with malformation risk,^{65,66} and it has been shown to be effective in hyperemesis gravidarum, with or without promethazine.^{67,68} A combination of vitamin B₆ and metoclopramide was shown to be more effective than prochlorperazine or promethazine for NVP.⁶⁹

Dosage

Metoclopramide can be given orally in 5- to 10-mg doses three times daily before meals.

Precautions

The side effects of metoclopramide are similar to those of the phenothiazines, but occur less frequently.

5-Hydroxytryptamine₃ Receptor Agonists

Ondansetron (Zofran), a 5-hydroxytryptamine₃ receptor agonist, is a potent antiemetic originally used for treatment of chemotherapy-induced nausea and vomiting. Data on NVP are limited, but several small studies have found it to be as effective as promethazine,⁷⁰ or as effective as metoclopramide in women with hyperemesis gravidarum.⁷¹ Another trial, which more accurately reflects what is often used in practice, demonstrated ondansetron to be superior to the combination of pyridoxine and doxylamine.⁷²

Dosage

Ondansetron is given orally or intravenously, 4–8 mg up to every 8 hours. Ondansetron is available in an orally disintegrating tablet. This can be useful if one becomes too nauseated to swallow any medication.

Precautions

Adverse reactions to ondansetron include headache, fever, and bowel dysfunction, although this agent has been reported to be better tolerated by patients than promethazine, with no dystonic or extrapyramidal side effects.

Two recent studies found no significant increase in major fetal malformations or outcomes,^{73,74} and the FDA has labeled ondansetron Pregnancy Category B. However, patients do need to be informed that there is a demonstrated association with an increased risk of cardiac septum defects, mainly atrial septal defect and ventricular septal defect.^{74,75}

In light of this evidence, as well as cost considerations, it is prudent to try the other measures and medications discussed previously prior to considering the use of ondansetron, and then discussing the risks with patients.

“No statistically significantly increased risk for a major malformation was found with ondansetron. The risks for a cardiovascular defect and notably a cardiac septum defect were increased and statistically significant (OR = 1.62, 95% CI 1.04–2.14, and RR 2.05, 95% CI 1.19–3.28, respectively). The teratogenic risk with ondansetron is low but an increased risk for a cardiac septum defect is likely.”⁷⁴

Corticosteroids

Several small studies have evaluated corticosteroids, primarily methylprednisolone, for efficacy in reducing NVP and hyperemesis. Methylprednisolone reduced symptoms of NVP along with hospital readmission rates for hyperemesis.⁷⁶ Another trial found that promethazine worked more rapidly than prednisolone, but after a week both medications worked equally well, and the prednisolone group had fewer side effects.⁷⁷ Various oral and intravenous dosages have been studied, but the most common regimen is 16 mg of methylprednisolone 3 times daily, with attempts to taper after 3 days. Most patients respond within 3 days, so if no improvement has been seen by that time, longer treatment is generally not indicated. Methylprednisolone may be continued for up to 6 weeks, but longer use may result in adverse maternal effects related to prolonged steroid exposure.^{76,78} Evidence also indicates that a shorter course of hydrocortisone is effective for treating intractable hyperemesis.⁷⁹ A meta-analysis found an increased risk of oral clefts associated with prednisone use.⁸⁰

Dosage

The dose of methylprednisolone is 16 mg orally or intravenously every 8 hours for up to 2 weeks (tapered course to avoid adrenal suppression). The dose of hydrocortisone is 300 mg intravenously daily for 3 days, then tapered over one week.

Precautions

Avoid corticosteroid use before 10 weeks of gestation if possible. Avoid prolonged use for more than 6 weeks to reduce the risk of maternal side effects.

Intravenous Fluids

Intravenous fluids have not been specifically studied for the treatment of hyperemesis, but they are often coadministered with other medications in the hospital setting for the treatment of dehydration. Intravenous fluid is generally recommended when patients fail to tolerate oral fluids for a prolonged period or show electrolyte abnormalities indicating dehydration.

Dextrose and intravenous thiamine can be added to fluids when vomiting has been prolonged and persistent.^{12,81}

Extreme Measures for Intractable Nausea and Vomiting in Pregnancy

Enteral or Parenteral Feedings

Evidence to support enteral or parenteral feedings comes from case reports and small series.^{82,83} In general, the prudent approach is to start with enteral feedings and move on to peripheral parental nutrition and finally to total parental nutrition if all other methods fail. Serious and even life-threatening complications have been reported with parenteral nutrition, so it is used only as a last resort.⁸⁴

Therapeutic Abortion

With current medical interventions such as intravenous hydration and medications, it is rare for NVP to be so severe as to be life threatening. This was not the case in the early twentieth century, when severe NVP represented an important cause of maternal deaths.⁸⁵ However, maternal morbidity in the form of Wernicke encephalopathy caused by vitamin B1 deficiency, esophageal rupture, acute tubular necrosis, and splenic avulsion have all been reported to be caused by intractable vomiting of pregnancy.¹ When the maternal condition is deteriorating as a consequence of hyperemesis gravidarum despite aggressive medical intervention, pregnancy termination may be indicated ([Fig. 54.2](#)). Fortunately, symptoms usually subside rapidly as HCG levels fall.

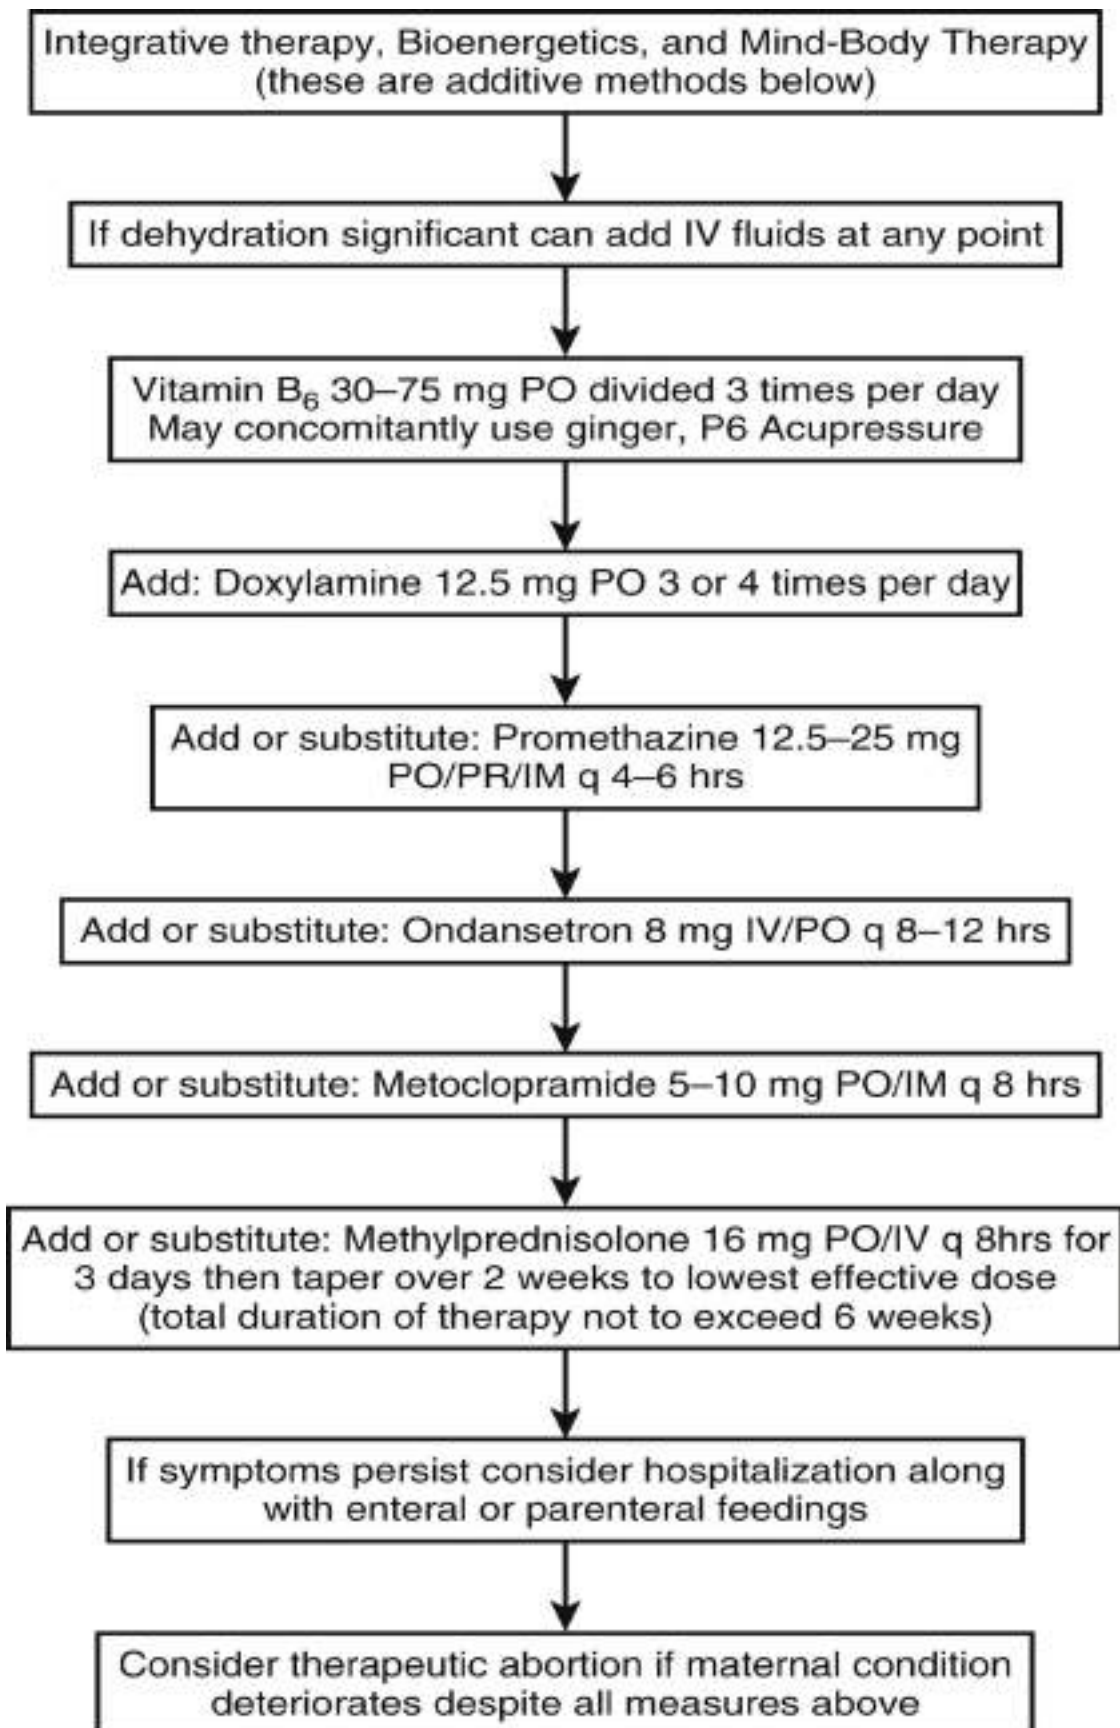

FIG. 54.2 Integrative therapy, bioenergetics, and mind-body therapy algorithm. *IM*, intramuscularly; *IV*, intravenous; *PO*, orally; *PR*, per rectum; *q*, every.

Therapies to Consider

Homeopathy

No studies have evaluated the efficacy of homeopathic remedies in the treatment of NVP. Practitioners cite anecdotal evidence of homeopathy use, but choosing the correct remedy can be complex because many subtle differences in symptoms are taken into account. Some of the remedies commonly used include nux vomica, sepia, and ipecac.⁸⁶ Because homeopathic preparations are extensively diluted, they should be safe for pregnant women and unlikely to have any adverse effects if they are not helpful. Some investigators recommend avoiding any remedies with potencies (dilutions) greater than 12C.⁸⁷

Traditional Chinese Medicine

Practitioners of traditional Chinese medicine (TCM) may recommend acupuncture, acupressure, and herbs, but they also use certain foods such as umeboshi plums (a very salty preserved fruit) to combat nausea. In addition, these clinicians may use practices such as moxibustion, cupping, or massage. The TCM views of health and the body's function are different from those in Western medicine, and different patterns of symptoms lead to different treatments,⁸⁸ so a certified TCM practitioner should advise about the use of these approaches.⁸⁹ Information about training and accreditation of TCM practitioners can be found at the National Certification Center for Acupuncture and Oriental Medicine (www.nccaom.org).

Umeboshi plums can be found in most Asian grocery stores. If the plum itself is too salty, some women obtain relief from nausea by sucking on the pit only. Another option is to use one-fourth to one-half a plum at a time.

Prevention Prescription

- Take a multivitamin prior to pregnancy or before 6 weeks of gestation.^{20,21}
- Eat frequent, small meals that are high in protein to avoid low blood glucose levels.
- Avoid overconsumption of simple carbohydrates such as cakes, candy, and starchy foods because they may lead to rebound low glucose levels, which could stimulate more nausea.
- Consider trying more salty foods and tart liquids because these are reported by some women to be better tolerated.
- Avoid triggers such as pungent odors or unpleasant visual stimuli that may worsen nausea.
- Increase rest as needed early in pregnancy.
- Do light to moderate exercise for 20 minutes three times a week.

Therapeutic Review

Lifestyle, botanical, bioenergetic, and mind-body therapies are additive to all the other methods listed here. If dehydration is significant, add intravenous fluids at any point.

Bioenergetics

- Acupuncture (P6) 

Mind-Body Therapy

- Hypnotherapy 

Supplements

- Vitamin B6: 30–75 mg PO divided three times per day 
- Ginger: 250 mg powdered in capsules four times daily or 500 mg twice daily 

Pharmaceuticals

- Doxylamine: 12.5 mg orally three to four times daily 

- Add or substitute promethazine: 12.5–25 mg orally, rectally, or intramuscularly every 4–6 hours 
- Add or substitute ondansetron: 8 mg intravenously or orally every 8–12 hours 
- Add or substitute metoclopramide: 5–10 mg orally or intramuscularly every 8 hours 
- Add methylprednisolone: 16 mg orally or intravenously every 8 hours for 3 days then taper over 2 weeks to the lowest effective dose (total duration of therapy not to exceed 6 weeks) 
- If symptoms persist, consider hospitalization along with enteral or parenteral feedings. 

Surgery

- Consider therapeutic abortion if the maternal condition deteriorates despite all the measures described here and in [Fig. 54.2](#).

CHAPTER 55

Managing Menopausal Symptoms

Marcia Klein-Patel, MD, PhD, Katherine Gergen-Barnett, MD, and Judith Balk, MD, MPH

Introduction

Since antiquity, menopause has been a marker of transition in a woman's life. Despite all the changes that have occurred in modernity, very little has moved the age at which menopause occurs. Our mothers, grandmothers, and great grandmothers all experienced menopause at the average age of 51 years, as women do today. However, women are now living to the average age of 81 years, spending roughly one-third of their lives after the cessation of menses. The impact of this duration of time, which includes the transition leading up to menopause, can be enormous both physiologically and psychologically. While there are many bothersome symptoms that women may experience during the perimenopausal and menopausal stages of their lives, this is also a time of enormous opportunity for wellness. In this chapter, we will be looking at the physiology and symptomatology of perimenopause and menopause, treatment options to mitigate some of the most bothersome symptoms of menopause, and finally, basic strategies for supporting wellness among women during this rich, reflective time in their lives.

Physiology of the Female Reproductive Life Cycle

At 20 weeks of gestation, female fetuses have the maximum number of oocytes they can have. From birth until menopause, these oocytes decrease, either through atresia or ovulation, until the final follicles diminish and menopause begins. However, there is a long journey from this 20-week-old fetus to the menopausal woman, and much of this

journey is dictated by the dance of a few key hormones.

At puberty, the long dormant follicles are recruited through the cyclic release of the follicle stimulating hormone (FSH) and luteinizing hormone (LH). FSH stimulates the ovary to recruit a follicle from the ovaries, and as this follicle develops, it secretes estrogen. This estrogen serves many roles, including the thickening of the uterine lining, maintaining vaginal blood flow and lubrication, and skin thickness and elasticity. As a dominant follicle develops, estrogen levels increase, and through a negative feedback loop on the pituitary, there is a surge in FSH and LH. This surge is the signal to ovulate. The remaining corpus luteal cells produce progesterone, which in turn further thickens and prepares the lining of the uterus for a possible fertilization. If the egg is not fertilized in the window of ovulation, progesterone will fall and a woman will menstruate. This pathway is called the *hypothalamic-pituitary-ovary axis*.

While there has long been nomenclature to define a woman's transition from regular menstruation to the more irregular (perimenopause) and ultimately cessation of menstruation (menopause), there has been much study over the last decade to clarify the exact physiology in each of these stages as well as work on further characterization of each of these transitions. In 2001, the first group of scientists came together to apply some of this knowledge toward menopause and created a set of standards called STRAW (Stages of Reproductive Aging Workshop), and this had been considered the gold standard for the characterization of reproductive aging through menopause ([Fig. 55.1](#)). In 2011, scientists from five different countries and a variety of backgrounds gathered to review data from a cohort of midlife women and evaluated changes in menstrual, endocrine, and ovarian markers of reproductive aging including antimullerian hormone (AMH), inhibin B, FSH, and antral follicle count (AFC).¹ STRAW-10, as this summit was called, was important at a number of levels as it not only helped stratify perimenopause and menopause into seven discrete categories but also revisited important population health questions that had not been addressed 10 years prior.

The STRAW-10 staging, though granular in its definition of each stage, was developed to promote the ability of future researchers and clinicians to determine exactly where a woman may be in her menstrual arc, as well as the sequelae at each stage. The hormonal shifts in each of these stages also bear clinical significance for the rest of the health and wellness of a woman. The original STRAW explicitly recommended

against applying the criteria of reproductive aging to smokers, women with a body mass index (BMI) $> 30 \text{ kg/m}^2$, women who had undergone hysterectomy, women engaged in heavy aerobic exercise, women with chronic menstrual cycle irregularities, and women with uterine or ovarian abnormalities. However, these groups are included in STRAW-10.

As already mentioned, as a woman ages through late reproductive age, the number of follicles diminish. In early and peak reproductive years (stages -5 and -4 by STRAW-10), a woman continues to have sufficient follicles for recruitment and her menstrual flow appears regular. However, in the late reproductive stages ($-3a$ and b), a woman may note that her cycles are becoming shorter in their length or frequency. This is because, as the follicle supply diminishes and less follicles are recruited, there is less inhibin-B, which in turn has a decreased negative feedback on the hypothalamic-pituitary axis, causing a surge in FSH (as it works to recruit more follicles for stimulation), earlier follicle recruitment, and shorter cycles. This increased number of follicles leads to the increased secretion of estrogen, which can in turn increase the heaviness of the flow and exacerbate estrogen-dominant symptoms, such as increased PMS-like symptoms and agitation. The early phases of the menopause transition are characterized by relative hyperestrogenism and hypoprogesteronism, whereas hypoestrogenism dominates later phases.

Stage	-5	-4	-3b	-3a	-2	-1	+1a	+1b	+1c	+2
Terminology	Reproductive				Menopausal transition		Postmenopause			
	Early	Peak	Late		Early	Late	Early		Late	
Duration	Variable				Variable	1-3 years	2 years (1+1)	3-6 years	Remaining lifespan	
					Perimenopause					
Principal criteria										
Menstrual cycle	Variable to regular	Regular	Regular	Subtle changes in flow/length	Variable length; persistent ≥7-day difference in length of consecutive cycles	Interval of amenorrhea of ≥60 days				
Supportive criteria										
Endocrine			Low	Variable	↑ Variable	↑ >25 IU/L**	↑ Variable	Stabilizes		
FSH			Low	Variable	↑ Variable	↑ >25 IU/L**	↑ Variable	Stabilizes		
AMH			Low	Low	Low	Low	Low	Very low		
Inhibin B			Low	Low	Low	Low	Low	Very low		
Antral follicle count			Low	Low	Low	Low	Very low	Very low		
Descriptive characteristics										
Symptoms						Vasomotor symptoms likely	Vasomotor symptoms most likely			Increasing symptoms of urogenital atrophy
* Blood draw on cycle days 2-5 † = elevated ** Approximate expected level based on assays using current international pituitary standard ⁵⁷⁻⁶⁰										

FIG. 55.1 STRAW stages of reproduction.

In early menopausal transition, estrogen levels increase and progesterone decreases. This can result in heavier and longer menstrual flow, mood changes, and agitation due to estrogen dominance.

There is no particular amount of time for which a woman remains in this late reproductive stage where the rate of follicular release is increased (it can be up to 10 years), but all women will note that their cycles become increasingly varied in length; when their cycles are persistently greater than or equal to a 7-day change in the length of consecutive cycles, women are considered to have entered into early menopausal transition. This stage is characterized by a reduced number of follicles to recruit and thus a decrease in the amount of circulating estrogen, inhibin-B, and AMH. As the follicles continue to decrease, there

is decreased ovulation and progesterone production, which in turn leads to lighter and more infrequent bleeds (often with > 35 days between cycles). The length of time between the bleeding can grow longer and longer, and eventually, at the average age of 51, a woman has her final menstrual period (FMP). At this stage, follicles are no longer being released and very little estrogen is produced ([Fig. 55.2](#)). After 1 year without menstruation, the patient has officially entered stage 1+ or menopause.

FIG. 55.2 Progressive decrease in the number of primordial follicles (shown by *arrow*) with aging. (From Erickson G. An analysis of follicle development and ovum maturation. *Semin Reprod Endocrinol.* 1986;4:233-254.)

Vasomotor Symptoms in Menopause and the Menopausal Transition

The variable secretion of estrogen as well as the overall declining amount being produced in this menopausal transition (stages -2 and -1, +1) cause many of the first, and often most bothersome, symptoms of the menopausal transition: hot flashes and night sweats. These symptoms are caused by the fluctuations in estrogen and the variable dilation of the blood vessels, resulting in unexpected and sudden increases of blood flow, often to the chest, face, and neck, which in turn can produce

profuse sweating, heart palpitations, anxiety, and flushing. These symptoms can last anywhere from 1 to 5 minutes and can occur at night. These “night sweats” often lead to poor and disrupted sleep patterns and can lead to downstream consequences of being overtired and more prone to depression.

While vasomotor symptoms (VMS) vary greatly in their frequency and intensity among menopausal transition women, symptoms typically are most debilitating for 1–2 years. However, for some women symptoms may last as long as 14 years. Risk factors for VMS include obesity, smoking, depression/anxiety, and low socioeconomic status. Interestingly, there also may be ethnic and genetic predispositions for VMS. According to the results of the SWAN study (Study of Women’s Health Across the Nation), which assessed menopausal symptoms in 14,906 women with diverse ethnic backgrounds aged 40–55 years in the United States, African American women are most likely to report having VMS and Asian women (Japanese and Chinese) are the least likely to report these symptoms.

Nonvasomotor Symptoms in Menopause

Without circulating estrogen, VMS can be accompanied by increased vaginal dryness and atrophy, weight gain, bone loss, increased risk of osteoporosis, increased risk of heart disease, skin dryness and wrinkles, and increased risk for bladder infections. VMS can also create a domino effect. Hot flushes and night sweats can lead to sleep disruption, which then leads to many other changes—from weight gain to decreased sexual function and desire, to mood changes such as depression and anxiety.

Well-Being in the Menopausal Transition

Despite these physiological changes, this can also be a time for many women to reach what Jung characterized as “individuation,” a time to bring the “consciousness into a working relationship with our inner *terra incognita* or our unknown inner terrain.”² In other words, a time to integrate the experiences of their lives into a well-functioning whole. How, in our role as providers for women in the menopausal transition, can we support this change with health, growth, and well-being?

Supporting this journey is part of our role as medical providers. It is our role to be knowledgeable and able to provide patients an array of treatments for perimenopause and menopause, including

pharmacological treatments, such as hormones and nonhormonal medications, and integrative approaches. Each visit is an opportunity to provide insight and knowledge into the menopausal transition, understand the patient's expectations and desires for treatment, and determine which treatment is most suited to her. Thus, we discuss each approach, with its risks, benefits, research evidence, and typical use. In each section, we primarily target commonly used modalities for hot flushes.

Integrative Therapy

Pharmaceuticals

After an in-depth discussion about the causes and likely duration of VMS, it is paramount to establish the level of burden of these symptoms on the patient's quality of life and well-being. All medications and supplements have side effects, and it is important for a woman to decide which risks and side effects she is willing to accept to reduce her VMS. Additionally, it is important to discern if there is a pattern to when her symptoms are most troublesome and if her symptoms could be caused by any other disease processes.

Evaluation of the Literature for Management of Vasomotor Symptoms

As with many trials to address patient symptoms, evaluation of effectiveness of an intervention in menopause has several limitations. The first is that there is a high placebo response rate for any intervention, with improvement rates reported to be as high as 50%. Second, the natural course of hot flushes is variable, and in general, over many years, hot flushes will improve. Therefore it is difficult to obtain adequate power. Last, there is no perfect way to measure hot flushes. The diary is most commonly used, but it may be cumbersome for participants and inexact in reporting. Additional research difficulties specific to modality are addressed where appropriate.

Estrogen

Without debate, the most effective therapy for hot flushes is estrogen. By increasing circulating estrogen, the thermoneutral zone is restored. The current recommendation remains "to use the lowest effective dose for the

shortest duration” for the woman who decides that the benefits of therapy outweigh the risks. In general, patients should be started on a lower dose of estrogen and titrated upwards until the desired reduction in symptoms is achieved. There are multiple routes and formulations available in the United States and Canada. The transdermal route, which is available in patches, gels, and sprays, is preferred as it avoids the hepatic first-pass metabolism and may decrease venous thromboembolism risk. In our experience, these modes of delivery are highly acceptable to patients. Additionally, with the vast array of doses and delivery systems available, an acceptable method can be found by most women. The newer FDA-approved oral 0.0625 mg of conjugated estrogen with 20 mg bazedoxifene, which is a selected estrogen receptor modulator with antagonistic action on the endometrium, was designed to eliminate the need for progestogen. Awaiting further benefits, the limitation of this medication is its oral route, single available dose, and additional side effects of muscle spasm, nausea, and diarrhea.

The discussion of “bioidentical” hormone therapy is often confusing for our patients, as it is primarily a marketing term used to describe hormone therapy that has been compounded for each patient. The primary estrogen, estradiol, is the same as in the previously reviewed FDA-approved transdermal medications, although oral routes may use conjugated estrogens. There is no evidence at this time that compounded medications are safer. We do use compounded therapy when necessary for patients with allergies. Additional concerns about compounded medications include dosage variation and the common use of transdermal progesterone, which may be inadequate for endometrial protection.

Estriol is a weak estrogen, and some favor its use for vaginal atrophy. Whereas some research suggests that it may be less stimulating to the breast and endometrium, other research suggests that at effective dosages, the risk of endometrial and breast stimulation is present. More research is necessary on whether estriol is advantageous over other vaginal estrogen products.

