Cholesterol has been associated not only with BPH but also with prostate cancer. Cholesterol metabolites (epoxycholesterols) have been found to accumulate in the hyperplastic and cancerous prostate gland. For this reason, hypocholesterolemic drugs (3-hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors or “statins”) have been associated with a lower risk of BPH and prostate cancer.^{14,35} In addition, treating the dyslipidemia of metabolic syndrome (high triglyceride and low high-density lipoprotein levels) with exercise and a low-glycemic index/load diet (see [Chapter 87](#)) may also prove beneficial because of the association of BPH with metabolic syndrome. Foods high in cholesterol and saturated fat are rich in arachidonic acid as well, which is the main precursor of inflammation. Reducing consumption of these foods can benefit BPH patients by reducing inflammatory triggers.

Omega-3 Fatty Acids

A diet rich in omega-3 fatty acids helps reduce the influence of prostaglandins and leukotrienes on the inflammatory component of BPH (see [Chapter 88](#)). Recommend foods rich in omega-3 fatty acids such as cold-water fish (salmon, mackerel, and sardines), vegetables, and ground flaxseed or flaxseed oil. Flaxseed oil can be taken in capsule form. Recommend lignan-rich flaxseed oil, two to four 500-mg capsules twice a day. Patients can also buy whole flaxseeds, grind two tablespoons (approximately 30 g) of the seeds, and sprinkle the ground flaxseed on salads or yogurt or add it to a smoothie. Flaxseed has the added benefit of lignan fiber, which helps bind estrogen in the gut and thus promotes estrogen removal.

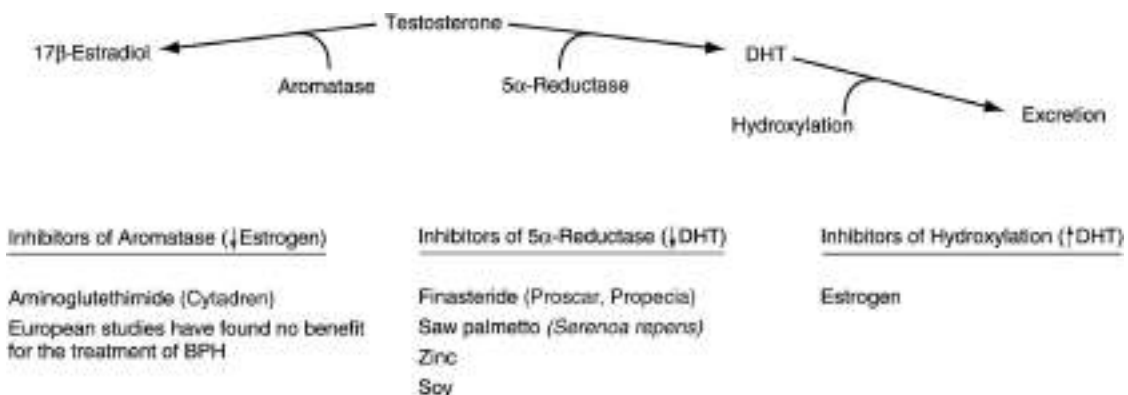

FIG. 60.1 Inhibitors of aromatase, 5-alpha-reductase, and hydroxylation. *BPH*, benign prostatic hyperplasia; *DHT*, dihydrotestosterone.

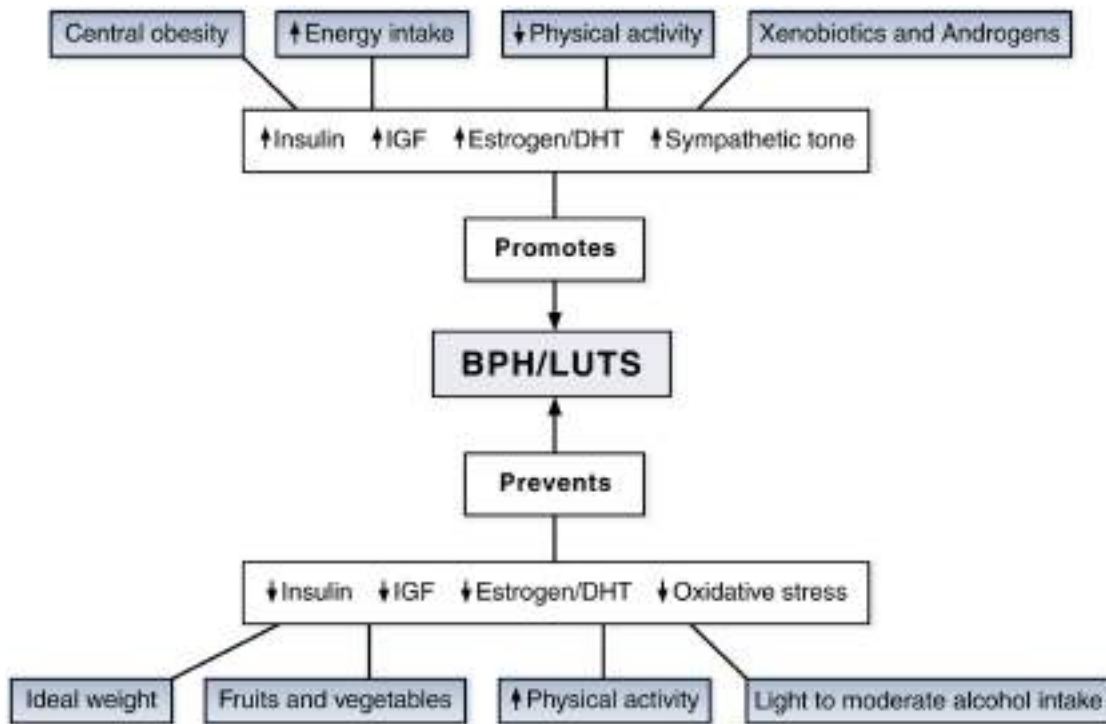

FIG. 60.2 Influences affecting the promotion and prevention of benign prostatic hypertrophy (BPH) and lower urinary tract symptoms (LUTS). *DHT*, dihydrotestosterone; *IGF*, insulin-like growth factor.

Supplements

Beta-Sitosterol

Beta-sitosterol is a sterol found in almost all plants. It is one of the main subcomponents of a group of plant sterols known as phytosterols that are very similar in composition to cholesterol. These plant sterols are the active ingredients in popular margarine spreads (Take Control, Benecol) used to lower cholesterol. Beta-sitosterol is found in rice bran, wheat germ, peanuts, corn oils, and soybeans. High levels are also found in botanicals such as saw palmetto, rye grass pollen, pygeum, and stinging nettles, which have been found to be beneficial for BPH. Unlike cholesterol, beta-sitosterol cannot be converted to testosterone. It also

inhibits aromatase and 5-alpha-reductase. Beta-sitosterol is likely one of the many reasons that eating vegetables is good for health. Encourage adequate consumption of these plants in the diet.

Two randomized studies showed a benefit of beta-sitosterol in treating BPH, with little potential harm.^{15,16} This benefit persisted for up to 18 months of use.¹⁷ A Cochrane Review found beta-sitosterol to improve urinary symptoms and flow measures. This supplement does not appear to reduce the size of the prostate gland.¹⁸

TABLE 60.1

Mechanism of Action of Common Pharmaceuticals, Botanicals, and Supplements Used for Benign Prostatic Hyperplasia

Mechanism of Action	Therapy
Alpha ₁ -adrenergic blockade	Nonselective: Terazosin (Hytrin) Doxazosin (Cardura) Selective: Tamsulosin (Flomax) Alfuzosin (Uroxatral) Silodosin (Rapaflo)
5-Alpha-reductase inhibition	Finasteride (Proscar) Dutasteride (Avodart) Saw palmetto (<i>Serenoa repens</i>)
Phosphodiesterase-5 inhibitors	Tadalafil (Cialis)
Antiproliferative action	African wild potato (<i>Hypoxis hemerocallidea</i>) Beta-sitosterol Lycopene Pumpkin seed (<i>Cucurbita pepo</i>) Pygeum (<i>Prunus africana</i>) Red clover (<i>Trifolium pratense</i>) Soy Stinging nettle root (<i>Urtica dioica</i>)
Antiinflammatory action	Rye grass pollen (<i>Secale cereale</i>) (Cernilton)

Modified from <http://naturaldatabase.com>.

TABLE 60.2

Products That Can Worsen Symptoms of Benign Prostatic Hyperplasia

Mechanism of Action	Product
Sympathetic stimulation: Increases tone of prostatic stroma, causes constriction of urethra, and can also stimulate bladder spasm	Bitter orange Caffeine, gotu kola Ephedra (commonly found in over-the-counter cold remedies) Country mallow Yohimbe

Anticholinergic stimulation: Makes urination more difficult by inhibiting bladder contraction and causing urinary retention	Henbane Scopolia Jimson weed Wild lettuce Many pharmaceuticals (tricyclics, antispasmodics, etc.)
Hormonal stimulation: Accelerates growth of the prostate	Androstenediol Dehydroepiandrosterone (DHEA) Androstenedione Pregnenolone

Adapted from Lee M. Management of benign prostatic hyperplasia. In: *Pharmacotherapy: a pathophysiological approach*. 5th ed. New York, 1999, McGraw-Hill.

Dosage

The dose is 60 mg twice daily. This dose can be reduced to 30 mg twice daily after symptoms improve.

Precautions

In general, beta-sitosterol is well tolerated. Gastrointestinal side effects are the most common. This supplement can enhance the cholesterol-lowering effects of antihyperlipidemic medications.

Zinc

Intestinal uptake of zinc is inhibited by estrogen. Because aging men have increased estrogen levels, men with BPH may have low zinc levels. In fact, marginal zinc deficiency is common in older adults, and in men, it may worsen the symptoms of BPH. In the 1970s, research showed that supplementing with zinc resulted in a reduction in the size of the prostate gland and in symptoms of BPH.¹⁹ Further research showed that zinc inhibits 5-alpha-reductase,²⁰ and it also inhibits the binding of androgens to their receptors in the prostate.²¹ This effect on androgens is thought to result from zinc's ability to inhibit prolactin, which, like estrogen, increases the receptors for DHT in the prostate. Therefore, zinc not only decreases the production of DHT but also inhibits DHT binding to its receptors.

Coffee can decrease zinc absorption by 50%. Because caffeine stimulates the adrenergic nervous system (smooth muscles of the prostate), encourage patients with BPH to limit their intake.

Prescription drugs that can result in low serum zinc levels include angiotensin converting enzyme inhibitors (ACE), thiazide diuretics, steroids, methotrexate, tetracyclines, and fluoroquinolones. Consider

zinc supplementation in patients with BPH who are taking these medications. Do not give zinc to patients taking tetracycline or fluoroquinolone antibiotics; however, because zinc can affect the absorption of these drugs. Pumpkin seeds are a rich source of zinc, and this may explain their potential therapeutic benefit for BPH.

Dosage

The dose of zinc is 30 mg per day.

Precautions

When prescribing zinc supplements, be aware that zinc competes with copper, calcium, and iron absorption. Make sure that the patient does not take more than the recommended dose and does not take calcium and iron supplements with zinc.

Botanicals

Saw Palmetto (*Serenoa repens*)

Saw palmetto has been found to be a weak inhibitor of 5-alpha-reductase, but it may have a more active role in reducing the number of estrogen and androgen (DHT) receptors, as well as an antiinflammatory effect on the prostate. Saw palmetto inhibits fibroblast growth factor and epidermal growth factor and stimulates apoptosis, thus further slowing prostate cell proliferation. Its principle ingredient, beta-sitosterol, is also found in soy products (see earlier), as well as in other herbs used to treat diseases of the prostate including pygeum bark, stinging nettle root, and pumpkin seed extract.

Saw palmetto reduces the inner prostatic epithelium but does not reduce the size of the gland. Nonetheless, saw palmetto has been found to improve symptom scores, nocturia, residual urine volume, and urinary flow in patients with BPH. It does not affect prostate-specific antigen (PSA) levels.²² In a large randomized study, saw palmetto was found to be as effective as finasteride (Proscar), but without the drug's side effects, and the International Prostate Symptom Score (IPSS) was reduced by 37%.²³ However, a more complete evaluation of 32 randomized trials by a 2012 Cochrane Review of 5666 subjects, concluded that no significant difference existed between *Serenoa repens* (saw

palmetto) and placebo for the treatment of urinary symptoms related to BPH.²⁴

Although the evidence for BPH improvement is marginal, saw palmetto has three positive influences on the prostate gland: it is antiandrogenic, antiproliferative, and antiinflammatory.

Dosage

The recommended dose is 160 mg twice daily. Allow 8 weeks before seeing therapeutic benefit.

Precautions

Mild adverse effects include headache, nausea, diarrhea, and dizziness. Saw palmetto does not influence the cytochrome P-450 enzyme system of the liver, and drug interactions are rare.

Accumulative data suggest that saw palmetto has little benefit over placebo. Like pygeum, it can be used for its beneficial influence on prostate health that includes being rich in plant sterols. However, if LUTS symptoms are significantly affecting a man's quality of life, using an alpha-blocker will result in a quicker, more effective therapeutic outcome.

Rye Grass Pollen (*Secale cereale*)

Rye grass pollen is also known as *grass pollen* and *grass pollen extract*. Clinical studies used a form called Cernilton (flower pollen), a brand manufactured by Cernitin. This has been bought by the company Graminex and is now marketed under the name of PollenAid.

This extract has been used in Europe for BPH since the 1970s. Double-blind clinical studies found it to be effective, with an overall response rate near 70%.²⁵ Rye grass contains a substance that has been found to inhibit prostatic cell growth²⁶ and reduce inflammation of the prostate by inhibiting prostaglandins and leukotrienes.²⁷

Studies have shown the greatest improvement in nocturia, urinary frequency, and residual urine volume.²⁸ Rye grass and flower pollen are also used for symptomatic relief of prostatitis and prostatodynia.

Dosage

The typical dose of rye grass pollen is 126 mg three times daily. A standardized extract 20:1 of *Secale cereale* can be obtained through the following companies: Graminex PollenAid, 500 mg three times daily, or Pure Encapsulations ProstaFlo, 320 mg three to five capsules per day in divided doses.

Precautions

Abdominal distention, heartburn, and nausea may occur. This product is not likely to cause allergy because allergenic proteins are removed in the manufacturing process.

***Pygeum africanum* (synonym: *Prunus africana*)**

Pygeum is obtained from the bark of the African plum tree. As with saw palmetto, its benefits are thought to come from fatty acids (sterols) that reduce inflammation through the inhibition of prostaglandins, as well as prostatic cholesterol levels that are precursors to testosterone production. Pygeum also increases prostatic and seminal fluid secretions.

A meta-analysis revealed that men taking pygeum had a 19% reduction in nocturia and a 24% reduction in residual urine volume. Peak urine flow was increased by 23%, and side effects were mild and similar to those reported with placebo.²⁹ The TRIUMPH study included treatment outcomes of BPH from six European countries. After 1 year of therapy, participants who received either *Pygeum africanum* or *Serenoa repens* (saw palmetto) showed a 43% improvement in IPSS scores and improvement in quality of life compared with no treatment.³⁰

Pygeum is more expensive than saw palmetto, and overharvesting of the bark is threatening the survival of the species.

Dosage

The recommended dose is 100 to 200 mg per day.

Precautions

Nausea and abdominal pain may occur.

Cranberry

The phenols found in cranberry and other dark colored grapes and berries may also prove beneficial for the symptoms of LUTS. In a small study 21 men were given 500 mg of dried cranberry powder three times daily (1500 mg a day) for 6 months versus control. The cranberry group had a greater improvement in their IPSS, quality of life, and urinary flow measurements than the control group.³¹

Dosage

Dried cranberry powder, 500 mg three times daily.

Precautions

Well tolerated. High doses can cause gastrointestinal intolerance.

Pharmaceuticals

Alpha-Adrenergic Blocking Agents

The TRIUMPH study mentioned earlier followed 2351 men with BPH.³⁰ After 1 year, the therapies that showed the most benefit in IPSS scores were, in descending order, alpha blockers (68%), finasteride (57%), and *Serenoa repens* or *Pygeum africanum* (43%) compared with watchful waiting. Of the therapies discussed, the alpha blockers are likely to give the most subjective improvement. Blocking the alpha-adrenergic system results in relaxation of the smooth muscle fibers of the prostate gland, with reduction of symptoms and improved urinary flow. The response is rapid (within hours), and studies have shown long-term efficacy.

The most common nonselective alpha blockers, terazosin (Hytrin) and doxazosin (Cardura), require dose titration to avoid postural hypotension. The newer and more expensive selective alpha_{1a}-adrenergic antagonists include tamsulosin (Flomax), alfuzosin (Uroxatral), and silodosin (Rapaflo). These are more specific for the prostatic tissue, thus reducing the incidence of hypotension and the need to titrate the dose.

Dosage

For terazosin (Hytrin), start at 1 mg nightly and titrate every week to

effect, up to a maximum of 20 mg. Terazosin is available in 1-, 2-, 5-, and 10-mg formulations. For doxazosin (Cardura), start at 1 mg nightly and titrate every week to effect, up to a maximum of 8 mg. Doxazosin comes in 1-, 2-, 4-, and 8-mg formulations. The recommended dose of tamsulosin (Flomax) is 0.4 mg 30 minutes after a meal every day, up to a maximum of 0.8 mg per day. Tamsulosin is available in a 0.4-mg formulation. Alfuzosin is available in a 10-mg formulation only and silodosin is available in 8 mg only.

Precautions

Postural hypotension, dizziness, fatigue, headache, nasal stuffiness, and retrograde ejaculation may occur. This class of drugs should be avoided prior to cataract surgery as they may increase the risk of floppy iris syndrome. Tamsulosin has the greatest risk of this.

5-Alpha-Reductase Inhibition

Finasteride prevents the conversion of testosterone to DHT and lowers DHT serum levels. This drug can take as long as 6 months to work, but it appears to halt the progression of prostate growth. In terms of patient satisfaction and symptom reduction, finasteride is not a great drug unless the goal includes treatment of male-pattern baldness. Finasteride causes a 50% reduction of PSA.

Dosage

The recommended dose of finasteride is 5 mg once a day, and it comes in 5-mg tablets. The recommended dose of dutasteride is 0.5 mg once daily, and it is available in 0.5-mg tablets.

Precautions

Side effects such as decreased ejaculatory volume (2.8%), impotence (3.7%), and decreased libido (3.3%) have been reported. These drugs can take up to 6 months to show benefits.

Phosphodiesterase-5 Enzyme Inhibitors

Studies have shown that although urodynamic testing (detrusor

pressure, bladder outlet obstruction, and maximum urinary flow rate) did not show improvement compared to placebo, the subjective quality of life did improve with improvement in the IPSS.^{32,33} Consider this therapy in men who have both LUTS and erectile dysfunction.

Dosage

Tadalafil (Cialis), 5 mg daily

Precautions

Headache, myalgia, and upper respiratory tract infection and irritation are the most common side effects. This is also an expensive drug compared to previously discussed treatments.

Anticholinergics

Occasionally anticholinergic agents are used in men with irritative triggers that result in worsening symptoms related to bladder neck contraction. These medicines (tolterodine and others) should not be used in those with a large postvoid residual bladder (>250 mL), as anticholinergics can worsen dilation of the bladder. Long-term use of anticholinergic medicines has also been found to increase the risk of dementia due to the reduction of acetylcholine.³⁴

Surgery

When severe symptoms are not controlled with the previously discussed therapies, consider urological referral for minimally invasive therapy or surgical resection, as follows:

- Transurethral microwave thermotherapy (TUMT) uses a microwave antenna that generates heat in the transition zone and results in coagulation necrosis. This procedure is performed on an outpatient basis.
- Transurethral needle ablation (TUNA) involves the placement of small needles in the prostate via cystoscopy that emit radiofrequency energy resulting in necrosis of prostatic tissue.

The minimally invasive procedures described here have a lower

morbidity compared with transurethral resection of the prostate; however, they are not as effective in reducing symptoms, and no tissue is obtained for pathological evaluation.