Dosage

A common recommendation is to use the lowest dosage of estrogen for the shortest duration of time. For recently postmenopausal women, we typically start with estradiol transdermal patches at 0.025 mg and

increase it based on symptoms. We may also check serum levels if we have increased the dosage and patients are still symptomatic. For recent surgically menopausal patients, such as a premenopausal patient with bilateral oophorectomy, we typically start with a higher dosage such as 0.1 mg estradiol patch.

Precautions

The major side effects to be discussed with the patient are the increase in cerebral vascular and thromboembolic events, increase in breast cancer risk, and a possible increase in risk of ovarian cancer with prolonged use.

Progestogen/Progesterone

Progestogen refers to the class of both natural progesterone and the synthetic hormones usually derived from testosterone that mimic progesterone. Progestogen is a necessary adjuvant treatment for endometrial protection when the patient retains her uterus or has a history of endometriosis and is using estrogen. In order to prevent growth of the endometrial lining that can lead to endometrial hyperplasia and cancer, a minimum of 10–14 days of progestogen therapy should be given per month. Additionally, there is evidence that a more extended cycle of 14 days every 3 months can be used and that the levonorgestrel-intrauterine device (IUD) may be effective.

Dosage

Our preferred progestogen is oral micronized progesterone at 200 mg 14 days per month. Alternately, if the patient is unable to comply with cyclic progesterone, 100 mg nightly can be used.

Precautions

We do not use progesterone for women with breast cancer. The most common side effect of progesterone is sedation, and patients are recommended to take it at night. For some women, progesterone is too sedating and some notice depressive symptoms and low energy. For women with these symptoms, we change to a different progestin or consider a levonorgestrel IUD.

Nonhormonal Medications

Selective Serotonin Reuptake Inhibitors (SSRIs)/Selective Norepinephrine Reuptake Inhibitors (SNRIs)

For those patients in whom there is a contraindication for estrogen containing therapy or the risks outweigh the benefits, consideration should be given for selective serotonin reuptake inhibitors (SSRI) or selective norepinephrine reuptake inhibitors (SNRI). While their mechanism of action is not completely understood, they may widen the thermoneutral zone. The current theory is that as estrogen levels decline, norepinephrine levels increase, which results in an increase in hypothalamic serotonin receptors, further narrowing the thermoregulatory zone ([Fig. 55.3](#)).³ Many SSRI and SNRI have been studied for use in the management of menopausal hot flashes. Because there is an increased prevalence of comorbid psychiatric illness in the menopausal transition, they are particularly useful in the patient who has VMS and endorses mood changes. Many SSRIs and SNRIs have been studied to date and have been generally well tolerated. The SSRIs studied include paroxetine, fluoxetine, citalopram, and sertraline.

Dosage

Sertraline at starting doses of 25 mg is the most easily tolerated. Both venlafaxine and desvenlafaxine have been proven useful. The only FDA-approved nonhormonal medication at this time is low dose (7.5 mg) paroxetine.

Precautions

For patients with a history of breast cancer on tamoxifen, SNRIs are preferred as they do not increase the CYP2D6 metabolism system.

Gabapentin

Gabapentin, a medication used primarily as an anticonvulsant, has also been shown to decrease VMS. Its mechanism is also unknown. In our experience, this medication is most useful in patients who wish to avoid estrogen therapy and whose primary bothersome symptoms are night sweats. A randomized trial found nonsuperiority of gabapentin 2400 mg

with conjugated equine estrogens, but at this dosage the side effects can become limiting.⁴

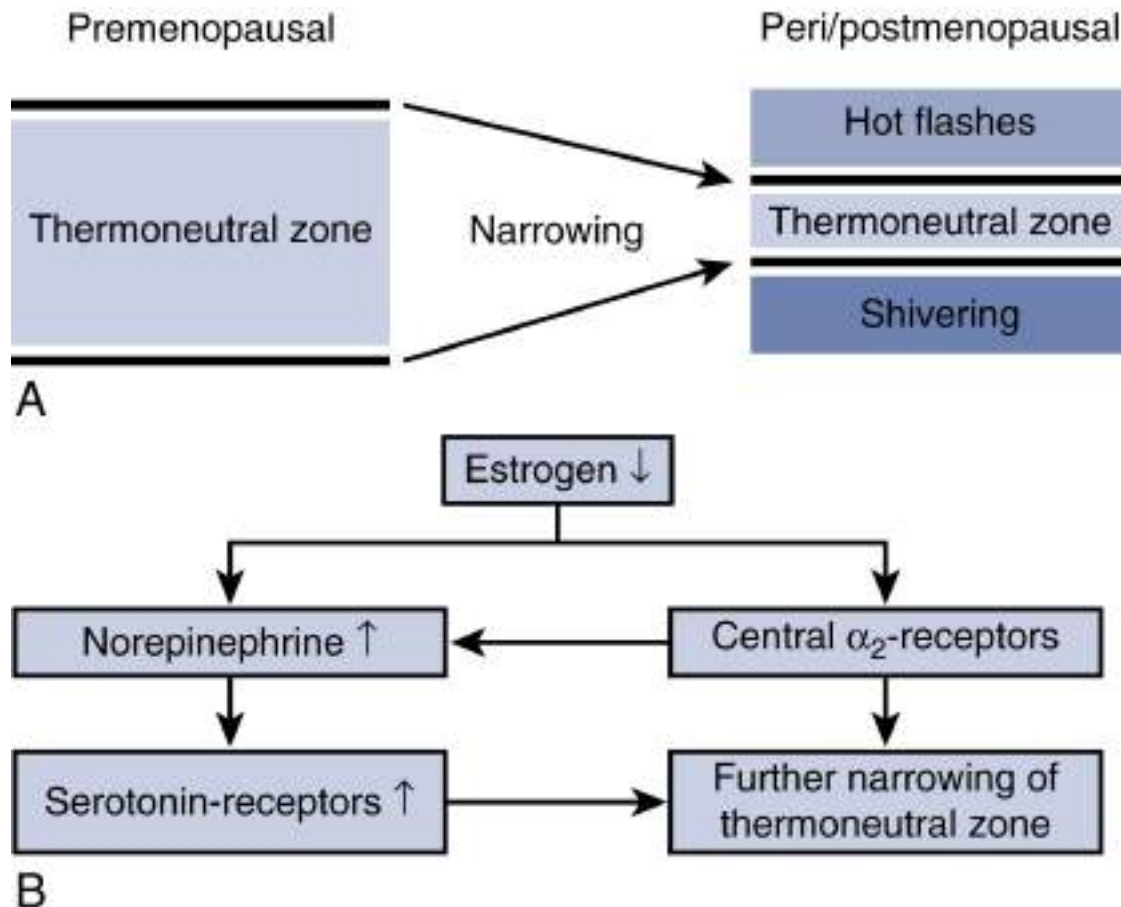

FIG. 55.3 Mechanism of Decreased Thermoregulatory Zone.

The changes associated with menopausal narrowing of the thermoneutral zone (A) and the presumed neurotransmitter mechanism (B). (From Krause MS, Nakajima ST. Hormonal and nonhormonal treatment of vasomotor symptoms. *Obstet Gynecol Clin N Am.* 2015;42:163-179.)

Dosage

While less effective than hormone therapy, gabapentin starting at 300 mg three times a day is well tolerated.

Precautions

Its major side effects are sedation, headache, and edema.

Clonidine

Clonidine is an antihypertensive, which was previously used for VMS management in the 1970s for patients with breast cancer. It is a centrally acting α -agonist, which has been theorized to work through raising the thermoneutral threshold by reducing norepinephrine release.

Dosage

Dosage for clonidine is 0.1 mg per day as a patch or 0.05 mg orally every 12 hours. Titrate up to a maximum of 0.4 mg every 12 hours.

Precautions

It is not used frequently now secondary to modest improvements in hot flush symptoms with a large symptom burden including mouth dryness, constipation, itchiness, drowsiness, and difficulty sleeping.

Bioenergetics

Acupuncture

Acupuncture is effective for hot flushes. The exact mechanism of acupuncture improving hot flushes is unknown. Acupuncture changes levels of beta-endorphins and other neurotransmitters potentially affecting the thermoregulatory center in the hypothalamus. Traditional Chinese Medicine (TCM) colleges in China and nationally accredited acupuncture schools in the United States teach differential diagnosis and treatment strategies for menopausal symptoms. According to the TCM theory, the main cause of menopausal symptoms is a decline in kidney essence, leading to a yin/yang imbalance. A recent meta-analysis of acupuncture showed improvement in both severity and frequency in hot flushes, with effects up to 3 months.⁵ Twelve studies with 869 participants were included. Acupuncture significantly reduced the frequency and severity of hot flushes and improved psychological, somatic, and urogenital subscale scores. Long-term effects, up to 3 months, were found. While the authors did not report an analysis of the acupuncture points used, commonly used points include St-36, Sp-6, CV-

4, LI4, PC-6, GV-20, Lr-3, and Ht-6. In our clinical practice as well, these are the points most commonly used, although we individualize each session.

Acupuncture for VMS is best given weekly or biweekly. The patient generally notices improvement in intensity before a reduction in frequency and often undergoes at least two to three sessions to have an effect.

Hot flush and acupuncture trials are challenging to conduct because of several factors ubiquitous to all acupuncture trials. The first is the lack of a valid, inactive placebo, and studies that use “sham” acupuncture are likely actually receiving an active procedure. If the skin is penetrated, physiological changes occur. The second limitation is that acupuncture treatments are typically individualized making research with a standard approach not actually representative of clinical care. This may be one cause of the variations in effectiveness seen in these trials.

Avis et al.⁶ compared true acupuncture to “sham” acupuncture (superficial needling in “nontherapeutic” sites) and to usual care in a pilot trial involving 56 perimenopausal and postmenopausal women. Patients received a standard true acupuncture regimen including the points CV-4, Ki-3, Sp-6, Bl-23, Ht-6, and Ki-7. Additional points were also needled depending on clinical judgment. The intervention occurred twice weekly for 8 weeks. The primary outcome variable was a hot flush score calculated from a daily diary. True and sham acupuncture were not statistically different from each other and both were superior to usual care.

The ACUFLUSH study by Borud et al.⁷ was also a randomized controlled trial. This was a multicenter, pragmatic trial including postmenopausal women with at least seven hot flushes per day. The intervention group received up to 10 acupuncture sessions over a 12-week period, and the treatments were individualized. The intervention group also received advice on self-care, and the control group received only advice on self-care. Among the 134 women in the acupuncture group, hot flush frequency decreased by almost 6 per day, and almost 4 per day in the 133 women in the control group. This difference of 2.1 per day was statistically significant. Hot flush intensity was also statistically significantly better in the acupuncture group. The acupuncture group also had statistically significant improvements in vasomotor, sleep, and

somatic symptoms.

Most recently, Chiu et al.⁵ published a meta-analysis of randomized controlled trials on acupuncture for menopause-related symptoms and quality of life in women with natural menopause. Twelve studies with 869 participants were included. Acupuncture significantly reduced the frequency and severity of hot flushes as well as improved psychological, somatic, and urogenital subscale scores. Long-term effects, up to 3 months, were found.

Yoga

Similar to acupuncture, yoga is difficult to adequately control because it is impossible to mask the treatment arm to the subject, although the hypothesis could be kept from the patient and the researcher conducting the outcome measures could be masked to the treatment group. Also similar to acupuncture, there is a long practice of yoga for menopausal symptoms, with the initial reports being case series and then progressing to randomized controlled trials.

Joshi et al.⁸ randomized 200 women to either a yoga group or to a nonyoga group for 90 days. The Menopause Rating Scale was the primary outcome variable. The groups were similar at baseline, but only the yoga group significantly improved by the end of the study period, and the improvement was in the total score and each of the subscales. Yoga occurred daily in this study, which might be difficult to replicate in the United States.

Chattha et al.⁹ conducted an 8-week trial comparing yoga therapy (physical movement in the form of sun salutations, breathing, and meditation) to simple physical exercises under supervision in 120 participants. Outcomes were the Greene Climacteric Scale, Perceived Stress Scale, and the Eysenck's Personality Inventory before and after the interventions. VMS statistically and significantly improved in the yoga group, as did perceived stress scores and neuroticism. Other changes were not statistically significant. Thus it may not be merely physical exercise that helps women with hot flushes, as the control group was doing physical exercise. Yoga's effect on perceived stress, thus lowering sympathetic output, may be responsible for effects on hot flushes. Paced respiration, as studied by Freedman and Woodward,¹⁰ significantly reduces hot flush frequency. Breathing techniques are common in yoga.

Available research suggests that yoga therapy has the greatest effect on

psychological symptoms of menopause.

In 2012, a meta-analysis of randomized controlled trials found moderate evidence for short-term effectiveness of yoga for psychological symptoms but not for somatic symptoms, VMS, or urogenital symptoms.¹¹ Improving psychological symptoms is important, and we do recommend yoga for our patients. In our practice, we commonly refer women to hatha yoga because no evidence suggests that it is detrimental for hot flashes, has other health benefits, and women tend to enjoy it. One word of caution: while we do not know of research specifically for “hot” yoga, where yoga is done in a hot room, we do know that high ambient temperatures increase hot flashes. We suggest avoiding “hot” yoga.

Botanicals

Many different botanical regimens have been recommended for the management of hot flashes, such as black cohosh, isoflavones, and multibotanical preparations. One overall concern that we have with botanicals is the lack of oversight and quality control on the products. When recommending supplements of any type, we recommend specific brands that have rigorous quality standards; however, patients are free to choose other brands and may choose ones that are not of high quality and maybe exceedingly expensive.

Black Cohosh

One important study of botanical supplements compared black cohosh alone to four parallel arms: a multibotanical including black cohosh and nine other ingredients, a multibotanical plus dietary soy counseling, hormone therapy with estrogen/progestogen, and to placebo.¹² The botanical regimen did not differ from placebo with one exception, where the botanical was worse than placebo. As expected, hormone therapy improved symptoms. The authors note that differences between treatment groups smaller than 1.5 VMS per day cannot be ruled out. As previously mentioned, due to the variable nature of hot flashes, studies may be underpowered to show a difference. Other studies have also failed to show improvement compared with placebo for black cohosh, red clover, the Chinese herbal preparation Dang Gui Buxue Tang, or in any combinations of these therapies. In our experience, herbal remedies with black cohosh appear to help with mild symptoms for short periods

of time; the appearance of improvement may be due to placebo, to the natural course of hot flushes, or to a true effect.

Dosage

The dosage of black cohosh extract used in the majority of clinical studies has been based upon the level of a key marker, 27-deoxyactein. For instance, for menopause, the dosage is 1 mg daily of 27-deoxyactein. There is 1 mg of 27-deoxyactein in one 20-mg tablet in the most common studied brand, *Remifemin*. The dose is 20 mg one to two times daily.

Precautions

It is important to be mindful that it remains unclear if botanicals affect estrogen receptors and that long-term usage should be discouraged.

Rheum rhaponticum

Another botanical studied for hot flushes is the special extract ERr 731 from the roots of *Rheum rhaponticum* that has been recently studied for the treatment of VMS.¹³ In a prospective multicenter, double-blind, placebo-controlled study of perimenopausal women with climacteric complaints over the course of 12 weeks, menopausal symptoms significantly decreased in the ERr 731 group compared to the placebo group. This also showed an increase in quality of life.

Dosage

The dosage used in the abovementioned investigation used enteric-coated tablets (250 mg) containing 4 mg of *R. rhaponticum* dry extract.

Precautions

From this limited data, it appears to be safe and well tolerated.

St. John's Wort

St. John's wort can be used in menopause.¹⁴ As previously discussed, antidepressants such as SSRIs can reduce hot flushes. It is postulated that

if St. John's wort has a similar mechanism, it is possible that it could help with hot flushes too.

Dosage

Dosage in the previously mentioned study used drops that included 0.2 mg/mL hypericin, 20 drops three times per day. A common dosage recommendation for both depression and seasonal affective disorder is 300 mg three times daily capsule/tablet, oral: standardized extract (0.3% hypericin content).

Precautions

We tend not to recommend this due to the number of drug interactions that St. John's wort has, including drug-herb interactions and concern over a serotonin effect.

Mind-Body

Relaxation Exercise

The early research on the use of mind-body medicine included case studies and case series. Similar to yoga and acupuncture, this research is challenging to blind, as study participants know if they are meditating or having hypnosis. However, participants can be hypothesis blind, and good evidence is possible. Stress triggers hot flushes and stress reduction may reduce hot flushes. The mechanisms of action for mind-body approaches are likely similar to those of yoga and acupuncture, with decreasing sympathetic output playing a role.

In 1990, Swartzman, Edelberg, and Kemmann¹⁵ studied the impact of stress on objectively recorded hot flushes and flush report bias, asking if women under stress were more likely to report hot flushes than women not under stress. The findings were consistent with what many women experiencing hot flushes know: significantly more flushes occur during the stress session compared to the nonstress session, and there was no bias to reporting more hot flushes. We counsel patients that this study showed that lab stress increases hot flushes. We can predict that the effects of "real life" stress may be even more substantial than lab stressors, and anecdotally, patients certainly report stress as a trigger for hot flushes.

One of the first controlled studies investigated relaxation training on menopausal symptoms. Irvin et al., in 1996, randomized women to relaxation response training, reading, or a control group.¹⁶ Participants listened to a 20-minute relaxation audio tape daily, and the reading group read for 20 minutes daily. Hot flush intensity, tension-anxiety, and depression were significantly reduced in the relaxation training group, whereas trait-anxiety and confusion-bewilderment were decreased in the reading group. The control group had no changes. The relaxation training group showed a trend towards decrease in all scores, but the sample size was small and may be underpowered. The authors postulate that the reading group may have chosen to take action and get control over their symptoms and may have read about menopause. This is possible, but it is also possible that relaxing for 20 minutes while reading leisure material is also a form of relaxation training (see [Chapter 94](#)).

Hypnosis

Hypnosis now has a solid research backing, thanks to Dr. Gary Elkins and his team at Baylor University. Elkins et al. have studied a hypnosis intervention first in breast cancer survivors (2008) and then in women without breast cancer (2012).^{17,18} In breast cancer survivors, hypnosis decreased hot flush scores by 68% from baseline, with significant improvements in anxiety, depression, interference of hot flushes on daily activities, and sleep compared to the no treatment control group. The subjects received a standardized hypnosis intervention. In 2012, Elkins et al.¹⁸ published a large study that included 187 postmenopausal women with at least seven hot flushes per day at baseline. The hypnosis intervention included specific suggestions for mental imagery for coolness, safe place imagery, and relaxation. They had five weekly sessions with home self-hypnosis practice. The control group was structured attention control, which matched the hypnosis intervention in all ways except the actual hypnosis, and also met weekly for 5 weeks with the therapist discussing symptoms and encouraging the subject. No specific cooling suggestions were made. Hot flush frequency reduced 74% in the hypnosis group compared to 17% in the control group. Hot flush score decreased 80% compared to 15% for the control group. Hot flush interference, sleep quality, and treatment satisfaction all improved in the hypnosis group. Finding a local hypnotherapist is helpful for patients, and reaching out to mental health colleagues may be a good way to find a trusted professional to provide hypnosis for hot flushes (see [Chapter 95](#)).

Mindfulness

Mindfulness-based stress reduction (MBSR) may reduce the bothersomeness and distress due to hot flashes. MBSR is an approach that allows a nonreactive awareness to an experience. For instance, some women may react to a hot flush with a sense of despair and concern that the hot flushes will never stop and that they will never get a good night's sleep again. The mindfulness approach would halt that thought process and allow a woman to label the hot flush just as a hot flush, something temporary and while it may be uncomfortable, it will go away. It would make sense then, for the mindfulness training to reduce the distress and bothersomeness of hot flashes. Carmody et al.¹⁹ randomized 110 women with hot flashes to either an MBSR intervention or to a waitlist control. The MBSR arm significantly improved in hot flashes, quality of life, sleep quality, anxiety, and perceived stress. Improvements were not only maintained at 3 months, but the hot flush score continued to improve postintervention. Mindfulness-based stress reduction is a learned skill and the effects of it continued to work even when the classes were over (see [Chapter 100](#)).

Cognitive Behavior Therapy

Cognitive behavior therapy (CBT) is not traditionally considered an integrative modality; it is a well-known therapeutic technique. However, CBT is much less well known for its effects on menopausal symptoms. Much like MBSR that can decrease the bothersomeness of hot flashes by decreasing the reaction to the hot flush, CBT can also decrease symptomatology by moderating the emotional reactions, negative beliefs, and catastrophic thoughts that can occur with hot flashes. Ayers et al.²⁰ compared CBT, delivered as a group intervention, to self-help CBT, to a no-treatment control group. Both forms of CBT significantly improved hot flush problem rating, mood, quality of life, and emotional and physical functioning. Learning a different way to think about and react to hot flashes may allow women to gain control over the symptoms. A self-help CBT for menopause workbook is commercially available, and parts of this book may be helpful for both patients and providers to help reframe the menopause experience.

Nutrition

Calcium

As the concentration of the protective hormone of estrogen declines, a woman's bones are more at risk for decreased bone density, making a diet rich in calcium perhaps more important than ever. Calcium is found in abundance in dark leafy greens such as spinach, broccoli, kale, Brussel sprouts, and dandelion greens to name a few. These greens are also high in vitamins A, C, and K, which further serve to strengthen the body and bones. Other traditional sources of calcium such as dairy (milk, cheese, ice cream) can be continued during this time, but search for dairy that has no added hormones. We recommend that a woman lean on vegetable sources or fish such as sardines to supply her with most of her food-derived calcium.

Fiber

A woman's chance for cardiac disease starts to rise after she goes through menopause. Fiber has been well studied for its role in lowering "bad cholesterol" (LDL), improving insulin resistance, decreasing inflammation, and protecting against heart disease. The Institute of Medicine recommends that women over age 50 get 21 g or more of fiber a day. Excellent fiber sources are vegetables, fruits, beans (all kinds), nuts, bran, bulgur, whole-wheat flour, prunes, peas, barley, and potato skins.

Healthy Fats

To further improve cardiac health, decrease inflammation, and potentially improve mood, foods rich in omega-3s are highly recommended. Foods such as almonds, walnuts, flax seeds, chia seeds, cold-water fish such as mackerel, wild coho or Alaskan salmon, sardines, and herring are all excellent sources of omega-3 fatty acids. Food sources are a more reliable source of nutrients, but if needed, a supplement of fish or flax seed oil can be taken.

Fluids

As the body is moving through shifts in temperature and fluid regulations, it is best to treat the body kindly with decreased caffeine intake, moderate alcohol, teas, and plenty of room temperature water. Alcohol, though known to protect against heart disease in moderate amounts, has been less studied in women, and when used in amounts of larger than one drink per day has been shown to increase the risk of breast cancer. Coffee often increases symptoms of hot flashes in

menopausal women. Black tea, however, is linked to a decreased risk of osteoporosis and green tea with its antioxidants and vitamin K can help protect against breast cancer. We advise patients that hot beverages can exacerbate hot flushes, so drink when cooled.

Exercise/Movement

Regular and vigorous exercise such as walking, jogging, biking, and swimming are all highly encouraged. The benefits of regular cardiac exercise (at least 30 minutes 5 days per week) and weight-bearing exercises two to three times a week can help protect against heart disease, osteoporosis, insulin resistance, breast cancer, and memory impairment, as well as keep women feeling more alert and well in the day. Movement can bring them back to their bodies and help them feel more at home in their changing bodies (see [Chapter 91](#)).

Spiritual Exploration

As a woman is no longer riding the waves of hormone cycles and likely no longer responsible for the continuous needs of children, she may find that she has more space to start focusing on her mind and the larger things that give her meaning. As Dr. Gaudet so beautifully illustrates in her “Consciously Female” guide for women,^{2a} this is a time to start asking questions such as “*What are my expectations? Who are my role models? What do I love? What have I accomplished so far with my life, personally as well as professionally? What have I not been able to accomplish yet?*” She urges us to dream big, zero in on ideas, take action, and re-reflect. These questions can be answered alone, explored with communities, or brought to a place of worship. It is noted that while having an opportunity to ask these questions may connote a place of privilege, all women have been granted the opportunity to mark this time of profound change and use it as grist for their future wisdom.

We tell patients: this time is an invitation. Go forth and flourish.

Prevention Prescription

We find that the cornerstones of a healthy menopause overlap with the cornerstones of a healthy life, and that the menopause transition is much easier for healthy women. The cornerstones are coping with

stress, eating appropriate portions of real food, sleeping at night, moving the body, social support, and finding meaning in life.

Therapeutic Review

Lifestyle

- Nutrition: vegetables, lean proteins, fiber, and fluids 
- Maintain active lifestyle for 30 minutes five times per week 

Bioenergetic

- Acupuncture: one to two sessions per week 
- Yoga 

Mind-Body

- Hypnosis 
- Mindfulness-Based Stress Reduction 
- Cognitive-Based Therapy, group or self-help 

Pharmaceuticals

- Hormone therapy, start 0.025 mg estradiol transdermal patch, and titrate to control symptoms. Add micronized progesterone 100 mg nightly or 200 mg for 14 days of the month. 
- SSRIs, start low dose SSRI (sertraline 25 mg daily) or low dose SNRI (venlafaxine 75 mg daily) and titrate to effect 
- Gabapentin 300 mg three times daily. Titrate to effect 

Botanicals

- Black cohosh 20 mg one to two times daily 
- *Rheum rhaponticum*, one enteric-coated tablet (250 mg) containing 4 mg of dry extract daily 

*Note: For more information on treating vaginal dryness, see

CHAPTER 56

Premenstrual Syndrome

Tieraona Low Dog, MD

Pathophysiology

Premenstrual syndrome (PMS) is defined as a recurrent, cyclic set of physical and behavioral symptoms that occurs 7–14 days before the menstrual cycle and is troublesome enough to interfere with some aspects of a woman's life. PMS is estimated to affect up to 40% of menstruating women, and the most severe cases occur in 2%–5% of women who are between 26 and 35 years of age.¹ PMS has been recognized as a medical disorder for many years; however, its cause remains a mystery ([Table 56.1](#)). The complex relationships that exist among hormones may offer insight into why some women suffer more than others. For instance, mild elevations of prolactin, a hormone that is primarily involved in regulating the development of the breast during pregnancy, have been associated with PMS, menstrual irregularities, and breast tenderness, whereas low levels of thyroid hormone can contribute to depression, fatigue, and heavy menses.