- Transurethral resection of the prostate (TURP) is the gold standard and will likely result in the greatest symptomatic improvement (95% of patients reported improved symptoms). Complications, such as incontinence (1%), blood transfusion (3% to 5%), retrograde ejaculation (20% to 75%), and stricture formation (5%) are becoming less severe with the use of laser prostatectomy that reduces bleeding. TURP is the most invasive procedure (except for open prostatectomy) and requires a hospital stay.
- Transurethral incision of the prostate (TUIP) involves endoscopic placement of one to two incisions along the prostatic capsule to reduce urethral constriction. This procedure has been found to be effective (83% of patients have improved symptoms) and safe for men with smaller glands (smaller than 30 g) who may not need TURP.

Prevention Prescription

- Avoid excessive amounts of saturated fats, such as those found in red meat, fried foods, and dairy.
- Consume omega-3-rich fats found in cold-water fish, nuts, greens, and ground flaxseed.
- Consider light to moderate (one glass or less daily) alcohol consumption.
- Eat plenty of natural plants, particularly those rich in beta-sitosterol, such as green leafy vegetables, rice bran, wheat germ, peanuts, corn oils, nuts, and soybeans.
- Encourage soy-based foods such as soy milk, edamame, soy nuts, and tofu. Try to eat 1–2 oz per day, and consider substituting soy milk for dairy milk.
- Avoid dietary supplements or environmental exposures that may increase circulating hormone levels such as pesticides, herbicides, and recombinant bovine growth hormone (rBGH)-rich dairy products. Also avoid drugs that include dehydroepiandrosterone (DHEA), androstenedione, testosterone, and human growth hormone.

- Maintain appropriate weight and perform regular aerobic exercise.
- Treat metabolic syndrome with exercise, weight loss, and a low-glycemic index/load diet to reduce inflammation of the prostate (see [Chapters 32](#) and [87](#)).

Therapeutic Review

This is a summary of therapeutic options for benign prostatic hyperplasia (BPH). A patient presenting with severe symptoms (BPH Symptom Index Score or International Prostate Symptom Score [IPSS] greater than 19) will benefit by jumping ahead to a more aggressive therapy such as alpha blockers or referral to a surgeon. For the patient who has mild to moderate symptoms, however, this ladder approach is appropriate.

Removal of Exacerbating Factors

- Ask the patient to stop taking over-the-counter cold remedies or diet aids (phenylpropanolamine [PPA]), nasal decongestants (pseudoephedrine), herbs (ma huang, Ephedra), or caffeinated products that contain sympathomimetics, which increase prostatic muscle tone.
- Consider asking the patient to stop taking pharmaceutical products that have anticholinergic effects leading to urinary retention. These agents include antihistamines, bowel antispasmodics, bladder antispasmodics, tricyclic antidepressants, and antipsychotics.
- Avoid excessive water consumption before bed.

Nutrition

- Increase soy-rich foods in diet. A 1-oz serving each day (approximately the size of the palm of the hand) provides approximately 25 mg. 
- Encourage a diet that is low in saturated fat from red meat and dairy. 
- Encourage foods rich in omega-3 fatty acids (salmon, nuts, or flax), or take one tablespoon of lignan-rich flaxseed oil twice daily or one to two tablespoons of ground flaxseed twice daily. 

Supplements

- Beta-sitosterol: 60 mg twice daily 
- Zinc: 30–40 mg daily 

Botanicals

- Consider pygeum: 100 to 200 mg twice daily or saw palmetto: 160 mg twice daily 
- If no improvement after 8 weeks, consider adding rye grass pollen: 126 mg three times daily.  Rye grass pollen has more of an antiinflammatory effect, which may act synergistically with saw palmetto or pygeum.
- Other herbal products that have potential benefit include stinging nettles and pumpkin seed extract and cranberry.

Pharmaceuticals

- If no improvement occurs with the use of botanicals, discontinue them and start an alpha-adrenergic blocker (see text for doses). 
- If the patient is unable to tolerate an alpha blocker or if a greater response is desired, consider finasteride, at 5 mg daily. 
- For those with both erectile dysfunction and symptoms of BPH, consider a PDE-5 inhibitor such as tadalafil, 5 mg daily. 

Surgical Therapy

- If the patient's symptoms persist or worsen despite the foregoing measures, refer for urological evaluation and treatment, with the following options:
- Transurethral microwave thermotherapy (TUMT) 
- Transurethral incision of the prostate (TUIP) 
- Transurethral resection of the prostate (TURP)

CHAPTER 61

Urolithiasis (Kidney and Bladder Stones)

Jimmy Wu, MD, MPH

Pathophysiology

Over the past few decades, an increasing percentage of Americans has had the misfortune of experiencing the disabling pain that accompanies urolithiasis. A recent National Health and Nutrition Examination Survey (NHANES) in 2007 reported that about 1 in 11 Americans will have experienced at least one symptomatic stone in their lifetime.¹ Notable epidemiological risks include being white, male, obese, insulin resistant, and living in hot, arid regions.² As evidenced by Hippocrates' reference to "...persons laboring under the stone,..." in his famous oath, this common medical problem has challenged even history's most renowned healers.³

In addition to being responsible for so much morbidity in the individual patient, kidney stones were estimated by several recent studies to cost between \$4.5 and \$5.3 billion in lost work hours and direct health care costs.^{4,5} Because most patients with idiopathic kidney stones have some underlying urine metabolic abnormality, there is a recurrence risk of 40% at 5 years and 75% at 20 years.⁶ This tendency for urological stones to recur within the same people presents an opportunity for health care providers to promote a preventive and integrative approach in protecting against stone recurrence.

There are data that demonstrate certain epidemiological disparities in gender, geographic location, and race. For reasons that are still unclear, men consistently have a higher risk of developing kidney stones. Geographically, the "stone belt," consisting of the southeastern U.S. region, also tends to have higher prevalence of renal lithiasis; this is

likely due to its hotter climate. Finally, black Americans appear to suffer less from this disease than their white counterparts.⁷

Increased research on the consequences of the growing obesity epidemic is also demonstrating that obesity is an independent contributing factor for kidney stone formation. There are several theories behind this including the idea that the increased adiposity leads to an altered thermogenesis situation which produces a dehydrated state (thereby predisposing the body to supersaturation of stone ingredients). Obese individuals also tend to experience hyperuricemia and hypocitraturia, which are known risk factors for kidney stones.²

To provide the most appropriate counseling, it is important to understand how kidney stones form and what elements are commonly present in stones. Kidney stones are a product of normally soluble material (i.e., calcium, oxalate, etc.) that supersaturate in urine to a level that facilitates crystallization of that very material ([Fig. 61.1](#)).⁸ With this etiology in mind, any approach that discourages urinary crystallization or promotes crystallization inhibition forms the basis for the following preventive recommendations.

Individuals with recurrent kidney stones or with urolithiasis before age 30 should get a 24-hour urine test done to check for high levels of calcium, oxalate, and uric acid or for low levels of citrate. See [Table 61.1](#) for recommendations based on the test results.

More than 80% of kidney stones primarily consist of calcium, with most being calcium oxalate. These oxalate stones can also contain phosphate or uric acid. The remainder kidney stones can be divided into uric acid, struvite (magnesium ammonium phosphate or infection stone), and cystine as their primary constituents. Most calcium stone formers possess some sort of urinary metabolic abnormality that can be detected with a 24-hour urine sample⁸ (see [Table 61.1](#)).

The majority of patients (33%–66%) who suffer from calcium-based kidney stones have hypercalciuria, which is mostly idiopathic but can be familial as well. The urine is supersaturated, with a high enough level of calcium that calcium renal calculi begin to form. It is important to note that if there is accompanying hypercalcemia, other disorders must be ruled out (i.e., hyperparathyroidism, sarcoidosis, cancer, etc.).⁹

Similarly, patients who are found to have high urinary oxalate levels are predisposed to passing calcium oxalate stones. Hyperoxaluria is due

to two main causes. There is a rare primary form that is inherited in an autosomal recessive fashion. There is also a more common acquired form that involves increased oxalate absorption secondary to ileal compromise and fat malabsorption (enteric fat does not get absorbed and subsequently binds to dietary calcium, which results in higher levels of absorbed oxalate).¹⁰

The third metabolic disorder found in patients with calcium stones is hypocitraturia. Citrate serves as a protective factor against calcium stone formation because it can chelate calcium in urine, thereby forming a soluble complex that is harmlessly excreted. Therefore people with low levels of citrate in their urine are at risk for calcium stone formation.¹⁰

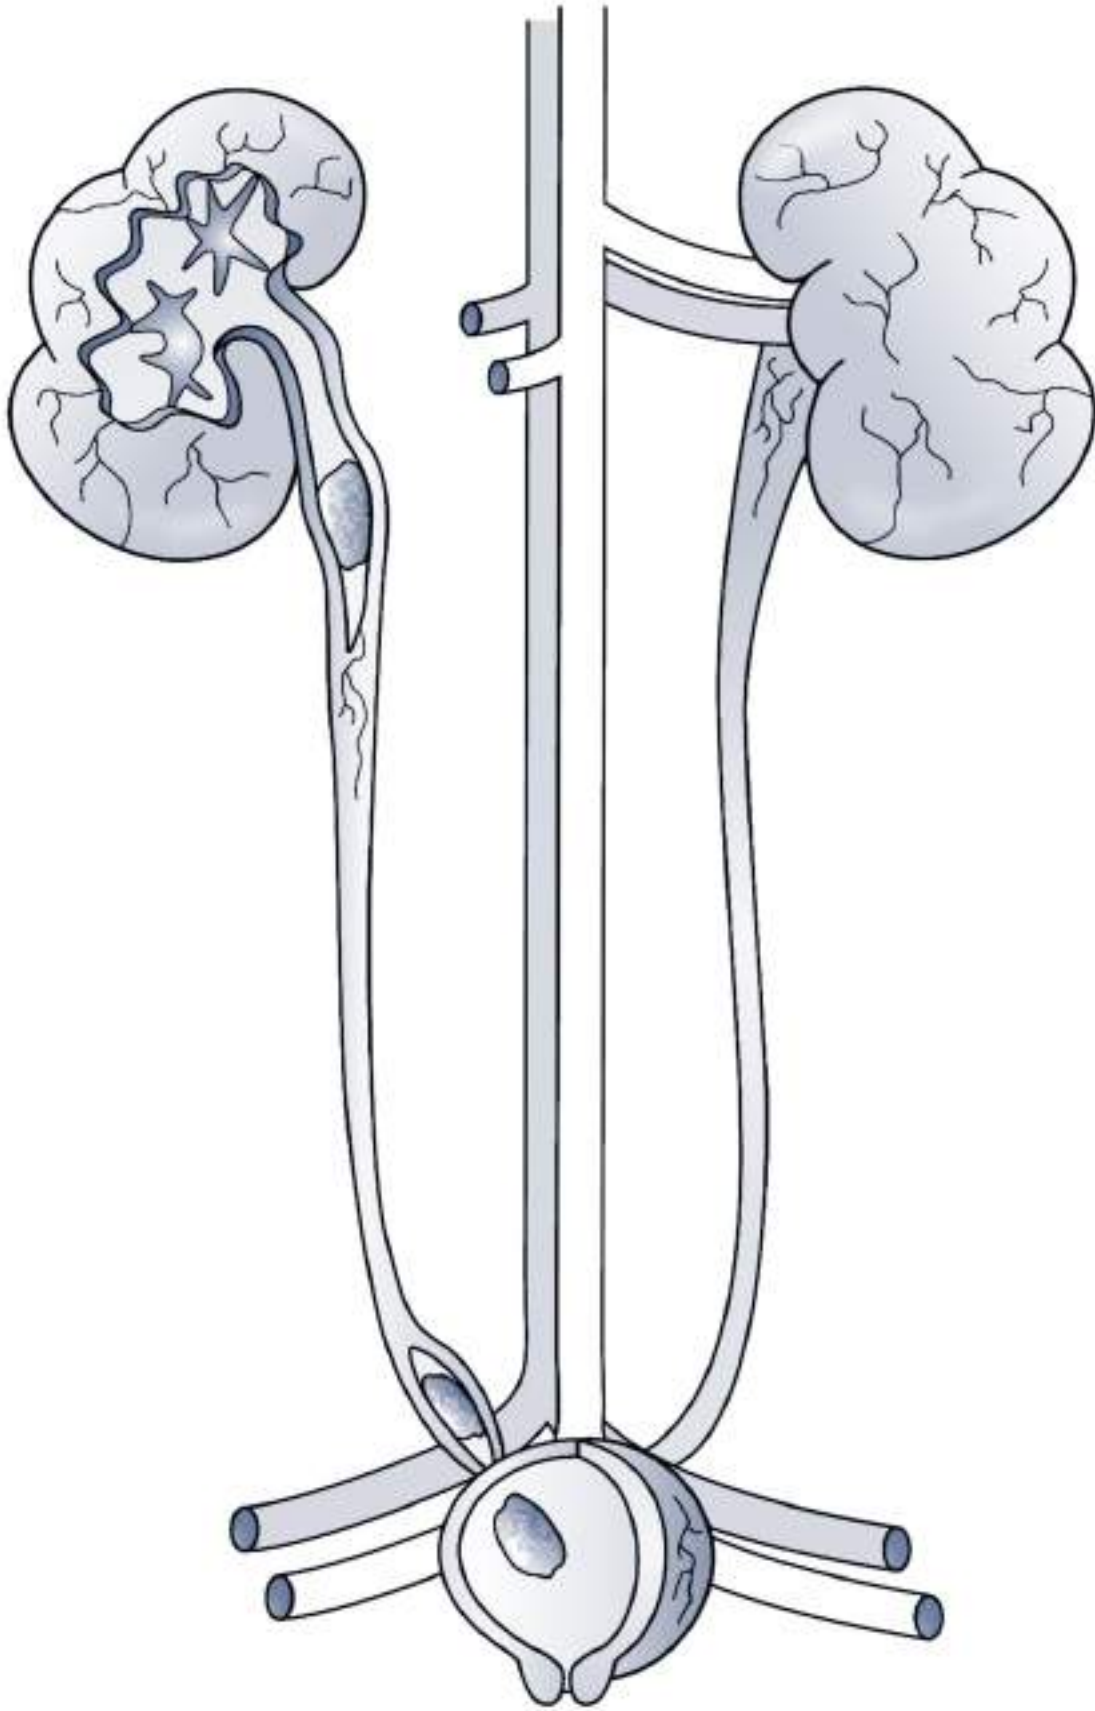

FIG. 61.1 Kidney stones in the kidney, ureter, and bladder. (From National Kidney and Urologic Diseases Information Clearinghouse: <http://kidney.niddk.nih.gov/kudiseases/pubs/stonesadults/index.htm>).

Of the stones that are not composed of calcium, primary uric acid nephrolithiasis is the next most common (10%). Any factor that acidifies the urine pH (i.e., protein intake, insulin resistance) creates an environment that is more susceptible to stone formation. The other two factors that contribute to uric acid stone formation include low urinary volume (i.e., dehydration, diarrhea) and hyperuricosuria (i.e., enzymatic deficiency syndromes, drugs, gout, etc.).¹¹

Struvite stones typically form in patients who have chronic urinary tract infections due to urease-producing bacteria such as *Proteus* or *Klebsiella*. These patients classically develop staghorn calculi that are found in the renal pelvis. The stones consist of multiple magnesium ammonium phosphate crystals and calcium carbonate-apatite.¹²

Finally, cystine stones (1%) are the result of cystinuria, which is a rare genetic autosomal-recessive metabolic disorder. Cystine stones should be considered in patients who present with their first stone during early childhood (median age = 12 years).¹³

Integrative Therapy

Nutrition

Any dietary recommendation that limits lithogenic ingredients and promotes lithoprotective factors serves as the basis for the following nutritional and supplemental suggestions (Tables [61.1](#) and [61.2](#)). There is an abundance of literature regarding the role of nutrition and supplements in kidney stone prevention, but there is a relative lack of solid evidence to support the following dietary recommendations.

Weight

As mentioned previously, obese people who develop qualities of metabolic syndrome are at increased risk for stone formation. There is no research that directly studies the potential protective impact of weight loss on the development of kidney stones. However, it has been well established that the risk for stones increases with BMI¹⁴; therefore one can reasonably infer that weight loss in individuals with unhealthy BMIs

should decrease their risk for nephrolithiasis. This underlines the overall importance of promoting healthy nutrition and physical activity in the prevention of kidney stones.¹⁵⁻¹⁷

TABLE 61.1

Lithogenic Values of Urinary Biochemical Factors With Dietary Prescription

Urine Factor	24-Hour Urine Value	Dietary Prescription
Fluid volume	<2 L/24 hours	Maintain total fluid intake > 2 L/day Reduce caffeine Stay more hydrated if strenuous physical activity
Calcium	Female >250 mg/24 hours Male >300 mg/24 hours	Maintain adequate dietary calcium intake Reduce sodium and animal protein intake Reduce calcium supplements Reduce carbohydrate intake
Oxalate	>40 mg/24 hours	Maintain adequate dietary calcium intake Reduce dietary oxalate intake Avoid vitamin C supplements Increase magnesium-rich foods
Citrate	Female <550 mg/24 hours Male <450 mg/24 hours	Increase fruit and vegetable intake Reduce sodium and animal protein
Uric Acid	Female >600 mg/24 hours Male >800 mg/24 hours	Reduce purine-high foods Reduce animal protein intake Reduce alcohol intake

Adapted from Graces F, Costa-Bauza A, Prieto RM. Renal lithiasis and nutrition. *Nutr J.* 2006;5:1-7 and Taylor EN, Curhan GC. Diet and fluid prescription in stone disease. *Kidney Int.* 2006;70:835-839.

Water

Increasing fluid intake is a dietary recommendation that possesses strong scientific support for its role in preventing recurrent renal lithiasis. Several observational studies dating to 1966 have postulated that increased fluid intake is beneficial; results from one randomized control trial in 1996 showed that fluid intake achieving a urinary volume of 2 liters reduced stone recurrence rate from 27% to 12%.¹⁸⁻²¹

A safe recommendation would be to ask patients to drink 2–3 liters of water per day. One approach is to tailor the fluid recommendation with the calculated urine volume from the 24-hour urine test. For example, if the 24-hour urine volume were 1.5 liters, it would be best to advise the patient to drink two more 8-ounce (2 × 240 = 480 mL) cups of water to achieve a total of 2 liters.²² There is no evidence for the following, but

some doctors recommend their patients maintain urine at a very light color. Some have also advocated drinking water at bedtime because urinary concentration usually occurs during sleep.²² It is especially important for endurance athletes with stones to be aware of their fluid loss through sweat. Furthermore, mineral water should be ingested with some caution because it may contain calcium or other lithogenic material.

TABLE 61.2
Foods High in Bioelements Related to Calcium Oxalate Stone Formation

Lithoprotective		
Calcium (dietary)	Magnesium	Citrate
Milk Yogurt Cheese Broccoli Salmon	Almonds Cashews Soybean Potato Nuts	Orange Lemon Cranberry Pineapple High-citrate juices and sodas

Lithogenic		
Sodium	Oxalate	Purine
Potato chips Canned foods Frozen dinners Soy sauce Table salt	Rhubarb Spinach Chocolate Peanuts Cashews	Legumes Spinach Red meat Alcohol Sardines

Adapted from <http://ods.od.nih.gov/factsheets/list-all/> and Graces F, Costa-Bauza A, Prieto RM. Renal lithiasis and nutrition. *Nutr J.* 2006;5:1-7.

Beverages

There is a smattering of studies that have examined the efficacy of encouraging or discouraging intake of different types of beverages for the prevention of stones. Fruit-based juices have especially been studied because of their citrate (lithoprotective) content. However, vitamin C has been shown to increase urine oxalate (lithogenic); not surprisingly, evidence for fruit-based juices is still ambiguous.¹⁵ Several studies have shown that grapefruit juice increases the risk for stones; on the other hand, lemon juice, orange juice, and cranberry juice have mostly been viewed as protective against renal stones.^{7,15,23-26}

Not much is discussed about the role of soft drinks in stone formation, but the general recommendation would be to limit consumption, possibly because of their high fructose content.²⁷ However, sodas with higher citrate content may theoretically neutralize any lithogenic effect.²⁴ The effects of caffeinated beverages such as coffee and tea (especially black) on stone formation are quite mixed.²⁶⁻²⁷

Sodium

Studies have shown that increase in dietary sodium results in an increased urinary excretion of calcium and a decreased urinary excretion of citrate. This combination effect makes high sodium intake a potential risk factor for higher stone recurrence; such intake is associated with a 50%–61% increase in risk of kidney stones.²⁸ Recent studies have shown that a low-salt diet could reduce calcium excretion.²⁷ It is recommended that sodium intake be restricted to less than 3–6 grams per day, especially for patients with hypercalciuria.^{7,15,20}

Protein

Increased protein intake appears to increase urinary calcium and uric acid and decrease urinary citrate levels.^{7,15,20} Therefore, reducing protein intake may also benefit individuals with calcium and uric acid stones. There have been some studies that have examined combination diets, and those that consisted of a low-protein component had a lower stone recurrence rate.²⁹

Carbohydrates

Some postulate that a possible relationship between higher intake of carbohydrates / refined sugar and increased urinary calcium is partially responsible for why wealthier countries have higher rates of kidney

stones.⁷ However, the association is too weak to recommend carbohydrate cessation as a form of protection against stone recurrence.

Omega-3 Fatty Acids

Increased intake of dietary omega-3 fatty acids does not reduce the risk for kidney stone formation. However, there is promise that fish oil supplements may have a role in preventing stone formation because small studies have shown that it reduces the urinary excretion of calcium and oxalate.³⁰⁻³²

Purines

People with uric acid stones are generally advised to avoid a high-purine diet. Purine-containing foods include organ meats, legumes, mushrooms, spinach, alcoholic, sardines, and poultry.¹¹

Oxalate

Despite several studies, there is currently no consensus regarding the effect of dietary oxalate on stone formation, even in those with hyperoxaluria.^{15,27} Dietary oxalate may not be readily absorbed due to its low bioavailability.^{7,20} Therefore, there is no firm recommendation about limiting dietary oxalate; however, there is also little harm in such advice. Oxalate-rich foods include nuts (almonds, peanuts, pecans, walnuts, cashews), vegetables (rhubarb, spinach), and chocolate.^{15,20}

Calcium (Dietary and Supplemental)

Contrary to conventional wisdom, it is not recommended to limit dietary intake of calcium. This conclusion has been proven several times with strong evidence. Two prospective observational studies from the 1990s concluded that kidney stone formation was inversely associated with dietary calcium intake.^{30,33,34} In addition, a 5-year randomized control trial comparing groups that differed by the calcium load in their diet showed that decreasing dietary calcium was a risk factor for symptomatic stone recurrence.^{30,35}

The theory behind this conclusion is that dietary calcium protects against stone formation by binding with oxalate, thereby reducing urinary oxalate levels. It takes a smaller increase of urinary oxalate, than of urinary calcium, to precipitate stone formation, which makes a high urinary oxalate level a larger risk factor in calcium oxalate stone

formation. This finding explains why dietary calcium is actually lithoprotective.³³

Supplements

Calcium

Contrary to dietary calcium, it has been suggested that calcium supplements increases risk of urolithiasis. A 1997 study showed that women using calcium supplements had a higher risk of calcium stone formation. This finding was explained by the fact that the supplements were not taken with food, thereby nullifying calcium's function in reducing dietary oxalate absorption. However, other data have shown a neutral effect of calcium supplements for men and younger women.^{20,30,34,36}

Vitamin C

Vitamin C can be metabolized to oxalate and therefore could theoretically increase the risk of stone formation. A trial has shown that supplemental vitamin C increases urinary oxalate excretion; however, there has been no evidence that it actually causes an increase in symptomatic stone formation. Therefore, recurrent stone formers should not be instructed to limit their dietary vitamin C intake, especially since foods high in vitamin C are also high in citrate. However, it is reasonable to suggest limited intake of supplemental vitamin C.^{7,15,20,37}

Vitamin D

Recently, increased vitamin D intake has been encouraged as sound general health advice. However, due to its role in calcium absorption, there is a theoretical possibility of increased vitamin D being a risk factor for calcium stones. On the contrary, several studies have shown that high serum vitamin D levels are not associated with a high prevalence of kidney stone disease.^{27,38}

Zinc

High dietary zinc intake has also been shown to increase the risk of kidney stone formation. This may partially explain why animal protein intake also possesses strong lithogenic properties.³⁹

Magnesium

In theory, magnesium binds to oxalate, potentially decreasing one's risk for calcium oxalate stones. There is sparse data suggesting that dietary and supplemental magnesium can lower risk of stone formation in men.^{28,40} Dietary magnesium can be mostly found in dairy products, meat, seafood, avocados, dark green vegetables, and cocoa.¹⁵

Botanicals and Other Herbal Medicines

There are many studies that have examined the potential use of various botanicals and herbs for prevention of stone formation. However, most studies have used in vitro or animal models. There are only a few that have demonstrated some promise within human models.⁴¹

Phyllanthus niruri (i.e., Stonebreaker, Chanca Piedra, etc.) is a plant that has been studied and used in Brazil; it has been studied in the human population and has shown efficacy in preventing stone recurrence.⁴¹ Other studied herbals include *Andrographis paniculata*, *Hibiscus sabdariffa*, and *Orthosiphon grandiflorus*.⁴¹ Most of these are frequently consumed as teas.

Phyllanthus niruri may potentiate insulin and other antidiabetic medications, as well as antihypertensive medications. Do not take during pregnancy.

Probiotics

Oxalobacter formigenes is an anaerobic bacterium responsible for degrading oxalate in our body. It has been postulated that a probiotic containing this species would be useful for preventing stone formation in those with hyperoxaluria. Results from a study that evaluated some probiotic products on the market showed that they did not contain any *Oxalobacter formigenes* and therefore would be unlikely to benefit patients with calcium oxalate stones.⁴² There have not been many studies that have shown actual benefit in decreasing symptomatic stone incidents, but several have demonstrated its physiological significance in decreasing urinary oxalate levels.^{27,43,44}

Traditional Chinese Medicine

Acupuncture

There is a paucity of data in the literature about acupuncture as a preventive measure for kidney stones, but it has been used extensively as an analgesic for both the acute renal colic presentation and for those who are receiving a planned extracorporeal shock wave lithotripsy (ESWL) procedure.⁴⁵

There is some anecdotal evidence that acupuncture utilizing techniques that facilitate energy manipulation of the kidney and bladder organs may help with acute stone-related pain and with stone recurrence.⁴⁶

Herbals

There is limited data from the Kampo traditional Japanese herbal medicine tradition indicating that some herbal mixtures, including chorei-to, wullingsan, jin qian cao, and niao shi mixture, have been helpful mostly as diuretics in stone prevention.^{45,47}

Ayurvedic Medicine

Including *P. niruri*, as described previously, there have been several other ayurvedic medicines commonly used for nephrolithiasis management including *Tribulus terrestris*, *Orthosiphon stamineus/grandiflorus* (java tea), and *Dolichos biflorus* (horse gram).⁴⁷ One of the more studied ayurvedic products is known as Cystone. It contains several ingredients that have been claimed to decrease urinary supersaturation. There has been one good study on the Cystone that does not support its efficacy.⁴⁸

Pharmaceuticals

The following text contains a discussion on medicines that have demonstrated efficacy for the prevention of stone recurrence. Management of acute nephrolithiasis-related symptoms (i.e., pain, nausea, etc.) will not be discussed in this chapter.

Alkalinizers

This class of drugs primarily works by increasing urine pH. Because uric acid stones tend to supersaturate in acidic urine, alkalinizers such as potassium citrate and sodium bicarbonate are mostly used to prevent documented uric acid stones. Potassium citrate is preferred because it can also reduce urinary calcium and provide citrate as a lithoprotective element.⁴⁹

Potassium Citrate

Dosage

10 mEq three times a day (if $U_{\text{citrate}} > 150 \text{ mg/day}$) or 20 mEq three times a day (if $U_{\text{citrate}} < 150 \text{ mg/day}$) with meals, up to 100 mEq/day. Comes in 5- and 10-mEq pills.

Precautions

Nausea, hyperkalemia (especially when taken with other medicines that may cause hyperkalemia).

Sodium Bicarbonate

Dosage

650 mg three times a day. Comes in 325 and 650 mg tablets. Also in powder form.

Precautions

Bloating.

Calcium-Channel Blockers

Data indicate that this class of medicines acts as an “expulsive” medicine that assists with stone passage. It works as an antispasmodic on the ureter, eliminating the fast, uncoordinated components of ureteral smooth muscle contraction. Most studies have examined its use in conjunction with a steroid (25 mg/day of methylprednisolone) and results have demonstrated a higher stone-expulsion rate, shorter

expulsion time, and a reduced need for analgesia.⁴⁹

Nifedipine

Dosage

30 mg daily extended release (ER) for 20–30 days. Comes in 30 mg ER tablets.

Precautions

Flushing, peripheral edema, lightheadedness / dizziness, headache, gastrointestinal upset.

Alpha-1 Channel Blockers

Alpha-1 channel blockers also work as antispasmodics, especially on the distal ureter. Several studies, especially for distal ureteral stones, have demonstrated a higher stone-expulsion rate with their use.⁴⁹

Tamsulosin, Doxazosin, Alfuzosin

Dosage

- *Doxazosin*: Start 1 mg at night and titrate every week to effect. Maximum dose is 8 mg / day. Comes in 1, 2, 4, and 8 mg tablets.
- *Tamsulosin*: Take 0.4 mg, 30 minutes after a meal each day. Maximum dose is 0.8 mg daily. Comes in 0.4 mg tablets.
- *Alfuzosin ER*: 10 mg daily. Comes in 10 mg ER tablets only.

Precautions

Postural hypotension, dizziness, fatigue, headache, nasal stuffiness, and retrograde ejaculation.

Recommendation is that medical expulsive therapy can be used for stones up to 10 mm. Alpha channel blockers appear to perform better with stones 5–10 mm.⁵⁰

Thiazide Diuretics

Thiazides can lower calcium excretion by as much as 50% and therefore benefit patients with recurrent stones due to hypercalciuria. Thiazides should be considered if recurrence of stones persists despite appropriate dietary changes. Studies have shown a 90% reduction in incidence of new stones with the use of thiazides. Chlorthalidone can be given just once a day because of its lower half life. However, be wary of hypokalemia because low potassium can reduce urinary citrate excretion. To avoid hypokalemia, it is advisable to add potassium citrate.⁴⁹

Hydrochlorothiazide, Chlorthalidone

Dosage

- *Hydrochlorothiazide*: 25 mg daily, but higher doses may be needed to achieve adequate calcium-lowering effect. Comes in 12.5, 25, and 50 mg tablets.
- *Chlorthalidone*: 25 mg daily. Comes in 25 mg tablets.

Precautions

Hypokalemia, hyperuricemia, hyponatremia, dizziness, and headache.

Xanthine Inhibitors

Frequently used in patients with gout, these medicines can also be used for management of stone formers with hyperuricosuria (with either uric acid or calcium stones). It interferes with the conversion of xanthine into uric acid.¹¹

Allopurinol

Dosage

200–300 mg per day divided once daily to three times a day.

Precautions

Use with caution in patients with renal failure.

FIG. 61.2 Extracorporeal shockwave lithotripsy. (From National Kidney and Urologic Diseases Information Clearinghouse:

Surgery

Most stones smaller than 4 mm are generally watched conservatively and felt to have a 90% chance of passing by themselves, especially if they are located in the distal ureter. Stones between 4 and 6 mm have a dramatically lesser chance of passing (50%), whereas stones between 7 and 10 mm have only a 20% chance of spontaneously passing. Besides those of a larger size, stones that are more proximally located in the ureter have greater difficulty for spontaneous resolution.⁵¹

Surgery is considered for kidney stones that are felt to have a low chance of self-resolution. This includes lithotripsy, ureteroscopy, and percutaneous nephrostomy—choice of therapy depends on several factors including the position and size of the stone.

Extracorporeal Shockwave Lithotripsy

Of the three surgical options, extracorporeal shockwave lithotripsy (ESWL) is the least invasive and considered to be first-line therapy for the appropriate context. Lithotripsy has been considered to be just as effective as ureteroscopy for stones that are smaller than 10 mm (86% vs. 90% stone free rate, respectively), regardless of location in the ureter. If the stone is large, lithotripsy may have to be performed several times ([Fig. 61.2](#)).⁵²

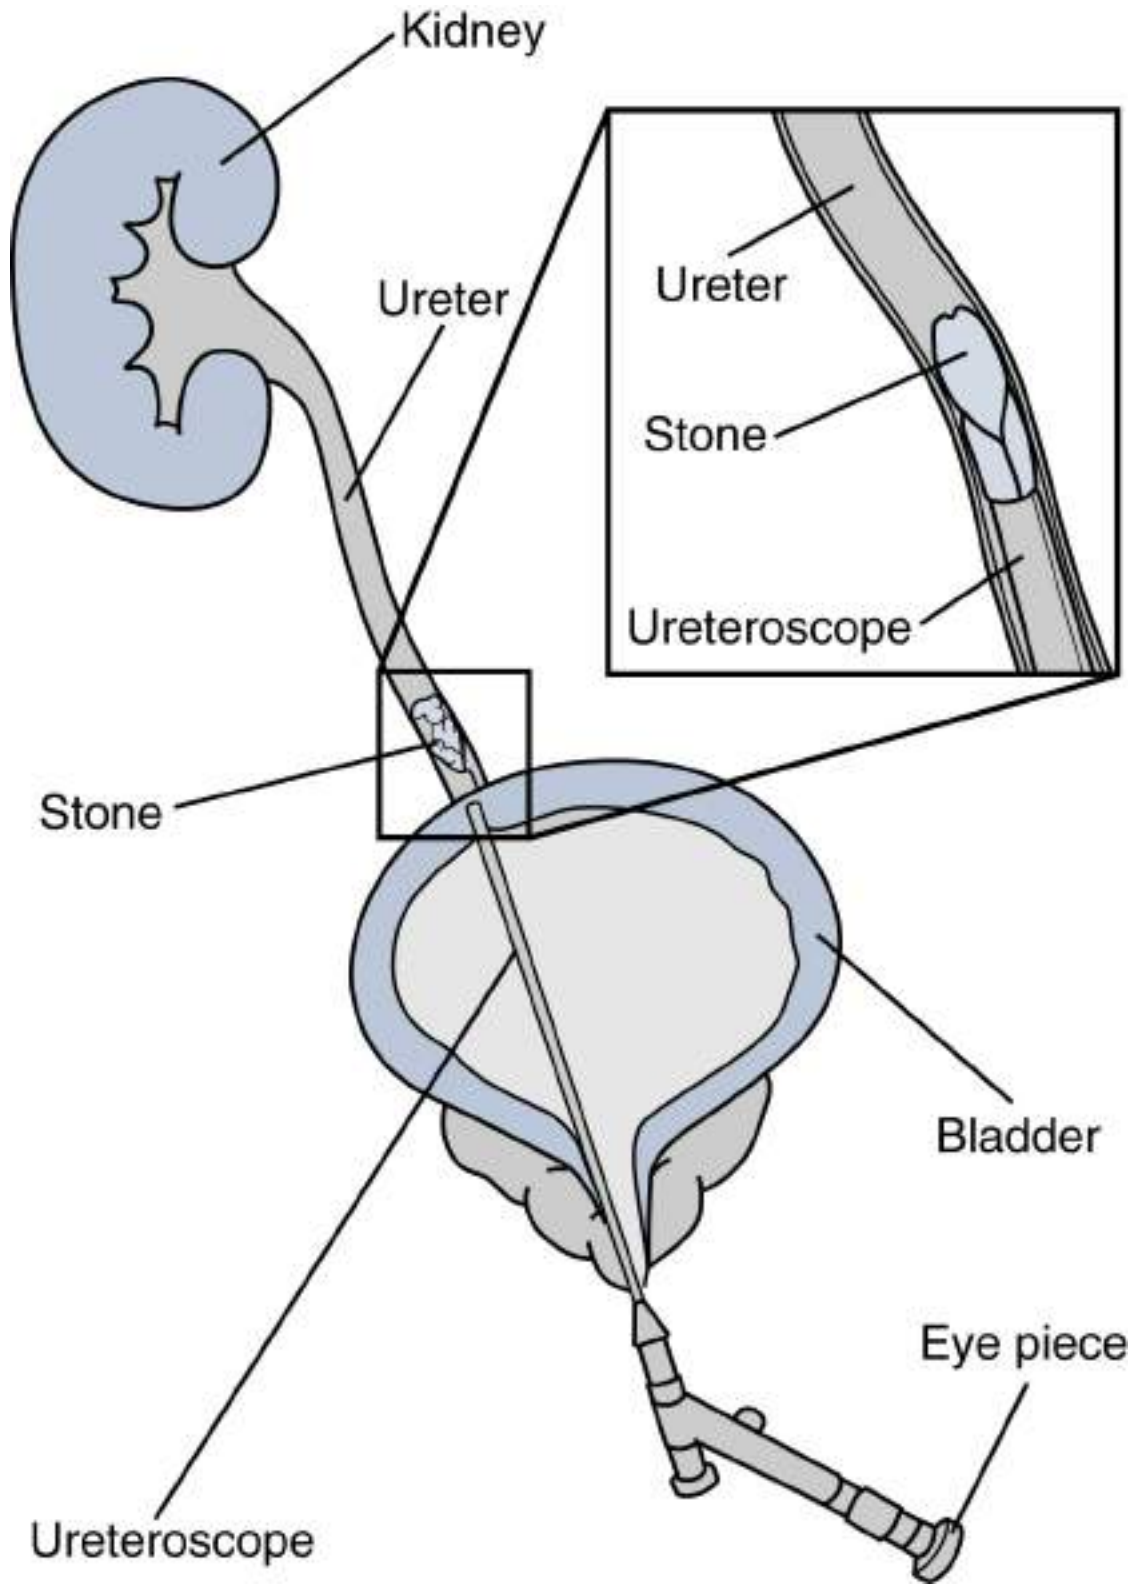

FIG. 61.3 Ureteroscopic stone removal. (From National Kidney and Urologic Diseases Information Clearinghouse:

Serious complications of ESWL are not common, but the procedure can cause transient pain, hematuria, nausea, and vomiting. More life-threatening complications have been common in patients who have required multiple treatments for larger stones. Pregnancy, uncontrolled hypertension, uncontrolled coagulopathy, and distal obstruction to stone are absolute contraindications.⁵²

Rigid and Flexible Ureteroscopy

In stones that are larger than 10 mm, while ESWL can still be considered, ureteroscopy has been reported to have better success (67% vs. 73%, respectively). This technique involves passing a scope through the ureter to physically remove the stone, sometimes with the help of laser (Fig. 61.3). This technique is preferred, especially for larger, proximal, and impacted stones. In patients who have absolute contraindications to ESWL therapy, ureteroscopy is an acceptable alternative.⁵²⁻⁵³ Especially with the development of more advanced technology (flexible and smaller caliber scopes) and techniques, complications such as ureteral perforation or stricture formation have become much less common.⁵²⁻⁵³

Percutaneous Nephrolithotomy

Because of a larger side-effect profile, this is reserved for treatment of renal calculi (especially staghorn struvite stones) and large impacted proximal ureteral stones. Stones that have failed ureteroscopy are also candidates for percutaneous nephrolithotomy. This procedure involves inserting a needle through the skin into the kidney's collecting system and dilating the tract to 1 cm, which allows the urologist to break up and remove the stones (Fig. 61.4). Just like any other invasive procedure, percutaneous nephrolithotomy has complications such as bleeding, injury to other organs, or infection.⁵²⁻⁵³