Hormonal Influences

A deficiency of progesterone or an abnormally high estrogen-to-progesterone ratio during the luteal phase has been a popular theory of the origin of PMS for many years, although studies comparing hormone levels in women with PMS with those in women without the disorder have failed to support this hypothesis.² In the 1950s, Dr. Katherina Dalton was the first to postulate this theory. Dr. Dalton administered natural progesterone in the form of injection, suppositories, or subcutaneous pellets; 83% of women in the study reported complete relief of PMS symptoms.³ Because of the strict inclusion criteria of the

study, however, only 18% of women with PMS appeared to be suitable candidates for this therapy. Due to insufficient data, a Cochrane review of two eligible clinical trials was unable to determine if progesterone is beneficial for PMS.⁴

Prolactin

Prolactin levels peak at ovulation and generally remain elevated during the luteal phase of the menstrual cycle. Prolactin excess is associated with menstrual irregularities, diminished libido, depression, and hostility.⁵ Some authorities suggested that up to 62% of women with menstrual disorders have some elevation of prolactin.⁶ Prolactin plays a role in breast stimulation and may be related to premenstrual breast tenderness. However, no consistent abnormalities have been found in women with PMS.²

Aldosterone

Aldosterone levels normally rise at ovulation and remain elevated during the luteal phase of the menstrual cycle. This elevation of aldosterone may be responsible for the congestive symptoms of PMS, such as edema, breast swelling, abdominal bloating, weight gain, and headaches. However, differences in absolute levels of aldosterone between symptomatic and asymptomatic women have not been noted in the literature.⁷

Endogenous Opiates

Some researchers, who have observed an increase in beta-endorphin levels after ovulation, hypothesized that women with PMS may have a lower level of these circulating endogenous opiates or a more sudden withdrawal that causes them to experience greater sensitivity to pain and depression in the luteal phase of the menstrual cycle.⁸

Hypoglycemia

The body appears to be more sensitive to insulin in the luteal phase of the menstrual cycle, a finding that has led some researchers to hypothesize that transient hypoglycemia may account for some PMS symptoms.

Prostaglandins

Prostaglandins are associated with breast pain, fluid retention, abdominal cramping, headaches, irritability, and depression.⁹ Patients with physical premenstrual complaints and dysmenorrhea have been shown to respond to prostaglandin inhibitors.

Psychosocial Theory

Emotional and physical stressors have been found to influence the menstrual cycle. Travel, illness, stress, weather changes, and other environmental factors may affect ovulation, length of menstrual cycle, and the severity of PMS.¹⁰ Cultural, societal, and personal attitudes toward menstruation also appear to play a role in the presence and severity of PMS. The dynamic interplay of environment, spirit, and physiology demands an integrated biopsychosocial approach to treatment.

Symptoms

More than 150 symptoms have been associated with PMS; the most common are listed in [Table 56.2](#).

TABLE 56.1
Proposed Causes of Premenstrual Syndrome

Hormonal factors	Estrogen deficiency
	Estrogen excess
	High estrogen-to-progesterone ratio
	Progesterone deficiency
	Prolactin excess
Fluid and electrolytes	Beta-endorphin deficiency
	Aldosterone excess
	Vasopressin excess
	High sodium-to-potassium ratio
Neurotransmitters	Renin-angiotensin abnormalities
	Serotonin deficiency
	Cortisol excess
	Hypoglycemia
	Reduced glucose tolerance
	Thyroid abnormalities
	Adrenal insufficiency
Prostaglandins	Prostaglandin excess
	Prostaglandin deficiency
	Essential fatty acid deficiencies

Vitamins and minerals	Pyridoxine deficiency
	Vitamin A deficiency
	Vitamin E deficiency
	Magnesium deficiency
	Calcium excess
	Calcium deficiency
	Potassium deficiency
	Trace mineral deficiency
	Zinc deficiency
	Dopamine deficiency
	Norepinephrine deficiency
	Low platelet monoamine oxidase activity
Hereditary	Genetic risk
Psychological factors	Beliefs about menstrual cycle
	Coexisting psychiatric disorders
	Poor coping skills
	Poor self-esteem
Social factors	Current marital and sexual relationships
	Former marital and sexual relationships
	Social stress
	Psychosexual experiences
	Cultural attitudes about PMS
	Societal attitudes about PMS
	Poor social network

PMS, premenstrual syndrome.

TABLE 56.2

Symptoms of Premenstrual Syndrome

Abdominal bloating	Insomnia
Acne	Irritability
Anxiety	Joint pain
Back pain	Lethargy
Change in appetite	Low libido
Clumsiness	Low self-esteem
Constipation	Mood swings
Depression	Nervousness
Diarrhea	Social isolation
Dizziness	Sugar cravings
Fatigue	Tender breasts
Headache	Water retention

The American Psychiatric Association (APA) defined the diagnostic criteria for premenstrual dysphoric disorder (PMDD), a more severe form of PMS. To be diagnosed with PMDD, a woman must have at least five of the following symptoms, and they must occur cyclically and be serious enough to interfere with her normal activities:

1. Feeling of sadness or hopelessness; possible suicidal thoughts
2. Feelings of tension or anxiety
3. Mood swings marked by periods of teariness
4. Persistent irritability or anger
5. Disinterest in daily activities and relationships
6. Trouble concentrating
7. Fatigue or low energy
8. Food cravings or binging
9. Sleep disturbances
10. Feeling out of control
11. Physical symptoms such as bloating, breast tenderness, headaches, and joint or muscle pain

Although this addition to the fourth edition of the APA's *Diagnostic and Statistical Manual of Mental Disorders*, published in 1994 (DSM-IV), is useful for recognizing PMDD as a valid disorder, it is disturbing that behavioral aspects comprise the primary focus of the disorder. With the vast numbers of physiological and hormonal interactions taking place in a woman's body, a multitude of explanations would seem to exist for the variety of symptoms. Thus assuming that numerous therapies may help and that not all remedies are universally effective is reasonable.

Clinical Evaluation

A complete physical examination, including pelvic evaluation and laboratory tests, should be performed to rule out anemia and hypothyroidism. A prolactin test may be included. An extremely useful approach is for a woman to record her symptoms on a daily basis for at least two complete menstrual cycles to allow the clinician to see just what her symptoms are and how they are related to her menses.

The clinician must address any other underlying medical conditions that may masquerade as PMS. One report found that 75% of women receiving care for PMS at specialized clinics had another diagnosis that accounted for many of their symptoms, primarily major depression and other mood disorders.¹¹

Integrative Therapy

Once the diagnosis has been established, an integrative approach should be considered. Therapies to be explored include exercise, dietary manipulation, dietary supplements, mind-body approaches,

acupuncture, traditional Chinese medicine, counseling, and conventional medications.

Exercise

Exercise remains understudied in the scientific world because it does not fit well into the double-blind, placebo-controlled, study design. The few studies that have been conducted on the role of exercise in PMS have clearly shown that women who engage in regular physical exercise have fewer symptoms of PMS than women who do not. Women who exercise regularly note improvement in all symptoms of PMS.¹² The frequency, rather than the intensity, of exercise appears to diminish the negative mood and physical symptoms that occur during the premenstrual period.¹³ Exercise may reduce symptoms by reducing estrogen levels, decreasing circulating catecholamines, improving glucose tolerance, and raising endorphin levels.¹⁴ Aerobic activity appears to be most beneficial; however, yoga and tai chi are probably equally effective if they are performed at least three times per week.

Diet and Nutrition

Many people in the United States fail to eat a healthy diet, but some researchers have found this observation to be even more accurate for women with PMS. A 1983 report noted that women with PMS consumed 275% more refined sugar, 79% more dairy products, 78% more sodium, 62% more refined carbohydrates, 77% less manganese, and 53% less iron than women without PMS.¹⁵ These dietary excesses and deficiencies may explain some of the symptoms women experience during their premenstrual period. Dairy products are high in sodium and interfere with magnesium absorption. Refined sugars increase the urinary excretion of magnesium.¹⁶ Heavy intake of sugar also increases sodium and water retention owing to the rapid release of insulin. Dietary salt may exacerbate swelling. Consumption of caffeine-containing beverages can increase irritability. Women experiencing irritability or difficulty sleeping during the premenstrual period should be encouraged to try a caffeine holiday for a couple of cycles to see if they notice a difference ([Table 56.3](#)).

TABLE 56.3

Caffeine Amounts in Common Foods and Beverages

Serving Size (oz)	Caffeine (mg)
Coffee, instant (6-8)	65-100
Coffee, percolated (6-8)	85-135
Coffee, filtered (6-8)	115-175
Coffee, decaffeinated (6-8)	1-5
Tea, instant (6-8)	35-70
Tea, brewed (6-8)	28-150
Tea, iced (6-8)	40-45
Chocolate, dark semisweet (1)	5-35
Chocolate, milk (1)	1-15
Cola beverage (8)	25-30

From Thys-Jacobs S, Starkey P, Bernstein D, et al. Calcium carbonate and the premenstrual syndrome: effects on premenstrual and menstrual symptoms. *Premenstrual Syndrome Study Group. Am J Obstet Gynecol.* 1998;179:444-452.

Fiber-rich, low-fat diets suppress the ability of fecal bacteria to deconjugate estrogen and thereby enhance fecal estrogen excretion.

Dietary Fat

Fiber-rich, low-fat diets may be beneficial for women with PMS because these diets reduce blood levels of estrogen. Estrogen is conjugated in the liver and sent to the small intestine for elimination in the feces. Certain intestinal bacteria are able to deconjugate estrogen, allowing it to be reabsorbed into the body.

Several studies have shown that reducing fat (less than 20% of total calories) and increasing fiber for only 3 months can lower a woman's serum estrogen level.¹⁷ If one accepts the theory that elevations of estrogen can worsen PMS symptoms, then consuming a diet high in fruits, vegetables, and whole grains and low in saturated fat may be wise. Four to six small meals should be consumed throughout the day to ease both food cravings and mood swings. Alcohol consumption should be limited because it can worsen PMS symptoms.

No food-based strategy has been adequately tested to determine its effects on PMS. However, recommendations such as eating a high-fiber diet, limiting caffeine, and cutting back on high-sugar foods have few drawbacks and numerous health benefits.

Supplements

Calcium

Ovarian hormones influence calcium, magnesium, and vitamin D metabolism. Estrogen is involved in calcium metabolism, calcium absorption, and parathyroid gene expression and secretion. Clinical trials in women with PMS have found that calcium supplementation improves several mood and somatic symptoms.

A prospective randomized, double-blind, placebo-controlled, parallel-group multicenter clinical trial was conducted to evaluate the effectiveness of calcium carbonate for PMS. Healthy premenopausal women were recruited nationally at 12 outpatient centers and screened for moderate to severe, cyclically recurring premenstrual symptoms. Symptoms were prospectively documented over two menstrual cycles with a daily rating scale that included 17 core symptoms and 4 symptom factors (negative affect, water retention, food cravings, and pain). Of the 720 women screened for the trial, 497 were enrolled and results for 466 were valid for the efficacy analysis. Women were randomly allocated to receive either 1200 mg calcium carbonate or placebo daily for three menstrual cycles. Routine blood chemistry analysis, complete blood cell count, and urinalysis data were obtained for all participants. Each participant kept a daily diary to document symptoms, adverse effects, and compliance with therapy. The primary outcome measure was a 17-parameter symptom complex score. No differences in age, weight, height, use of oral contraceptives, or menstrual cycle length were reported between the treatment and control groups. No differences existed between the groups in the mean screening symptom complex score of the luteal phase ($p = .659$), menstrual phase ($p = .818$), or intermenstrual phase ($p = .726$) of the menstrual cycle. During the luteal phase of the treatment cycle, a significantly lower mean symptom complex score was noted in the calcium-treated group by the third month ($p < .001$). The researchers concluded, "Calcium supplementation is a simple and effective treatment for premenstrual syndrome, resulting in a major reduction in overall luteal phase symptoms."¹⁸

A review of studies focusing on calcium for the management of premenstrual symptoms was published in the *Annals of Pharmacotherapy*.¹⁹ On the basis of the medical literature, the reviewer concluded, "Calcium supplementation of 1200–1600 mg/day, unless contraindicated, should be considered a sound treatment option in women who experience premenstrual syndrome." Given that many

women, especially adolescents, do not meet the adequate intake recommendations for dietary calcium, a clinical trial seems reasonable.

Dosage

The dose used in the clinical trials was generally 600 mg twice per day of calcium carbonate or citrate.

Precautions

Calcium products made from oyster shell, dolomite, or bone meal occasionally contain lead.²⁰ Labels containing the letters “USP” indicate that the product meets the purity and dissolution standards established by the U.S. Pharmacopeia; however, this is a voluntary standard, and many products do not bear USP on their labels. Calcium supplements should not be taken at the same time as tetracycline, iron supplements, thyroid hormones, or corticosteroids because calcium binds to these substances and interferes with their effectiveness and its own absorption. Iron absorption can be reduced by as much as 50% by many forms of calcium supplementation.

Magnesium

Women with PMS have been shown to have low levels of magnesium in their red blood cells. Magnesium deficiency produces fatigue, irritability, mental confusion, PMS, menstrual cramps, insomnia, muscle cramps, and symptoms of heart disturbances. A 2002 Cochrane Review found that magnesium was superior to placebo for relieving dysmenorrhea, likely through inhibition of prostaglandin $F_{2\alpha}$.²¹ One small, short-term randomized controlled trial did show that 200 mg of magnesium per day was better than placebo at alleviating the bloating symptoms of PMS.²² Two small trials found that the combination of 200 mg of magnesium plus 50 mg of vitamin B6 was beneficial for alleviating PMS symptoms.²³

Magnesium may be beneficial for women with significant bloating and cramping associated with their menstrual cycles and for women with menstrual migraines. Dietary sources of magnesium include green leafy vegetables, tofu, legumes, nuts, seeds, and whole grains.

Dosage

The dose is 200–400 mg/day of magnesium as chelate, citrate, or glycinate. Doses of 600 mg per day might be necessary for women with PMS and also migraines.

Precautions

Adverse effects of magnesium excess include abdominal cramping and diarrhea. Signs of magnesium toxicity are hypotension, irregular heartbeat, muscle weakness, nausea, diarrhea, and change in mental status. The kidneys excrete magnesium, so women with renal insufficiency must be cautious with magnesium supplementation.

Vitamin B6

Pyridoxine is a water-soluble B vitamin that serves as a cofactor in more than 100 enzyme reactions, many of which are related to the production and metabolism of neurotransmitters. The use of pyridoxine (vitamin B6) to alleviate PMS symptoms has been evaluated in more than 28 trials since 1975. This research was inspired by the work of Adams et al.,²⁴ who first reported that vitamin B6 successfully alleviated the depression associated with use of oral contraceptives. Wyatt et al.²⁵ performed a systematic review of these studies. Ten randomized placebo-controlled, double-blind, parallel or crossover studies were examined. Studies of cyclic mastalgia and multivitamin preparations with at least 50 mg of vitamin B6 were also included. Only three of these trials scored higher than 3 on the Jadad scale for methodological quality. Most trials were small (fewer than 60 women). One of the largest studies included women who were also taking oral contraceptives, analgesics, diuretics, and psychotropic medications, thus making the effects of vitamin B6 difficult to ascertain. None of the trials included power calculations. Using a random effects model, Wyatt et al.²⁵ found the overall odds ratio in favor of pyridoxine to be 1.57 (95% confidence interval [CI], 1.40–1.77). When the researchers looked at the effects on depressive symptoms in five trials, they found the overall odds ratio in favor of pyridoxine to be 2.12 (95% CI, 1.80–2.48).

Current thinking postulates that pyridoxine may ease symptoms of PMS through its ability to increase the synthesis of serotonin, dopamine, norepinephrine, histamine, and taurine.²⁶ Serotonin is important for the

regulation of sleep and appetite and the prevention of depression. Low levels of serotonin and dopamine may play a role in premenstrual symptoms.²⁷ Trials have used doses ranging from 50–500 mg/day. For most women, the prudent approach is probably to limit single doses of vitamin B6 to 50 mg and not to exceed 100 mg/day. Research suggests that the liver cannot process more than a 50-mg dose of pyridoxine at one time.²⁸ Conversion of pyridoxine to its active form depends on other nutrients, such as magnesium and riboflavin. Taking vitamin B6 as part of a multiple-vitamin supplement or using the active form, pyridoxal-5-phosphate, is advisable.

Dosage

The dose is 50–100 mg/day of pyridoxal-5-phosphate.

Precautions

Although pyridoxine is a water-soluble vitamin, it can be associated with toxicity when it is taken in moderate to large doses over time. A few reports have noted nerve damage occurring with prolonged ingestion of 150 mg/day.²⁹ Toxicity may occur if large doses of pyridoxine overwhelm the liver's ability to add a phosphate group to form pyridoxal-5-phosphate, the active form of vitamin B6.

Combining chaste tree with vitamin B6 may be a beneficial first step in the treatment of premenstrual syndrome.

Botanicals

Chaste Tree (*Vitex agnus-castus*)

Dioscorides, the Greek physician, described the dried ripe fruits of the chaste tree (*Vitex agnus-castus*) some 2000 years ago. The Latin name *agnus castus* means “chaste lamb,” in reference to the belief that the seeds reduce sexual desire. From this belief stemmed the other common name of the herb, monk's pepper. Many herbalists consider *V. agnus-castus* one of the primary herbs for alleviating PMS, a use that is supported by randomized human trials. The most rigorous study to date of chaste tree for PMS was a 3-month, double-blinded, placebo-controlled trial by Schellenberg³⁰ that randomized 170 women diagnosed with PMS to receive either 20 mg of fruit extract (Ze 440: 60% ethanol mass/mass

[m/m], extract ratio, 6 to 12:1; standardized for casticin) or placebo. Five of six self-assessment items indicated significant superiority for chaste tree (irritability, mood alteration, anger, headache, and breast fullness). Other symptoms, including bloating, were unaffected by treatment. Overall, the reduction in symptoms was 52% for the active versus 24% for the placebo group ($p < 0.001$). The trial investigators concluded: “*Agnus castus* is a well-tolerated and effective treatment for premenstrual syndrome, the effects being confirmed by physicians and patients alike.”

Two studies conducted in Chinese women also reported favorable results. A randomized, double-blinded, placebo-controlled multicenter 16-week study of 217 women with moderate to severe PMS found that 40 mg of chaste tree extract was superior to placebo, as measured by the PMS diary 17-item daily rating scale ($p < .0001$).³¹ No serious adverse events were reported. A smaller, randomized, placebo-controlled 3-month study of 64 Chinese women with moderate to severe PMS also found that 40-mg/day chaste tree extract significantly reduced symptoms in the PMS diary 17-item daily rating scale ($p < .05$).³²

One study evaluated the use of chaste tree in PMDD. A single-blind, rater-blinded study of 41 women (age 25–45 years) who were diagnosed with PMDD and who had regular menstrual cycles failed to note any significant difference between fluoxetine and chaste tree with respect to the Hamilton Depression Rating Scale (HAM-D), the Clinical Global Impression Scale-Severity of Illness (CGI-SI), or the Clinical Global Impression-Improvement (CGI-I).³³ Unfortunately, the investigators did not provide any details regarding the chaste tree product (e.g., extraction method, extract strength).

One comparative trial found chaste tree to be as effective as pyridoxine for relieving PMS symptoms,³⁴ whereas a pilot study using the combination of St. John’s wort (*Hypericum perforatum*) and chaste tree found the combination highly effective for relieving PMS symptoms in perimenopausal women.³⁵

The chaste tree preparation is known to act, in part, by reducing prolactin, increasing progesterone, and binding opiate receptors.³⁶ Binding of opioid receptors may be the primary mechanism involved in PMS, given that symptoms such as anxiety, food cravings, and physical discomfort are directly and inversely proportional to the decline of beta-endorphin levels. *Vitex* has an inhibitory action on prolactin because of its dopamine agonist properties. Women with hyperprolactinemia often experience menstrual dysfunction. Some researchers postulate that the correction of hyperprolactinemia causes the reversal of luteinizing

hormone suppression and results in full development of the corpus luteum during the luteal phase of the cycle.³⁷ Studies in both animals and humans have demonstrated prolactin inhibition with *Vitex*. The German health authorities approved the use of chaste tree fruit for irregularities of the menstrual cycle, premenstrual complaints, and mastodynia.³⁸

Dosage

The dose varies according to the preparation used in trials. Generally, practitioners recommend 250–500 mg/day of dried fruit or 20–40 mg/day of chaste berry extract.

Precautions

Chaste tree has been rarely associated with gastrointestinal reactions, alopecia, headaches, tiredness, dry mouth, and increased menstrual flow.

Binding of opioid receptors may be the primary mechanism of action of chaste tree. As beta-endorphin levels decline, so do common premenstrual syndrome symptoms such as anxiety, food cravings, and physical discomfort.

Black Cohosh (*Actaea racemosa*, *Cimicifuga racemosa*)

The Eclectics (early physicians who used botanical medicines extensively) used black cohosh for restlessness, nervous excitement, breast pain, and menstrual headaches.³⁹ Although most research has focused on black cohosh for the alleviation of menopausal complaints, a study of 135 women found a standardized extract of black cohosh to be effective in reducing the symptoms of anxiety, tension, and depression in women with PMS.⁴⁰ Researchers found that compounds in black cohosh bind 5-HT₇ receptors, a characteristic that could partially explain the positive effects of this botanical on mood.⁴¹ The German health authorities endorsed the use of black cohosh for premenstrual discomfort and dysmenorrhea.⁴²

Dosage

The dose is 20–40 mg of the standardized extract twice daily (generally

standardized to triterpene glycosides as a marker compound) or 150–300 mg of the crude herb equivalent twice daily.

Precautions

The most common complaint is gastrointestinal disturbance. Other potential adverse effects are headache, heaviness of the legs, and weight gain. Two safety reviews concluded that black cohosh is relatively safe when it is used appropriately; since these reviews, however, case reports suggesting a possible link between black cohosh use and liver damage have been published in the medical literature. After an extensive review of the literature, the U.S. Pharmacopeia Dietary Supplements Expert Information Committee recommended that women who have, or who are at risk for, liver disease check with their health care provider before they use black cohosh.⁴³

Ginkgo (*Ginkgo biloba*)

If women experience primarily congestive symptoms in the premenstrual period (fluid retention, breast tenderness, and weight gain), a trial of ginkgo may offer some relief. A double-blind, placebo-controlled trial of ginkgo was conducted in a cohort of 165 women complaining of premenstrual symptoms. Participants received placebo or a standardized extract of ginkgo (EGb761 24% ginkgo flavones and 6% terpenes; Dr. Willmar Schwabe GmbH & Co., Karlsruhe, Germany), 80 mg twice daily, from day 16 of one menstrual cycle through day 5 of the next cycle. Evaluations by patient and physician found ginkgo to be effective for alleviation of breast pain and tenderness and fluid retention.⁴⁴ Ginkgo is known to augment venous tone and reduce capillary fragility.

A single-blind, randomized, placebo-controlled trial of 90 women with PMS (85 completed the trial) found that ginkgo was superior to placebo in reducing physical and psychological symptoms when administered at a dose of 40 mg of the standardized leaf extract three times per day from the 16th day of the cycle to the 5th day of the next cycle.⁴⁵ The mechanism of action is not completely understood.

Dosage

The dose is 80 mg of a standardized extract twice daily or 40 mg three

times daily from day 16 of one menstrual cycle through day 5 of the next cycle.

Precautions

Ginkgo may cause gastrointestinal symptoms, headache, dizziness, palpitations, and allergic skin reactions.

Caution

Patients should be carefully supervised if ginkgo is used with anticoagulant medications; however, bleeding risk is probably quite low in otherwise healthy individuals taking ginkgo. A randomized, double-blind, placebo-controlled, crossover study found no change in coagulation factors, platelet aggregation, or bleeding times in 50 healthy male volunteers who took 240-mg ginkgo extract (EGb761).⁴⁶

Evening Primrose Oil (*Oenothera biennis*)

Evening primrose oil is extracted from the seeds of the evening primrose plant, a wildflower native to North America and introduced to Europe in the early 1600s. The seed oil has been studied for medicinal effects for decades because it is a rich source of linoleic acid and gamma-linolenic acid. Some researchers reported that women with PMS have impaired conversion of linoleic acid to gamma-linolenic acid, thus leading to the investigation of gamma-linolenic supplementation for symptom alleviation. However, a systematic review identified seven placebo-controlled trials of evening primrose oil and reported that all suffered from methodological flaws.⁴⁷ The two highest-quality studies failed to show any beneficial effects of evening primrose oil in PMS, although the sample sizes were small in both trials.

Dosage

Evening primrose oil products are generally standardized to specific amounts of gamma-linoleic acid. Capsules typically contain 320–360 mg linoleic acid and 40 mg gamma-linolenic, although levels vary among manufacturers. Vitamin E is often added to prevent rancidity. The range of doses used in clinical studies is 1–6 g/day.

Precautions

Evening primrose oil is extremely well tolerated. Minor gastrointestinal symptoms have been occasionally reported in the literature.

St. John's Wort (*Hypericum perforatum*)

Clinical trials using selective serotonin reuptake inhibitor (SSRI) medications have shown that approximately 60% of women with severe PMS obtain significant relief with use of these drugs. This finding is interesting, given that some herbalists recommend the popular herbal antidepressant St. John's wort (*Hypericum perforatum*) for women reporting depression and irritability during the premenstrual period.

A randomized, double-blind, placebo-controlled, crossover study in the UK evaluated 36 women (ages 18–45 years) with PMS. After a two-cycle placebo run-in phase, the women were randomized to receive St. John's wort 900 mg/day (standardized to 0.18% hypericin; 3.38% hyperforin) or identical placebo tablets for two menstrual cycles. St. John's wort was found to be statistically superior to placebo in improving physical and behavioral symptoms of PMS ($p < 0.05$) but not mood or pain.⁴⁸

Dosage

The dose generally used for depression is 300–600 mg of St. John's wort, standardized to contain 3%–5% hyperforin or 0.3% hypericin, three times per day.

Precautions

Women taking medications that increase photosensitivity, protease inhibitors (for human immunodeficiency virus), cyclosporine, or other medications that are metabolized by the cytochrome P-450 CYP3A4 system or P-glycoprotein should avoid St. John's wort.

Kava (*Piper methysticum*)

Physicians sometimes prescribe alprazolam, a benzodiazepine, for the treatment of PMS. Because of the risk of habituation and side effects, practitioners have looked for other anxiolytics that could be of benefit. Numerous practitioners have recommended the South Pacific herb, kava, for this purpose. A meta-analysis concluded that kava is an effective

treatment for anxiety when compared with placebo, although no studies of kava for the treatment of PMS are available for review.

Concerns have been raised about the safety of kava, however. Approximately 30 cases of hepatotoxicity potentially related to the use of kava products have been reported in the literature. Numerous countries have banned the sale of kava, including Germany, Switzerland, Ireland, Canada, Australia, and the United Kingdom. The U.S. Food and Drug Administration (FDA) issued a cautionary statement, but the herb is still sold in the United States. Until the safety issue is further elucidated, looking for other approaches to help alleviate troublesome symptoms of PMS seems wise. A better option for women reporting irritability and difficulty sleeping during the premenstrual period may be valerian (discussed in the following section).

Valerian (*Valeriana officinalis*)

Valerian is a common ingredient in over-the-counter relaxants and sleep aid products in both Europe and the United States. It is often included in herbal formulations for PMS with a dominant profile of anxiety or irritability. The herb is sold as a single ingredient but is often found in combination with other relaxant herbs such as hops (*Humulus lupulus*), passionflower (*Passiflora incarnata*), or lemon balm (*Melissa officinalis*). The German Commission E endorses valerian for restlessness and sleeping disorders caused by nervous conditions,⁴⁹ and the World Health Organization recognizes it as a “mild sedative, sleep-promoting agent, and milder alternative to or possible substitute for stronger sedatives (e.g., benzodiazepines) and for treatment of nervous excitation and sleep disturbances induced by anxiety.”⁵⁰ No clinical trials have evaluated the use of valerian for PMS, but this botanical is often included in formulations on the basis of its mild anxiolytic effects and ability to promote sleep.