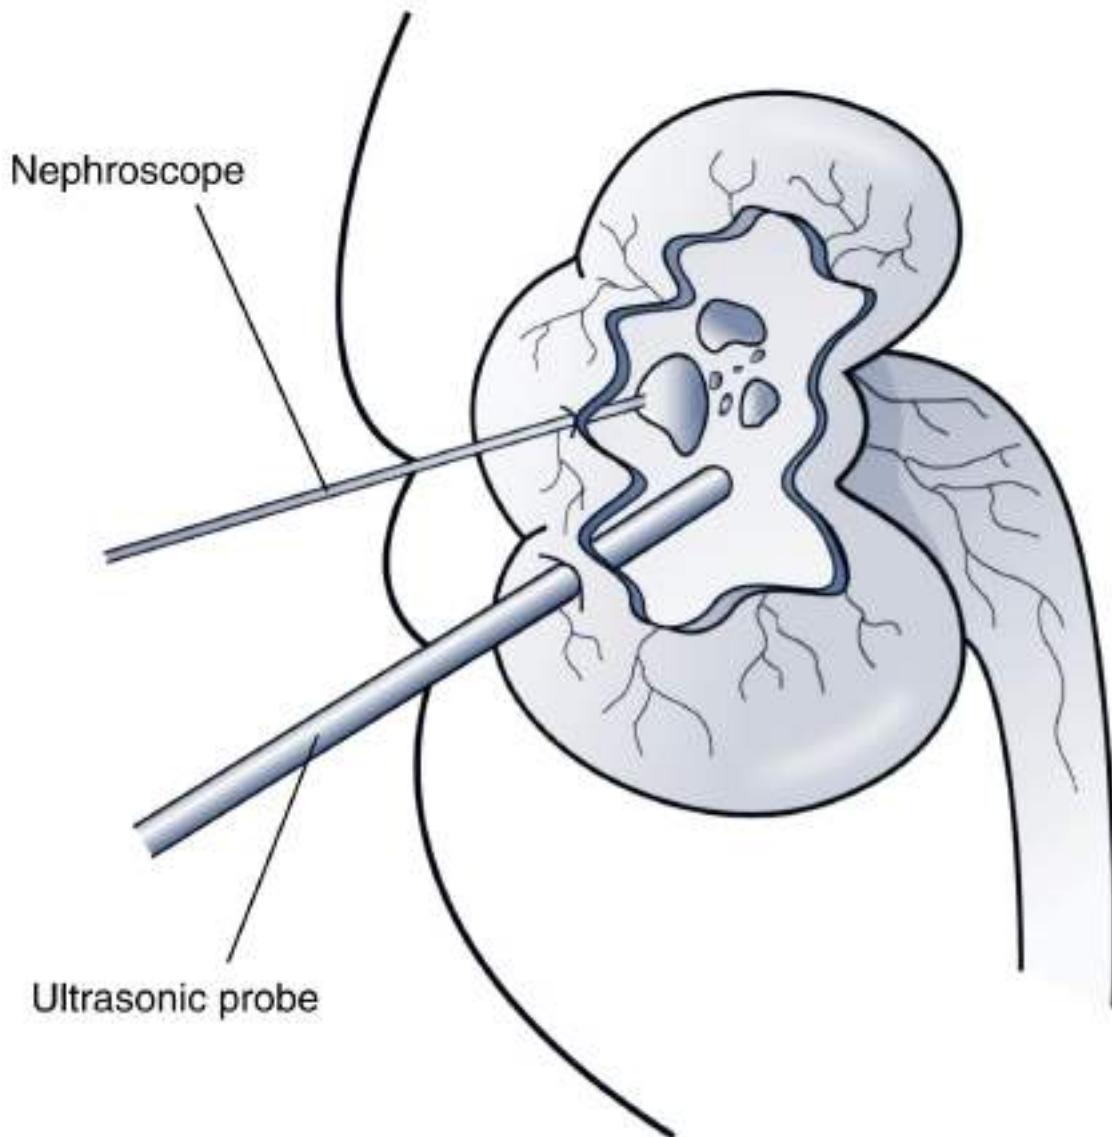

FIG. 61.4 Percutaneous nephrolithotomy. (From National Kidney and Urologic Diseases Information Clearinghouse:

<http://kidney.niddk.nih.gov/kudiseases/pubs/stonesadults/index.htm>).

Prevention Prescription

- Maintain a daily fluid intake of 2–3 L (~8–10 glasses of water). Try to limit situations that would exacerbate dehydration (i.e., hot weather, endurance exercise, etc.).
- Do NOT limit your dietary calcium intake (strive for 1000–1200 mg/day).

- A low sodium, low protein diet can be helpful.
- Drink lemonade, orange juice, and cranberry juice, but limit grapefruit juice and sodas.
- Develop a healthy lifestyle that maintains a normal body mass index.
- For those with hyperoxaluria, limit intake of foods with high oxalate levels, including nuts (almonds, peanuts, pecans, walnuts, cashews), vegetables (rhubarb, spinach), and chocolate.

Therapeutic Review

Following is the summary of therapeutic options for kidney stones. The purpose behind these suggestions is to prevent recurrence of symptomatic stones. Regardless of composition, all patients with kidney stones should be advised to increase their water intake.

Depending on the type of stone and results of the metabolic evaluation, additional dietary, supplemental, and medical recommendations can also be made. Surgery is reserved for large stones, recalcitrant disease, obstructing disease, and for stones located in certain difficult-to-access positions along the urological tract.

Remove Exacerbating Factors

- Avoid excessive exposure to any environment or activity that promotes dehydration (warmer climates or strenuous physical activity).
- Maintain general healthy eating and physical activity habits that prevent development of metabolic syndrome conditions (obesity, hypertension, hyperlipidemia, etc.).

Nutrition

- Drink lots of water. Two to three liters per day is recommended (8–10 glasses of water). 
- Do not limit dietary calcium intake. 
- Limit caffeine, soda, grapefruit juice, protein, carbohydrate, and salt intake (<2.5 g daily). 
- Drink lemonade, orange juice, and cranberry juice. 

- Decrease consumption of oxalate-containing foods, especially in those with hyperoxaluria. These include nuts (almonds, peanuts, pecans, walnuts, cashews), vegetables (rhubarb, spinach), and chocolate. 
- Decrease intake of purine-rich foods, especially in those with uric acid stones. 
- Tailor your diet based on type of metabolic abnormality. 

Supplements

- Limit supplemental calcium, but if needed for bone fortification, take with food. 
- Limit supplemental vitamin C. 
- Take supplemental omega-3 fatty acids. 
- Take supplemental magnesium. 
- Probiotics containing *Oxalobacter formigenes* can be used, especially for those with hyperoxaluria. 

Botanicals

- *Phyllanthus niruri* (a.k.a. Stonebreaker, Chanca Piedra)—take 250 mg daily to twice a day before meals. 
- Other Chinese herbs can be tried (chorei-to, wullingsan, jin qian cao, and niao shi). 
- Other herbs frequently used in Ayurvedic medicine (*Tribulus terrestris*, *Orthosiphon stamineus/grandiflorus* (java tea), and *Dolichos biflorus*) can be considered. 

Energy Medicine

- Acupuncture can be used for post-ESWL pain and possibly as a kidney/bladder energy modifying treatment. 

Pharmaceuticals

- Diuretics, especially thiazides, can be used for their hypocalciuric

effects. 

- Potassium citrate is useful as an alkalinizer and citrate promoter. 
- Alpha-1 blockers and calcium channel blockers can facilitate stone expulsion. 
- Allopurinol can help prevent uric acid stones. 

Surgical Therapy

- ESWL is very successful for smaller stones (<1 cm) located in the distal ureter. 
- Ureteroscopy can be utilized for larger stones that are located more proximally or are impacted. 
- Percutaneous nephrolithotomy is reserved for recalcitrant stones and for staghorn calculi.

CHAPTER 62

Chronic Prostatitis/Chronic Pelvic Pain Syndrome

Myles Spar, MD, MPH

Pathophysiology

Chronic prostatitis affects an estimated 9% of men in the United States.¹ The name is misleading as no infectious or causative agent is identified in the majority of cases. In fact, among specialists and researchers, this condition has come to be more accurately termed as chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) because most men with the condition describe symptoms of intermittent pelvic or urethral discomfort or pain. Patients often have other symptoms, similar to women with CPPS, including fatigue, depression, and irritative voiding symptoms; these symptoms are similar to those of benign prostatic hypertrophy (BPH). Sexual dysfunction, including erectile dysfunction and premature ejaculation, has also been shown to be strongly correlated with CPPS symptoms.^{2,3}

The exact etiology of CP/CPPS is unknown, and there is no single established course of treatment. However, the condition is not only prevalent but also the impact of CPPS on quality of life is sizeable—comparable to that of Crohn’s disease or myocardial infarction.⁴

The impact of CPPS on quality of life is sizeable—comparable to that of Crohn’s disease or myocardial infarction.

Diagnosis

The diagnosis of CP/CPPS is made by screening for infectious causes of symptoms by looking for leukocytes in prostatic secretions using expressed prostatic secretions (EPS) or by postdigital rectal exam urinalysis (post-DRE U/A). Postprostatic massage urinalysis has been shown to correlate well with expressible prostatic secretions.⁵

The National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), which is the institute within the National Institutes of Health that oversees research devoted to CP/CPPS, recognizes five categories of prostatitis syndromes, with type III (CP/CPPS) being by far the most common, comprising 90% of all cases of symptomatic prostatitis⁶ ([Table 62.1](#)). This chapter focuses on type IIIB, which is the most prevalent as well as the most challenging to treat.

Risk factors for CP/CPPS have not been clearly identified, and traditional risk factors for many diseases, such as smoking, obesity, or alcohol consumption, were not associated with CP/CPPS risk as assessed from the longitudinal Health Professionals Follow-Up Study (HPFS),⁷ although higher leisure-time physical activity has been shown to be associated with a lower risk of CP/CPPS.⁸

The intensity of CP/CPPS symptoms can be measured using the National Institutes of Health Chronic Prostatitis Symptom Index (NIH-CPSI), which is a self-administered questionnaire that focuses on location, quality, and severity of pain; irritative and obstructive urinary symptoms; and overall quality of life ([Fig. 62.1](#)). The NIH-CPSI reports subscores for pain (0–21), urinary symptoms (0–10), and quality of life (0–12), as well as a total score (0–43).⁹

Since the NIH-CPSI was validated in 1999, the recognition of CP/CPPS as a heterogeneous disorder with multiple causes and various presenting symptomology has explained why clinical treatments have, in general, largely failed to have a substantial impact. This has led to other approaches for categorizing the disorder so that treatment can be better studied for each type of presentation. Thus, the urinary, psychosocial, organ-specific, infection, neurological/systemic, and tenderness (UPOINT) phenotype system has been validated as an effective phenotype system in classifying patients with CP/CPPS.¹⁰ The identification of which phenotype a patient presents with helps guiding the course of treatment.

With the UPOINT system, history review, physical examination, urine cultures, and EPS or post-DRE urine results lead to a yes/no classification for each of the six UPOINT domains:

- Urinary is positive if the patient has bothersome urinary symptoms or

- high postvoid residual.
- Psychosocial is positive in the presence of clinical depression or catastrophizing.
 - Organ-specific is positive if there is specific prostate tenderness on examination, leukocytosis on microscopic examination of prostatic fluid or post-DRE U/A, or presence of hematospermia.
 - Infection is positive (in the absence of a current or previous urinary tract infection) if gram-negative bacilli or enterococci are found in prostatic fluid or if urine is positive for ureaplasma.
 - Neurological/systemic is positive if there is pain outside the abdomen and pelvis or a concurrent diagnosis of fibromyalgia, chronic fatigue syndrome, or irritable bowel syndrome.
 - Tenderness is positive if there are palpable muscle spasms or trigger points in the abdomen or pelvic floor.

TABLE 62.1**National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK)–Recognized Prostatitis Syndromes**

Type I: Acute bacterial prostatitis

Type II: Chronic bacterial prostatitis (bacteria can be cultured from semen or post-DRE urine)

Type III: Chronic abacterial prostatitis, chronic pelvic pain syndrome (CPPS)

Type IIIA: Inflammatory CPPS (Leukocytes > 10/hpf in EPS/post-DRE urine)

Type IIIB: Noninflammatory CPPS (Leukocytes < 10/hpf in EPS/post-DRE urine)

Type IV: Asymptomatic inflammatory prostatitis

DRE, digital rectal exam; *hpf*, high-power field.

The most common presenting phenotypes are urinary, organ specific, and tenderness.

The most appropriate diagnostic approach in a patient suspected of having CP/CPSP may be the use of the self-administered NIH-CPSI and then identification of the particular phenotype through history, physical examination, and lab analysis to decide on the best course of treatment. Then NIH-CPSI can be used to monitor the impact of treatment over time.

Integrative Therapy

There are several interventions that have been shown to be helpful in studies grouping all phenotypes of CP/CPSP together. One meta-analysis of randomized controlled trials of all interventions from 1947 through 2011 included 35 controlled trials for CP/CPSP treatment.¹¹ Symptom improvement was observed with several therapies, including some medications not approved in the United States (meparttricin and a muscle relaxant, thiocolchicoside), with each showing benefit in one study. Urinary symptom improvement was demonstrated with percutaneous tibial nerve stimulation, especially when combined with acupuncture. Interestingly, across all studies, placebo administration resulted in symptom improvement over time for all outcomes, indicating a strong mind-body component of CP/CPSP symptoms and/or a natural waning of symptoms over time.

Pharmaceuticals

The previously mentioned analysis showed no therapeutic effect of alpha-blockers or antibiotics, either alone or in combination. However, another review looked at the effectiveness of the following: alpha-blockers, antiinflammatories, antibiotics, finasteride, phytotherapy, gabapentin, glycosaminoglycans, and placebo.¹² The authors concluded that alpha-blockers, antibiotics, and a combination of both appeared to improve symptoms compared with placebo, while antiinflammatory drugs, finasteride, and phytotherapies (pollen extract or Quercetin) also had a measurable effect on symptoms. The authors noted that publication bias and small-study effects may have accounted for the positive findings, especially regarding alpha-blockers and antiinflammatories. A further systematic review failed to demonstrate the effectiveness of pregabalin in improving overall symptom scores.¹³

Alpha-Blockers

Alpha-adrenergic blockers relax the smooth muscle in the prostatic urethra and bladder neck.

Dosage

Doxazosin and terazosin must be titrated up from a starting dose of 1 mg, usually taken at bedtime, to 8 mg maximum for doxazosin and 10 mg maximum for terazosin. The typical dosage for alfuzosin is 10 mg; for silodosin is 8 mg, and for tamsulosin is 0.4 mg, all to be taken with food.

Precautions

All of the alpha-blockers can cause dizziness, postural hypotension, retrograde ejaculation, and nasal congestion. Rarely, alpha-blockers can cause syncope. Alfuzosin and silodosin should not be taken by men with severe hepatic or renal insufficiency.

Antibiotics

The most commonly studied and used antibiotics for CPPS are the quinolones, including ciprofloxacin and levofloxacin. These may help reduce inflammation, explaining the improvement observed in some studies, even among men with abacterial prostatitis.

Trimethoprim-sulfamethoxazole represents an alternative treatment for CPPS.

Dosage

Ciprofloxacin is dosed at 500 mg twice a day and levofloxacin at 500 mg once a day. Both are used for 4 weeks. Trimethoprim-sulfamethoxazole is used at double strength (160/800 mg) twice daily for 4 weeks.

Precautions

Excessive use of antibiotics can lead to resistant infections, as well as dysbiosis of the gut. Specific precautions with the fluoroquinolones

include risk of tendon rupture and aortic aneurysm. Trimethoprim-sulfamethoxazole can cause photosensitivity and possible severe allergic reactions in those sensitive to sulfa drugs.

Lifestyle

Because of the paucity of good evidence on the use of pharmaceuticals for CPPS, it is recommended to consider nutrition and exercise recommendations as these can make significant impacts on symptoms.

Nutrition

Herati and Moldwin published a systematic review of studies of the following therapies for CP/CPPS: diet and lifestyle modifications, phytotherapy, acupuncture, myofascial physical therapy, and stress management/cognitive behavioral therapy.¹⁴ They found that dietary modification frequently helps in alleviation of symptoms, with the most common aggravating foods being spicy foods and caffeine. The most common alleviating consumables were water and fiber supplements.

Pelvic Pain Questionnaire
Male NIH Symptom Index (NIH-CPSI)

Name: _____

Date: _____

Pain or Discomfort

1. In the last week, have you experienced any pain or discomfort in the following areas:

	Yes	No
a. Area between rectum and testicles (perineum)	1	0
b. Testicles	1	0
c. Tip of the penis (not related to urination)	1	0
d. Below your waist, in your pubic or bladder area	1	0

2. In the last week, have you experienced:

	Yes	No
a. Pain or burning during urination	1	0
b. Pain or discomfort during or after sexual climax (ejaculation)	1	0

3. How often have you had pain or discomfort in any of these areas over the last week?

- 0 Never
- 1 Rarely
- 2 Sometimes
- 3 Often
- 4 Usually
- 5 Always

4. Which number best describes your AVERAGE pain or discomfort on the days that you had it, over the last week?

0 1 2 3 4 5 6 7 8 9 10
NO PAIN PAIN AS BAD AS YOU CAN IMAGINE

Urination

5. How often have you had a sensation of not emptying your bladder completely after you finished urinating, over the last week?

- 0 Not at all
- 1 Less than 1 time in 5
- 2 Less than half the time
- 3 About half the time
- 4 More than half the time
- 5 Almost Always

6. How often have you had to urinate again less than two hours after you finished urinating, over the last week?

- 0 Not at all
- 1 Less than 1 time in 5
- 2 Less than half the time
- 3 About half the time
- 4 More than half the time
- 5 Almost Always

Impact of Symptoms

7. How much have your symptoms keep you from doing the kinds of things you would usually do, over the last week?

- 0 None
- 1 Only a little
- 2 Some
- 3 A lot

8. How much did you think about your symptoms, over the last week?

- 0 None
- 1 Only a little
- 2 Some
- 3 A lot

Quality of Life

9. If you were to spend the rest of your life with your symptoms just the way they have been during the last week, how would you feel about that?

- 0 Delighted
- 1 Pleased
- 2 Mostly satisfied
- 3 Mixed (about equally satisfied and dissatisfied)
- 4 Mostly dissatisfied
- 5 Unhappy
- 6 Terrible

Scoring the NIH-Chronic Prostatitis Symptom Index Domains

Pain: Total of items 1a, 1b, 1c, 1d, 2a, 2b, 3, and 4 ____

Urinary Symptoms: Total of items 5 and 6 _____

Quality of Life & Impact: Total of items 7, 8, and 9 _____

FIG. 62.1 Pelvic pain questionnaire. (Adapted from Litwin M, McNaughton-Collins M, Fowler FJ, et al. The National Institutes of Health chronic prostatitis symptom index: development and validation of a new outcome measure. *J Urol* 1999;162(2):369-375).

The most powerful dietary recommendations would be increasing water and fiber intake and decreasing intake of spicy foods and caffeine.

Exercise

Exercise has definitively been shown to be helpful in the treatment of CPPS. One randomized controlled trial, in particular, with excellent methods and analysis reported significant improvements in NIH-CPSI scores as well as VAS pain and quality of life scores in the group that performed aerobic exercises for 18 weeks compared with the group that performed stretching only. Pain initially increased at 4 weeks in the aerobic exercise group (to a tolerable level) but then decreased significantly.¹⁵

Supplements

Rye Grass Pollen Extract

The Herati review included several studies reporting statistically significant improvements with pollen extract. Pollen therapy is thought to exert smooth muscle spasmogenic and spasmolytic effects as well as antiinflammatory effects specifically in prostate tissue.

Specifically, Elist et al. performed a randomized controlled trial demonstrating improvements in pain, sexual function, and lower urinary tract symptoms with pollen extract; 73% of extract users reported improvements compared with 36% in the control group. One brand that is widely available is called Pollen-Aid.¹⁶ Saw palmetto was not found to be helpful in studies on its use in treating CP/ CPPS.

Dosage

Pollen-Aid (*Secale cereale*); one to two capsules three times daily before meals.

Precautions

Rarely can cause digestive symptoms such as mild nausea.

Quercetin

A study reporting beneficial effects with quercetin was included in the two previously mentioned reviews. Quercetin, a bioflavonoid, has antioxidant and antiinflammatory properties. Quercetin was shown to significantly improve symptoms in a double-blind, placebo-controlled trial by Shoskes et al. When a subgroup was given a special preparation, including quercetin as well as bromelain and papain, symptoms improved even more dramatically.¹⁷

Dosage

250–500 mg on an empty stomach three times daily. Bromelain improves the absorption of quercetin, so it is best to take an equal amount of bromelain along with quercetin.

Precautions

Quercetin is well tolerated, but does interact with some pharmaceuticals. It can increase blood levels of digoxin, cyclosporine, estrogen, and doxorubicin. Quercetin should not be taken along with the chemotherapy drug cisplatin.

Cannabis

A survey of 342 men regarding cannabis use for CP/CPPS published in the Canadian Urological Association Journal showed that more than 50% reported using cannabis, with more than half reporting improvement of symptoms with regard to mood, pain, muscle spasms, and sleep but not weakness, fatigue, numbness, or urination.¹⁸

Acupuncture

Acupuncture has also been shown to help with CPPS symptoms. In a

randomized controlled trial of acupuncture versus antibiotics and nonsteroidal antiinflammatory drugs (NSAIDs), acupuncture was shown to be better at improving pain, urinary symptoms, quality of life, and NIH-CPSI scores among 54 participants.¹⁹ Lee et al. published a summary of clinical trials on acupuncture in treating CP/CPPS, including pilot studies, randomized trials, and nonrandomized trials. Although they did not perform a systematic review or meta-analysis, they described many studies reporting overall improvements in most CP/CPPS symptoms with acupuncture treatments with or without electrical stimulation or moxibustion.²⁰

Acupuncture has been shown to be better than antibiotics or NSAIDs at improving pain and quality of life.

Physical Therapy

There is a vicious cycle of pain with urination, leading to straining and pelvic floor tightening, which worsens symptoms in many men with CP/CPPS. Myofascial physical therapy, including trigger point physiotherapy and relaxation techniques such as biofeedback, manual manipulation, and teaching self-use of a trigger-point “wand,” have been shown to be helpful.¹⁴ It can be difficult to find practitioners with expertise in treating trigger points, which are often located at the puborectalis and/or pubococcygeus muscles and which cause pain directly in the area when manipulated or referred pain to the prostate or penis. This referral pattern of pain is a frequent complaint among men with CP/CPPS and can be elicited by any pressure, including bicycle riding or long periods of sitting, in the puboanal area.

Mind-Body Therapy

Mind-body approaches can be a powerful intervention for men with CPPS.

Cognitive Behavioral Therapy

Cognitive behavioral therapy (CBT) and stress management have been shown to be helpful, given the comorbidity of depression, anxiety, and panic disorder that is common in men with this condition. Stress has

been shown to worsen symptoms, and CBT can help teach men how to cope with the debilitating nature of their symptoms, making symptoms feel less intense or less bothersome.

Matching the Therapy to the Clinical Presentation

There is some benefit to individualizing therapy according to which clinical symptoms predominate. Of course, most patients will have overlapping symptomatology but many will present with a preponderance of one or two symptoms.

Lower Urinary Tract Symptoms

For example, men with mostly lower urinary tract symptoms similar to those of BPH complain of straining with urination and a feeling of constantly needing to void. For this population, similar treatments used for BPH, including alpha-blockers or antimuscarinics, may be helpful.²¹ Pollen extract and acupuncture, as previously noted, are especially useful in men with a preponderance of lower urinary tract symptoms.²²

Tenderness and Pain

Patients who predominantly present with tenderness on perineal or anal palpation and complaints of trigger point pain (perhaps elicited by sexual activity or bicycle riding) may respond best with expert physical therapy that includes biofeedback as well as antiinflammatory supplements, including quercetin along with bromelain and papain, and mind-body techniques, including CBT and stress management training.

Neurological/Systemic Symptoms

A man with primarily neurological/systemic symptoms has a presentation similar to those with tenderness but also has generalized symptoms such as fatigue, irritable bowel, or generalized pain. He may have leukocytes in his post-DRE U/A without bacteria. Such men may respond to potent antiinflammatories as previously described, perhaps adding curcumins or prescription NSAIDs. Herbalists may use *Eryngium yuccifolium* (rattlesnake master root), corn silk, or *Pulsatilla occidentalis* (western pasque flower); however, trials with these herbs have yet to be published. For these men, urinary symptoms may be relatively minor.

Mind-body therapies and adaptogens are useful, with therapies focusing on the fatigue or gut symptoms.²³

Psychological Phenotypes

Patients with psychosocial phenotypes present with anxiety and/or depression, perhaps with a history of abuse. Mind-body therapies and antianxiety or antidepressant modalities and herbs, supplements, or medications are most appropriate for these men.

Infectious

Men with the infection phenotype may have bacteria in their post-DRE U/A, but often do not respond to antibiotics. Unless systemic signs of infection are present or greater than 100,000 colonies of specific bacteria are identified, antibiotics are unlikely to be useful. These men should be treated using the previously described therapies depending on their specific symptoms.

Treating Intestinal Permeability

Even those men who do not describe gastrointestinal symptoms may benefit from treatment for presumed leaky gut. CP/CPPS is an inflammatory condition, and we know that stimulation of gut-associated lymphoid tissue can be a large factor in upregulating the inflammatory system. A traditional leaky-gut 4R treatment approach (see [Chapter 41](#)) may be very helpful in men with CP/CPPS ([Table 62.2](#)). This would include an elimination diet and the use of glutamine and probiotics along with antiinflammatory herbs or supplements in an attempt to heal leaky gut and overstimulation of the immune and inflammatory systems.

TABLE 62.2

Chronic Prostatitis/Chronic Pelvic Pain Syndrome (CP/CPPS) Treatment by UPOINT Phenotype

Urinary	Alpha-blockers Pollen extract Acupuncture
Psychosocial	Mindfulness classes CBT Stress management Antidepressant treatment
Organ specific	Herbal remedies Antiinflammatory approach

Infection	Antibiotics if > 100,000 colonies Pollen extract Acupuncture
Neurological/systemic	Antiinflammatories Curcumin, quercetin, bromelain Leaky gut 4R approach Elimination diet
Tenderness	Physical therapy Trigger point treatment Biofeedback Quercetin, bromelain, papain

CBT, cognitive behavioral therapy; *UPOINT*, urinary, psychosocial, organ specific, infection, neurological/systemic, and tenderness.

Prevention Prescription

- Engage in a daily stress management practice, such as meditation, yoga, or journaling
- Exercise aerobically at least 4 days a week for 30 minutes
- Drink plenty of water every day, enough to keep urine fairly clear (more lemonade than apple juice in appearance)
- Eat five to nine servings a day of various colored fruits and vegetables

Therapeutic Review

CP/CPPS is a relatively common and tremendously impactful problem with no specific cause. As it is considered inflammatory in nature, most treatment regimens should start with an antiinflammatory approach including mind-body and leaky gut treatments. Beyond those, treatment may include diet, exercise, supplements, and/or use of acupuncture or physical therapy, but it should be based on the specific symptoms reported by the sufferer as the condition is heterogeneous and best treated using a symptom-targeted individualized approach.

Lifestyle

- Exercise aerobically at least four times per week at moderate intensity for at least 30 minutes 

Nutrition

- Add fiber to the diet
- Eat five to nine servings of fruits and vegetables every day
- Avoid spicy foods, caffeine, and alcohol 

Supplements

- A 6-week trial of supplements may be helpful
- Quercetin: 500 mg tid with equal amounts Bromelain 
- Rye grass pollen (Pollen-Aid): two capsules tid 
- Consider cannabis in states where medicinal use is allowed 

Physical Therapy

- Consider physical therapy or prostatic massage by a well-trained practitioner, especially focusing on pelvic floor release and trigger-point treatment 

Mind-Body Therapy

- Cognitive-behavioral therapy 
- Meditation or biofeedback 
- Encourage stress management 

Acupuncture

- Acupuncture by a trained practitioner 

Any Others You Want to Include

- Treatment for leaky gut using a 4R approach

CHAPTER 63

Erectile Dysfunction

Luke Fortney, MD, FAAFP

Pathophysiology

Erectile dysfunction (ED), the most common sexual problem among men, affects up to one-third of men at some point in their lives. ED is defined as the inability to achieve or maintain a sufficient erection for satisfactory sex. The prevalence of ED increases with age,¹ and it is most commonly associated with poor cardiovascular health, psychosocial factors, hormonal disorders, recreational drug abuse, and adverse effects from prescribed medications. Less common are anatomic, traumatic, or infectious causes.² Normally, an erection is stimulated by a combination of neurovascular, hormonal, and environmental factors beginning with sexual interest and desire (which is mediated predominantly by testosterone). Through parasympathetic activation, nitric oxide (NO) synthase (NOS) in endothelial cells is activated to produce NO from the precursor amino acid l-arginine. With NO present, the corpus cavernosum is engorged with arterial blood as a result of smooth muscle endothelial relaxation while venous return is simultaneously restricted.³

Evaluation

The World Health Organization and the American Urological Association recommend an initial limited evaluation for ED symptoms,⁴ starting with the simplified five-item International Index of Erectile Function Questionnaire (IIEF-5) ([Table 63.1](#)).^{5,6} A careful review of medications that contribute to ED ([Table 63.2](#)) is recommended in addition to substance abuse screening for alcohol, tobacco, marijuana, and other drugs.⁷

Cardiovascular risk factors should be assessed in all patients

presenting with ED ([Box 63.1](#)).^{8,9} Blood pressure and body mass index (BMI) scores are quick, but useful, initial assessments of cardiovascular health, which is the most important risk factor for ED.^{10,11} Testicular, prostate, penis, and breast inspection should also be considered to rule out endocrine abnormalities such as hypogonadism, mammary hypertrophy, genitourinary masses, and Peyronie's disease.¹²

Nocturnal penile tumescence can be assessed by patient self-report or use of the "stamp test,"¹³ Rigiscan, or Snap-Gauge cuff testing.^{8,14} However, advanced imaging such as penile duplex ultrasonography is not recommended or necessary for the diagnosis of ED.^{8,15} Typically the presence of nocturnal erections in a patient with ED suggests a psychogenic origin such as stress, fatigue, or mood disorders.^{8,16}

Additional ED evaluation should also include the following laboratory tests: fasting glucose and lipid panel, thyroid-stimulating hormone, complete blood count, prostate-specific antigen, urinalysis, creatinine, electrolytes, and liver function panel.^{4,8} Serum total testosterone level should be considered for men older than 50 years as well as younger men with signs of hypogonadism, which can be a sign of other comorbidities.¹⁷ In addition to positive physical examination findings, hypogonadism is defined as a morning serum total testosterone level less than 300 ng/dL (10.4 nmol/L).^{2,4,8,18} The prevalence of hypogonadism in men ranges from 5% to 15% with age-related increases.^{19,20}

Presentation of erectile dysfunction provides a window of opportunity to improve health and reverse the development of cardiovascular disease.

Integrative Therapy

Pharmaceuticals

Phosphodiesterase Inhibitors

Phosphodiesterase type 5 (PDE5) inhibitors ([Table 63.3](#)) such as sildenafil, vardenafil, and tadalafil remain first-line therapy options for ED.^{8,21} These drugs are very effective, used as needed, and generally well tolerated and safe.^{22,23} Common side effects can include headache, nasal congestion, flushing, abnormal vision, and gastrointestinal upset.

Evidence supports equal effectiveness of these agents.²⁴⁻²⁶ However, approximately one-third of men do not respond to PDE5 inhibitors. Additionally, these agents are not considered effective for improving libido, which is more a function of testosterone.²⁷ That being said, it is worth noting that testosterone does indirectly influence PDE5 activity. For example, research shows that administration of finasteride (which inhibits 5-alpha-reductase, the enzyme responsible for converting testosterone to its more potent form dihydrotestosterone, or DHT) increases the severity of erectile dysfunction and decreases testosterone levels in men.²⁸

Dosage

Doses are provided in [Table 63.3](#).

Testosterone

Testosterone supplementation in hypotestosteronism and hypogonadism is superior to placebo in improving erections, sexual function, and libido.^{19,29,30} Close supervision with clinic follow-up and laboratory tests are needed every 2 weeks with initiation of a new testosterone supplementation until satisfactory subjective and objective results are achieved. However, testosterone supplementation, with either compounded bioidentical testosterone or pharmaceutical brands, should continue to be monitored every 6 months over time with the following laboratory tests: morning serum testosterone level, complete blood count, liver function panel, and prostate-specific antigen.³¹

TABLE 63.1

International Index of Erectile Function Questionnaire (IIEF-5)

Over the Past 6 Months:	Score				
	1	2	3	4	5
1. How do you rate your confidence that you could get and keep an erection?	Very low	Low	Moderate	High	Very high
2. When you had erections with sexual stimulation, how often were your erections hard enough for penetration?	Almost never/harder	A few times (much less than half the time)	Sometimes (about half the time)	Most times (much more than half the time)	Almost always/easy
3. During sexual intercourse, how often were you able to maintain your erection after you had penetrated your partner?	Almost never/harder	A few times (much less than half the time)	Sometimes (about half the time)	Most times (much more than half the time)	Almost always/easy
4. During sexual intercourse, how difficult was it to maintain your erection to completion of intercourse?	Extremely difficult	Very difficult	Difficult	Slightly difficult	Not difficult
5. When you attempted sexual intercourse, how often was it satisfactory for you?	Almost never/harder	A few times (much less than half the time)	Sometimes (about half the time)	Most times (much more than half the time)	Almost always/easy
IIEF-5 Scoring:					
The IIEF-5 score is the sum of the ordinal responses to the five items.					
22-25: No erectile dysfunction					
17-21: Mild erectile dysfunction					
12-16: Mild to moderate erectile dysfunction					
8-11: Moderate erectile dysfunction					
5-7: Severe erectile dysfunction					

From Rosen RC, Cappelleri JC, Smith MD, et al. Development and evaluation of an abridged, 5-item version of the International Index of Erectile Function (IIEF-5) as a diagnostic tool for erectile dysfunction. *Int J Impot Res.* 1999;11:319-326.

Dosage

Pharmaceutical testosterone (e.g., Androderm, AndroGel, Striant, and Testim) is prescribed at 12.5 to 100 mg applied topically every morning and titrated to normal serum total testosterone laboratory levels.³¹ Compounded bioidentical testosterone preparations are available through reputable compounding pharmacies³² (see [Chapter 64](#)).

Prostaglandin E₁ Injection

The prostaglandin E₁ agent alprostadil is self-administered as an intracavernosal injection (e.g., Caverject, Edex) or urethral suppository (e.g., Muse). Alprostadil is considered the gold standard of ED therapy, but is still second-line therapy behind oral PDE5 inhibitors.^{8,33,34} Furthermore, alprostadil in either formulation requires training and patient education for self-administration; it can be uncomfortable or inconvenient for some men. Dosing for alprostadil intracavernosal injection ranges from 2.5 to 7.5 mcg three times a week as needed. Alprostadil intraurethral suppository treatment ranges from 125 to 1000 mcg daily as needed.

TABLE 63.2

Medications That May Contribute to Erectile Dysfunction

Medication Class	Examples
Alcohol and drugs of abuse	Alcohol, amphetamines, barbiturates, cocaine, heroin, marijuana, tobacco
Analgesics	Opiates
Anticholinergics	Tricyclic antidepressants
Anticonvulsants	Phenytoin, phenobarbital
Antidepressants	Lithium, monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, tricyclic antidepressants
Antihistamines	Dimenhydrinate, diphenhydramine, hydroxyzine, meclizine, promethazine
Antihypertensives	Alpha blockers, beta-blockers, calcium channel blockers, clonidine, methyldopa, reserpine
Antiparkinsonian agents	Bromocriptine, levodopa, trihexyphenidyl
Cardiovascular agents	Digoxin, disopyramide, gemfibrozil
Cytotoxic agents	Methotrexate
Diuretics	Spirolactone, thiazides
Hormones	5-Alpha-reductase inhibitors, corticosteroids, estrogens, LH-releasing hormone agonists, progesterone
Immunomodulators	Interferon-alfa
Sedatives	Benzodiazepines, butyrophenones, phenothiazines

Data from references [2](#), [6](#), and [7](#).

BOX 63.1 Risk Factors for Erectile Dysfunction

- Advancing age
- Alcohol abuse or alcoholism
- Cardiovascular disease
- Diabetes mellitus
- Drug abuse (e.g., marijuana, cocaine, methamphetamine)
- Dyslipidemia or hypercholesterolemia
- History of pelvic/prostate irradiation or surgery
- Hormonal disorders (e.g., hypogonadism, hypothyroidism, hyperprolactinemia)
- Hypertension
- Medications (e.g., cardiovascular and antihypertensive medications, antihistamines, benzodiazepines, selective serotonin reuptake inhibitors)
- Neurologic disorders (e.g., dementia, multiple sclerosis, parkinsonism, paraplegia or quadriplegia, stroke)
- Obesity
- Penile venous leakage
- Peyronie's disease
- Psychological conditions (e.g., anxiety, depression, guilt, history of sexual abuse, marital or relationship strain, stress)
- Sedentary lifestyle
- Tobacco use

Vacuum Erection or Constriction Device

For men who are comfortable, motivated, and open-minded, vacuum erection or constriction devices (e.g., Erec-Tech, Firma) have shown promise for ED due to postsurgical, structural (e.g., Peyronie's disease), and prostate cancer radiation rehabilitation.³⁵⁻³⁷ Satisfaction rates are higher than 80%, but these devices should be avoided in men with sickle cell disease or other bleeding disorders.^{38,39} Patients should be counseled by a health care worker experienced with these devices.

Nutraceuticals

In general, supplements have proven to be much less effective than pharmaceutical options in treating ED.⁴⁰ In 2009, the U.S. Food and Drug Administration reissued a statement warning consumers to avoid ED supplements.⁴¹ Patients should be counseled to avoid email promotions and internet advertisements for these and other products that falsely claim to enhance male libido and sexual function. Furthermore, most of these products are contaminated or adulterated,⁴² and they are not considered reliable or safe for use ([Box 63.2](#)). Recent developments in quality testing have revealed rampant adulteration of "natural" supplements with PDE-5 inhibitor analogues (dimethylsildenafil, thiodimethylsildenafil, and thiomethisosildenafil).^{43,44} Other products may be commonly used but are ineffective ([Box 63.3](#)).^{40,45,46} However, some evidence indicates that the judicious use of some high-quality nutraceuticals may be considered in appropriate situations ([Table 63.4](#)).⁴⁷⁻⁶⁸

Manual Therapies and Bioenergetics

Evidence is generally lacking for acupuncture and massage in treating ED.⁶⁹ Further, massage therapy may be socially inappropriate in this context. Evidence is also lacking for osteopathic and chiropractic manipulation.⁴⁵ Furthermore, evidence for yoga, energy medicine, physical therapy, and the Alexander technique for the specific treatment of ED is insufficient.⁴⁵

Mind-Body Therapy

Sexual desire, arousal, and climax are mediated through complex psychoneurological mechanisms. In general, sexual problems are highly prevalent among patients with psychiatric disorders, stemming from both adverse effects of medication and primary underlying psychopathology.⁷⁰ Psychological interventions have a strength of recommendation taxonomy category 1B for ED resulting from anxiety, depression, posttraumatic stress disorder, guilt, sex abuse history, relationship strain, performance anxiety, postsurgical adjustment disorder, and general stress.^{8,45,71-76} There is insufficient evidence to recommend art therapy, hypnosis, aromatherapy, meditation, or guided imagery.⁴⁵

TABLE 63.3

Phosphodiesterase Type 5 Inhibitors for Erectile Dysfunction

Medication	Dose	Onset	Duration	Precautions	SOR/HARM
Sildenafil (Viagra)	25–100 mg	15–60 min	4 hr	Avoid with nitrates and alpha blockers	
Vardenafil (Levitra)	5–20 mg	30 min	4 hr	Avoid with nitrates and alpha blockers	
Tadalafil (Cialis)	5–20 mg	15–45 min	36 hr	Avoid with nitrates and alpha blockers	

SOR, strength of recommendation.