Dosage

The crude herb is usually taken at a dose of 2–3 g (equivalent to 10–15 mL of tincture [1:5 strength]) approximately 1 hour before bedtime. Smaller doses are often used during the day for relieving mild irritability and anxiety. Standardized extracts are also widely available and should be taken as directed on the label.

Precautions

Valerian is generally safe when taken appropriately and is not considered habit-forming. The World Health Organization noted that the use of valerian is contraindicated during pregnancy and lactation because of the lack of studies in this area.

Mind-Body Therapy

Mind-body therapies are approaches grounded in the emerging scientific understanding that thoughts and feelings affect physiology and physical health. Mind-body therapies for PMS include psychotherapy (cognitive-behavioral therapy and group therapy), relaxation techniques and training, body work (massage and reflexology), hypnotherapy, biofeedback, guided imagery, yoga, and qigong. An emerging body of evidence shows that when women are given psychological support and taught self-regulatory techniques, their quality of life and PMS symptom severity significantly improve.⁵¹

Acupuncture

Acupuncture is only one tool used in traditional Chinese medicine (TCM) for the treatment of disease and promotion of health. Traditional Chinese medicine has a long history of treating what would be called PMS in conventional medicine. Although many women report benefit, a systematic review of clinical trials using acupuncture for the relief of PMS found the data inconclusive.⁵² Given the overall safety of acupuncture and its potential benefits, clinicians should not dissuade women who choose to explore traditional Chinese medicine or acupuncture for relief of their symptoms.

Pharmaceuticals

Selective Serotonin Reuptake Inhibitors

In addition to the numerous lifestyle recommendations already mentioned, growing numbers of physicians are prescribing SSRIs for the treatment of PMS and PMDD. A Cochrane Review of 31 trials that evaluated the efficacy of SSRIs in the management of PMS reported that these medications are highly effective for improving both behavioral and

physical symptoms. However, adverse effects are relatively frequent, the most common being nausea and asthenia.⁵³ SSRIs should be considered for women with severe forms of PMS, and particularly PMDD, that do not respond to lifestyle, mind-body, or supplement approaches.

Prevention Prescription

Preventive strategies should be directed at those that improve overall health and seem appropriate based on our current understanding of PMS:

- Limit alcohol consumption and avoid drugs of abuse.
- Exercise at least three times per week for a minimum of 30 minutes.
- Limit consumption of salt, sugar, and caffeine, especially 10 days before the onset of menses.
- Eat a well-balanced diet that is rich in fiber and low in saturated fat.
- Take a multivitamin every day that includes pyridoxal-5-phosphate (active vitamin B6).
- Ensure the diet provides 1000–1200 mg of calcium and 320–400 mg magnesium every day; use supplements to make up for any dietary shortcomings.

Therapeutic Review

Lifestyle

- Learn strategies for effective stress management, obtain adequate sleep, and maintain a regular exercise routine. Consider mind-body approaches such as breathing techniques and yoga. 

Nutrition

- Eat a well-balanced diet rich in fiber and low in fat. 
- Limit intake of alcohol, salt, caffeine, and refined sugar products. 

Supplements

- Calcium: 500–600 mg twice daily 

- Vitamin B6 as pyridoxal-5-phosphate: 50 mg/day 
- Magnesium: 200–600 mg/day 

Botanicals

- Chaste tree (*Vitex*): 250–1000 mg crude herb or 20–40 mg/day of a standardized extract 

Treatment for Specific Symptoms

- Breast tenderness
 - Caffeine restriction 
 - Chaste tree (*Vitex*): 250–500 mg crude herb or 20–40 mg/day of a standardized extract 
 - Evening primrose oil: 1.5 g twice daily (continuous) 
 - *Ginkgo biloba*: 80 mg standardized extract twice daily (ovulation through menses) 
- Anxiety and mood swings
 - Black cohosh: 20–40 mg standardized extract twice daily or 150–300 mg crude herb equivalent (continuous therapy) 
 - Calcium: 500–600 mg twice daily 
 - Chaste tree (*Vitex*): 250–500 mg crude herb or standardized extract daily 
 - St. John's wort: 300–600 mg standardized extract three times daily (continuous therapy) 
 - Valerian root: 2–3 g crude herb or standardized extract 45 minutes before bed 
 - Kava root: up to 210 mg kavalactones in standardized extract daily 
- Depression
 - St. John's wort: 300–600 mg standardized extract three times daily (continuous therapy) 
 - Vitamin B6: 50 mg once or twice daily 

- Cramps
 - Magnesium: 200–600 mg/day 
- Insomnia
 - Valerian root: 2–3 g crude herb or standardized extract before bed 
- Severe PMS or PMDD
 - Chaste tree (*Vitex*): 250–1000 mg crude herb or 20–40 mg/day of a standardized extract 
 - St. John's wort: 300–600 mg standardized extract three times per day (continuous therapy) 
 - Serotonin reuptake inhibitors.  Low doses often are effective.
 - Fluoxetine: 10–20 mg
 - Sertraline: 50–75 mg
 - Paroxetine: 10–20 mg
 - Citalopram: 10–20 mg

CHAPTER 57

Dysmenorrhea

Greta J. Kuphal, MD

Dysmenorrhea refers to painful uterine cramping associated with menses. In addition to lower pelvic discomfort, women may also experience low back pain, radiation of pain to the anterior thighs, nausea, vomiting, diarrhea, headache, and various other symptoms starting 1 to 3 days before the onset of menses and typically lasting through the first few days of bleeding. *Primary dysmenorrhea* refers to pain that is not associated with other, obvious pelvic disease and typically begins with the onset of ovulatory cycles just after menarche. *Secondary dysmenorrhea* is associated with another diagnosis (e.g., cervical stenosis, endometriosis) and typically has a later onset, usually after the age of 20 years. This discussion focuses on primary dysmenorrhea because treatment for secondary dysmenorrhea is determined by the underlying cause.

Estimates of the percentage of women affected by dysmenorrhea range from 16% to 90%. Some investigators claim the most reliable estimate to be approximately 75%, based on a large Swedish study of 19-year-old women. Most of these women's symptoms were mild, but 23% and 15% reported suffering from moderate and severe pain, respectively.¹ In addition to the discomfort endured by affected women, dysmenorrhea also results in significant missed school and work as well as a decreased quality of life.²

Dysmenorrhea seems to be more significant in women with an earlier age at menarche and in those with longer episodes of bleeding. Being overweight appears to significantly affect the likelihood and duration of painful cramping. Smoking has been associated with prolonged pain, and although alcohol consumption does not increase the probability of painful cramping, it seems to increase the duration and severity of cramping in women with dysmenorrhea.³ Other predisposing factors include age less than 30 years, low body mass index, longer menstrual

cycles, heavy menstrual bleeding, nulliparity, clinically suspected pelvic inflammatory disease, history of sexual abuse, psychological symptoms, chronic exposure to stress, and exposure to secondhand smoke.⁴⁻⁷

Pathophysiology

The pathogenesis of primary dysmenorrhea seems to involve elevated levels of prostaglandins in response to the rise and fall of progesterone that occur after ovulation. As progesterone production decreases by the corpus luteum, lysosomes in the endometrial cells break down and release phospholipase A2, which converts cell membrane fatty acids into arachidonic acid, the precursor to prostaglandins. In women with dysmenorrhea, excessive elevation of prostaglandins, specifically prostaglandin F2 α and prostaglandin E2 α , leads to uterine hypercontractility; painful cramping; and other prostaglandin-related symptoms such as nausea, vomiting, and diarrhea. These contractions decrease blood flow to the uterus and cause ischemia, which sensitizes nerve fibers to the inflammatory prostaglandins and endoperoxides.^{8,9} Elevated levels of vasopressin have also been found in women with dysmenorrhea. This hormone increases uterine contractility, thereby contributing to cramping and ischemia.¹⁰

Integrative Therapy

Lifestyle

Exercise

Evidence for exercise as a treatment modality for dysmenorrhea has been mixed and limited in quality.¹¹ Early studies indicated that the type of exercise was less important than the desire to alleviate symptoms with exercise.¹² However, evidence has supported the use of both aerobic and stretching exercise regimens.¹³ A 20-minute yoga regimen of Cobra, Cat, and Fish poses combined with yogic breathing decreased intensity and duration of menstrual pain when done for 14 days per month during the luteal phase of the cycle.¹⁴ Given that chronic stress seems to increase perimenstrual symptoms,⁵ and exercise is certainly a valid tool for managing stress and overall health, discussing regular exercise with patients suffering from dysmenorrhea certainly has a place.

Substance Use

Tobacco and alcohol use have been associated with worse symptoms of dysmenorrhea. Patients should be counseled on this and supported in addressing unhealthy use of these substances.

Nutrition

Omega-3 Fatty Acids

The release of arachidonic acid from the membranes of cells of the endometrium leads to an increase in proinflammatory prostaglandins. Omega-6 fatty acids are precursors to arachidonic acid, and our consumption of omega-6 compared with omega-3 fatty acids has greatly increased over the past century. The antiinflammatory diet (see [Chapter 88](#)) can change the ratio of omega-6 to omega-3 polyunsaturated fatty acids in our bodies and may thereby modulate the levels of prostaglandins, inflammation, and painful uterine contractions produced. Studies have shown that higher a consumption of omega-3 polyunsaturated fatty acids (either through supplementation or diet) leads to a decrease in painful menses and decreased need for NSAIDs.^{15-17,18} [Table 57.1](#) lists dietary sources of omega-3 polyunsaturated fatty acids, as well as other nutrients described in the following section that have been found to be helpful in the treatment of primary dysmenorrhea.^{19,20}

TABLE 57.1

Dietary Sources of Nutrients Found to Decrease Pain of Dysmenorrhea

OMEGA-3 Fatty Acids	Magnesium	Vitamin B1	Vitamin B6	Vitamin E
Cold-water fish (e.g., salmon, herring, sardines) Leafy green vegetables Flaxseeds (ground) Walnuts	Halibut Almonds, dry roasted Cashews, dry roasted Soybeans Spinach	Fortified grains (breaks, cereals, pasta, whole grains) Lean pork Fish Dried beans Pine Soybeans	Fortified cereals Peanuts with skin Bananas Garbanzo beans (chickpeas) Chicken breast Pork loin, lean only	Vegetable oils (soybean, canola, safflower) Almonds Safflower seeds Spinach Broccoli Fortified cereals, juices, and grains

Data from MedlinePlus. *Thiamin*. <http://www.nlm.nih.gov/medlineplus/ency/article/002401.htm> Accessed 24.02.11; Office of Dietary Supplements, National Institutes of Health. *Dietary Supplement Fact Sheets*. <http://ods.od.nih.gov/factsheets/> Accessed 20.02.11.

Dosage

If supplementing with omega-3 fish oil capsules, the dose is 1500–2000 mg daily of docosahexaenoic acid and eicosapentaenoic acid or two to three servings of cold-water fish per week.

Supplements

Magnesium

Magnesium has been found to be beneficial in the treatment of arrhythmias, severe asthma, migraine, dyspepsia, and constipation. Its role in dysmenorrhea may be related to its effect on intracellular calcium concentration,²¹ a reduction in prostaglandin synthesis,²² or its muscle relaxant properties. A Cochrane Review found three studies showing that magnesium was more effective than placebo in decreasing menstrual pain and the use of analgesic medications. The studies were small, but the results are encouraging.²³

The form of magnesium is important because some forms are more likely to cause diarrhea (see the section on [dosage](#)). Foods rich in magnesium include fish, nuts, leafy greens, whole grain cereals, and baked potatoes with the skin.²⁰ Magnesium is a largely intracellular cation, so red blood cell magnesium may be a more accurate measure of nutrient status than the typically used serum magnesium.

Dosage

Unless constipation is present, consider doses of 200–600 mg daily of forms of magnesium less likely to cause loose stools: magnesium glycinate (chelated magnesium), magnesium gluconate, or magnesium chloride. See [Table 57.1](#) for dietary sources of magnesium.

Precautions

Use magnesium with caution in individuals who have impaired renal function. If diarrhea develops, decrease the dose until this condition is relieved because diarrhea is one of the first signs of magnesium toxicity.

Vitamin B6 (Pyridoxine)

A series of small studies (n = 21 to 24) in 1988 compared various

permutations of vitamin B6 versus magnesium versus vitamin B6 and magnesium versus placebo. The results revealed that vitamin B6 was better than placebo and a combination of vitamin B6 and magnesium at decreasing visual analogue pain scores and the number of ibuprofen tablets used.²³ A mechanism offered to explain the possible beneficial effect of vitamin B6 is its role in increasing the influx of magnesium into the cells, thereby supporting the effects of magnesium described earlier.

Dosage

The dose is 100 mg daily. If a higher dose is used, close monitoring is needed. See [Table 57.1](#) for dietary sources of vitamin B6.

Precautions

Vitamin B6 toxicity typically manifests as neuropathy that reverses with decreased intake.²⁰ Doses described were 100 mg twice daily; however, the Institute of Medicine established the upper tolerable intake level for vitamin B6 as 100 mg daily for adults.

Vitamin B6 and magnesium may work synergistically because vitamin B6 increases the influx of magnesium into the muscle cells.²⁴

Vitamin B1 (Thiamine)

One of the largest double-blind, placebo-controlled studies investigating the effect of a nutritional supplement on dysmenorrhea was a trial of vitamin B1. This crossover trial involved 556 Indian adolescents who were randomized to receive either 100 mg of vitamin B1 daily for 90 days, followed by placebo for 60 days or placebo for 60 days, followed by 100 mg of vitamin B1 daily. In both groups, complete resolution or significant improvement in pain did not occur until the participants had received thiamine for at least 30 days. “Cure” rates by the end of the trial were approximately 90% in both groups.²⁵ This overwhelming success at “curing” dysmenorrhea certainly raises the question of whether the results could be confirmed with another study in a different population. The mechanism by which this treatment works may simply be reversal of a deficiency that can manifest with decreased pain tolerance, muscle cramping, and fatigue, which are symptoms similar to those of premenstrual syndrome.²²

Dosage

The dose is 100 mg daily for 90 days. Consider continuing treatment if symptoms recur after initial improvement. See [Table 57.1](#) for dietary sources of thiamine.

Precautions

Orally, thiamine is usually well tolerated. It rarely causes dermatitis or a hypersensitivity reaction.²⁶

Vitamin E

Vitamin E has been proposed to provide relief from dysmenorrhea through antiinflammatory action and through induction of a marked rise in beta-endorphin levels.^{27,28} Several randomized, placebo-controlled studies, including a total of 383 women 15–21 years old, showed a significant decrease in the severity and duration of pain with the intake of vitamin E compared with placebo. The doses used varied from 150 to 500 units daily for either 2 days before and 3 days after or for 10 days before and 4 days after the onset of menses.²⁹⁻³¹ The tolerable upper intake level in healthy people is 1000 mg/day, equivalent to 1100 units of synthetic vitamin E (D-L-alpha-tocopherol or alpha-tocopherol or SRR-tocopherol) or to 1500 units of natural vitamin E (D-alpha tocopherol or RRR-tocopherol).^{32,33}

Dosage

The dose is 400 units daily for a few days before and a few days after the onset of menses. See [Table 57.1](#) for dietary sources of vitamin E.

Precautions

Doses higher than 400 units of vitamin E have higher potential for adverse effects in unhealthy individuals.

Botanicals

French Maritime Pine Bark Extract (Pinus pinaster)

Pycnogenol is the trade name for this extract of French maritime pine

bark. It has numerous active constituents such as flavonoids, procyanidins, and phenolic acids; the list of indications ranges from asthma, chronic venous insufficiency, and hypertension to coronary artery disease and diabetes. In dysmenorrhea, it may have antispasmodic effects and inhibit uterine contractions through its components ferulic acid and caffeic acid. A study of 116 women with low menstrual pain (did not require analgesic medication) or dysmenorrhea were monitored for two cycles and then treated with either 30 mg twice daily of Pycnogenol or placebo through another two menstrual cycles. Although no difference was noted in the treatment group compared with placebo in the women with low menstrual pain, a significant decrease in pain scores and in analgesic use was reported in women with dysmenorrhea, and the effect seemed to persist for at least 1 month after cessation of the extract.³⁴

Dosage

The dose is 30 mg twice daily for 2 months. The effect may last for at least 1 month after cessation.

Precautions

Pycnogenol is generally well tolerated. Side effects may be limited to gastrointestinal problems, dizziness, and vertigo but have possibly included headache and mouth ulceration.³⁵

Fennel (*Foeniculum vulgare*)

Fennel essential oil has been found to be comparable to the nonsteroidal antiinflammatory (NSAID) medication, mefenamic acid.^{36,37} The mechanism seems to involve the inhibition of uterine contraction induced by prostaglandin E2 and oxytocin.³⁸

Dosage

The dose is 30 drops of fennel extract at the onset of menses and then continuously every 6 hours for the first 3 days of menses.

Precautions

Fennel has a Generally Recognized as Safe (GRAS) status in the United States, but there have been case reports of neurotoxicity in two breastfeeding infants whose mothers drank an herbal combination tea containing fennel.³⁹ Fennel supplements should be avoided during pregnancy because in vitro studies have shown some toxic effects on fetal cells.⁴⁰

SCA by Gol Daro Herbal Medicine (Saffron [Crocus sativus], Celery Seed [Apium graveolens], Anise or Fennel [Foeniculum vulgare])

An Iranian blend of highly purified extracts of saffron, celery seed, and anise (SCA by Gol Daro Herbal Medicine) was compared with mefenamic acid and placebo for effectiveness in alleviating symptoms of dysmenorrhea in 163 women 18–30 years old. SCA, at 500 mg three times daily, was found to be more effective than placebo and the NSAID, at 250 mg three times daily, in decreasing menstrual pain intensity and duration. All agents were taken for 3 days at the start of the menstrual cycle. No side effects were noted.⁴¹

Dosage

The dose of SCA is 500 mg three times daily for 3 days, starting at the onset of pain or bleeding.

Precautions

Saffron is generally well tolerated and has a GRAS rating unless it is taken at high doses. Taking 5 g or more of saffron can cause severe side effects, and doses of 12–20 g can be lethal.⁴² Celery seed also has a GRAS rating but may cause an allergic reaction (especially in individuals sensitive to mugwort, birch, dandelion, or wild carrot); large amounts should be avoided during pregnancy because of the potential abortifacient effects.⁴³

Willow Bark Extract (Salix cortex)

The major active ingredient of willow bark, salicin, was the original source of aspirin. It appears to inhibit the cyclooxygenase-2 pathway.

Other components of willow bark may have other antiinflammatory properties. Willow bark seems to inhibit platelet aggregation, but not as much as aspirin.

Dosage

The dosage is 240 mg daily of salicin, in divided doses. This is roughly equivalent to 87 mg of aspirin. Willow bark extract may work better if it is started the day before expected symptoms.⁴⁴

Precautions

Willow bark extract is generally safe, but avoid it in children with viral infections, given a theoretical risk of Reye syndrome. It can cause gastrointestinal side effects but less than those seen with NSAIDs. Avoid in patients with kidney disease and in patients allergic to aspirin.

Cramp Bark (*Viburnum opulus*) and Black Haw (*Viburnum prunifolium*)

Traditionally, these herbs have been used as uterine relaxants. Very few data are available regarding their efficacy. The root bark and stem bark of black haw contain certain active ingredients, including scopoletin and oxalic acid. Scopoletin may be a uterine relaxant. Because of the presence of oxalic acid, black haw should be avoided in patients with a history of renal stones. Black haw also contains salicylates that could trigger an allergic reaction in patients sensitive to aspirin.⁴⁵

Dosage

The dose of black haw is 2–3 mL of a tincture made in 1:3 proportion every 2 hours or as needed; or 4–8 mL of fluid extract (1:1) three or four times daily; or simmer one tablespoon of bark in 12 oz of water for 15 minutes and drink one-third cup every 2–3 hours as needed.⁴⁶

Precautions

Avoid black haw in persons with a history of renal stones or aspirin

allergy.

Other Herbs

Many other herbs used traditionally by herbalists can be effective in easing the pain of dysmenorrhea, but scientific trials are lacking. [Table 57.2](#) summarizes other herbs from which patients may benefit.

Pharmaceuticals

Nonsteroidal Antiinflammatory Drugs

As inhibitors of prostaglandin formation, NSAIDs such as naproxen, ibuprofen, and mefenamic acid have been shown to be quite effective for the treatment of dysmenorrhea when compared with placebo or acetaminophen. These medications are used and tolerated by a great number of women and bring relief from painful menstrual cramping. NSAIDs are not effective in approximately 20% of cases, however, and they can be associated with significant side effects. Gastrointestinal symptoms such as nausea and indigestion seem to be especially common with naproxen. Overall, NSAIDs are associated with a higher risk than placebo of such mild neurological adverse effects as headache, drowsiness, dizziness, and dryness of the mouth. Naproxen and indomethacin seem to be more likely to produce these types of symptoms.⁴⁷

Hormonal Treatments

Combined oral contraceptive pills have been shown to reduce menstrual pain significantly. A meta-analysis of nearly 500 women showed decreased pain with both low-dose and medium-dose estrogen formulations. The type of progesterone does not seem to matter. Side effects noted were nausea, headache, and weight gain.⁴⁸ More serious side effects of oral contraceptive pills include thromboembolic and cardiovascular events; the risks of these adverse effects rise greatly with age and cigarette smoking.

Levonorgestrel-containing intrauterine devices have been reported to be equal or superior to oral progestins or oral contraceptives in their ability to decrease menstrual cramping in women of all reproductive ages,⁴⁹ perhaps by inhibiting buildup of the endometrium and thus reducing the total prostaglandin load. Such devices also frequently

reduce menstrual flow, which may be desirable in some cases. Uterine perforation, one of the more serious risks of placement of an intrauterine device, occurs at a rate of approximately 2 in 1000 women. The expulsion rate is approximately 5% in the first year. These devices have the advantage of providing contraception for up to 5 years before they must be replaced.

TABLE 57.2

Other Herbs That May Be of Benefit for Easing Menstrual Pain

Herb	Dose	Comment
Black cohosh <i>Actaea racemosa</i>	Tea: 2 tsp dried root steeped in two cups boiling water for 10 minutes. Drink one-fourth cup two to three times daily Capsule: 40–200 mg dried rhizome daily in divided doses Tincture: 1–2 mL three times daily Standardized extract: 20–40 mg twice daily	Popularly used as an herb for menopausal symptoms. Seems to have antiinflammatory and antidepressant activity that can reduce experience of and sensitivity to pain. Few, rare reports suggested potential of liver damage—use with caution in those at risk.
Dong quai <i>Angelica sinensis</i>	Tea: Steep 1–2 tsp root in one cup water for 5–7 minutes. Drink one cup two to three times daily. Capsules: 1 g two to three times daily Tincture: 3–5 mL, two to three times daily	May cause photosensitivity. May increase bleeding risk in those on anticoagulants or with bleeding disorders. May increase heaviness of menstrual bleeding.
Shatavari <i>Asparagus racemosus</i>	Tea: Steep 1 tsp dried root in one cup water for 15 minutes. Drink one to two cups daily Capsules: 500 mg one to two times daily Tincture: per manufacturer’s dosing	Well tolerated and safe.
Chamomile <i>Matricaria recutita</i>	Tea: Steep 1 tsp flowers in one cup water for 5–7 minutes or longer	Use with caution in those with severe ragweed allergies. May be especially helpful in those with menstrual cramps and gastrointestinal discomfort.
Hops <i>Humulus lupulus</i>	Tea: Steep 1 tsp female flowers in one cup water for 5–7 minutes Capsules: 500 mg one to three times daily Tincture: 2 mL, one to three times daily	Can be sedating. Potential for hormonal activity; avoid in women at risk for breast cancer. ^a
Bee balm (Oswego tea) <i>Monarda didyma</i>	Tea: Steep 1 tsp powdered herb in one cup water for 7–10 minutes. Take one to three cups daily	Avoid in pregnancy as it may stimulate menstrual flow. Also used for flatulence and as a diuretic, which may help other symptoms uncomfortable menstrual-related symptoms. ^b

Mind-Body Therapy

A comprehensive health plan for any individual with chronic pain often involves recognition of the component of the experience of the pain that is influenced by the perception of that experience. Chronic pain is frequently accompanied by mood disturbances such as depression and

anxiety. At times, distinguishing whether mood affects pain or the other way around may be difficult; the relationship is likely bidirectional. Given the risk factors listed previously of a history of sexual abuse and psychological symptoms, it is easy to see that a significant mind-body relationship may play a role in some cases of dysmenorrhea.

A 2007 Cochrane Review (reprinted in 2010) included five studies that evaluated behavioral interventions such as biofeedback, relaxation techniques, and pain management training. An overall benefit was apparent, but the studies were small, and some had relatively poor methodology.⁵⁰ A small 2014 study compared as needed use of NSAIDs to hypnosis for dysmenorrhea and found that both were effective for decreasing pain while being actively employed. However, only the hypnosis seemed to have a lasting effect of at least 3 months after cessation of treatment on the decrease of nonpain symptoms such as nausea, vomiting, diarrhea, headache, and dizziness.⁵¹

In areas such as this, the relationship between the provider and the individual is very important. Listening to and understanding the individual on a deeper level allows the provider to determine more appropriately whether, for example, referral to a counselor or health psychologist may be beneficial. Providers skilled in relaxation techniques or guided imagery may be able to strengthen their therapeutic relationship with patients by employing those skills for symptoms of dysmenorrhea. More research is needed in this area to develop protocols for techniques that can be easily taught to patients for their use during times when they are symptomatic.

Bioenergetic Therapy

Heat Therapy

Patients may report that they have tried using heating pads or microwavable bean bags, with some relief of symptoms. Studies have shown that heat does indeed decrease pain and, when combined with NSAIDs, reduces the time until noticeable pain relief is achieved.^{52,53} Recommend heat of approximately 39°C (102°F) for up to 8–12 hours on the lower abdomen or back.

Precautions

Ensure that the heat is not so high that it causes burns or is applied to

areas of decreased sensation because an injury may not be recognized.

Magnet Therapy

A study of 35 women in London found a significant decrease in pain over one menstrual cycle by using a 2700-gauss magnet that attached to the underwear over the suprapubic area. The noncompletion rate in this study was significant, but the investigators reported that this was a pilot study for a much larger study using the same device. The manufacturer of the device was involved in the funding of the study.⁵⁴ The device is sold in England and on the Internet for approximately \$40 U.S. A Korean study using 800- to 1299-gauss magnets over the suprapubic area, lower back, and medial lower leg revealed similar results.⁵⁵

Transcutaneous Electrical Nerve Stimulation

By delivering electrical currents and various frequencies through the skin, transcutaneous electrical nerve stimulation (TENS) machines appear to affect the body's ability to receive and understand pain signals. TENS devices are used quite commonly for musculoskeletal pain, including low back pain; they are portable, thus making them available for home and clinic use. A 2010 Cochrane Review found seven small studies covering a total of 164 women suffering with dysmenorrhea that compared high- or low-frequency TENS therapy or TENS therapy with placebo TENS, a placebo pill, or medical treatment (NSAIDs). The results of the meta-analysis showed that high-frequency TENS (using 50–100 Hz) was significantly more effective than placebo for the relief of dysmenorrhea. The effect of low-frequency TENS (1–4 Hz) was not significant, but trended toward benefit over placebo. Neither was as effective as medical therapy.⁵⁶ Consideration of the long-term effects of electromagnetic radiation to the pelvis, especially in young women, may be wise.