BOX 63.2 Food and Drug Administration Statement: Hidden Risks of Erectile Dysfunction “Treatments”⁴²

Since 2004, the FDA has identified several unsafe products that have been advertised as treatments for erectile dysfunction and/or to enhance sexual performance. These products have contained potentially harmful and undeclared ingredients:

- Actra-Sx
- Actra-Rx
- Libidus
- Nasutra
- Neophase
- Vigor-25
- Yilishen
- Zimaxx
- 4EVERON
- Liviro3
- Lycium Barbarum L.
- Adam Free
- Rhino V Max
- V.Max
- True Man
- Energy Max
- HS Joy of Love
- NaturalUp
- Blue Steel
- Ereextra
- Super Shangai
- Strong Testis
- Shangai Ultra
- Shangai Ultra X
- Lady Shangai
- Shangai Regular, also marketed as Shangai Chaojimengnan
- Hero
- Naturalë Super Plus
- Xiadafil VIP tablets (Lots 6K029 and 6K209-SEI only)

Data from U.S. Food and Drug Administration (FDA). *Hidden risks of erectile dysfunction “treatments” sold online:*

BOX 63.3 Supplements With Insufficient Evidence

- 5-Hydroxytryptophan (5-HTP)
- Ambra grisea (ambrein)
- Androstenediol
- Ashwagandha
- Brazilian wandering spider venom (peptide Tx2-6)
- *Bufo* toad (bufotenine, Chan Su)
- *Butea superba*
- Chaste tree berry
- Clove
- Coleus
- Creatine
- Deer velvet
- Ephedra
- Horny goat weed
- Maca (*Lepidium meyenii*)
- Melatonin
- *Muiria puama* (potency wood)
- Niacin
- Pomegranate
- Pygeum
- Rhinoceros horn
- Rhodiola
- Saffron
- Saw palmetto
- Spanish fly (cantharides)
- *Tribulus terrestris* (TT)
- Wild yam

Data from references [38](#), [42](#), and [43](#).

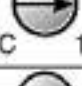

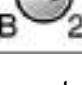

Lifestyle

A very strong association exists between lifestyle-associated chronic diseases and ED (see [Box 63.1](#)). Most importantly, research shows that

ED is predominantly the result of advancing cardiovascular disease.⁷⁷⁻⁷⁹ One study found that ED symptoms manifest, on average, 2–3 years earlier than symptoms of CAD.^{80,10} Conversely, blood pressure control with lifestyle change is associated with a lower prevalence of ED, particularly in older patients.⁸¹ However, antihypertensives such as thiazide diuretics, aldosterone-blockers, and beta-blockers are also known to aggravate ED in men with hypertension that is uncontrolled by lifestyle change alone.⁸²

Metabolic syndrome plays an important role in the pathogenesis of ED.⁸³⁻⁸⁵ For men diagnosed with diabetes mellitus, the prevalence of ED is as high as 89%^{80,81} while obesity (BMI > 30) nearly doubles the risk of ED.^{1,84} The risk of ED is also nearly double in men who smoke.⁸⁶ Alcohol abuse is known to adversely affect sexual function.⁸⁶ New data also suggests that the severity and extend of periodontal disease may be a significant risk factor for ED, sperm motility, and time to conception.^{87,88}

TABLE 63.4
Common Supplements for Erectile Dysfunction

Supplement/Herb	Mechanism	Dose	Precautions	Tip	SOR/How
<i>Panax ginseng</i> ^{1,2,3,4}	Ginsenosides, increased NO	600 mg tid	Insomnia, anxiety, dyslipidemia	SS-craze ⁵ may help promote circulation	B  1
Yohimbine ^{6,7,8,9} (Yohim)	MAO inhibitors, calcium and alpha-blockade, NO	5–10 mg tid	HTN, CAD, DM, myocardial infarction, angina, asthma, DPH	Use very cautiously, monitor closely	B  2
L-Arginine ^{10,11} (Proton, Argonine, L-Carni-10 Solution)	Preursor to NO	3000–2000 mg tid	Gas, reflux, GI upset	Additive effect with pyrogallol ¹²	B  1
Pyrogallol ¹² (Proton, Argonine)	Flax bark extract, activates NO synthesis	40 mg tid	GI upset, vertigo, warfarin use	Above any take up to 12 wk; additive effect with 500 mg L-arginine tid	B  1
Propylethyl-carbosteol ¹³	Acetylcholinesterase, mediates NO	300 mg tid	GI upset	Impresses sildenafil ¹⁴ effect reverses after prostate surgery and DM	C  1
<i>Gilgja laticifolia</i> ¹⁵	Flavonoids, improves	60–120 mg tid	ASA, warfarin use, GI upset	May help ED caused by SSRIs	B  2

ASA, acetylsalicylic acid; *bid*, twice daily; *BPH*, benign prostatic hyperplasia; *CAD*, coronary artery disease; *DM*, diabetes mellitus; *ED*, erectile dysfunction; *GI*, gastrointestinal; *HTN*, hypertension; *MAO*, monoamine oxidase; *NO*, nitric oxide; *PDE5*, phosphodiesterase type 5; *SOR*, strength of recommendation; *SSRIs*, selective serotonin reuptake inhibitors; *tid*, three times daily.

<http://naturaldatabase.therapeuticresearch.com/nd/Search.aspx?cs>; Accessed 22.03.11

(subscription required).

ED therefore presents a window of opportunity to identify early cardiovascular disease and recommend lifestyle modifications.^{10,84} One study found that men who seek treatment for ED may prefer alternatives to pharmaceutical intervention, such as lifestyle change.⁷³ As such, comprehensive treatment should include counseling for weight loss, healthy nutrition, stress management, and regular exercise (see Prevention Prescription in the following text).^{2,7,8,77,83}

The most important recommendation to prevent and treat erectile dysfunction is to encourage overall healthy behaviors that reduce the incidence and severity of cardiovascular disease.

No particular exercise or nutrition regimen is specifically designed to treat ED. However, exercise and nutrition should be tailored to each patient's specific needs, with special emphasis on adopting a Mediterranean-style diet that has been shown to improve cardiovascular function in patients with ED.⁸⁹ Interestingly, analysis of the National Health and Nutrition Examination Survey (NHANES) of 3724 men found that two to three cups of caffeinated coffee per day reduced the odds of prevalent ED, even among obese and hypertensive men.⁹⁰ Other lifestyle recommendations include regular dental care, which may be beneficial for both cardiovascular disease and ED.⁹¹ In addition, prolonged or frequent bicycle riding may inhibit neurovascular flow to the perineum and thereby negatively influence ED. In these patients, a trial of rest, change in exercise routine, or cycling adaptations (e.g., split seat or recumbent posture) can be tried.

Therapies to Consider

Emerging Therapies

Novel approaches for ED target inhibition of arginase, an enzyme that competes with NOS for l-arginine. Excessive arginase activity and expression in the corpora cavernosa has been implicated in ED, while inhibition of arginase has been shown to increase blood flow in penile circulation.⁹² Ongoing investigation into gene therapies that target arginase include *RhoA/Rho-kinase (ROCK)* and *p38-MAPK*, among others. Another example is the Maxi-K protein gene (*MKPG*) that is expressed as

a potassium channel whose function is needed to initiate and sustain an erection. Local injections of a plasmid containing the *MKPG* gene appears to be safe, but it is invasive, relatively new, expensive, often not covered by insurance, unavailable in many locations, and the long-term effects have not been well established. Advantages include enabling sexual spontaneity, twice-yearly injection therapy, synergistic activity with PDE5 inhibitor medications, and it can be used by men taking nitrates.^{8,93-}
[95](#)

Prevention Prescription

- Exercise in any capacity for at least 150 minutes a week.
- Follow a healthy calorie-controlled Mediterranean diet rich in phytonutrients and antioxidants (organic fruits and vegetables), omega-3 fatty acids, whole grains, nuts, seeds, and legumes.
- Reduce stress through exercise, rest, vacation, retreats, meditation, breathing exercises, yoga, journaling, or various manual therapies.
- Maintain healthy sexual relationships, good communication, and regular erections and ejaculations (three times/week).
- Avoid tobacco, marijuana, and other illegal or recreational drugs.
- Be moderate with alcohol consumption (one to two drinks or less per day).
- Avoid highly processed foods that contain high amounts of “antinutrients” (e.g., high-fructose corn syrup, trans fats, and artificial sweeteners / colors / preservatives).
- Avoid overexposure to pesticides, herbicides, and overuse of chemical or cleaning products.
- Avoid heating or storing food in plastics (e.g., endocrine and hormone disruptors such as bisphenol-A).

Therapeutic Review

Workup and Evaluation

- History with International Index of Erectile Function-5 (IIEF-5) short survey and medication review.
- Physical examination with blood pressure, body mass index, and

genitourinary examination.

- Laboratory tests (complete blood count, fasting glucose and lipids, electrolytes, creatinine, liver function tests, thyroid-stimulating hormone, prostate-specific antigen, and morning total serum testosterone).

Lifestyle

- Mediterranean diet
- Weight loss (goal BMI < 30)
- Regular exercise > 150 minutes per week
- Stress reduction
- Smoking cessation⁹⁰
- Alcohol reduction
- Two to three cups of coffee per day

First-Line Pharmaceuticals

- Trial of phosphodiesterase type 5 inhibitor 
- Sildenafil (Viagra): 25–100 mg orally daily as needed, or
- Vardenafil (Levitra, Staxyn): 5–20 mg orally daily as needed, or
- Tadalafil (Cialis): 5–20 mg orally every 72 hours as needed

Nutraceuticals

- Yohimbine: 5–10 mg three times daily 
- *Panax ginseng*: 900 mg three times daily 
- Pycnogenol: 40 mg three times daily with or without 500–1000 mg of L-arginine three times daily 
- L-Arginine: 1000–2000 mg three times daily 
- Propionyl-L-carnitine: 1000 mg twice daily (to improve sildenafil response) 

Mind-Body Therapy

- Psychotherapy for patients with mood disorder, posttraumatic stress disorder, sex abuse history, relationship strain, or performance anxiety 

- professionals follow-up study. *Ann Intern Med.* 2003;139:161–168.

CHAPTER 64

Testosterone Deficiency

Robert Z. Edwards, MD

Pathophysiology

The most important human androgen is testosterone. Testosterone is a steroid hormone composed of 19 carbons ([Fig. 64.1](#)). Another prominent androgen is dehydroepiandrosterone (DHEA), which belongs to a group of prohormones collectively referred to as 17-ketosteroids. In adult males, the testes produce approximately 7 mg of testosterone per day.¹ In females, the daily rate of testosterone production is approximately 0.25–0.3 mg.² In males, an additional 0.25 mg of testosterone is produced per day in the adrenal glands, but the amount can vary depending on the patient.³ In females, the adrenal glands contribute to approximately 25% of daily testosterone production or about 50–75 mcg/day, the ovarian contribution is 25%, and the remaining 50% of daily testosterone production is from peripheral conversion.² The rest of the discussion will be directed toward testosterone deficiency (TD) in men and the mechanisms of control related to male physiology.

Testosterone is regulated by luteinizing hormone (LH) from the anterior lobe of the pituitary gland. LH stimulates the release of testosterone from the Leydig cells in the testes. Sperm production is under the influence of follicle-stimulating hormone (FSH), also released from the anterior lobe of the pituitary gland. Testosterone inhibits the secretion of LH by negative feedback.¹ Testosterone plasma levels follow a circadian rhythm, with the highest peak in the early morning around 7:00 a.m. and another, smaller peak in the afternoon around 4:00 p.m.⁴ However, the peak and nadir of testosterone are not as dramatic as those of cortisol.

Testosterone is generally found in the body bound to proteins, most specifically to the sex hormone-binding globulin (SHBG). Testosterone

bound to SHBG is measured as total testosterone (TT). SHBG production in the liver is controlled by a number of hormones. Liver disease, estrogen, and thyroid hormones increase SHBG. SHBG decreases in response to androgens, insulin resistance and diabetes, and in the presence of hypothyroidism.⁵ Plasma SHBG levels tend to increase with increasing age. The fraction of testosterone bound to SHBG in the serum is proportional to the SHBG level.⁵ This helps explain the faster rate of reduction of free testosterone (free T) compared with TT (2%–3% per year decline compared with 1%–2%, respectively) after 40 years of age.

Diabetes, metabolic syndrome/insulin resistance, obesity, and hypothyroidism can lead to falsely low TT despite normal free T levels. Checking free T is a more accurate test in these individuals.

Testosterone can be converted to estradiol by aromatase, especially in adipose tissue, and to dihydrotestosterone (DHT) by 5-alpha reductase in specialized tissues such as sebaceous glands, hair follicles, and prostate tissues ([Fig. 64.2](#)). Testosterone governs the development of secondary sex characteristics in the male. Sufficient testosterone is essential for normal libido, fertility, and potency of the male. It can also influence erythropoiesis. Testosterone exerts anabolic effects on muscularity and can affect behavior and aggressiveness. Testosterone is metabolized in the liver and primarily excreted in the urine.¹

There are many clinical manifestations of TD, thereby making diagnosis challenging. Physical symptoms include decreased bone mineral density, decreased muscle mass and strength, increased body fat or body mass index (BMI), gynecomastia, anemia, axillary/genital hair loss, and fatigue. Psychological symptoms may include depressed mood, diminished energy/sense of vitality or wellbeing, decreased self-confidence, and impaired cognition/memory. Many times, however, men will present with a chief complaint of sexual dysfunction. Sexual symptoms include diminished libido, erectile dysfunction, difficulty in achieving orgasm, decreased morning erections, and decreased sexual performance⁶ ([Box 64.1](#)).

While there is debate regarding what level of TT constitutes deficiency, most experts agree that a healthy range for TT is 300–1050 ng/dL when considering testosterone replacement therapy.^{7,8} Data suggest that levels <440 ng/dL are associated with elevated 10-year cardiovascular risk in middle-aged and elderly men.^{8a} There is general agreement that free T or

bioavailable T (free T plus albumin-bound T) would provide a better estimation of T status; however, there is concern about the reliability of these assays and a general lack of research using these measures. There is evidence of an excellent correlation between saliva testosterone levels and free T levels obtained simultaneously.⁹ This may prove to be a reliable alternative to serum testing; however, some of the same concerns mentioned previously remain. A single low AM testosterone level should be repeated to confirm the diagnosis of TD.

Much of our current data on the normal changes in adult testosterone levels related to aging are from the Massachusetts Male Aging Study (MMAS). This study followed men over 3 decades. At the beginning of the study in 1987, there were 1667 participants, and by the end of the study in 2004, there were 584 participants remaining. Longitudinal data revealed an average of 1%–2% TT decline per year, with a more rapid decline in free T due to the increases in SHBG with aging as discussed previously.^{5,10} Interestingly, there was variability in the rate of decline with some subjects' TT levels not declining over time and a few participants had increases with age. The mean TT level at 45 years old was approximately 540 ng/dL, while it dropped down to approximately 440 ng/dL by 70 years old.⁵ The prevalence of TD is estimated to be about 6%–12% in the general primary care population.¹¹ One other interesting trend from the MMAS was an age-independent decline in testosterone levels over the past 3 decades. The analyses indicate a 1% per year decrease in TT.⁵ Put another way, the mean TT of a 60-year-old man in 1988 was 500 ng/dL compared to approximately 440 ng/dL in 2003. This seems to be consistent with other observations of population-level declines in sperm counts and other reproductive disorders in men.^{12,13}

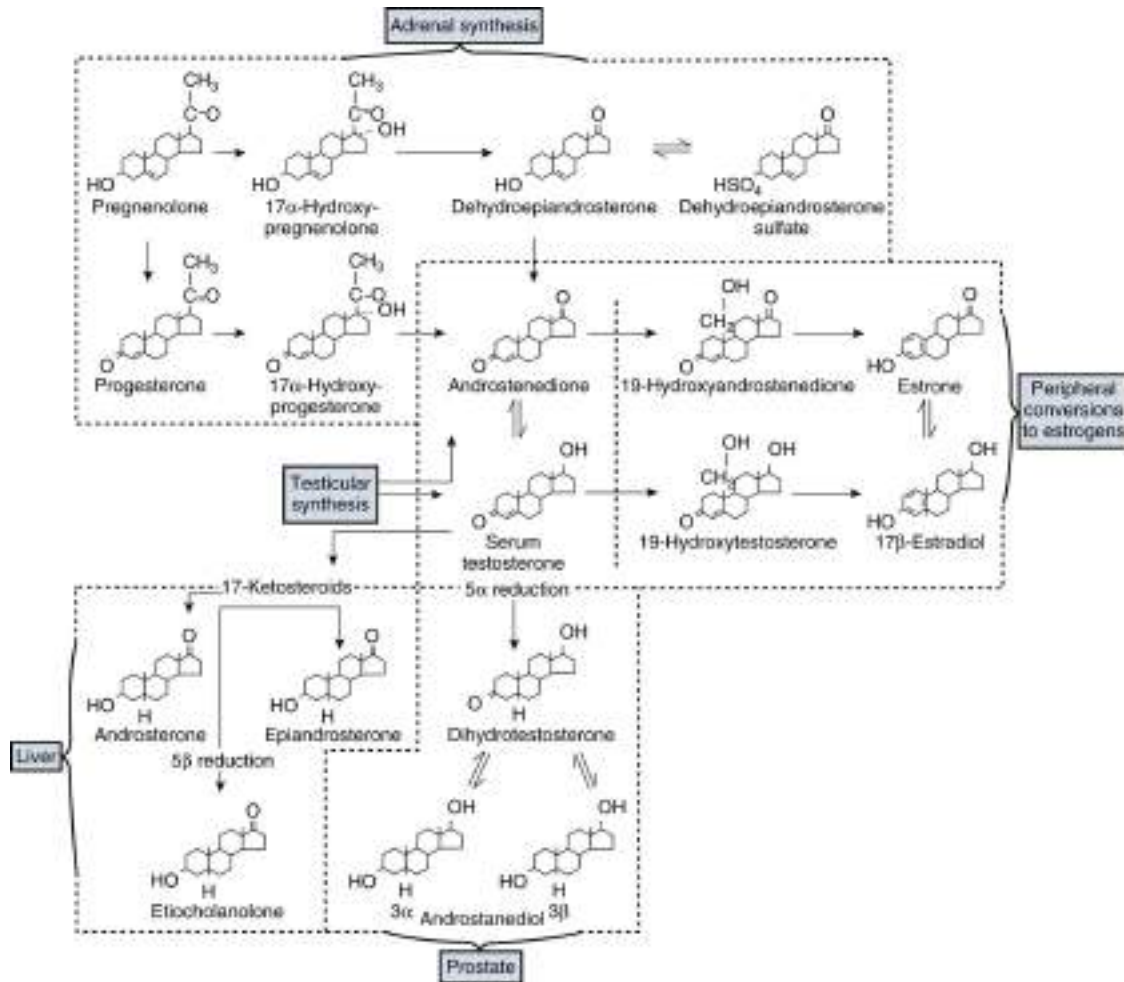

FIG. 64.1 Overview of the synthesis and metabolism of testosterone in four main body compartments: adrenal synthesis of androstenedione, peripheral conversion of androgens (androstenedione and testosterone) to estrogens, formation of active androgen (DHT) within the prostate, and inactivation in the liver of testosterone to three types of 17-ketosteroids. (From Ross AE.

Development, molecular biology, and physiology of the prostate. In: Wein et al., eds.

Campbell-Walsh urology /Elsevier; 2016:2393–2424.e9.)

Integrative Therapy

Nutrition

Most of the focus here can be on reducing metabolic syndrome and diabetes.^{14,15} Many of the same guidelines used to promote cardiovascular health and prevent cardiovascular disease (CVD) apply to reducing the risk for TD and sexual dysfunction.¹⁵ Thus, reducing refined

carbohydrates and educating men on the concepts of glycemic index and glycemic load are worthwhile (see [Chapter 87](#)).

In addition, promoting diets higher in vegetables and fruits while reducing animal-based foods makes sense on many fronts. Fruits and vegetables are high in flavonoids, which, along with isoflavones from soybean, have been studied as aromatase inhibitors and 5-alpha reductase inhibitors.¹⁶⁻¹⁸ The polyphenol epigallocatechin gallate (EGCG), the most abundant catechin found in tea (white, green, and black), has been studied as a 5-alpha reductase inhibitor and aromatase inhibitor as well.¹⁶⁻¹⁸ Reducing consumption of animal products reduces exposure to toxins that can bioaccumulate up the food chain. We will discuss endocrine disruptors in more detail later.