Acupuncture

Acupuncture is becoming more and more widely accepted in the Western world as a treatment modality for various indications, pain being among the most common. Investigating efficacy can be difficult, however, in that control arms for acupuncture studies are challenging to design because even sham acupuncture may indeed have some therapeutic benefit. A 2009 systematic review of 27 trials showed that

only 9 trial groups adequately described their randomization methods, and none described their allocation and concealment methods. However, the results of the studies included did support significant benefit of acupuncture over pharmaceutical or herbal interventions. Two of the studies did not show a benefit of acupuncture over sham acupuncture.⁵⁷ A 2011 Cochrane Review found 34 trials that studied acupuncture and acupressure for dysmenorrhea.⁵⁸ Ten trials were included in the review: six involving acupuncture and four involving acupressure. Of the 24 trials not used, nearly all were excluded because of either details around randomization or the use of multiple interventions (e.g., Chinese herbs, moxibustion). Meta-analysis of the 6 included acupuncture trials (n = 673) did indeed show significant benefit of acupuncture for dysmenorrhea compared with control, NSAIDs, and Chinese herbs. Acupuncture was also shown to have a positive impact on other menstrual symptoms (e.g., headache, nausea) and quality of life.⁵⁸ Several reviews^{59,60} pointed to a methodologically sound trial of 48 women randomized to acupuncture, sham acupuncture, no treatment control, or visitation control (office visits only without treatment). This study found a significant decrease in the number of patients who had “improved” symptoms (greater than 50% reduction in pain scores) with true acupuncture compared with controls.⁶¹ There is also some evidence that acupuncture may be more beneficial after osteopathic manipulation.⁶² A larger study of a similar design would certainly be beneficial in securing acupuncture’s role in the treatment of dysmenorrhea.

The World Health Organization lists primary dysmenorrhea as one of the indications “for which acupuncture has been proved—through controlled trials—to be an effective treatment.”⁶³ Dysmenorrhea was also on the National Institute of Health’s 1997 list of indications for which acupuncture was deemed potentially useful.⁶⁴

Acupressure

Acupressure has an advantage over acupuncture in that it can be performed on oneself, or with simple devices, and is therefore practically and financially more accessible to greater numbers of women with primary dysmenorrhea.

A 2010 review of randomized controlled trials of acupressure alone as treatment for primary dysmenorrhea, trials that used outcome measures of pain relief and adverse effects, found four that met inclusion criteria (total n = 458; range, 61–216). Although considerable deficits were noted

in descriptions of the randomization and allocation concealment methods, acupressure treatments did seem to bring about an overall significant reduction in menstrual pain.⁶⁵ The acupressure points used varied in each study. One study that showed benefit used a “cotton Lycra panty brief with a fixed number of lower abdominal and lower back latex foam ‘acupads’ that provide pressure” on specific acupressure points and that was worn for as long as comfortable.⁶⁶ The 2011 Cochrane Review of acupuncture and acupressure for primary dysmenorrhea also included four acupressure studies (n = 271).⁵⁸ Meta-analysis of these studies showed a significant decrease in pain with acupressure compared with placebo. Two of the four studies in this review used auricular acupressure,^{67,68} which may decrease the accessibility of treatment.

Simple regimens described have used the acupressure points spleen 6 (SP6) and large intestine 4 (LI4).^{69,70} Figs. 57.1 and 57.2 illustrate the locations of these points. Consider alternating between 6 seconds of pressure and 2 seconds off, for a total of approximately 5 minutes. Pressure should initially be relatively light (just shy of “really hurting”) but increase as the treatment continues. Work on each point on both sides of the body for a total treatment time of approximately 20 minutes. To decrease the treatment time required, if performing on oneself, consider acupressure on the right SP6 with the left hand while pressing on the left LI4 with the right hand for 5 minutes and then reversing for another 5 minutes.

Biomechanical Therapy

Spinal Manipulation Therapy

Therapies such as osteopathic or chiropractic manipulation of the spine may increase spinal mobility and blood flow to the pelvis and lead to improvement in symptoms of dysmenorrhea. A 2006 Cochrane Review concluded that spinal manipulation therapy showed no benefit over sham manipulation in improvement of symptoms of dysmenorrhea, although both interventions decreased pain.⁶⁵ The investigators acknowledged, however, that significant challenges exist with the control arm in such studies in that, similar to acupuncture, sham manipulation may actually have some clinical benefit.⁷¹ One of the studies included in

the review also measured pretreatment and posttreatment serum levels of a prostaglandin F_{2α} metabolite. Both pain and the metabolite were decreased in both spinal manipulation therapy and sham manipulation groups.⁷² This finding may indicate that spinal manipulative therapies do indeed have a role in the treatment of dysmenorrhea, but the evidence is challenged by the inability to find a true placebo.

FIG. 57.1 Spleen 6 (Sanyinjiao): Four finger widths superior to the prominence of the medial malleolus posterior to the medial margin of the tibia. When a patient is experiencing dysmenorrhea, the point may be very tender.

Surgery

Laparoscopic presacral neurectomy and laparoscopic uterine nerve ablation (LUNA) are surgical approaches to relieving dysmenorrhea. A 2010 update of a 2005 Cochrane Review found two studies with a total of

68 women that showed decreased menstrual pain after LUNA compared with diagnostic laparoscopy at 12 months, but not at 6 months, postoperatively. A third trial in the review found that laparoscopic presacral neurectomy resulted in significantly better relief scores compared with LUNA at 12 months, but not at 3 months, after surgery.⁷³

Therapies to Consider

Aromatherapy with Massage

A study of 57 Korean college women with dysmenorrhea compared abdominal massage with aromatherapy (a mixture of two drops of lavender, one drop of clary sage, and one drop of rose in 5 mL of almond oil), abdominal massage with almond oil only, and no intervention. The aromatherapy group showed a significant decrease in menstrual discomfort based on scoring using a visual analogue scale compared with massage alone or no treatment. Massages in the study took place for approximately 15 minutes daily for 1 week before the start of menses. No side effects were reported.⁷⁴

FIG. 57.2 Large intestine 4 (Hegu): On the dorsum of the hand midway between the first and second metacarpals at the level of the midpoint of the shaft of the second metacarpal. When a patient is experiencing dysmenorrhea, the point may be very tender.

Aromatherapy Massage for Dysmenorrhea

Use slow, smooth, and continuous strokes with mild to moderate pressure and a mixture of lavender, clary sage, and rose oils in almond oil (see previous section). The strokes should start with the masseur's left hand on top of the right in the right lower quadrant of the abdomen, go up to the ribs, and then across the abdomen to the left lower quadrant. The masseur can then provide gentle kneading of the left and right lower abdomen, followed by stroking across the abdomen. This sequence can be repeated for a total of 15 minutes and performed daily for 1 week before the expected onset of menses.

Prevention Prescription

- Maintain a healthy weight.
- Follow an antiinflammatory diet.
- Participate in regular, moderate-intensity aerobic exercise.
- Avoid use of tobacco.
- Avoid alcohol in excess.
- Employ effective stress management techniques.

Therapeutic Review

Exercise

- The benefits of exercise on stress reduction and maintenance of a healthy weight may reduce risk factors for dysmenorrhea. 

Nutrition

- Diets rich in omega-3 fatty acids can reduce menstrual pain. Supplement with 1500–2000 mg daily of docosahexaenoic acid and eicosapentaenoic acid. Through diet, omega-3 fatty acids can be obtained with two to three servings of cold-water fish weekly and other, plant-based sources. 

Supplements

- Magnesium (glycinate, gluconate, or chloride): 600 mg daily, decreased if diarrhea develops. Use with caution in patients with kidney disease. 
- Vitamin B6 (pyridoxine): 100 mg daily (may work better with magnesium) 
- Vitamin B1 (thiamine): 100 mg daily for 90 days, or longer if symptoms recur after cessation 
- Vitamin E: 400 units daily 

Botanicals

- French maritime pine bark extract/Pycnogenol: 30 mg twice daily. The effect may last for at least 1 month after cessation. 
- Fennel: 30 drops of extract at the onset of menses, then every 6 hours for the first 3 days of menses. Avoid during pregnancy or lactation. 
- SCA (saffron, celery, and anise, by Gol Daro Herbal Medicine): 500 mg three times daily for 3 days, starting with onset of pain or bleeding. 
- Willow bark extract: 240 mg daily of salicin in divided doses, starting on the day before expected symptoms. 
- Cramp bark and black haw: 2–3 mL of a tincture made in 1:3 proportion every 2 hours or as needed; or 4–8 mL of fluid extract (1:1) three or four times daily; or simmer one tablespoon of bark in 12 oz of water for 15 minutes, one-third cup consumed every 2–3 hours as needed. 
- Other herbs per [Table 57.2](#). 

Pharmaceuticals

- Nonsteroidal antiinflammatory drugs such as ibuprofen, 400–600 mg with food every 6 hours, starting the day before symptoms expected to occur until symptoms cease 
- Combined contraceptive pills 

- Levonorgestrel-containing intrauterine device  _{C 2}

Mind-Body Therapy

- Consider counseling or health psychology referral for relaxation techniques, biofeedback, or pain management training, for example, if determined relevant given the individual's history.  _{C 1}

Bioenergetic Therapy

- Use a heating pad or microwavable bean bag on the low back or abdomen for up to 8–12 hours.  _{B 1}
- Consider purchasing a magnet therapy device (e.g., mn8; see [Key Web Resources](#)).  _{B 1}
- Consider using a transcutaneous electrical nerve stimulation unit.  _{B 2}
- Consider acupuncture.  _{B 2}
- Consider acupressure.  _{B 1}

Biomechanical Therapy

- Consider spinal manipulation therapy (chiropractic or osteopathic treatment).  _{B 2}
- As a last resort, laparoscopic presacral neurectomy may be more effective than laparoscopic uterine nerve ablation.  _{B 3}

Other Therapies to Consider

- Aromatherapy with abdominal massage using a mixture of two drops of lavender, one drop of clary sage, and one drop of rose in 5 mL of almond oil  _{B 1}

CHAPTER 58

Uterine Fibroids (Leiomyomata)

Allan Warshowsky, MD, FACOG, ABIHM

Pathophysiology

Prevalence and Etiology of Uterine Fibroids

Uterine fibroids affect 5.4%–77% of women, depending on the method of diagnosis.¹ Fibroid tumors can be small and difficult to feel, especially in obese women. These benign tumors have been known to grow to the size of a watermelon. Most gynecologists do not consider fibroid tumors to be a surgical problem until they reach the size of a 12-week pregnancy. At that size, it becomes difficult to feel small ovarian tumors.

Ultrasonography and other imaging techniques make size less of a concern. Now, larger fibroid tumors allow for evaluation of ovaries through sonography, magnetic resonance imaging (MRI), and computed tomography (CT) scan. Reasons for considering surgery include symptoms such as menorrhagia and dysmenorrhea. Historically, hysterectomy has been the procedure of choice for patients with large fibroid tumors. Approximately 300,000 hysterectomies are performed per year for these benign tumors. Hysterectomy is an invasive procedure; in 1975, 1700 deaths occurred among 787,000 hysterectomies performed.² More recent studies have confirmed the morbidity of these invasive procedures.^{3,4} Conventional medicine has little else to offer other than a “watch and wait” attitude to women who suffer from small fibroids. However, if these small fibroids are approached from an integrative holistic perspective when they are initially observed, much of the disability and invasive surgical procedures can be avoided.

The second edition of the American College of Obstetrics and Gynecology's *Guideline for Women's Health Care* suggests the following: “As benign neoplasms, uterine leiomyomata (fibroids) usually require

treatment only when they cause symptoms.”⁵ An integrative, holistic approach that eliminates symptoms and stops the growth of these benign fibroid tumors can help women to avoid invasive surgery and disability.

Hormonal Changes in the Normal Ovulatory Menstrual Cycle

The healthy menstrual cycle is a marvel. In the first part of the well-orchestrated cycle, follicular cells of the ovary produce estradiol. This follicular phase lasts from 7 to 21 days. During this part of the cycle, follicle-stimulating hormone (FSH) and luteinizing hormone (LH) are produced and secreted by the anterior pituitary gland in the brain.

The necessary midfollicular phase peak of estradiol affects an LH surge during this part of the cycle. Ovulation occurs after the LH surge. Only after ovulation is progesterone produced and secreted by the corpus luteum of the ovary.

LH and FSH are in an inhibitory feedback loop relationship with the main ovarian hormone, estradiol. The anterior pituitary gland is also under the control of the hypothalamus through the secretion of gonadotropin-releasing hormone (GnRH). The limbic system, which contains the amygdala and hippocampus, encircles the hypothalamus and pituitary gland and is the known repository of emotions in the body. The limbic system and thus our emotions and perceptions affect the production and secretion of GnRH. The physiology of this is not clear, but all clinicians know that women become menopausal after a significant stressor in their lives.

We must also consider the association of ovarian hormones with the thyroid and adrenal glands. Alterations of thyroid function are invariably associated with menstrual irregularities. Low progesterone-to-estradiol (P/E_2) ratios are associated with reduced conversion of less active thyroxin (T_4) to more active triiodothyronine (T_3). Therefore, hypothyroidism with normal levels of T_4 and low levels of T_3 can be an indicator of sex hormone imbalance and estrogen dominance. Adrenal gland function also affects sex hormone production and metabolism and must be evaluated along with the thyroid and ovarian hormones.

The origin of fibroids is not well understood. Some evidence indicates that chromosomal abnormalities may play a role. Chromosomal translocations, deletions, inversions, and breakpoints have been shown to be associated with familial patterns of fibroid growth.⁶ The fibroids in

these affected families tend to be quite large.

The incidence of uterine fibroids seems to be higher in African-American, obese, nonsmoking, and perimenopausal women than in other women. Fibroid tumors are associated with high estrogen levels or estrogen dominance. Obesity and the perimenopausal state are often associated with higher estrogen levels. Studies have shown that estrogen levels are actually higher in perimenopausal women. With obesity, adipocytes act as endocrine organs that produce estrone, another strong estrogen. The inflammatory mediators interleukin-2 (IL-2), IL-6, tumor necrosis factor-alpha (TNF-alpha), and leukotriene B₄ (LTB₄) are also produced in adipocytes and contribute to fibroid formation.⁷

Vitamin D research has begun to shed light on the higher incidence of fibroids in African-American and other dark-skinned women.⁸ Low vitamin D (measured as 25-hydroxyvitamin D₃) levels are associated with increased inflammatory cytokines and have been shown to be associated with higher incidences of epithelial cancers such as those of the breast, colon, and prostate.⁹ Vitamin D is necessary for healthy cell apoptosis, or regulated cell death, and also has profound effects on glucose metabolism. Later discussion explains how unhealthy glucose metabolism can contribute to fibroid growth through the development of insulin resistance.¹⁰ The form of vitamin that circulates to all the cells of the body is 25-hydroxyvitamin D₃, and it is a good measure of the total body reserve of vitamin D₃. The optimal range of 25-hydroxyvitamin D₃ is between 40 and 80 ng/mL.¹¹ Low levels are treated with vitamin D₃ in the range of 50,000 units/week for 12 weeks, at which time the measurement should be repeated.¹²

Studies by Dr. Elizabeth Stewart et al.¹³ in Boston support the connection between systemic inflammation and fibroid growth. She showed that various growth factors, such as fibroblast growth factor, vascular endothelial growth factor, and transforming growth factor, which are concentrated in fibroid cells, are responsive to inflammatory mediators. These stimulated growth factors increase blood vessel growth or angiogenesis in the fibroid and thereby stimulate and support growth. All successful tumors, whether benign or malignant, increase their own blood supply through this process of angiogenesis and enable growth. Controlling vascularity with antiangiogenesis factors, as shown by the work of Dr. Judah Folkman,¹⁴ can reduce the growth of the tumor or fibroid by decreasing its blood supply and supporting shrinkage.

The “gut connection” to fibroid growth concerns bacterial imbalance or intestinal dysbiosis and a “leaky gut.” A dysbiotic intestinal environment

produces gut-associated inflammatory mediators. These inflammatory mediators include IL-2, IL-6, TNF-alpha, and other leukotrienes and cytokines. They surround the pelvis, where nature's fertilizer, estradiol, stimulates the growth of atypical cells that develop into autonomously growing leiomyomata or fibroids. Intestinal dysbiosis with associated bacterial and yeast overgrowth also contributes to estrogen dominance through the estrogenic effects of bacterial toxins and yeast mycotoxins. Associated constipation can also increase serum estrogens by breaking down the estrogen-glucuronic acid bond by the action of the enzyme beta-glucuronidase, which is produced in this dysbiotic environment.¹⁵

Estrogen Dominance

Estrogen dominance is a term coined by the late Dr. John Lee ([Fig. 58.1](#)).¹⁶ It applies to conditions associated with stronger estrogen effects than can be balanced with existing progesterone. Estrogen dominance can also manifest through imbalanced estrogen metabolism, as discussed later. Fibroids are just one condition associated with estrogen dominance ([Table 58.1](#)). Others are as follows:

- Autoimmune diseases: Hashimoto thyroiditis, systemic lupus erythematosus, rheumatoid arthritis, multiple sclerosis, ulcerative colitis, scleroderma, Sjögren syndrome, and others
- Fibrocystic breast problems
- Gallbladder disease
- Cervical dysplasias and other hormone-dependent cancers (breast, uterine, and ovarian)
- Endometriosis
- Infertility

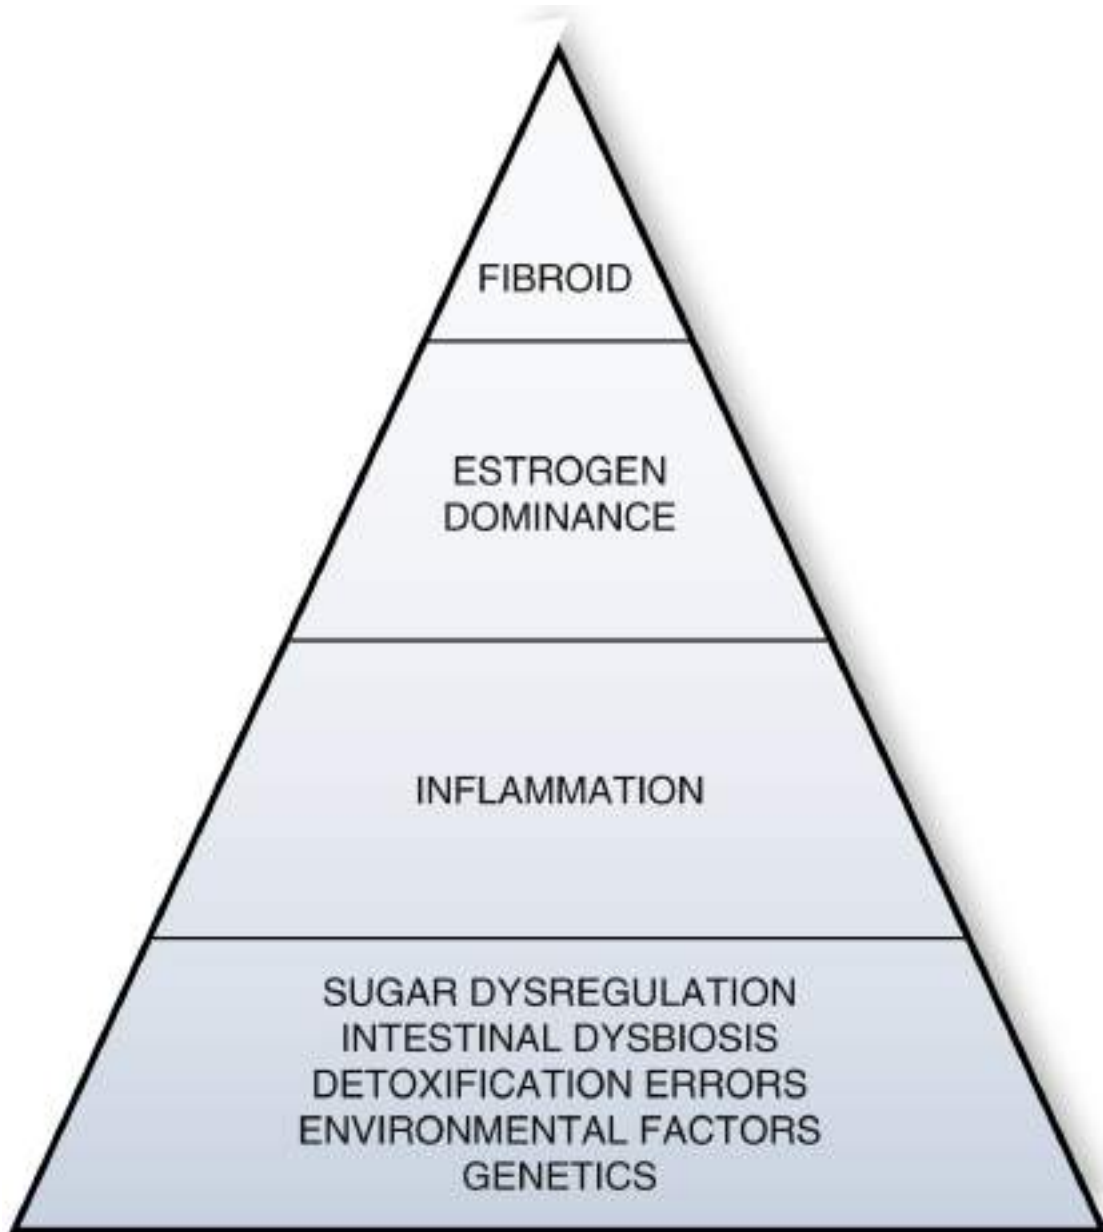

FIG. 58.1 The fibroid that can be felt and measured is the physical manifestation of estrogen dominance and inflammation. Estrogen dominance and inflammation in the body are created and supported by underlying sugar dysregulation, intestinal dysbiosis, detoxification errors, environmental factors, and genetics.

- Menstrual irregularities of all kinds
- Polycystic ovary syndrome
- Premenstrual syndrome

Effects of Diet, Digestion, Absorption, and the Intestinal

Environment on Hormone Balance

Hormone imbalance and estrogen dominance are often associated with intestinal dysbiosis. Intestinal dysbiosis designates an unhealthy gut environment often associated with increased intestinal permeability or a “leaky gut.” Signs and symptoms of dysbiosis include digestive issues, such as bad breath, body odor, bloating, gas, nausea, and constipation. The concept of a leaky gut describes a condition in which, instead of normal protein digestion into amino acids that are actively transported through the intestinal cells, large peptides and proteins are absorbed intact through or in between intestinal mucosa cells in the intestinal wall and stimulate inflammatory reactions due to an overstimulated and out-of-balance immune system.

Intestinal dysbiosis can be caused by antacid abuse and resultant hypochlorhydria, antibiotics, chronic stress, eating practices that do not enhance digestion and absorption (“eating on the run”), intestinal infection, and birth control pills.

Intestinal dysbiosis can contribute to estrogen dominance through several mechanisms. Beta-glucuronidase is an enzyme produced by pathogenic gut bacteria.¹⁷ It cleaves the glucuronic acid molecule conjugated to estradiol that would enable its excretion and thus allows the estradiol to be reabsorbed into the body. The result is an elevation of total body estrogen that puts more stress on the liver and its detoxification capacities. Pathogenic intestinal bacteria and pathogenic yeasts can also produce bacterial toxins and mycotoxins having strong estrogenic effects. Concomitant inflammation can increase estrogen production and the growth factors that reside in the fibroid tissue thus supporting angiogenesis.

TABLE 58.1

Factors That Promote Estrogen Dominance and Subsequent Fibroid Growth

Poor Dietary Choices*	Low-isoflavone, low-fiber foods (constipation)
	High glycemic index foods
	Hormone-rich meats, poultry, and dairy
	Excessive inflammation—causing saturated fats
	Excessive gluten grains
Intestinal Dysbiosis	High beta-glucuronidase levels [‡]
	Estrogen-like mycotoxins
	Intestinal parasites
Sugar Dysregulation	Insulin resistance

	Low sex hormone-binding globulin
	Anovulation with low progesterone-to-estradiol ratios
Environmental Issues [‡]	Xenobiotics
	Polychlorinated biphenyls, dioxins, heavy metals
	Birth control pills and hormone replacement therapy [§]
	Violence and sex effects on the limbic system
Stress	High cortisol levels contribute to low progesterone
Reduced Estrogen Detoxification	Leading to estrogen dominance

[‡] Data from Goldin BR, Adlercreutz H, Gorbach SL, et al. Estrogen excretion patterns and plasma levels in vegetarian and omnivorous women. *N Engl J Med*. 1982;307:1542–1547.

[†] Data from Minton JP, Walaszek Z, Hanausek-Walaszek M, et al. β -Glucuronidase levels in patients with fibrocystic breast disease. *Breast Cancer Res Treat*. 1986;8:217–222.

[‡] Data from Wolff MS, Toniolo PG, Lee EW, et al. Blood levels of organochlorine residues and risk of breast cancer. *J Natl Cancer Inst*. 1993;85:648–652.

[§] Data from Gruber CJ, Tschugguel W, Schneeberger C, et al. Production and actions of estrogens. *N Engl J Med*. 2002;346:340.

Intestinal dysbiosis can be diagnosed with the proprietary Comprehensive Digestive Stool Analysis (Genova Diagnostics; see [Key Web Resources](#)). Elevations of the organic acid indican can indicate poor protein digestion and suggest intestinal dysbiosis (Organix test; Genova, see [Key Web Resources](#)). Greater intestinal permeability is evaluated using the lactulose-mannitol test. In this test, the variable absorption of the two sugars lactulose and mannitol determines whether permeability in the intestines is increased. The larger sugar lactulose should not find its way into the urine, unlike the smaller sugar mannitol. Finding abnormal ratios of these two sugars in the urine after oral ingestion indicates increased intestinal permeability or dysbiosis.

Intestinal dysbiosis is treated with an intestinal restoration program such as the 4-R program described by Jeffrey Bland.¹⁸ The four Rs are as follows:

- Remove irritants affecting the gut. This includes microorganisms, food allergens, and other toxins.
- Replace betaine hydrochloride, enzymes, bile salts, and fiber.
- Reinoculate with prebiotics (inulin) and probiotics.
- Repair, which is done with gut restorative nutrients, including zinc, glutamine, *N*-acetylcysteine, *N*-acetylglucosamine, *Boswellia*, cat's claw, licorice root, and curcumin.

For further information, see [Chapter 86](#).

For a woman to have symptomatic fibroids and not to have functional intestinal dysfunction and associated dysbiosis would be unusual and

uncommon.

Effects of Insulin Resistance on Hormone Balance and Estrogen Dominance

Elevations of insulin and insulin-like growth factor-I can also contribute to estrogen dominance and fibroid growth. Metabolic syndrome (prediabetes) is a disorder of elevated insulin related to increasing insulin resistance.¹⁹ The syndrome is defined by a constellation of signs and symptoms including abdominal obesity with a waist-to-hip ratio greater than 0.8:1 (waist circumference larger than 35 inches in women), a high level of triglycerides with a low level of high-density lipoprotein cholesterol and a high level of low-density lipoprotein cholesterol, hypertension, impaired glucose tolerance, increasing hypoglycemia, and a higher incidence of adult-onset diabetes. Metabolic syndrome is associated with these laboratory markers:

- Elevation of fasting insulin and blood glucose
- Elevation of fasting fructosamine
- High hemoglobin A1c measurement (greater than 5.6%)
- Increased inflammatory mediators: IL-2, IL-6, TNF-alpha, LTB₄
- Increased levels of the prostaglandin-2 series thus increasing inflammation
- Strong estrogen produced in adipocytes as estrone (E₁)
- Estrogen dominance, most apparent in polycystic ovary syndrome, which is highly associated with insulin resistance
- Decreased sex hormone-binding globulin (SHBG) increases the amount of free estradiol available at the cellular level²⁰
- Increased aromatase enzyme activity, increasing conversion of testosterone and androstenedione (testosterone precursor) to estradiol and estrone, and increasing estrogen dominance

Insulin sensitivity can be improved by various methods, all thoroughly discussed in [Chapter 32](#).

Liver Detoxification and Estrogen Dominance

Metabolic detoxification consists of three phases that need to be in balance. In phase one, lipid-soluble substances—toxins, hormones, or drugs—are transformed into intermediate substances, which are more water soluble, by the cytochrome P450 set of enzymes.²¹ This enzyme system can be upregulated or downregulated by various drugs, stressors (e.g., alcohol, cigarette smoke, smoke from charred meat), and herbs. An

example in the world of estrogen dominance and uterine fibroids is the effect of gluten grains on estrogen metabolism. Gluten, the active protein in wheat, rye, and barley, reduces the cytochrome P450 isoenzyme 3A4 and leads to reduced estrogen metabolism and subsequent estrogen dominance.

The intermediate substances that are formed in phase one must be made more water soluble, enabling excretion from the body. In phase two of the detoxification process, these intermediates are conjugated with amino acids and peptides such as glucuronic acid, glutathione, and glycine, or they undergo conjugation processes such as methylation, sulfation, acetylation, and sulfoxidation.²² These now water-soluble substances can be excreted in stool, urine, or sweat or as water vapor through the lungs.

In phase three, the now ready for excretion estradiol–glucuronic acid molecule previously discussed is eliminated through the bile into the intestines. This molecule is cleaved in the dysbiotic gut by elevated amounts of the enzyme beta-glucuronidase, which is produced by imbalanced gut bacteria. This allows estradiol to be reabsorbed into the circulation.

Phase one and phase two detoxification errors cannot be determined by conventional aspartate aminotransferase and alanine aminotransferase (AST/ALT liver function tests) enzyme levels, which are indicators only of hepatocyte breakdown (see [Chapter 106](#)). More integrative and functional assessments of detoxification can be made through organic acid testing or functional detoxification tests that evaluate the phase one cytochrome P450 enzyme system and phase two conjugation factors. Estrogen metabolites and their intermediaries consist of catechol (hydroxy) estrogens and methyl-estrogens. The anticarcinogenic estrogen modulator 2-hydroxyestrone (2OH-E₁) comes from naturally produced ovarian estrogens; high levels of this substance because 2-methoxyestrone reduce the risk for breast cancer. Higher amounts of 4-hydroxyestrone (4OH-E₁) occur with metabolism of conjugated estrogens (Premarin) to form DNA-damaging quinones.

Recent studies confirm that the 2-methoxyestrogens are protective against hormone-dependent cancers while the 4- and 16-hydroxyestrogens are most carcinogenic.²³

Epigallocatechin gallate (the main polyphenol in green tea) and other antioxidants, such as vitamins A, C, and E; selenium; *N*-acetylcysteine; and lipoic acid, convert damaging quinones into mercapturates. This process occurs through the production of glutathione. The 16alpha-

hydroxyestrone (16OH-E₁) forms a very strong bond with the estrogen receptor, is a strong estrogen, and has carcinogenic potential. These estrogen metabolites are not all good or bad. Like everything else in nature, they need to be in balance.

Appropriate levels of 16alpha-hydroxyestrone support good bone density.²⁴ The ratio of the three hydroxyestrogens and their methylated end products, which can be measured in urine or blood (Genova Diagnostics), can help evaluate risk in estrogen dominance conditions. In menstruating women, the ratio of 2OH-E₁ to 16OH-E₁ should be evaluated during the luteal (late) phase of the cycle. The following factors increase either this ratio or the level of 2OH-E₁:

- A diet rich in cooked cruciferous vegetables (broccoli, Brussels sprouts, kale, cabbage, cauliflower, etc.)
- Indole-3-carbinol (I-3-C) from cruciferous vegetables (broccoli, Brussels sprouts, cabbage, kale): 200–800 mg/day
- Diindolylmethane (I-3-C activated by stomach acid), used alone or in conjunction with I-3-C
- Epigallocatechin gallate (green tea polyphenol)
- Isoflavones, including soy, flaxseed, and kudzu²⁵
- Omega-3 fatty acids
- Vigorous exercise, a minimum of 30 minutes three times/week

The ratio of 2OH-E₁ to 16OH-E₁ can be reduced, with an increased proportion of 16OH-E₁, by the following conditions:

- Obesity
- Hypothyroidism
- Xenoestrogens: any estrogenic substances, including dioxins and polychlorinated biphenyls
- Cimetidine (Tagamet) and other drugs that interfere with the cytochrome P450 system²⁶
- Estriol: Although in most people, estriol is a metabolic end product, concern exists that as a stereoisomer it can revert to the 16alphaOH-E₁ from which it was formed; this is more of a concern when estriol is prescribed as part of a bioidentical hormone replacement therapy program. Regular monitoring of hormone levels can prevent problems from these imbalances.

Most of the studies of hormone imbalance and fibroid tumors of the uterus have concerned themselves with estrogen dominance, although mifepristone studies create some controversy and doubt.²⁸ Mifepristone is also known as RU-486, the “abortion pill.” It functions as a progesterone receptor antagonist. Long-term use of mifepristone has

been associated with fibroid regression.²⁸ As a progesterone receptor antagonist, mifepristone's action would suggest that progesterone also stimulates fibroid growth. The answer may not be that simple because progesterone also increases blood vessel support in the endometrium in anticipation of a fertilized egg. My opinion is that some fibroids may take advantage of the increased progesterone-supported blood supply and increase in size because of it. Studies also show that there are two isoforms of progesterone receptors: A and B (PRA and PRB). If PRA is stimulated, there will be increased inflammation. Stimulating PRB will reduce inflammation.²⁹

The negative effects associated with long-term mifepristone use are bone loss and endometrial hyperplasia, conditions indicating that more complicated mechanisms concerning PRA and PRB are at work.

Determining Whether a Fibroid Has Malignant Potential

The malignant potential (sarcomatous change) of fibroids or leiomyomata is less than 1%. Recent complications of minimally invasive surgery for fibroid tumors have created controversy related to the malignant fibroid and the process of intraabdominal morcellation of the fibroids.

The American College of Obstetricians and Gynecologists (ACOG) estimates of malignant fibroids are approximately 1/325 fibroid tumors. The morcellation procedure allows for removal of large fibroids through small incisions, but it does increase the risk for spreading malignant cells throughout the abdominal cavity. The results of this can be disastrous, causing a rapidly growing, widely disseminated malignant sarcoma.^{31,32}

Whether a fibroid changes from benign to malignant or is malignant to begin with is not well established. One sign that can indicate a malignant fibroid or leiomyosarcoma is rapid growth. Unfortunately, the only conventional way to confirm malignancy is to remove the fibroid and examine a sample for the number of mitotic events per high-power field; more than 20 mitoses per high-power field would indicate a sarcoma. [Table 58.2](#) lists tests that should be considered in evaluating a patient with fibroid tumors of the uterus.

Integrative Therapy

Nutrition

The patient should begin a hormone-balancing diet that involves foods with low inflammation effects, low acidity, and low glycemic load.

Foods That Increase Estrogen Dominance

Acidic and inflammatory foods, such as commercial red meats, poultry, and dairy products, are sources of arachidonic acid, which increases inflammatory prostaglandins and other inflammatory mediators that help to support fibroid growth through the process of angiogenesis. Avoiding commercial meat products also reduces exposure to added hormones and pesticide residues in these products.³³ Small amounts of organic grass-fed meats can be added back as inflammation subsides (see [Chapter 88](#)).

Sweets and other foods with a high glycemic index are potentially stressful and can increase insulin resistance, increase estrogen dominance, and support fibroid growth. Eating a breakfast that contains good-quality protein, fats, and carbohydrates in combination is imperative to avoid hypoglycemic stress-induced cortisol and norepinephrine elevations, which deplete lean muscle and increase the tendency for insulin resistance through gluconeogenesis (see [Chapter 87](#)).

Gluten grains, especially wheat, rye, barley, and spelt, contain genetically engineered gluten that is much stronger than that found in the more ancient gluten grains such as spelt. These newer grains can increase estrogens by inhibition of the cytochrome P450 3A4 enzyme system and can also affect thyroid hormones. Because all the wheat in this country is now genetically modified to be glyphosate ready (Roundup) and all the corn and soy in this country are now genetically modified to be 2,4-D-ready (a component of Agent Orange), it would be best to avoid these when trying to lower inflammation.³⁴

Alcohol is not a problem if it is consumed in moderation. Studies show that women consuming more than five alcoholic drinks per week have a higher risk for breast cancer. This increase probably results from the effect of alcohol on the detoxification of estrogens. Organic coffee in moderation (1–2 cups per day) is also safe. Artificial ingredients, colorings, flavorings, and preservatives should be eliminated. Margarines and other sources of trans-fatty acids and hydrogenated oils are also unhealthy and must be avoided.

TABLE 58.2**Tests to Consider for Evaluation of a Patient With Fibroid Tumors of the Uterus**

25-Hydroxyvitamin D measurement [‡]	Low levels increase fibroid growth by several mechanisms (see text)
Vitamin A measurement [†]	Low levels have been shown to increase menorrhagia
Iron or total iron-binding capacity measurement, ferritin measurement	Low iron stores reduce myometrial contractility and increase menstrual blood loss
Progesterone/estradiol ratio (100–300:1) Luteal phase progesterone measurement	Low luteal phase progesterone level supports estrogen dominance and fibroid growth
Thyroid function testing	Hypothyroidism is associated with menstrual dysfunction
<i>MTHFR</i> polymorphism	35% weakness in methylation, increased estrogen dominance
Comprehensive digestive stool analysis	Intestinal dysbiosis is a cause of estrogen dominance through several mechanisms (see text)
Phase one and phase two detoxification evaluation	Unhealthy estrogen metabolism contributes to estrogen dominance
Transvaginal and abdominal ultrasonography	To determine the sizes and locations of fibroids and rule out ovarian tumors
Testing for celiac disease (antigliadin antibodies)	Gluten grain sensitivity is common in fibroid tumor sufferers and can lead to further estrogen dominance

[‡] Data from Chiu KC, Chu A, Vay LWG, et al. Hypovitaminosis D is associated with insulin resistance and beta cell dysfunction. *Am J Clin Nutr.* 2004;79:820–825.

[†] Data from Lithgow DM, Politzer WM. Vitamin A in the treatment of menorrhagia. *S Afr Med J.* 1977;51:191–199.

Foods That Reduce Estrogen Dominance

Deep sea, cold-water fish, such as wild Pacific salmon, sardines, mackerel, and cod, have large quantities of omega-3 oils (eicosapentaenoic acid [EPA] and docosahexaenoic acid [DHA]).³⁵

Because heavy metals, such as mercury, contribute to estrogen dominance, I recommend eating fish with lower levels of mercury. These are fish at the lower end of the food chain. The larger game fish, such as swordfish, tuna, and bass, concentrate the contaminants from eating smaller fish. Krill, small crustaceans, are a good source of noncontaminated EPA and DHA. Algae sources of DHA are also available.

Seeds and nuts, especially flaxseed, hemp seed, and chia seed, contain isoflavones.³⁶ These are hormone-balancing. I recommend 2–4 tablespoons per day added to a yellow pea-rice protein powder shake first thing in the morning. Coconut oil (1 tbs) would be another good addition to this morning shake.

Other seeds and nuts, such as pumpkin seeds, sunflower seeds, and walnuts, are also good sources of omega-3 oils.³⁷

Cooked cruciferous vegetables, such as broccoli, Brussels sprouts, cabbage, and cauliflower, support healthy estrogen metabolism (Fig.

58.2). Legumes, such as adzuki beans, peas, lentils, and edamame, all have hormone-modulating flavonoids and can safely be eaten.³⁸

A head of cabbage contains approximately 1200 mg of I-3-C. Eating one-fourth of a cabbage daily would provide 300 mg of I-3-C daily. Cabbage should be cooked and not raw to avoid goitrogens.

I have been consistently impressed by the reduction of symptoms related to estrogen dominance by the elimination of milk casein, high-glycemic index carbohydrates, and gluten grains. The symptoms that seem to be most affected are gastrointestinal symptoms, headache, dermatologic rashes, fatigue, insomnia, and mood issues.

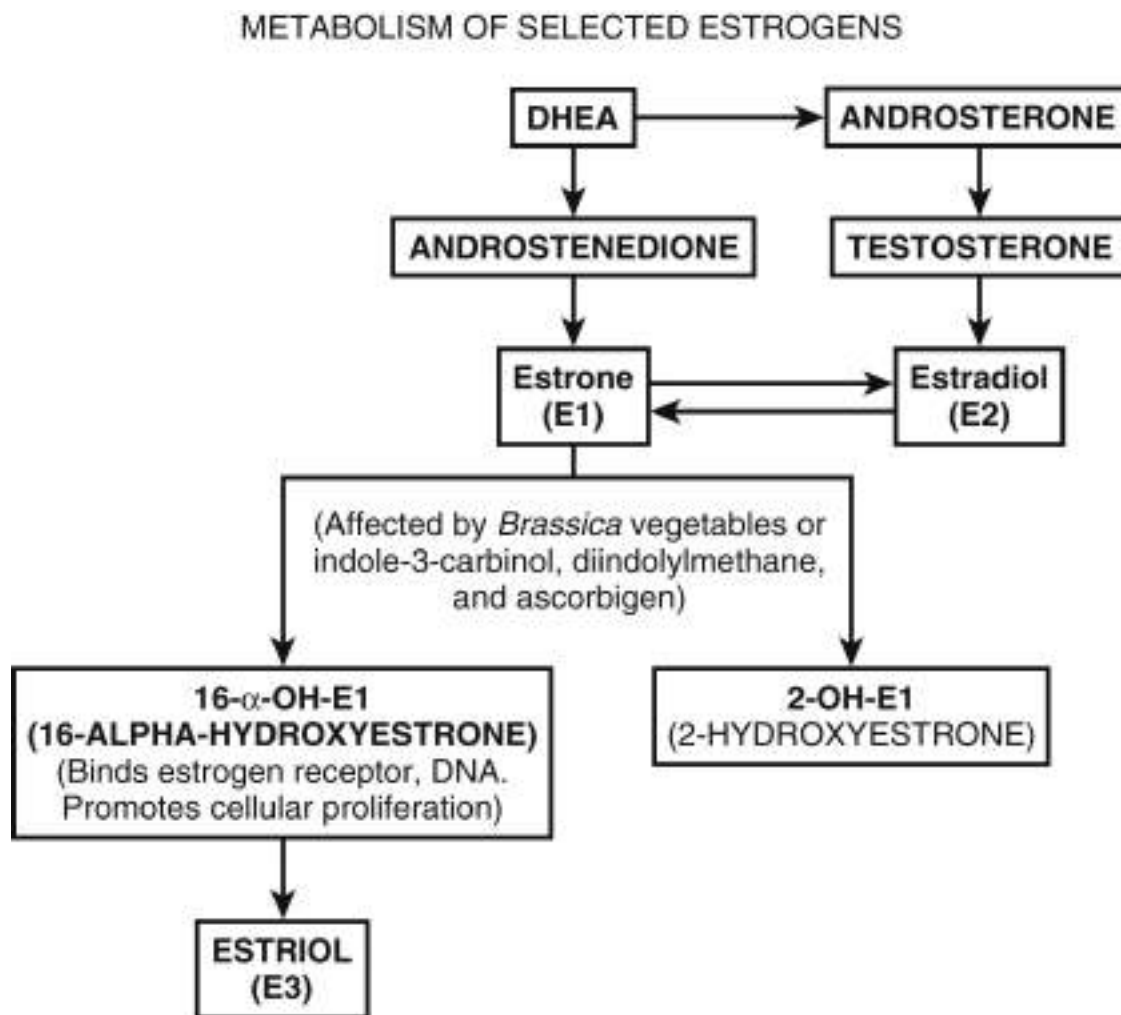

FIG. 58.2 Metabolism of selected estrogens. DHEA, dehydroepiandrosterone.

Lifestyle

Exercise

Aerobic exercise consumes oxygen and helps “burn” carbohydrates (glucose). Oxygen-consuming exercises are exemplified by running, fast walking, and swimming. Because carbohydrates are consumed during aerobic exercise, this form of exercise is associated with improvements in insulin resistance and sugar use.

Anaerobic exercise classically uses fats (triglycerides) as an energy source. Weight trainers consume medium-chain triglycerides during their workouts to enhance energy and “fat burning.” Weight training also helps stabilize hormones such as growth hormone and testosterone. Because fat cells (adipocytes) are hormone factories that produce inflammatory mediators and estrone, limiting adipose tissue also reduces estrogen dominance. A regimen of 30 minutes of regular exercise three times per week has also been shown to lower the incidences of breast and colon cancer.

Botanicals

Botanical therapies can be very useful in reducing fibroid growth and decreasing fibroid symptoms.³⁹ Recent studies indicate that curcumin from the spice turmeric and green tea extracts are effective in reducing angiogenesis by supporting peroxisome proliferator-activated receptor (PPAR) activation.⁴⁰

Botanicals for Liver and Detoxification Support

Healthy estrogen metabolism must be reestablished to reverse estrogen dominance. By obtaining functional liver detoxification studies performed by laboratories such as Genova Diagnostics and Doctor’s Data, the clinician can determine in which specific aspects of the detoxification pathway the patient is lacking and provide the appropriate nutritional support. Many botanicals and nutraceuticals can be helpful in restoring and maintaining healthy detoxification.

Epigallocatechin Gallate from Green Tea

Epigallocatechin gallate reduces the DNA-damaging effects of 4OH-E₁. It may also be an antiangiogenesis factor.

Dosage

The dose is 600 mg two times/day with 60% polyphenols.

Precautions

These agents can cause insomnia if caffeine is consumed in large amounts.

Indole-3-Carbinol or the Stomach-Activated Diindolylmethane

I-3-C increases the production of estrogen-modulating 2OH-E₁.⁴¹

Dosage

The dose is 200–400 mg/day.

Precautions

I-3-C is generally free of side effects.

Milk Thistle (*Silybum marianum*)

Milk thistle is a general liver antioxidant that supports healthy detoxification and estrogen metabolism.

Dosage

The dose is 280–420 mg of milk thistle per day standardized to 70%–80% silymarin content.

Precautions

This agent is virtually devoid of negative effects.

Botanicals to Modulate Pelvic Lymphatic Drainage

These botanical formulas are used in combination to modulate pelvic lymphatic drainage. Scudder's alterative (a combination herbal product containing corydalis, alder root, mayapple root, figwort, and yellow dock) modulates cellular metabolism. Echinacea/red root compound modulates toxin elimination, immune system, and inflammatory mediators.

Dosage

The dose is 30 drops of Scudder's alterative combined with echinacea/red root compound as a tea twice/day for 3 months. This is followed by 2 weeks without this treatment.

Precautions

This combination of formulas has no known negative effects.

Anecdotally, the technique of dry skin brushing has also been used to support healthy lymphatic drainage.

Botanical Therapies for Specific Symptoms

Menorrhagia

Heavy menstrual bleeding (menorrhagia) due to fibroids is the symptom that brings most women to the operating room. Menorrhagia is defined as blood loss of more than 80 mL per menses. Controlling heavy bleeding, or menorrhagia, is probably the most important first step in the fibroid healing program. Severe iron deficiency anemia is one of the most common symptoms of problematic fibroids and a main reason for surgery. Combinations of botanicals that act differently within the uterus can be very effective in reducing blood loss and keeping women out of the operating room. Use of a combination of the following herbal types can significantly reduce menstrual bleeding.

Uterotonics: these include red raspberry, false unicorn root, and black cohosh.

Astringents: these include yarrow, lady's mantle, beth root, and cinnamon.

Oxytocics: I have only used shepherd's purse for its oxytocic (contracting) effect. It has a long history of use among midwives to help control postpartum bleeding.

These botanicals are also used in combination. A combination botanical preparation consisting of tinctures of a tonic such as red raspberry and an astringent such as yarrow can be used at a dose of 30 drops each twice a day for 2 weeks before the period. This protocol supports healthy uterine contractions during menses. The result is a more normal menstrual flow and nonspasmodic uterine contractions. When bleeding begins, add 30 drops of an oxytocic tincture such as shepherd's purse. The combination of all three herbal tinctures can be taken every 30 minutes for up to six doses. No scientific reason exists for using six doses as an arbitrary cutoff. I believe that if the patient is still hemorrhaging after 3 hours of using these herbs, something else needs to be considered. However, this protocol has been extremely useful in reducing menorrhagia and reversing iron deficiency anemia. Other herbs in the same categories can be substituted if the patient has a reaction to one of the herbs or if the effect is less than desired. Several botanical companies such as Gaia and Herbpharm create standardized herbal tinctures (see [Key Web Resources](#), later).

Dosage

See the preceding protocol.

Precautions

These herbs have minor gastrointestinal effects. Yarrow rarely causes rash or sun sensitivity. Shepherd's purse in large doses may interfere with thyroid function. Follow-up with thyroid function testing is suggested.

Antiinflammatory Botanicals

Inflammatory prostanoids, cytokines, and leukotrienes increase the cellular growth factors that support vascularization and neoangiogenesis of the fibroid. Specific botanicals can reduce this inflammation. Botanicals are often found in combination products, such as those containing *Boswellia* (400 mg), ginger (200 mg), turmeric (300 mg), and cayenne (50 mg) in every two tablets.

Dosage

One to two tablets are taken three times/day. The patient may take one to two tablets every 2 hours as needed.

Precautions

Taking such a combination product on an empty stomach can cause abdominal pain in sensitive individuals. These botanicals can be taken with food.

Systemic Enzymes

Elimination of excessive inflammation with potent (serratiopeptidase-containing) systemic enzyme formulations may reduce the size of fibroids by limiting vascularization of fibroids and by enzymatic myolysis of the fibroid.⁴⁴ Such systemic enzymes are Neprinol, Wobenzym, Vitalzyme, and bromelain (from pineapple stems).⁴⁵ Other preparations of proteases can also be used. Neprinol⁴⁶ has the following ingredients: SEBkinase, Peptizyme SP, serratiopeptidase, lipase, protease, amla, papain, NattoSEB, nattokinase, bromelain, rutin, coenzyme Q10, and magnesium.

Dosage

These enzyme formulations should be taken on an empty stomach to avoid action on food rather than on the protein of the fibroid. The dose is gradually built up from one tablet three times/day to 15 tablets per day in divided doses.

Precautions

As with any antiinflammatory agent taken on an empty stomach, the clinician must caution the patient about stomach pain. Such enzyme preparations must be used with caution in patients with gastritis and a history of gastric ulcer, as well as in patients who take blood thinners.

Antiangiogenesis Factors

The work by Judah Folkman⁴⁴ in cancer therapy illustrates the effect of antiangiogenesis on reducing tumor growth. The convolvulus product and other antiangiogenesis factors are used to reduce blood flow to the fibroids.⁴⁷ *Convolvulus arvensis* (bindweed) works as an antiangiogenesis factor.⁴⁸ Green tea catechins and polyphenols also have antiangiogenic effects.

Dosage

The dose of *Convolvulus arvensis* (bindweed) is two tablets three times / day, slowly increased from one tablet twice / day.

Precautions

Headaches are a side effect if the dosage is increased too rapidly. Increase slowly to avoid headaches.

Nutraceuticals

Vitamin C and the Citrus Bioflavonoids (Rutin and Hesperidin)

Vitamin C strengthens capillary desmosomes and can also be helpful in reducing menorrhagia.⁴⁹ Citrus bioflavonoids such as rutin and hesperidin enhance this vitamin C effect and are also mildly estrogenic, and as such, can have a tonic effect by reducing the effects of estrogen dominance.

Dosage

The dose is 1000–2000 mg / day, but the dosage can be increased up to 75% of bowel tolerance.

Precautions

Vitamin C has been known to cause diarrhea. This is what has been referred to as *bowel tolerance*. Reducing the dosage to 75% of the amount that causes diarrhea may be the most appropriate individualized approach. Some question exists about the use of vitamin C in patients

with a history of kidney stones.

B Vitamins

Vitamins B₁, B₂, B₃, B₅, and B₆ are important for sugar, fat, and neurotransmitter metabolism, hormone balance, and healthy cortisol production from the adrenal glands.⁵⁰ Vitamin B₃ in the form of niacinamide is also a potent antiinflammatory agent. Niacin can be used to reduce menstrual cramping often associated with fibroids.⁵¹ Other B vitamins, such as choline and inositol, support healthy liver function. Vitamins B₂, B₆, B₁₂, and folic acid support the process of methylation, which is necessary for healthy hormone metabolism and for DNA repair. Vitamins B₅ and B₆ also support adrenal function, which is important in healthy hormone balance.

Dosage

A 50-mg B-complex vitamin can supply basic vitamin B needs. Separate additional B vitamins may be necessary. The recommended dose of vitamin B₁₂ is 2000 units/day.

The dose of folic acid is 800 mcg or more per day. Doses up to 5–10 mg/day have been used for cervical dysplasias. Approximately 35% of the population is estimated to have a mutation of the *MTHFR* gene that decreases their ability to methylate. Most laboratories check for the *MTHFR* C677T and the A1298C gene mutations. I recommend this test, and if a patient is heterozygous or homozygous for the mutations, supplementation, at least in part, with methylfolate or methylcobalamin seems wise. A reasonable dose of methylfolic acid is 5 mg/day.

Methylcobalamin doses are in the 2000–5000 mcg/day range and are best as intramuscular (IM) injections or buccal lozenges.

Precautions

When high doses of folic acid are used, attention must be taken to supplying vitamin B₁₂ in addition to avoid masking the signs of pernicious anemia. Peripheral neuropathies have been reported with vitamin B₆ dosages larger than 200 mg/day. Practicing caution when

dosing and educating patients to report any tingling in their fingers and toes are important.