- Bone mineral density
- Epiphyseal fusion
- Fat mass
- Sexual function
- ? Mood and cognition
- ? HDL cholesterol

- Prostatic growth
- Skin
- Hair follicles in androgen-sensitive areas

FIG. 64.2 Active metabolism of testosterone. Testosterone may be converted to the potent estrogen, 17beta-estradiol, by the enzyme aromatase (CYP19) or to the more potent androgen, dihydrotestosterone (DHT), by the enzyme 5alpha-reductase. The effects of testosterone on prostatic growth, skin, and hair follicles in androgen-sensitive areas require 5alpha-reduction of testosterone to DHT. The effects of testosterone that require aromatization to estradiol are prevention of bone resorption, increase in bone mineral density, epiphyseal fusion, decrease in fat mass, sexual differentiation of the brain, sexual function, and possibly some aspects of cognitive function, mood, and plasma lipids (high-density lipoprotein [HDL] cholesterol). (Modified from Bhasin S. Testicular disorders. In: Kronenberg HM, Melmed S, Polonsky KS, et al., eds. *Williams textbook of endocrinology*. 11th ed. Philadelphia: Elsevier; 2008:645–698; Matsumoto AM. Testicular disorders. In: Kronenberg HM, Melmed S, Polonsky KS, et al., eds. *Williams textbook of endocrinology*, Elsevier; 2016:694–784.)

Aromatase promotes the conversion of testosterone to estrogen. Inhibiting aromatase by eating vegetables, fruit, and drinking green tea raises levels of testosterone while reducing estrogen. Estrogen (more than testosterone) is the main trigger of benign prostatic hyperplasia.

Exercise

In a study by Khoo et al. in 2013, improvements in TT levels were documented with moderate and high levels of exercise. The moderate-level exercise group exercised for 90–150 minutes per week at 55%–70% of the maximum heart rate (HR). The high-intensity group exercised for 200–300 minutes per week at a similar HR intensity. Both groups were encouraged to eat approximately 400 kcals less per day. After 24 weeks, the high-intensity exercise group had a statistically significant increase in both TT and FT. Both groups had improvement in erectile dysfunction measures.¹⁹

BOX 64.1 Signs and Symptoms of Testosterone Deficiency

Unexplainable weight gain with muscle loss
Osteoporosis/osteopenia
Fatigue

- Anemia
- Depressed mood
- Loss of self-confidence
- Impaired cognition
- Loss of libido
- Erectile dysfunction
- Diminished sexual performance

Mind–Body

Can posing make a difference in testosterone levels? It appears a “high-power pose,” in which there is expression of expansiveness and openness of the limbs held for 2 minutes, can lead to an increase in testosterone levels and decrease in cortisol levels measured in the saliva.²⁰ Over time, practicing power poses may improve a person’s general health and wellbeing. It is a very simple practice that also has a very low risk. Many yoga poses possess qualities of high-power poses. Pursuing training in yoga would be another reasonable recommendation for men with TD.

The loss of a spouse can dramatically affect TT, equaling 10 years of aging decline.²¹ The effects of psychological stress have often been underappreciated in the field of endocrinology and generally are not discussed in treatment protocols. It is important to take a social history to fully understand in what context TD is being diagnosed in terms of a man’s life. If appropriate, suggesting psychological counseling, helping identify local social support, and serving as a healing, mindful presence can be extremely important for a patient recently diagnosed with TD.

Toxins

Opioids

Opioid-induced androgen deficiency (OPIAD) is often underrecognized in clinical practice. OPIAD is inappropriately low levels of gonadotropins (FSH, LH) in the face of low plasma testosterone levels. OPIAD can be seen for months to years while being treated with morphine. Levels can drop as quickly as a few hours after starting opioids. Once morphine therapy is interrupted, levels can recover within a few hours to days. Less is known about long-term opioid use and hypothalamus/pituitary suppression. In one case-control study on 40 cancer patients receiving opioids, 90% were hypogonadal compared with

40% of the controls. In women, DHEA and DHEA sulfate levels have been found to be suppressed, thus indicating adrenal androgen suppression as well. It appears that the higher the dose of opioids, the higher the risk for hypogonadism. One can anticipate OPIAD when the range of oral morphine equivalence exceeds 100–200 mg/day. An additional risk is being on opioids for more than 1 month.²² Even with that level of exposure, OPIAD should be reversible after opioid cessation. Given this information, health care providers are responsible for providing full consent regarding the risk for developing an endocrinopathy prior to starting opioids.

BOX 64.2 Recycling Symbols on Plastic

Avoid	Safer for use
3 (PVC/phthalates)	2
6 (polystyrene foam)	4
7 (BPA)	5
	7 PLA (polylactide biodegradable corn)

BPA, bisphenol A; PVC, polyvinyl chloride.

Endocrine Disruptors

There is increasing awareness that chemicals commonly encountered in our environment can interrupt normal endocrine function. These have been classified as endocrine disruptors by researchers. Two of the best studied and most commonly encountered of these are phthalates and bisphenol A (BPA). They are both chemicals used in the manufacturing of plastics that impart various favorable qualities to plastic products. Phthalates provide soft, flexible plastics, are a major component of polyvinyl chlorides (PVCs), and are common in personal care products. BPA is used to create hard plastics and epoxy resins used to line food and beverage cans to prevent corrosion. Human studies on phthalates have demonstrated decreased free T levels in infants exposed to phthalates in breast milk and abnormal sperm morphology and sperm DNA damage in adult males.²³ Human studies on BPA reveal that humans are exposed to concentrations similar to or higher than doses that have been found to increase the risk for precancerous cells in animal prostate tissue.²⁴ There is also evidence of increased risk for obesity with BPA exposure.²⁵ BPA acts as a weak estrogen in mammals as well. Taken together, these last two facts make BPA exposure a risk factor for

developing symptomatic TD.

The best advice is to avoid exposure to these chemicals when possible. Do not heat or microwave food or beverages in plastic. Do not heat or microwave plastic wraps. Avoid placing plastics in the dishwasher. If using hard plastic containers, do not use them for warm or hot foods or liquids. Avoid canned food and beverages when possible, unless verifying that they are BPA-free. Use a washable fabric shower curtain as opposed to plastic/vinyl. The new car smell, which is at least in part from PVC off-gassing phthalates, can increase exposure through inspiration. Plastic containers with the recycling symbol 1 on the bottom are generally safe but made for one-time use. Look for alternatives to plastic for repeated use containers such as glass and stainless steel. Avoid plastics with the symbols 3 (PVC/phthalates), 6 (polystyrene foam), and 7 (BPA) on the bottom of the container. Recycling symbols of 2, 4, 5, and 7 (polylactide [PLA] biodegradable corn) are safer options ([Box 64.2](#)) (see [Chapter 108](#)).

Supplements

Zinc

Zinc is a cofactor in numerous metabolic processes in the human body. There is evidence of a significant positive correlation between zinc supplementation and serum testosterone levels in elderly men.²⁶ A 2010 systematic review of randomized controlled trials on sexual dysfunction and chronic kidney disease identified zinc deficiency as a reversible cause of sexual dysfunction and TD in this high-risk population.²⁷ Zinc citrate, zinc acetate, or zinc picolinate may be best absorbed, although zinc sulfate is less expensive. Consider checking the zinc level in men with TD.

Dosage

The dose is 25–50 mg PO daily.

Precautions

Zinc taken orally seldom causes any immediate side effects other than an occasional stomach upset, usually when it is taken on an empty stomach. Some forms do have an unpleasant metallic taste. Use of zinc

nasal gel, however, has been associated with anosmia (loss of sense of smell). Long-term use of oral zinc at dosages of 100 mg or more daily can cause a number of toxic effects, including severe copper deficiency, impaired immunity, heart problems, and anemia.²⁸

Dehydroepiandrosterone

DHEA is an androgen prohormone that has been shown to decrease dramatically with age, and its decline is believed, by some, to accelerate the aging process. It is manufactured synthetically from soybean precursors. DHEA has shown some promise for improving erectile dysfunction in men who have low DHEA blood levels.²⁹ DHEA serum levels should also be checked in those with TD.

Dosage

The recommended dose is 5–50 mg PO 1–2×/day. I usually start men on 25 mg PO BID and titrate as needed.

Precautions

DHEA appears to be safe when taken in therapeutic doses, at least for a short term. Women may experience adrenergic side effects such as acne and unwanted hair growth. I would recommend similar precautions and contraindications for using DHEA, as described later for testosterone replacement therapy (TRT).

Botanicals

Quercetin

Quercetin may reduce aromatase activity, thereby increasing available testosterone ([Box 64.3](#)).

Dosage

The dose is 400 mg PO 1–2×/day.

Precautions

Quercetin may increase homovanillic acid on urine and serum tests, leading to false-positive tests for neuroblastoma.³⁰

Resveratrol/Grape Seed Extract

Resveratrol/ grape seed extract has been found to modestly improve glycemic and hypertension (HTN) control in type 2 diabetes mellitus (T2DM).³¹ They may also reduce aromatase activity.

Dosage

The dose is 100–300 mg PO 1–2× /day.

Precautions

It is well tolerated in short-term studies. There are concerns that resveratrol specifically may have mild estrogenic activity. In addition, it may have antiplatelet activity, so it should be cautiously used with other blood thinners.

Pycnogenol

Pycnogenol supplementation improves health risk factors in subjects with metabolic syndrome. Men's waist circumference decreased from 106 cm to 98 cm in 6 months with supplementation.³² Decreasing abdominal fat should decrease conversion of testosterone to estradiol.

Dosage

The recommended dose is 50 mg PO TID.

Precautions

Appears to be safe and is generally well tolerated, although a low incidence of adverse effects, including gastrointestinal symptoms, dizziness, and vertigo, have been reported.

Saw Palmetto

Saw palmetto (*Serenoa repens*) is a weak inhibitor of 5-alpha reductase

([Box 64.4](#)). It may also have a role in reducing the number of estrogen and DHT receptors.³³

BOX 64.3 Aromatase Inhibitors

Anastrozole (Arimidex)

Letrozole (Femara)

Quercetin

Resveratrol/grape seed extract

Zinc

Progesterone

Dosage

The dose is 160 mg PO 2×/day or 320 mg PO daily.

Precautions

Saw palmetto is thought to be essentially nontoxic. In addition, in clinical trials, it has shown little to no adverse effects. There is one report of excessive bleeding during surgery related to saw palmetto ingestion. Caution is recommended when adding to other blood thinners.

Maca

Maca (*Lepidium meyenii*) has been found to increase testosterone levels in some animal studies, but not all studies show this effect. Human studies have revealed subjective improvements in sexual function.³⁴

Dosage

The dose is 500–1000 mg PO up to 3×/day.

Precautions

In reported human clinical trials, use of maca has not led to any serious adverse effects.

Pharmaceuticals

Testosterone replacement in men with TD provides significant improvements in lipid profiles, decreases body fat, increases lean muscle mass, and decreases fasting glucose.³⁵ A well-publicized study by Basaria et al. in 2010 revealed an increased risk for cardiovascular adverse events with 100 mg of testosterone in a transdermal gel compared with placebo in elderly men with limited mobility and a high prevalence of chronic disease.³⁶ When looking at all-cause mortality, it appears men treated with testosterone for TD have decreased mortality in observational studies.³⁷ Calof et al. performed a meta-analysis of 19 randomized studies and did not find a statistically significantly greater risk for prostate cancer in men on TRT versus placebo. However, there was greater detection of prostate events (elevated prostate-specific antigen [PSA] and prostate biopsies) and hematocrit (HCT) greater than 50% in men on TRT.³⁸ Similar to female hormone replacement therapy (HRT) before the Women's Health Initiative (WHI), we will likely not have consensus on the long-term safety of TRT until large, long-term studies are completed. Until then, decisions to start HRT will need to be based on the clinical severity of TD and informed consent on the part of the patient.

BOX 64.4 5-Alpha Reductase Inhibitors

Finasteride

Dutasteride

Zinc

Progesterone

Saw palmetto

L-Lysine

Epigallocatechin gallate (ECGC)

Linolenic acid

Testosterone replacement does not appear to increase the risk for prostate cancer, but there is concern that it may increase the risk for cardiovascular events.

At a minimum, baseline labs should include AM free and TT, PSA, and a complete blood count (CBC; hemoglobin [HGB]/HCT). A digital rectal

exam should also be performed. Additional labs to consider are thyroid-stimulating hormone (TSH) and free T4, DHEA sulfate, LH, fasting glucose, HGB A1c, lipids, and liver function. In selected cases, SHBG, estradiol, prolactin (if LH/FSH are low), and zinc levels may be helpful. If LH is elevated in the face of low serum testosterone levels, consider Klinefelter syndrome, alcoholism, and heavy metal poisoning as the cause of primary hypogonadism. If there is confusion, consider requesting an endocrinology consult. My experience is that LH is rarely elevated with low testosterone levels related to aging or obesity ([Box 64.5](#)).

Contraindications to treatment are active prostate cancer (but not previously treated prostate cancer with a Gleason score of 7 or less), breast cancer, prostate nodule, unexplained PSA elevation, HCT of >50%, unstable congestive heart failure (CHF) or coronary artery disease (CAD), and severe obstructive sleep apnea (OSA) ([Box 64.6](#)).

Monitoring treatment should include a follow-up office visit to discuss symptoms and potential side effects (acne, behavior changes, and edema) and dose adjustments 1–3 months after starting treatment. TT and FT can be checked 2–4 weeks after starting TRT. The timing of the serum levels should be 3–12 hours after application of gels and creams, and about halfway between testosterone injections. Advise patients using topical preparations to be mindful of exposure to children and women. Also avoiding hairy areas and scrotal application is recommended to reduce conversion to DHT by 5-alpha reductase. Men should be followed every 3–4 months for the first year with testosterone levels, PSA, CBC, and digital rectal exam (DRE). Annual monitoring after that is acceptable if stable. Some authors recommend a target TT level of 400–700 ng/dL (possibly > 350 for elderly men).

BOX 64.5 Recommended Baseline Laboratory Testing for Testosterone Deficiency

AM free and total testosterone–serum

PSA

CBC

TSH

Fasting glucose

Also consider DHEA sulfate, zinc, LH, fasting glucose/hemoglobin A1c, lipids, and liver function tests.

BOX 64.6 Contraindications to Testosterone Hormone Replacement

- Active prostate cancer (not previously treated prostate cancer if the Gleason score is 7 or less)
- Breast cancer
- Prostate nodule
- Unexplained PSA elevation
- Polycythemia (caution if HCT > 50%)
- Unstable CHF or CAD
- Severe OSA

CAD, coronary artery disease; CHF, congestive heart failure; OSA, obstructive sleep apnea.

Testosterone Cypionate Injections

Dosage

The recommended dose is 50–200 mg IM q1–2 weeks or 30–50 SQ 1–2×/week.

Precautions

As with all testosterone, it is a controlled substance. Self-administration can lead to misuse and overdosing, injection site reactions, and infections. Men should be warned of the potential for infertility related to any form of testosterone replacement.

Testosterone Creams (Compounding Pharmacy)

Dosage

The dose is 10–200 mg topically daily. I usually start with 40–50 mg daily (qhs or qAM).

Precautions

The most common adverse reaction is local skin reactions, which can include redness. As with any of the topical hormone preparations, men

need to be mindful to avoid exposure to women, children, and pets after application.

Testosterone Gels and Patches (Available Commercially)

Dosage

Depends on the formulation

- 1% gel: 50 mg testosterone = four pump actuations = one 5-g pkt. 50–100 mg qAM
- 1.62% gel: 40.5 mg testosterone = two pump actuations = one 2.5-g pkt. 40.5–81 mg qAM
- 2 mg and 4 mg/24 hour patch. Apply 1–2 patches qhs. Adjust based on serum testosterone levels.

Precautions

The most common adverse reaction is local skin reactions, which can include redness. As with any of the topical hormone preparations, men need to be mindful to avoid exposure to women, children, and pets after administration.

Methyltestosterone

Dosage

The dose is 10–50 mg PO daily divided qd–qid.

Precautions

Generally not used because of concerns about liver toxicity. Studies reveal hepatotoxicity is extremely rare, but concerns with oral use persist, especially at higher doses required by some men.³⁹

Prevention Prescription

- Maintain a healthy weight and especially avoid obesity (BMI > 30).

There is evidence that maintaining a waist circumference less than 40 inches (approx. 102 cm) can reduce erectile dysfunction.

- Reduce the risk for diabetes and metabolic syndrome by eating foods with a lower glycemic index and with a low-to-moderate glycemic load.
- Eat a diet rich in fruits and vegetables.
- Exercise regularly to help maintain a healthy weight and physical fitness. Exercising 200–300 minutes per week has been shown to increase testosterone levels.
- Consider developing a yoga practice and embrace posing in a powerful way to naturally boost testosterone levels and lower cortisol.
- Establish and nurture strong social bonds throughout life to avoid social isolation during stressful and painful events such as the loss of a spouse.
- Avoid opioid medications if at all possible for chronic pain. If they must be used, try to use the lowest effective dose for the shortest amount of time.
- Avoid plastics and personal care products made with phthalates and BPA. Eliminate eating or drinking from containers made from plastics or cans unless you can verify they are BPA/phthalate free. Replace plastic stamped with the recycling symbols 3, 6, and 7 with ceramic, glass, or stainless steel.

Therapeutic Review

Nutrition

- Reduce metabolic syndrome and diabetes 
- Reduce refined carbohydrates 
- Increase a plant-based diet and reduce consumption of animal products 

Exercise

- Encourage moderate-to-high levels of exercise and weight loss 

Mind-Body

- Practice “power posing” on a daily basis 
- Encourage finding resources and help to support men dealing with difficult psychological problems and concerns 

Toxins

- If exposure to opioids is causing TD, try to limit exposure if possible 
- Avoid food and drink contamination from plastic products made from phthalates and BPA 

Supplements

- Zinc 25–50 mg PO daily 
- DHEA 5–50 mg PO 1–2×/day 
- Quercetin 400 mg PO 1–2×/day 

Botanicals

- Grape seed extract 100–300 mg PO 1–2×/day 
- Pycnogenol 50 mg 3×/day 
- Saw palmetto 160 mg PO 2×/day 
- Maca 500–1000 mg PO 3×/day 

Pharmaceuticals

- Testosterone cypionate 50–200 mg IM q1–2 weeks 
- Testosterone cream 10–200 mg topically daily 
- Testosterone gel 25–100 mg topically daily

CHAPTER 65

Osteoarthritis

Adam I. Perlman, MD, MPH, Lisa Rosenberger, ND, LAc, and Ather Ali, ND, MPH, MHS

Osteoarthritis (OA) is a slowly progressive degenerative disease of the joints that afflicts approximately 27 million Americans.^{1,2-7} OA is already the most frequently reported chronic condition in the elderly, and with the aging of the baby boomer population and increased rates of obesity, it is estimated that by 2030, more than 67 million Americans (25% of the population) will have OA.⁷⁻⁹ The costs of OA in terms of human suffering are extremely high, with increased all-cause mortality in adults with OA compared to those without OA.¹⁰

Conventional therapies for OA have limited effectiveness, and toxicities associated with suitable drugs often limit utilization, leaving many facing surgery or chronic pain, muscle weakness, lack of stamina, and/or loss of function.^{3,11-17} OA of the hip or knee is particularly disabling because it limits ambulation, but OA also strikes the hands, spine, feet, and other joints with the same destructive process.^{2,4,13-15} The endpoint of the OA disease process is total loss of joint cartilage in the affected area and the need for joint replacement.^{14,15} [Fig. 65.1](#) illustrates degenerative findings in the knee joint.

OA is a disease of multiple etiologies and should be considered not a consequence of wear and tear but rather a breakdown in normal physiological pathways that manifests as progressive damage of articular cartilage as well as bone remodeling or new bone formation.¹⁸ However, ultimately the whole joint is affected in OA, with pathological changes in not only the bone and cartilage but also synovium and ligaments.^{19,20} Imbalances within the joint occur between metabolic and degradative processes facilitated by cytokines, inflammatory mediators, and chondrocyte activity.¹⁹⁻²¹ OA is broadly broken down into two categories: primary (idiopathic) OA, in which no specific risk factors, except for age, can be identified, and secondary OA, in which changes can be related to

systemic and/or local factors.²² [Fig. 65.2](#) shows the systemic and local factors that increase susceptibility to OA.

Pathophysiology

Normal Joints

The major constituents of cartilage are water, proteoglycans (composed of protein cores plus chondroitin sulfate and keratin sulfate side chains), and collagen (predominantly type II). Collectively, they form the extracellular matrix (ECM). Chondrocytes are metabolically active cells that are responsible for synthesis of the ECM. Proteoglycans provide elasticity of cartilage, and collagen provides tensile strength. Muscles and ligaments provide support and protection, while nerve endings provide proprioceptive information. Cartilage health and function depends on compression (pumping fluid from the cartilage into the joint space and into capillaries and venules) and release (allowing cartilage to reexpand, hyperhydrate, and absorb nutrients).