For treatment of menstrual cramps, consider having the patient take niacin, 100 mg twice/day throughout the month, then 100 mg every 2 hours while having cramps.

Vitamin D

Vitamin D is very important for the healthy functioning of every cell in the body. Because of fear of sun exposure and resultant skin cancer, most people use ultraviolet-B-blocking, sun protective factor (SPF) 30 or higher sunblock.⁵² This situation has created almost an epidemic of low levels of vitamin D. Measuring 25-hydroxyvitamin D levels and restoring them to at least 40 ng/dL are imperative. Investigators have estimated that 32 ng/dL will be required to prevent rickets in children. Restoration of vitamin D levels can be accomplished by using 50,000 units/week of vitamin D₂ for 12 weeks and then reassessing. Supply 600 mg/day of calcium in supplements to a patient being treated with vitamin D.⁵³

Dosage

If the 25-hydroxyvitamin D blood level is low, give 50,000 units of vitamin D₂ once a week for 12 weeks; then recheck the 25-hydroxyvitamin D level.

Precautions

As with any fat-soluble vitamin, excessive amounts of vitamin D can be toxic. Measuring blood levels again after 12 weeks of supplementation is necessary. Supplying at least 600 mg/day of calcium in the diet and 600 mg as a supplement can prevent loss of calcium from bone.

Evaluation of parathyroid hormone levels screens for hyperparathyroidism and is important before supplementing. Evidence indicates that supplementation with the other fat-soluble vitamins A, E, and K may be necessary for optimal absorption.

It has been shown in many studies that vitamin K₂ (menatetrenone) either as the MK-7 (recommended dose is 45 mcg/day) or the MK-4

(recommended dose is 45 mg/day) form aids vitamin D₃ in supporting calcium mineralization of bones. It makes good sense to use a vitamin D₃ supplement that also includes vitamin K₂.⁵⁴

Calcium D Glucarate

Calcium D glucarate reduces the activity of the enzyme beta-glucuronidase, which is produced in patients with intestinal dysbiosis. This enzyme, which is produced by dysbiotic intestinal bacteria, cleaves the glucuronic acid–estrogen bond on estrogens meant for excretion in the stool and instead reabsorbs the estrogens back into the circulation. By the action of beta-glucuronidase, estrogen dominance increases and adds more stress to the already stressed detoxification system.⁵⁵

Dosage

The dose is 500 mg twice/day.

Precautions

No precautions are reported.

Iron

Women with fibroids tend to have heavy menses, or menorrhagia, which is defined as losing more than 80 mL of blood during menstruation. This greater iron loss associated with the blood loss sets up a vicious circle.⁵⁶ Low iron levels cause weak myometrial muscle cell contraction thus contributing to more menstrual blood loss. Evaluation and treatment of low iron stores by measurement of iron levels, total iron-binding capacity, and serum ferritin levels help guide restoration of iron levels and maintain healthy myometrial contractility. A boggy, noncontractile uterus bleeds more than a healthy, iron-rich, well-toned uterus.

Dosage

The dose is 325 mg/day of ferrous sulfate or its equivalent. Double doses may be needed during menses.

Precautions

Measuring serum iron levels during supplementation prevents iron overload. Some iron formulas can be constipating.

Selenium

Selenium is a potent antioxidant that supports the action of vitamin E and other antioxidants. It also is used in the production of the antioxidant glutathione. Selenium is necessary for the formation of thyroid hormones.

Dosages

The dose is 200–500 mcg/day.

Precautions

Dosages exceeding 1000 mcg/day can precipitate skin and nail changes. “Garlic breath” may be an early sign of too much selenium.

Magnesium and Zinc

Important for hormone support, magnesium and zinc are responsible for catalyzing approximately 500 different reactions in the body. These minerals are estimated to be deficient in 50%–75% of the population. One theory for the craving of chocolate in the premenstrual period is the need for magnesium⁵⁵; chocolate is rich in this mineral.

Dosages

The dose of magnesium is 400–600 mg/day, and the dose of zinc is 15–30 mg/day.

Precautions

Taking too much magnesium can increase diarrhea. Magnesium can also compete with calcium for absorption; if this problem is suspected, magnesium should be taken separately from calcium. Zinc may interfere with copper absorption, and supplementation requires that 2

mg copper be added to the protocol. Red blood cell levels should be checked.

Women who crave chocolate (a rich source of magnesium) before their period may benefit from magnesium replacement therapy.

Omega-3 Fatty Acids (Eicosapentaenoic Acid and Docosahexaenoic Acid)

The omega-3 essential fatty acids (EPA and DHA) help maintain the fluidity of all cell membranes, reduce inflammatory cytokines and leukotrienes, and are building blocks for hormones. These essential fatty acids are not synthesized by the body and must therefore be consumed.

Dosage

The dose is 3–6 g/day of EPA and DHA (fish oil).

Precautions

Caution is recommended when prescribing more than 3–4 g/day of omega-3 acids to diabetic patients. Reports have noted elevations of blood glucose. Also use caution with patients on blood thinners.

Mind–Body Therapy

Encourage patients to create emotional flexibility by “staying in the moment.” Stretching and yoga exercises not only help maintain physical flexibility but also promote emotional flexibility. When we live in the present moment,⁵⁷ we can modulate stress effects from worrying about a possible future that may never come and from fretting about the past that cannot be changed. This chronic stress, which raises cortisol levels and lowers dehydroepiandrosterone (DHEA) levels, contributes to estrogen dominance by “stealing” or shunting progesterone and pregnenolone to produce more cortisol.

Body awareness exercises, such as tai chi and qi gong, and meditation and visualization exercises help to reduce blood flow to fibroids and lessen their impact and growth. Moving and other meditation exercises

help to mobilize stagnated energy, as do acupuncture, deep tissue massage, craniosacral work, and psychotherapeutic techniques such as bioenergetics.

Exercise of all kinds has been shown to reduce the harmful effects of stress. Meditation also helps reduce cortisol levels.⁵⁸ Techniques that focus the chakras or energy centers that correspond to anatomical nerve plexuses and glands of the endocrine system help to promote balance. One such technique is Freeze Frame, developed by the HeartMath Institute: the patient is taught to focus on heart energy or the fourth chakra while “breathing in through the energy of the heart.” Thoughts that are stressful are not internalized but are instead blown out while exhaling. This is a simple but powerful way of staying in the moment and is effective in reducing the inflammatory effects of stress on the body (see [Chapter 96](#)).

Journaling is a technique used for ridding the body of stored emotional energy.⁵⁹ Removing this stagnating energy is like cleaning out the closet and getting rid of all the clutter in your life. Energy moves again. This might be similar to acupuncture’s effects on “needling the meridians.”

While meditating and performing visualization exercises, the patient is instructed to be aware of second chakra issues—relationships, creative blocks, and abuse issues. Journaling has been shown to help reduce the negative effects of these stored emotions (see [Chapter 98](#)).

Another powerful technique that supports meditation and stress reduction and thereby alleviates symptoms of fibroids and reduces their growth is visualization of the desired results and the intent of bringing healing energy into the area to be healed. The Freeze Frame technique allows for a new perspective about the fibroid. It is no longer loathed or feared. Instead, feelings of gratitude are expressed as the message of the fibroid, an imbalance of some kind, has been received and now the fibroid can “leave.”

Pharmaceuticals: Gonadotropin Receptor Agonists

The following GnRH receptor agonists may be used.

Leuprolide Acetate

Leuprolide acetate (Lupron) is used to shrink fibroids before surgery to enable easier tumor removal.⁶⁰ This drug can effect a 30%–60% reduction

in fibroid size. Surgeons sometimes complain that using leuprolide decreases their ability to enucleate fibroids easily during myomectomy.

Dosage

The dose is 3.75–7.5 mg/month that is intramuscularly administered for 1–6 months.

Precautions

Unfortunately, if nothing else is done to prevent regrowth, many fibroids rapidly achieve the same sizes as they were before treatment. This agent causes chemical castration, menopausal symptoms, and osteoporosis.

Danazol

Danazol (Danocrine), which suppresses LH and FSH, can also be used to shrink fibroids.

Dosage

The dose is 600–800 mg/day.

Precautions

Precautions are the same as those listed for leuprolide acetate, but they are more intense.

Agents for Menorrhagia Associated With Fibroids

Norethindrone Acetate

Norethindrone acetate is used for menorrhagia associated with fibroids.

Dosage

A dose of 5–15 mg/day has been effective in slowing bleeding.

Precautions

The risks for blood clots, fluid retention, breast tenderness, nausea, insomnia, and depression are increased.

Progesterone-Containing Intrauterine Devices

Studies have shown that progesterone-containing intrauterine devices (Mirena, Skyla, Progestasert) reduce menstrual flow.⁶¹

Precautions

An intrauterine device may be difficult to insert in a woman who has not experienced vaginal delivery, and it may not be effective for a submucous fibroid.

Birth Control Pills

Birth control pills have been shown to reduce menstrual flow.

Dosage

Either daily dosing or the newer 3-month (seasonal) dosing is effective.

Precautions

All the precautions considered when the pill is prescribed for contraception are relevant here.

Nonsteroidal Antiinflammatory Drugs

Studies have shown that nonsteroidal antiinflammatory drugs (NSAIDs), such as ibuprofen and naproxen (Aleve), reduce menorrhagia by 20%–50%.

Dosage

The dose of naproxen is one to two 220-mg tablets or capsules every 12 hours. The dose of ibuprofen is 400 mg every 4–6 hours.

Precautions

All NSAIDs can increase gastric discomfort and the risk for gastrointestinal bleeding.

Tranexamic Acid (an Antifibrinolytic Agent)

Tranexamic acid (TA; Lysteda) is a U.S. Food and Drug Administration (FDA)–approved medication for menorrhagia. TA is an antifibrinolytic agent such as Amicar, which is used in dental procedures to prevent bleeding after dental procedures. It is very effective at 1300 mg three times/day, during days of heavy bleeding only, in slowing menstrual flow by prevention of clot breakdown. This leads to the theoretical concern of peripheral thrombosis. In almost 30 years of using TA, I have not seen any negative effects other than the occasional stomachache.

Dosage

A dose of 650 mg three times daily during menses.

Precautions

The most common side effects include headache and sinus congestion.

Natural Hormones

Dehydroepiandrosterone

DHEA reduces IL-6, a potent inflammatory cytokine that can promote the production of estrogens in the body. DHEA stimulates the PPAR-gamma receptor thus reducing inflammation, increasing insulin sensitivity, and reducing estrogen levels by maintaining healthy sugar metabolism and normal insulin levels. It also helps balance the effects of stress on the body by being in equilibrium with cortisol.

Dosage

The dose of DHEA is 5–10 mg once or twice/day. The dose of 7-keto DHEA is 25–50 mg/day.

Precautions

DHEA can convert to estradiol. Use of the 7-keto form may obviate this issue. Following hormone levels is always necessary when supplementing.

Surgical Treatment

The conventional approach to dealing with uterine fibroids remains largely surgical.¹ Total abdominal hysterectomy—removal of the uterus with the cervix, ovaries, and fallopian tubes—is the most common procedure recommended. Subtotal procedures are also performed. These procedures may leave the cervix (supracervical hysterectomy) or the ovaries and fallopian tubes. Hysterectomy can also be performed by a vaginal or laparoscopic route. Robotic-assisted laparoscopies are now performed.

Hysterectomy and other invasive procedures are not without consequences. Postoperative recovery can take up to 4–6 weeks. Infectious complications can affect 10% of women. Major injuries to the bladder, bowel, ovaries, and ureters happen approximately 1% of the time.

Myomectomy involves removal of the fibroid only, thereby preserving the uterus. Myomectomy can also be performed abdominally or laparoscopically.

These “mini-surgeries” have evolved into robotically assisted operations. These high-tech surgeries allow for very large fibroids to be removed through small and easily healed abdominal incisions.

The morcellation (removing in small pieces) technique that allows for this process to be successful has recently been called into question because of its effect in disseminating previously unknown leiomyosarcoma (malignant fibroid). Performing the procedure within an intraabdominal bag may be an answer, but will make a difficult procedure more difficult.⁶⁵

Myolysis techniques require the use of an energy source, which is applied to the fibroid through various instrumentation methods. The energy used may be ultrasound, laser, or electrical. The interior of the fibroid is destroyed, and the fibroid shrinks. The U.S. FDA has approved a myolysis⁶⁶ procedure using magnetic resonance imaging guidance and ultrasound as an energy source (ExAblate).

Uterine artery embolization is another procedure that effectively

reduces blood flow to the fibroid and hastens shrinkage. Inert polyvinyl alcohol particles are placed in the uterine artery through an artery in the upper thigh.

Except for total hysterectomy, all these procedures have one thing in common: the fibroids grow back. Complications of the procedures include infections, pain, and injuries to major organs in the area, such as the ureters, bowel, and bladder.

Other Therapies to Consider

Castor Oil Packs

Castor oil packs are hot packs made with wool flannel and hexane-free castor oil. Evidence suggests that they work through the lymphatic system and reduce inflammation. The castor oil pack is applied over the fibroid for 20–60 minutes per session. This device is a very effective meditation and visualization tool. The patient meditates on her uterus and visualizes the fibroid shrinking. She also visualizes the blood supply to the fibroids as pipes with turnoff valves, and while doing the meditation, visualizes turning off the valves thus shutting down the blood supply to the fibroids. The spiritual aspects of healing come into play here.⁶⁷

Through meditation and visualizing the healing of their fibroids, patients are instructed to be aware of any thoughts, feelings, or memories that can be associated with stagnation of second chakra energy and subsequent growth of the fibroid. The classic second chakra issues include relationship issues, not only with people but also with jobs, money, control, and the outside world. Creativity issues may also be expressed here. Abuse issues may come up also and can be related to physical, emotional, or sexual abuse. The idea is to remove these blockages to the healthy flow of energy from the pelvis, where they are creating stagnation and the growth of the fibroid. The release of these issues can be ritualized by having the patient journal everything that comes up and then put the pages into a bowl and burn them—letting them go.

Acupuncture and Deep Pelvic Massage

Acupuncture and deep pelvic massage (Mayan massage is one technique) are other ways of moving or restoring pelvic energy. These modalities are all complementary with the other approaches presented

here.

Homeopathy

The following homeopathic remedies can be effective in reducing symptoms, as specified:

- *Aurum muriaticum*: to reduce the size of fibroids
- Belladonna: for heavy, red bleeding
- *Hydrastinum muriaticum*: for large anterior wall fibroids with bladder symptoms
- Ignatia: for grief associated with fibroids
- Medorrhinum 200C: fibroids; for benign tumors
- Phosphorus 6C, 200C: for bright red bleeding with no clots
- Sabina: for bright red bleeding with clots and for severe cramps
- Secale: for almost black blood and for profuse bleeding
- Sepia: for pressure and anger
- Silicea 6C: for heavy bleeding; for cold, thin, and fatigued patients
- *Thlaspi bursa pastoris* 6C (shepherd's purse): for frequent, heavy, dark bleeding

See [Chapter 115](#).

Prevention Prescription

- Consume a hormone-balancing, vegetarian-style, low saturated fat diet, including organic non-genetically modified soy, green tea, ground flaxseed, omega-3 fatty acid, and cruciferous vegetables.
- Follow a moderate exercise program (4–5 hours/week).
- Reduce xenobiotic (hormone-like) exposures such as pesticides, atrazine (herbicide), and polycyclic aromatic hydrocarbons (found in diesel exhaust), and avoid petroleum-based cosmetics.
- Maintain an appropriate weight.
- Practice stress modification techniques.
- Take a high-potency multivitamin and multimineral supplement.
- Foster healthy digestion and elimination.
- Maintain healthy relationships and have a sense of purpose in life.

Therapeutic Review

This integrative, holistic approach to healing fibroid tumors of the

uterus can avoid some of the invasive therapies offered. It is effective in reducing the symptoms associated with these benign tumors. I ask patients to commit to a 3-month trial period, during which they will do as much of the protocol as possible.

At the end of these first 3–4 months, we assess symptoms, such as menorrhagia and dysmenorrhea, and any growth or shrinkage of the fibroids. The protocol is considered successful if the patient perceives a reduction in symptoms and no further fibroid growth has occurred. We then continue the program for 3–4 month periods while continuing to monitor symptoms and uterine size. If at any time symptoms recur or worsen or the fibroids begin to grow, other more aggressive measures must be considered, including surgery.

Lifestyle

- Maintain an appropriate weight.
- Avoid xenoestrogens (dioxins, polychlorinated biphenyls) by eating local, in-season, and organic foods as much as possible.
- Obtain regular aerobic exercise.

Nutrition

- Follow a hormone-balancing diet. The patient should consume a diet that reduces inflammation, acidity, and hormone, pesticide, and antibiotic residues; these foods may encourage the growth of fibroids. High glycemic index foods similarly should be avoided because of their effects on insulin and sex hormones. Gluten grains that increase estrogens through action of the phase one cytochrome P450 enzyme 3A4 must be limited. There is evidence that fibroid cells concentrate the cytochrome P450 enzyme 1B1. The 1B1 enzyme converts estrogens into the potentially carcinogenic 4-OH estrogens. This may become another therapeutic target for nonsurgical treatment.
- The patient should add foods that will be hormone-balancing, such as non-genetically modified organic soy and flaxseed. She should approximate the Asian diet, with 30–70 mg/day of isoflavones (genistein and daidzein) and 2 tablespoons of ground flaxseed per day. Omega-3 fatty acids, found in foods such as wild Pacific salmon and sardines, should be consumed at approximately 2–4 g/day and

are also antiinflammatory. 

- Reduce intake of unhealthy saturated fats and trans-fatty acids (feedlot red meat, dairy, fried foods).
- Increase intake of omega-3 fatty acids (vegetables, nuts, flaxseed, cold-water fish).
- Eat a low glycemic index diet.
- Avoid gluten as much as possible and completely if gluten sensitive.
- Eat cooked cruciferous vegetables (broccoli, cabbage, cauliflower, Brussels sprouts).
- Drink 3 cups of green tea daily.

Gut and Detoxification Restoration

- The clinician should restore the hormone balance and remove sources of inflammation by looking for and healing intestinal dysbiosis and supporting liver detoxification.
- Search for and treat hidden reasons for intestinal dysbioses, such as heavy metal overload, parasites, and food sensitivities. 

Supplements

Add nutrients to support hormone metabolism:

- A B-50 complex vitamin daily. 
- Magnesium salts are taken at 400–600 mg/day. 
- Maintain vitamin D₃ levels in the range of 40–100 ng/mL. 
- Support normal levels of vitamin A to reduce menorrhagia. 
- Citrus bioflavonoids, 1000 mg once or twice/day, can also reduce menorrhagia. 
- Zinc needs to be at an optimal level; consider supplementing if low. 
- I-3-C or diindolylmethane is taken at 200–800 mg/day to reduce estrogen dominance. 
- Calcium D glucarate is taken at 500 mg twice/day to reduce increased enterohepatic recirculation of estrogens. 

Hormones

- Insufficiencies in adrenal or thyroid hormones have been shown to increase symptoms related to fibroids. Assess and treat low thyroid levels and adrenal insufficiency.
- DHEA has important implications related to the immune system, sugar metabolism, and stress modification. If the DHEA level is low, add 5–20 mg of DHEA/day. Watch for conversion to estrogens. 

Botanicals

- Add botanicals to reduce heavy bleeding. Red raspberry leaf and yarrow are used for 2 weeks before the period at 30 drops each; once the period starts, add 30 drops of shepherd's purse. 
- Botanicals to support lymphatic drainage from the pelvis are also added. These consist of Gaia herbal combinations such as Scudder's alterative and echinacea/red root formulas. They are taken twice/day at 30 drops each. 
- Antiangiogenesis factors such as *Convolvulus* and green tea extract may reduce blood flow to the fibroids. 
- To reduce inflammation, add antiinflammatory systemic enzymes (Wobenzyme, Vitalzyme, Neprinol) up to 15 tablets/day in divided doses taken on an empty stomach. 

Mind-Body Therapies

- Meditation and visualization exercises using castor oil packs help restore health to the pelvic organs by allowing for the free flow of energy in the meridians of the second chakra. These activities also help identify stored emotional issues in these energy areas of the body and their impact on the fibroid. 

Conventional Therapies

- Should the less invasive and more natural approaches fail to reduce the symptoms or growth of the fibroid, one can resort to the time-tested, more invasive conventional approaches. These powerful tools should be considered when necessary. The integrative holistic

approach can still be used to help prevent any further growth of fibroids after the conventional treatment is performed.

- Surgery (hysterectomy) 
- Strong pharmaceuticals: leuprolide acetate (Lupron), 3.75 mg intramuscularly once a month for up to 6 months 
- Interventional radiographic procedures

CHAPTER 59

Vaginal Dryness

Myrtle Wilhite, MD, MS

Description and Prevalence

Vaginal dryness is defined as a reduction of physiological lubrication of the luminal surface of the female vagina. Vaginal dryness can:

- Occur at any age, with prevalence ranging from 13% to 31%,¹ although rates are significantly higher for postmenopausal women (50%)² and women treated for breast cancer (63%).³
- Cause discomfort singularly, or be accompanied by other symptoms, such as itch or dyspareunia.
- Occur subsequent to a change or alteration of serum estradiol levels. For risk factors, see [Table 59.1](#), but the leading causes are as follows:
 - *Premenopausal women*: hormonal contraceptives, anticholinergic or chemotherapeutic medications, postpartum/breastfeeding, inflammatory conditions, or unwise health behaviors.
 - *Peri- and postmenopausal women*: menopausal decline in estrogen production, anticholinergic or chemotherapeutic medications, metabolic and inflammatory conditions, or unwise health behaviors.
- Progress to other conditions such as vulvovaginal atrophy (VVA, also known as atrophic vaginitis or urogenital atrophy). VVA is a tissue-altering inflammation of the vagina (and the distal urinary tract) caused by decreased blood flow.⁴ With chronic progression, VVA leads to dry, thin, friable tissue with poor capacity for blood flow or lubrication.⁵ Prevalence of vaginal atrophy in postmenopausal women is 43% in the United States but varies by nation.⁶

Physiology of Vaginal Lubrication

Vaginal lubrication is reliant upon healthy blood flow because vaginal lubrication is ultrafiltrated blood.

- The vagina contains no glands.
- Blood pressure pushes fluid from the capillaries through intracellular gap junctions between vaginal epithelial cells.⁷ The resultant vaginal transudate is mainly composed of water and very small proteins, which combine at the vaginal surface with dead epithelial cells.
- Sufficient pelvic blood flow is dependent on the bioavailability of nitric oxide (NO).⁴ Gaseous NO is produced in capillary endothelia in response to shear stress or vibration or in response to sexual arousal via parasympathetic nitrergic nerves.⁹ Once produced, NO induces vasodilation through a cyclic guanosine monophosphate (cGMP) cascade, which diminishes as phosphodiesterase enzymes subdue the effect.
- Therefore, vaginal lubrication production depends upon the synthesis, enzymatic facilitation, and bioavailability of NO (Table 59.2). The enzymatic function of NO synthase is enhanced by steroid hormones, most notably estrogen in a rapid-action nongenomic effect.¹⁰
- Importantly, the presence of NO is not sufficient for its effect. Many biological feedback mechanisms exist to suppress the production of NO as high production of NO in an inflammatory environment can lead to irreversible free radical production.¹¹ Metabolic conditions of low inflammation are supportive to the bioavailability of NO in facilitating vaginal lubrication.

TABLE 59.1

Risk Factors for Vaginal Dryness

Reduced Estrogen Availability

Postpartum, breastfeeding

Menopausal transition

Premature ovarian failure

Oophorectomy

Pelvic radiotherapy

Other Medical Conditions

Untreated hypertension

Diabetes (Types 1 and 2), metabolic syndrome

Pituitary disorders

Neuropathies, especially autonomic neuropathy

Dermatoses (psoriasis, lichen sclerosis, Sjögren syndrome)

Prescription Medications
Antihistamines and decongestants
Antidepressants (SSRI, atypical TCAs)
Antiestrogen therapy for chemoprophylaxis
Antiestrogen therapy for endometriosis/fibroids
Chemotherapy
Diuretics
Progesterone predominant oral contraceptives

Unwise Behaviors
Dehydration, including alcohol use
Use of douches, extremely hot baths, and/or strong detergents and dehydrating soaps
Use of highly absorptive tampons
Use of male condoms with insufficient external lubricant
Lack of sufficient arousal before vaginal penetration
Smoking

SSRI, selective serotonin reuptake inhibitors; TCA, tricyclic antidepressants.

The vagina's lubrication does not come from glands but from a transudative fluid expressed through vaginal epithelial cells from filtered blood that requires adequate perfusion and NO.

Pathophysiology of Vaginal Epithelium

Mature vaginal epithelial cells produce and store glycogen, which is released during normal cell death and provides nutritional support for *Lactobacillus sp. Lactobacilli* uniquely release hydrogen peroxide during metabolism, thereby acidifying the luminal vaginal pH. Vaginal maturation index (VMI)¹² correlates strongly with pH of noninfected, noninflamed vagina,¹³ and both can be used to assess the health of vaginal tissue.

Changes to the tissue and function of the vagina during the menopausal transition (perimenopause) are highly influenced by declining levels of sex hormones. Waning estrogen causes a decrease in cellular maturation (VMI decreases; pH increases), mitotic activity of the basement membrane (reduced cellular renewal), decreased collagen synthesis (weaker dermal structure), and thickened dermoepidermal junctions (making it harder for capillary fluid to move through to the surface).¹⁴ All of these factors lead to a dry, immature, weakened cellular structure, which is more susceptible to friction damage and decreased repair capacity.

TABLE 59.2

Manipulation of Nitric Oxide Function

Production of Nitric Oxide
Mediterranean diet: sufficient L-arginine intake
<ul style="list-style-type: none">• Nuts: peanuts, almonds, walnut, hazelnuts• Fruits: berries, chocolate• Beans• Some meats: fish, chicken• Some seeds: sunflower, flaxseed
Sufficient dietary calcium

Facilitation of Enzyme Activity of Nitric Oxide Synthase
Hormones
<ul style="list-style-type: none">• Estriol or estradiol: rapid action, nongenomic effect• Estradiol, soy phytoestrogens, testosterone(s): genomic effect
Medications, vitamins, and supplements
<ul style="list-style-type: none">• Niacin (recouples eNOS)• Angiotensin-converting enzyme inhibitors (ACE-i)• Ginseng (increases eNOS, inhibits iNOS)
Other
<ul style="list-style-type: none">• Reduce hyperglycemia

Prolonged Activity of Nitric Oxide

PDE-5 inhibitors (sildenafil, tadalafil, vardenafil)

Improve Bioavailability of Nitric Oxide (preventing free radical formation)
Medications, vitamins, and supplements
<ul style="list-style-type: none"> • Aspirin (reduces iNOS) • Vitamin D₃ (decreases iNOS) • Ginseng, American (decreases iNOS, increases eNOS)
Behaviors
<ul style="list-style-type: none"> • Routine moderate aerobic exercise

Anti-estrogen therapy can lead to moderate-to-severe vaginal atrophy.¹⁵ Selective estrogen receptor modulators, such as tamoxifen, increase mucin production and maturity of vaginal epithelium¹⁶ while simultaneously reducing blood flow to vaginal tissues in experimental models.¹⁷ Aromatase inhibitors cause severe vaginal dryness due to estrogen production suppression.¹⁸

Integrative Therapy

Topical Vaginal Lubricants

Sexual lubricants applied topically and intravaginally are highly effective at addressing vaginal dryness,¹⁹ as effective as topical estrogen treatment,²⁰ easy to use, readily available, and inexpensive. However, because the vagina is a biologically active organ, sexual lubricants are not without risk of harm, and the United States Food and Drug Administration (FDA) has made major changes to the classification and testing of products intended for sexual use inside the body.

Sexual Lubricant Safety

Prior to 2014, sexual lubricants had been minimally regulated by FDA as cosmetics (e.g., class I device) because it was felt that the use of sexual lubricants had little associated health risk. Serious consequences began appearing in clinical trials, however, as vaginal lubricants were used as drug delivery mechanisms:

- Spermicidal detergents such as nonoxynol 9 were shown in 2002 to increase transmission of HIV.²¹

- In 2010, sexual lubricants with high osmolality increased transmission of herpes type 2.²² Osmolality (a physical property of liquids whereby fluid is drawn out of cells) weakening the cell and damaging the protective function of skin cells impacts infection transmission. This data led the FDA to conclude that sexual lubricants are not harmless cosmetics but substances that deserve scientific attention prior to their release into the public marketplace. The FDA now considers sexual lubricants to be class II medical devices subject to formulation testing and rigorous manufacturing standards.
- All lubricants sold for sexual penetration are now considered FDA class II medical devices.
 - This is true whether the lubricant is used with a partner or solo, with a latex barrier (condom) or without, and whether it is applied inside the vagina or anus.
 - Products from both international and domestic manufacturers without FDA class II approval are being forced off the U.S. market.
- An unfortunate aspect of this regulation is that not all approved class II devices are equivalent or *necessarily* safe.
 - For example, some manufacturers conducted and registered products as class II devices years before these issues arose. Neither in past or at present have there been any published FDA manufacturing standards to use that if met suggest a low level of biological risk. Some FDA class II lubricant devices have received approval even though current testing procedures are more complicated than those that were originally accepted. Other products have been class II approved but were withdrawn from the market due to safety concerns.

Choosing Vaginal Lubricant(s)

Generally, the most effective sexual lubricants have the following properties:

- Incorporate *both* **moisturizing** and **moisture-sealing** qualities,
- Have a pH compatible with vaginal pH (between 4.4 and 5.5),
- Do not have allergenic, sensitizing, or contact-irritant botanical components, and
- Meet the physical slip and cushion needs of the user.

A successful outcome lies in knowing how to choose the right lubricant, and this task has become difficult. The chemical ingredients,²³ physical properties,²⁴ and the comfort in use determine both the degree of client acceptance and long-term compliance. **All** sexual lubricants

should **reduce** friction with skin-to-skin rubbing and evaporation. Other considerations include the following:

- **Moisturizing**, thinner, water-based lubricants are generally low in osmolality, so they are less likely to draw moisture from the skin and instead add more moisture to the skin and vagina. Hyaluronic acid improves vaginal dryness in women with severe dryness.²⁵
- **To seal** moisture in place, silicone-based lubricants have, generally, the highest tolerance for use during sexual play. This is compared with other organic oils, butters, and petroleum-based (mineral oil) lubricants.

Many people use **both** types of lubricants (watery, moisturizing lubricant plus silicone-based lubricants) during sexual play. Experimentation is highly encouraged as the specific needs of an individual might not be easily ascertained without home trials. See [Table 59.3²⁶⁻²⁹](#) for properties of commonly available sexual lubricants. Each of the following recommended OTC lubricants have a different formulation. Remember that formulations and availability change quickly, so check for availability locally or by Internet.

Evaluate Different Lubricants

Encourage experimentation with samples of different sexual lubricants available OTC. Product availability is highly variable as manufacturers comply with FDA standards. Suggested lubricants are listed in [Table 59.3](#).

TABLE 59.3

Features of Over-the-Counter Lubricants and Food-Grade Oils

Product	Preferred?	Base	pH	Moisture	Seals	Ideal Use	Comments
Oasis Silk	Yes	Water + silicone	4.8	Yes	Yes	Hybrid; both	Paraben-free
Sliquid Organics Silk	Yes	Water + silicone	6.5	Yes	Yes	Hybrid; both	Aloe; very thin for sexual use. Paraben-free
Aloe Cadabra	Yes	Water	4.0	Yes	No	Moisturizer	Aloe
Good Clean Love	Yes	Water	4.8	Yes	No	Moisturizer	Aloe; best as moisturizer as is very sticky in sexual use
KY Silk-E	Yes	Water	3.8	Yes	No	Moisturizer	Aloe
Liquid Assets	Yes	Water	4.8	Yes	No	Both	Aloe; hyaluronic acid; very thin for sexual use
Swiss Navy, water	Yes	Water	4.4	Yes	No	Both	Aloe
Femini Smooth	Yes	Silicone	4.4	No	Yes	Seals; sexual use	Excellent for sexual use
Uterfuhe	Yes	Silicone	4.0	No	Yes	Seals; sexual use	Excellent for sexual use
Coconut Oil ²⁵	Perhaps	Fruit oil	-	No	Yes	Seals only	Difficult to remove; coconut smell
Astroglide	No	Water	6.5	No	No		Glycerin/high osmolality
KY Jelly	No	Water	4.5	No	No		Glycerin/high osmolality/chlorhexidine
Pre-	No	Water	7.0	Yes	No	Pregnancy	Sperm friendly
Replens	No	Petroleum oil	2.8	No	Yes		Med-hi osmol; stings in use
Olive Oil ^{26,27}	No	Fruit oil	-	No	Yes	Exfoliant	Desquamates skin

Dosage

1–3 mL applied to the antecubital fossa (inside elbow). Wait for 1 hour and then check for redness or irritation. Check again in 24 hours to evaluate for delayed sensitivity.

Precautions

Because sexual lubricants are complicated substances (pH, osmolality, biological interactions, ingredient variability, and base variability), irritating reactions can occur to specific ingredients (propylene glycol,³⁰ aloe,³¹ and glycerin³²) or specific percentage composition in the formulation. Due to this complexity, users might tolerate/prefer different type(s) of lubricant(s) for different behaviors or at different times of their lives. *One* product will never be suitable for *every* person.

To Moisturize

Self-massage moisturizing lubricant on vulva or in vagina.

Dosage

1–3 mL massaged on vulva qhs or after showers. If internal vaginal

application is desired, suggest a 1–3 mL needleless syringe and apply *pv qhs* or as needed. Titrate dose depending on need.

Precautions

Users may use one product for moisturizing and a different product for sexual use as some moisturizers are too thin to reduce friction adequately.

Vaginal Renewal Program

The Vaginal Renewal (VR) program helps women recondition the health and flexibility of the skin of the vulva and vagina by reducing friction tearing of vulvar skin as well as increasing blood flow to the vulva and vaginal canal. VR is indicated for those just beginning to feel the effects of hormonal changes, women who have completed pelvic radiotherapy,³³ as well as women with vaginal atrophy who experience skin tearing and pain while penetration is being attempted. Dilation is not the goal, blood flow is. Because of this, static dilators (nonvibrating dilators) have not been found to be as useful for improving function as vibrating wands, and dilators with soft, textured, or adhesive surfaces tear fragile vaginal epithelium too easily.

VR is compatible with topical estrogen therapies, and the combination can be more effective and faster acting than estrogen alone or VR alone. Many women gain enough improvement from the combination of estrogen therapy and VR and are able to discontinue the use of estrogen completely. However, the VR program does not require the use of estrogen and is preferred by clients and clinicians for circumstances where topical estrogen is contraindicated.

Precaution

Because comfortable penetration depends on the flexibility of both the skin and pelvic floor muscles, some women recondition their vaginal skin only to experience uncomfortable penetration because their pelvic floor muscles are inflexible. Referral to a pelvic floor physical therapist is indicated before continuing VR, and no further vaginal penetration should be attempted until pelvic floor muscle evaluation is completed.

For women with vaginal dryness which causes daily discomfort:

- Choose a moisturizing lubricant and place it by the toilet and/or shower.
- Dispense a nickel-to-quarter-sized amount on the fingers.
- Use a press-release motion over the entire vulva.
- Dispense another nickel-to-quarter-sized amount on the fingers.
- Use a press-release and rolling motion to apply on the introitus.
- Repeat 1–2× per day as needed.
- If dryness is felt internally, use 1-cc lubricant in the vaginal applicator qhs.

For women with rehabilitation of the vaginal canal needing lubrication and dilation:

- Follow instructions for daily moisturizing.
- Help the client choose an appropriately sized vibrating wand.
 - The diameter of the wand is the most important criteria; choose one that can be inserted comfortably during pelvic examination. A smaller diameter is always better. The client can graduate to a larger size when a finger can be placed beside the wand comfortably during vaginal penetration.
 - Low-hertz vibration is more effective than high hertz.
- Instruct the following:
 - At home, the client is to lubricate the wand.
 - Insert it into the vagina to the deepest comfortable depth.
 - Turn on the vibration.
 - Lie back and let the wand vibrate for 5–10 minutes.
 - Remove the wand.
 - Repeat 3× weekly as needed.

For women with dryness-related dyspareunia:

- Follow instructions for moisturizing and vibrating the wand, as previous.
- Lubricate partner (penis, fingers, glass, or steel dildo) with silicone-based lubricant prior to penetration.
- If the object of penetration is made of silicone, cover the object with a nonlubricated condom and apply silicone to outside of the condom.

Behaviors

Regular Vaginal Penetration Through Sexual Activity

This has been associated with enhanced sexual function in postmenopausal women.³⁴

Dosage

Vaginal penetration once per week appears sufficient when symptoms are absent.

Precautions

It is easier to maintain function than it is to rehabilitate, so asymptomatic women should be encouraged to continue routine vaginal penetration, with or without a partner, even if the goal is for comfortable routine pelvic examinations.

Utilize Vibrating Wand Massage to Create Shear Stress

This stress on the endothelial capillaries increases blood flow and vaginal lubrication.

Habitual Physical Exercise

It is an effective way to combat vascular aging³⁵ and enhance the function of small vessel blood flow,³⁶ including vaginal perfusion.³⁷ Aerobic exercise positively affects NO³⁸ and is linked to improved endothelial and cardiovascular health³⁹ as well as improved sexual arousal in women taking antidepressants.⁴⁰

Dosage

Walking once per day, 30–60 minutes to the level of gentle sweat. Walking prior to anticipated sexual activity improves vaginal lubrication as well as subjective symptoms of arousal (see [Chapter 91](#)).

Precautions

Vigorous exercise is not indicated, but exercising to the level of gentle sweat is sufficient. Walking is ideal.

Nutrition

Dietary reduction in inflammation assists endothelial function⁴¹ by improving nitric oxide–dependent blood flow.⁴² For example, despite the

increased incidence of sexual dysfunction in women with diabetes,⁴³ adherence to a Mediterranean diet is associated with a lower prevalence of sexual dysfunction in diabetic women.⁴⁴

Mediterranean Diet

A low-glycemic, low-carbohydrate Mediterranean diet positively manipulates endothelial health and NO bioavailability. There is benefit of increasing NO bioavailability *prior* to NO production because increasing NO in the presence of inflammatory / oxidized conditions worsens NO bioavailability and damages endothelia directly.

- First, focus consumption on initially increasing both lipid- and water-based antioxidants and reduce high-glycemic index foods that spike blood glucose levels and increase insulin resistance (see [Chapter 87](#)).
- Second, increase food consumption that targets protein levels of L-arginine (See [Table 59.2](#)). Fortunately, these foods are beneficial to satiety, and many incorporate both antioxidants and L-arginine simultaneously.
- Finally, consider whether soy phytoestrogens might be of benefit. Experimentally, fermented soy may also function as a free radical scavenger.⁴⁵

Dosage

Strict adherence to a Mediterranean diet with small meal portions with mid-meal grazing on nuts + dried berries / cherries (see [Chapter 88](#)).

Precautions

Soy consumption (90 mg isoflavone / day) has shown positive effect on vaginal dryness,⁴⁶ but the safety is in question,⁴⁷ particularly for western populations.⁴⁸

Vitamins and Supplements

Although there is a slim positive evidence of supplements supporting sexual function, there is data on vitamin and supplement effect on endothelial function. Because endothelial function underlies the physiological mechanism for vaginal health and lubrication, recommendations are included here.

Vitamin D₃

Vitamin D receptors are present in all layers of the vaginal epithelium.⁴⁹ Vitamin D₃ plays an important role in absorbing dietary calcium, manipulating calcium at neural membranes, and in the calmodulin-cofactor⁵⁰ required for NO production and protects endothelial cells from glucotoxicity.⁵¹ Studies support the use of oral supplementation⁵² and intravaginal application.⁵³

Oral Dosage

Begin at Vitamin D₃ 2000 IU po qd taken with fish oil and calcium citrate. After 1 month, check blood levels of 25(OH)D and aim for serum level of at least 50 ng/mL. In women who are more symptomatic for menopausal symptoms, aim at serum level of 60 ng/mL.

Intravaginal Dosage

Vitamin D₃ 1000 IU per suppository qd × 8 weeks.

Precautions

Calcium metabolism and kidney disorders as well as some inflammatory disorders (sarcoidosis, tuberculosis) are worsened with vitamin D therapy.

Fish Oil (Highly Purified Omega 3)

Omega 3 oils assist absorption of vitamin D and act as lipid-based antioxidants helping endothelial and neural function.⁵⁴

Dosage

2–3 g po qd taken with vitamin D and calcium.

Precautions

Fish oil/omega-3s act as anticoagulants, so the dosage needs to be modified in those taking heparin, Coumadin, SSRIs, aspirin, ginkgo, high-dose garlic, or other potentially blood-thinning regimens.

L-Arginine

Take as a supplement. It acts as the protein substrate for NO production.

Dosage

500 mg po qd.

Precautions

Dietary supplementation is more strongly suggested than direct supplementation and may cause hyperglycemia, hypotension, and nausea; it is contraindicated in kidney disease. High serum levels of L-arginine and L-citrulline (production byproduct) also act as feedback inhibitors of NO production.

Sea Buckthorn Oil

Oral supplementation with sea buckthorn oil, an antiinflammatory phytosterol, has been shown to improve vaginal epithelium parameters but not significantly improve subjective symptoms of vaginal dryness.⁵⁵ Topical applications improve barrier function of full thickness skin⁵⁶ but have not been studied for vulvovaginal use.

Dosage

3 g po qd × 3 months.

Precautions

Sea buckthorn can act as a blood thinner and may lower blood sugar in diabetics taking hypoglycemic medication. They also may interfere in heart, gastrointestinal, cancer, or autoimmune treatments.

Niacin

Reversal of endothelial dysfunction is responsive to niacin therapy.⁵⁷

Dosage

500–1000 mg bid.

Precautions

Warning about flushing and prolonged incremental increase beginning at 100 mg/day is most successful. It may make vulvar dermatoses initially worse⁵⁸ as recoupling of NO production will temporarily advance inflammation.

Botanicals

American ginseng (*Panax quinquefolius*)

Improves blood flow related to NO bioavailability, reduces inflammatory NO release from macrophages,⁵⁹ facilitates endothelial NO release, and acts as a potent antioxidant.⁶⁰

Dosage

500 mg capsule bid or 2 g root tea infusion, tid.

Precautions

May cause insomnia or hypoglycemia if taken in conjunction with diabetes medications.

Ginkgo Biloba

Ginkgo acts on NO vasodilation in several different ways.⁶¹ It modulates NO second messenger action, scavenges excess NO, inhibits NO production under inflammatory conditions, and inhibits platelet activation. Ginkgo supplementation has been shown to improve sexual function,⁶² although the data is conflicting.⁶³

Dosage

Ginkgo biloba extract 50:1 60 mg bid; may be advanced to 120 mg bid.

Precautions

Do not use with anticoagulants, nonsteroidal antiinflammatory drugs, aspirin, or high consumption of garlic.

Not Recommended

Attempts to reverse vaginal dryness with oral black cohosh⁶⁴ and topical genistein⁶⁵ or red ginseng (*Panax ginseng*)⁶⁶ have been unsuccessful. Damiana (*Turnera diffusa*) blocks progesterone receptors without receptor activation but may boost unopposed estrogen activity.

Pharmaceuticals

Estriol Gel

Two weeks of vaginal daily estriol gel improves vaginal dryness⁶⁷ and may be indicated as initial therapy in severe cases of vaginal atrophy.

Dosage

Estriol cream (0.005%) 50 mcg intravaginally qd × 2 wks. Taper to 3×/wk for 2 months, then D/C.

Precautions

Estriol causes measurable systemic changes suggestive of estrogen effect in breast cancer survivors taking aromatase inhibitors.⁶⁸

Estriol is the main estrogen of pregnancy, which helps prepare the vagina for delivery. However, estriol does stimulate breast cell proliferation (although less than estradiol) and should only be used as very short-term therapy in cases of severe dysfunction. (See [Vaginal Renewal](#), previously described, for nonhormonal therapy.)

Estriol–*Lactobacilli* Combination (Gynoflor) Vaginal Tablet

Intravaginal tablets with a low-dose estriol/*Lactobacilli* combination improved sexual activity in women experiencing VVA due to breast

cancer treatment.⁶⁹

Dosage

Estriol cream (0.03 mg + *Lactobacilli*) intravaginally qd × 4 weeks. Taper to 3×/wk for 2 months, then D/C.

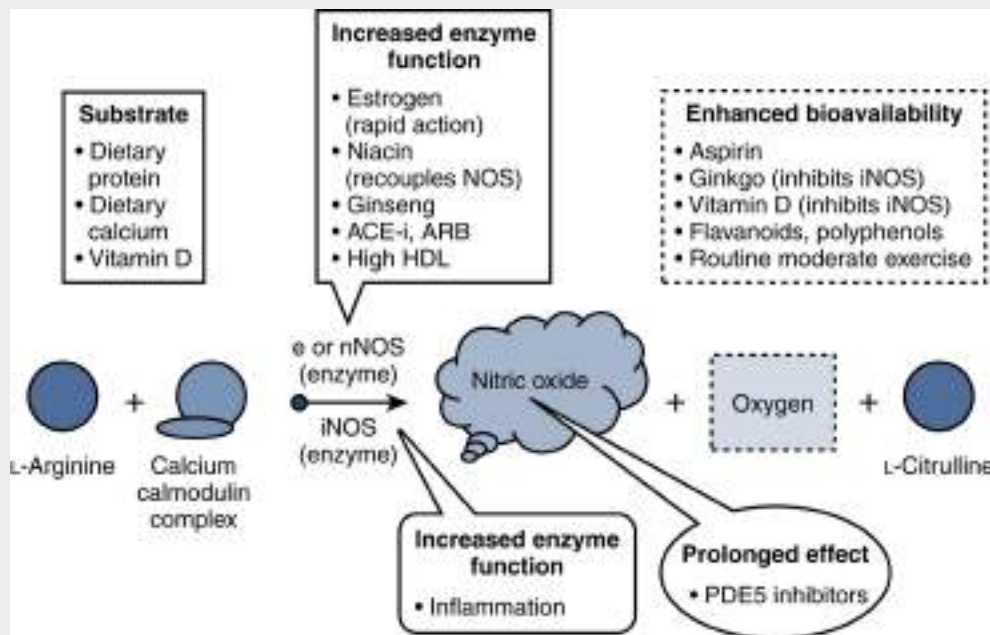

FIG. 59.1 Nitric oxide interventions. *ACE-I*, Angiotensin-converting enzyme inhibitor; *ARB*, angiotensin II receptor blocker; *eNOS*, endothelial nitric oxide synthase; *iNOS*, inducible nitric oxide synthase; *nNOS*, neuronal nitric oxide synthase; *PDE5*, phosphodiesterase-5.

Precautions

Estriol causes measurable systemic changes suggestive of estrogen effect in breast cancer survivors taking aromatase inhibitors.⁶⁸

Sildenafil [Phosphodiesterase-5 (PDE5) Inhibitors]

Physiologically, PDE5 inhibitors reduce insulin resistance in endothelial capillaries⁷¹ in addition to prolonging cGMP vasodilatory effect and show beneficial genital perfusion effect in women⁷² as well as sexual

function improvements among women taking antidepressants.⁷³

Dosage

12.5–50 mg qd. May be taken qhs to reduce hypotension symptoms. Client should experiment whether timing prior to sexual intimacy improves vaginal lubrication.

Precautions

It may cause nausea, headache, nasal congestion, renal or hepatic impairment, hypotension, change in vision, and ototoxicity. They are contraindicated with nitrates and α_1 -blockers.

Not Recommended

Oral raloxifene⁷⁴ or low-dose topical estradiol cream. The efficacy of topical local estradiol treatment is high,⁷⁵ but women are generally reluctant to use the therapy because of perceived risks,⁷⁶ including DVT, CVA, and breast cancer risk. Serum levels of estrone and estradiol increase in response to vulvovaginal topical treatment with estradiol after 1 week of therapy.⁷⁷

Prevention Prescription

- Maintain regular exercise and movement to enhance blood perfusion to the vulva and vagina.
- Encourage a Mediterranean diet that is rich in berry fruits, nuts, vegetables, and whole grains and low in red meat and processed carbohydrates. Focus on foods with high L-arginine levels. Encourage beverage choices of tea (black, green, red, or white), coffee, or water.
- Experiment to find a topical sexual lubricant that is comfortable and moisturizes the vulva and vagina.
- Maintain vaginal penetration (once a week) to stimulate vaginal lubrication and elasticity. Consider intermittent VR therapy if not interested in self sexuality or partner is not available.
- Check vitamin D levels and supplement to maintain levels above 50 ng/mL.

- Avoid tobacco products.

Therapeutic Review

There are three main strategies for resolving vaginal dryness without the use of hormones that are most effective when combined: topical vulvovaginal application of a suitable moisturizer, VR, and lifestyle improvements in NO-related blood flow.

Sexual Behavior

- Have the client experiment with a client-matched topical moisturizing lubricant. 
- Utilize massage and vibration (VR) to create sheer stress on the endothelial capillaries, increasing blood flow and vaginal lubrication.

When addressing a comprehensive lifestyle solution, holistically address diet and lifestyle issues that help facilitate the production and bioavailability of NO (see [Table 59.2](#) and [Fig. 59.1](#)). 

Nutrition

- First reduce overall metabolic inflammation with strict adherence to a Mediterranean diet with daily exercise. This enhances bioavailability and decreases inflammatory free radical production. 
- Then, focus the diet more specifically on foods high in L-arginine and selectively strip high-glycemic foods from the diet. Address satiety with proteins. 

Supplements

- Consider adding L-arginine 500 mg daily to enhance NO production; 
- Vitamin D₃ 2000 IU qd; achieving serum levels of 50 ng/mL ; omega 3 fish oil 2–4 g qd

Botanicals

- P. quinquefolius 500 mg–1 g bid. 
- Sea buckthorn 3 g po qd 

Medications

- Use an angiotensin converting enzyme inhibitor (instead of a β -blocker or diuretic) 
- For severe cases, apply estriol cream 0.005% ointment to the vulva and intravaginally daily $\times 2$ weeks, then reduce to $3\times$ /week for 2 months and then DC. 
 - Or estriol 0.03 mg + Lactobacilli suppository intravaginally qd $\times 4$ weeks. Taper to $3\times$ /week for 2 months, then DC. 
- Consider whether PDE5 inhibitors (sildenafil 12.5–50 mg daily) may facilitate daily genital perfusion to increase genital blood flow and vaginal lubrication.

CHAPTER 60

Benign Prostatic Hyperplasia

David Rakel, MD

Pathophysiology

Even though benign prostatic hyperplasia (BPH) is one of the most common diseases of aging men, its etiology remains relatively unknown. From our current understanding, BPH appears to be related to age, androgens (dihydrotestosterone [DHT]), estrogens, and detrusor dysfunction of the bladder neck. An accumulation of DHT inhibits prostatic cell death, promotes cell proliferation, and thus increases the size of the gland ([Fig. 60.1](#)).

As a man passes his fifth decade of life, serum testosterone levels decrease and estrogen (as well as prolactin, luteinizing hormone, and follicle-stimulating hormone) levels rise. Estrogen increases the number of androgen (DHT) receptors in the prostate and inhibits androgen metabolism by interfering with hydroxylation. As urinary outflow obstruction develops, the detrusor muscles of the bladder try to compensate by increasing pressure to expel urine, a process that leads to instability of the muscle and worsening symptoms. In summary, factors that promote the accumulation of DHT and estrogens lead to symptoms of BPH and obstruction of the lower urinary tract that, in turn, cause detrusor muscle dysfunction. Stimulation of the alpha-adrenergic system leads to contraction of the smooth muscle fiber that further restricts flow in an enlarged prostate gland. Finally, there is reason to believe that prostaglandins, leukotrienes, and insulin resistance play roles in the inflammatory process of the prostate.

Components of the metabolic syndrome have been shown to cause prostatic enlargement.^{1,2} Insulin resistance and truncal obesity appear to be the main culprits.³ Elevated insulin levels increase sympathetic nerve activity and also bind to insulin-like growth factor (IGF) receptors that

stimulate prostate cell growth.⁴ Excessive amounts of visceral fat also increase the circulation of estradiol and further stimulate prostate cell growth by increasing DHT levels ([Fig. 60.2](#)). Obesity, metabolic syndrome, and insulin resistance also increase systemic inflammation, which is also correlated with the incidence of BPH.⁵

Light to moderate alcohol consumption has been associated with a protective effect on BPH and lower urinary tract symptoms. The association of light to moderate alcohol consumption with an improvement in insulin sensitivity⁶ and a decrease in testosterone concentrations⁷ may help explain the beneficial influence of alcohol. However, this positive effect is not seen in men with high alcohol consumption.⁸ Consuming seven or more alcoholic drinks per week is associated with worsening symptoms.⁹

Integrative Therapy

[Table 60.1](#) gives the mechanism of action of common pharmaceuticals, botanicals, and supplements used for BPH, and [Table 60.2](#) gives information on botanicals and hormones that may worsen symptoms of BPH.

Nutrition

Soy

Soy is thought to work in two ways. It is an inhibitor of 5-alpha-reductase and a low-potency estrogen. Soy may block the receptor sites that the stronger estrogens use to increase the accumulation of DHT. Consumption of nonfermented soy products (tofu, soy milk, edamame) has also been found to result in a decreased incidence of prostate cancer.^{10,11}

Beta-sitosterol (a major phytosterol found in soy) was found to increase urinary flow and decrease residual volume in the bladder in a double-blind, placebo-controlled study using a 20-mg dose.¹² A 3.5-oz serving of soybeans, tofu, or another soy food preparation provides approximately 90 mg of beta-sitosterol.¹³ A 1-oz preparation (which is a portion approximately the size of the palm of the hand) equals approximately 25 mg.