Early Changes of Osteoarthritis

The articular cartilage surface becomes irregular with superficial clefts in the tissue with increased chondrocyte proliferation and cluster formation.²⁰ Increased hydration of the ECM leads to a failure of the elastic restraint of collagen (i.e., weakening of the collagen network) and also alters the proteoglycan distribution.^{19,20} Progression leads to a net decrease in proteoglycans and an increase in the permeability of water. Loss of elasticity and greater permeability of water lead to higher chondrocyte stress and more exposure to degradative enzymes. As the process continues, the articular cartilage has deepening of the clefts and irregularities, eventually resulting in ulceration and exposure of the bone.¹⁹⁻²¹

Late Changes of Osteoarthritis

Subchondral osteoblasts increase bone formation, leading to stiffer and less compliant bones. This in turn results in microfractures, followed by callus formation, more stiffness, and more microfractures. Osteophytes (outgrowths of bone) are formed, the hallmark of OA. They ultimately cause restricted motion. Subchondral cysts are formed in an attempt to

equalize pressure. Gross ulceration of articular cartilage will have focal and then diffuse areas of complete loss of cartilage. In later stages, proteoglycan and keratan sulfate levels in the ECM decrease, as does the length of chondroitin sulfate chains. These changes in concentrations of components within the ECM lead to cartilage resembling the composition of immature cartilage.²⁰ Soft tissues around the joint are also affected, leading to inflammatory infiltrates in the synovium, greater laxity of ligaments, and weakened muscles.

Other factors involved in inflammatory and destructive processes in the joint include the matrix metalloproteinase (MMP) family of proteinases, which degrade proteoglycans and collagen,^{20,21} as well as cytokines, IL-1, and TNF- α , which upregulate MMP gene expression, facilitate damage to the joint, and inhibit reparative pathways that would restore joint integrity.²³ Other cytokines involved in OA processes include the proinflammatory cytokines IL-6, IL-8, IL-11, IL-17, and leukemia inhibitory factor (LIF), as well as antiinflammatory cytokines IL-4, IL-10, and IL-13.²³

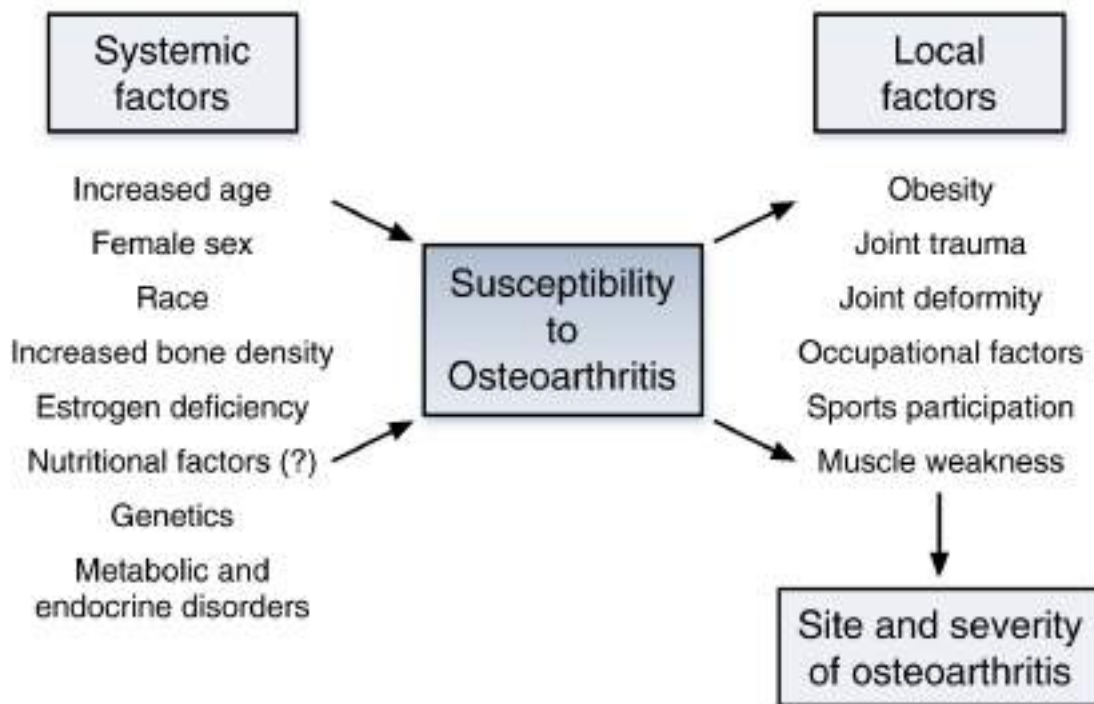

FIG. 65.1 Systemic and local factors that increase susceptibility to arthritis. (Modified from Dieppe P. The classification and diagnosis of arthritis. In: Kuettnner K, Goldberg V, eds. *Osteoarthritic disorders*. Rosemont, IL: American Academy of Orthopaedic

FIG. 65.2 Degenerative joint disease. Anteroposterior (A) and lateral (B) views of the knee show the characteristic finding of osteoarthritis. Joint space narrowing and osteophyte formation at the medial and patellofemoral compartments with varus alignment at the knee are visible. A large suprapatellar joint effusion is also apparent. (From Scott NW. *Insall and Scott Surgery of the Knee*. 4th ed. Philadelphia: Churchill Livingstone; 2005.)

Integrative Approaches

Integrative therapy in OA is aimed at reducing pain, improving joint functionality, and reducing the further progression of osteoarthritis. Some complementary therapies have potential disease-modifying effects, such as glucosamine and chondroitin sulfates, while others provide

symptomatic relief.

Lifestyle

Antiinflammatory Diet

An antiinflammatory diet is characterized by emphasizing omega-3 fatty acids (found primarily in deep-water fish), minimizing omega-6 fatty acids, with an emphasis on unprocessed whole grains, beans, and fruits and vegetables. Fish oil, especially EPA, is often added as a supplementary measure. There is significant overlap between the antiinflammatory diet and the Mediterranean diet that can reduce the risk of cardiovascular disease.^{24,25} A diet high in fruits and vegetables, independent of lifestyle effects and BMI, is likely to be protective against radiographic hip OA.²⁶

Antiinflammatory diets have demonstrated clinical benefits in persons with inflammatory diseases such as rheumatoid arthritis.^{24,27-30} Studies have largely demonstrated a reduction in number of tender joints and the duration of morning stiffness.³⁰ Fish oil supplements may reduce the need for nonsteroidal antiinflammatory drugs (NSAIDs).^{30,31}

Arachidonic acid, found only in animal foods, is eliminated from the diet in strict vegetarians; vegetarianism has been associated with symptomatic relief in rheumatoid arthritis.³²⁻³⁴ Other studies report symptomatic relief of rheumatoid arthritis symptoms with gluten-free vegan diets³⁵ (see [Chapter 88](#)).

Weight Loss

Dietary Measures

Weight is directly related to the development of OA; therefore, weight management is an important element in both the prevention and management of OA of the knees and hips.³⁶⁻³⁹ Rapid, substantial weight loss through dietary restriction may have significant benefits on symptoms and functionality in overweight patients.³⁸ Messier et al.⁴⁰ found that the combination of dietary weight loss plus exercise (compared to either alone, or a control group receiving educational materials) resulted in significant long-term symptomatic improvement in obese sedentary people with OA. In a 2010 study, it was found that a 10% weight loss in obese and overweight patients with OA had a reduction in biomechanical pathology of OA of the knee by reduction in lower knee

joint compressive loads during walking compared with low to no weight loss groups⁴¹ (see [Chapter 37](#)).

Exercise

A 2015 Cochrane Review of 54 randomized controlled trials found that land-based exercise provided short-term benefit for OA patients that is sustained for 2–6 months following treatment. Exercise can result in reduced knee pain and improves physical function in persons with knee OA.⁴² Furthermore, exercise programs can help prevent disability from OA.⁴³ Exercise programs may be more useful for knee OA compared to hip OA.

Although multiple guidelines with varying recommendations on the physical management of OA exist, exercise is an important strategy in the management of this condition.⁴⁴ Three types of exercise should be incorporated into a program for OA sufferers: aerobic training, resistance training with muscle strengthening, and flexibility or range of motion. Both group- and home-based programs may be effective, making patient preference an important consideration.⁴⁵ In addition, some evidence supports water-based exercise as an option for patients with OA.⁴⁶ Aerobic training can also reduce risk of cardiovascular disease and diabetes, thereby improving overall health status. Recommended exercises are walking, biking, swimming, aerobic dance, and aerobic pool exercises. For patients with symptomatic hip OA, aquatic exercises can be effective.^{47,48}

Exercise is an effective nonpharmacological treatment for reducing pain and improving function. Although formal guidelines vary, some form of physical activity should be done on most days, with a more formal exercise routine at least three days per week for a total of at least 150 minutes, or 75 minutes if more vigorous.⁴⁹

Muscles are important shock absorbers and help stabilize the joint; therefore, periarticular muscle weakness may result in progression of structural damage to the joint in OA. In addition, insufficient loading of a joint will lead to atrophy of both articular cartilage and subchondral bone.⁵⁰ In general, strength training helps offset the loss in muscle mass and strength typically associated with normal aging. Strength training has been found to be beneficial for older adults, but especially beneficial

for those older adults with OA because it not only improves muscle strength but also function and pain reduction.⁵¹ Reassure patients with OA that strengthening exercises will not exacerbate their symptoms if done in the appropriate manner and dose.⁵¹

Flexibility is a general term that encompasses the range of motion of single or multiple joints and the ability to perform certain tasks. The range of motion of a given joint depends primarily on the structure and function of bone, muscle, and connective tissue. Cartilage needs regular compression and decompression to enable it to remodel and repair damage and receive appropriate nutrients. OA affects the structure of these tissues, such that range of motion and flexibility are reduced. The basis for exercise interventions to improve flexibility is that the muscle and connective tissue properties can be improved, thereby enhancing function.⁵²

Dosing

Although the optimal exercise prescription and dosage is unclear, patients should consider following the guidelines for active adults or active older adults recommended by the Centers for Disease Control and Prevention.⁴⁹ These guidelines include a goal of a minimum of 150 minutes of moderate intensity or 75 minutes of more vigorous intensity aerobic exercise per week, with muscle strengthening activities at least 2 days per week. More benefits may be seen with increased time and/or intensity.

Another option is to consider 20 minutes of exercise three times a week, building up to at least 180 minutes of mild to moderate exercise per week. Better adherence to exercise regimens occurs in supervised settings in comparison to unsupervised settings.⁵³ In the following section are some exercise recommendations based on studies assessing exercise for the treatment of OA. These regimens are only guidelines and should be modified according to patient's current health status and severity of OA. These regimens can also be appropriate for those attempting a weight loss program.

Aerobic Exercise

Aerobic exercise consists of three phases: (1) the warm-up phase (slow walking, calisthenics: arm circles, trunk rotation, shoulder and chest stretches, and side stretches) for approximately 10 min, (2) the stimulus phase (walking at 50%–70% of heart rate reserve) for up to 40 min, and

(3) the cool down phase (slow walking, flexibility exercises, shoulder stretches, hamstring stretches, and lower back stretches) for 10 min.

Aerobic interventions: 1 hour per session, three times a week.⁵⁴

Dosing

The optimal exercise prescription and dosage remains unclear; however, patients should consider building up to exercising for 1 hour per session, three times weekly^{32,55} (see [Chapter 91](#)).

Resistance Training/Muscle Strengthening

A strength training program that provides progressive overload to maintain intensity throughout the exercise program has been found to be most beneficial for improvements in strength, function, and pain reduction in older adults with OA.⁵¹

A resistance program also consists of three phases: (1) warm-up phase, 10 min, (2) stimulus phase, 40 min, and (3) cool down phase, 10 min. During the stimulus phase, employ exercises that improve the overall muscular fitness of the person and strengthen major muscle groups of the both the upper and lower extremities. Each exercise should be done in two sets of 12 repetitions. Exercises can include leg extensions, leg curl, step up, heel raise, chest fly, upright row, military press, biceps curl, and pelvic tilt. These exercises can be performed using dumbbells, cuff weights, and/or resistance machines.⁵⁴

Dosing

The optimal exercise prescription and dosage remains unclear; however, patients should consider building up to exercising for 1 hour per session, three times weekly, with at least two sessions per week of resistance training.^{32,55}

Flexibility/Range of Motion

Exercises that develop and improve range of motion, also aid in maintaining flexibility. These exercises involve static movements and maintained stretching of the major muscle groups. These exercises should be performed two to three times per week and should be of moderate intensity (intensity of 5–6/10, with 10 being the most intense).^{52,56}

Dosing

When beginning a resistance/strength training program, one should start with the lowest possible resistance (1.3 kg for the upper body and 1.1 kg for the lower body). Weight should be increased in a step-wise fashion and based on patient tolerance. If a patient is able to complete 2 sets of 10 repetitions then the weight is tolerable. If a patient establishes a plateau in weight tolerance, then it is appropriate to increase the amount of weight when the patient is able to perform 2 sets of 12 repetitions for 3 consecutive days.⁵⁴

Precaution

Two precautions should be considered before implementation of an exercise program in patients with OA: (1) exercise of an acutely inflamed or swollen joint should be deferred until the acute process subsides and (2) an exercise stress test should be performed to identify cardiac disease in those at risk.⁵⁷

Mind-Body Therapies

Telemedicine Interventions

Interactive programs utilizing computers and web-based interactions with patients have been shown to have a benefit for patients with OA following arthroplasty as well as with those needing chronic pain management.⁵⁸⁻⁶⁰

Telephone-based strategies can be an integral part of the management of chronic disease. A randomized controlled trial evaluated whether telephone-based or office-based interventions, or both, improved the functional status of patients with OA.⁶¹ Subjects in the intervention groups were contacted monthly by telephone or scheduled clinic visits by trained people who were not health care professionals. At each contact, the following items were discussed: (1) joint pain, (2) medications, (3) gastrointestinal and other medication-related symptoms, (4) date of the next scheduled outpatient visit, (5) an established mechanism through which patients could telephonically contact a physician during weekends and evenings, and (6) barriers to keeping appointments. At 1-year follow-up, in comparison with the control group, persons receiving telephone calls reported less physical disability and pain and tended to have better psychological status.⁶² Smartphone and Internet-based interventions are ubiquitous and can be adapted to

large populations.

Dosage

Telephone calls (or possibly text messages) are typically made to patients biweekly⁶¹ or monthly.⁶²

Precautions

A good patient–provider relationship ensuring effective communication and the ability to understand and implement medical guidance over the telephone should exist before patients are counseled by telephone.

Group Programs

The Arthritis Self-Management Program (ASMP) is a community-taught, peer-led intervention, in which patients gain the confidence and the necessary tools to manage their disease. Participants attend 2-hour weekly sessions for 6 weeks. These sessions include education about pathophysiology and pharmacotherapy, as well as the design of individualized exercise and relaxation programs, appropriate use of injured joints, aspects of patient–physician communications, and methods for solving problems that arise from illness. The sessions are taught from an interactive model, which promotes individual participation and self-management techniques.⁶³ A 4-year follow-up study found that participants had reduced pain and fewer physician visits, and they spent fewer days in the hospital.⁶³

Dosage

Patients attend a group course with an experienced teacher twice weekly for at least 12 weeks.

Precautions

This approach may not work for patients who need more attention or individual face-to-face

Yoga

Yoga, a traditional Indian practice of a physical and mental nature, involves the use of postures or *asanas*, breathing techniques or *pranayama*, and mental concentration/meditation or *dhyana*. All of these are focused on the intention of promoting relaxation, *savasana*. As stress, physical dysfunction, and lack of exercise are confounders for OA and worsening of the disease, a therapy that can address all of these areas is ideal. Yoga has been studied as a complementary (adjunct therapy to conventional care) and an alternative therapy (tried instead of a conventional therapy, such as pharmaceuticals, injections, and/or surgery). A 2012 review assessing tai chi and yoga as complementary therapies in rheumatological conditions noted that most studies in knee OA were small and uncontrolled. Yoga was found to improve pain and functionality compared to control interventions in several randomized trials.⁶⁴ A 2013 review noted general safety and feasibility for yoga interventions in OA and at least short-term benefit.⁶⁵ More research on the various types of yoga practice as well as the specific joints affected by OA needs to be further studied. Long-term effects and benefit, as well as comparison to other OA interventions, both conventional and complementary, in different age groups should also be further studied.⁶⁵

Dosage

Although the dose is variable, patients should consider Hatha yoga at 1 hour per week for 8 weeks. Yoga can be done in conjunction with other physical therapy modalities.

Precautions

Several types of yoga practices exist; it is important to begin with gentle, easy exercises.

Tai Chi

Tai chi is also an effective exercise strategy for OA that has the benefit of not only improving pain and function, but also balance.⁶⁶ Tai chi has been noted to be particularly effective in improving pain, stiffness, and overall function in knee OA.⁶⁷

Physical Modalities

Reduction of Joint Loading

Patients with OA of the knee or hip should avoid prolonged periods of standing, kneeling, or squatting. In patients with unilateral OA of the hip or knee, a cane, when held in the contralateral hand, may diminish joint pain by reducing joint contact force. Bilateral disease may necessitate the use of crutches or a walker.⁶⁸ A Cochrane Review on the use of braces or orthoses for knee OA indicated only limited evidence to support the effectiveness of these devices.⁶⁹ However, the trials that have been undertaken indicate good symptom relief from the use of wedged insoles in patients with OA of the medial knee compartment.⁷⁰ The 2008 Osteoarthritis Research Society International (OARSI) guidelines indicated that patients with knee OA and mild to moderate varus or valgus instability may benefit from knee bracing because it can reduce pain, improve stability, and reduce the risk of falling.⁴⁷

Heat Therapy

Application of heat can raise the pain threshold and produce muscle relaxation. Moist heat produces greater elevation of the subcutaneous temperature than dry heat and is often preferable for relief of pain. A randomized, placebo-controlled, double-blind clinical trial examining the effects of local hyperthermia induced by 433.92-MHz microwave diathermy in OA of the knee found that three 30-minute sessions per week for 4 weeks produced significant improvements in pain reduction and physical function.⁷¹

Superficial heat penetrates the skin only a few millimeters and does not reach deeper joints such as the hip and knee. In contrast, a heat mitten may raise the temperature of the small joints of the hand.⁷²

Dosage

For commercial hot packs (temperature, 165–170°F), treatment time is 15–30 minutes, and the temperature is adjusted to the patient's tolerance by using commercial covers or increasing towel thickness between the patient and the hot pack. For diathermy, patients undergo 30-minute sessions three times weekly for 4 weeks.

Precautions

The risk of thermal injury is higher in patients with poor circulation or impaired sensation.⁶⁸ Use heat therapy with caution in patients who have reduced peripheral circulation or severe cardiac insufficiency. Be aware of superficial metal implants and open or closed wounds in the skin.

Cold Therapy

Cold applications are often recommended after strenuous exercise to relieve muscle aching. They may be delivered by ice packs, ice massage, or local spray. Superficial cooling can decrease muscle spasms and raise the pain threshold. A Cochrane Review of three randomized controlled trials showed that ice treatment may improve the range of motion and reduce edema in knee OA.⁷³

Dosage

Most cold applications are for 20–30 minutes and are reapplied in 2 hours. Rewarming times should be at least twice as long as cooling times, to avoid excessive cooling.

A classic ice pack (23–32°F) is a mixture of crushed ice and cold water wrapped in terry cloth or enclosed in a plastic bag. These packs usually maintain a surface temperature above freezing and thus do not require an insulator between the patient's skin and the pack.

Cold packs (33–50°F) are a mixture of water and antifreeze that forms a gel mixture in a vinyl cover. These gel packs may induce frostbite because of their low temperature, so a layer between the skin and the pack is warranted. Treatment should be limited to less than 30 minutes with these cold packs.

Precautions

Cold applications should not be used in patients with Raynaud's phenomenon, cold hypersensitivity, cryoglobulinemia, or paroxysmal cold hemoglobinuria.⁶⁸

Transcutaneous Electrical Nerve Stimulation

Transcutaneous electrical nerve stimulation (TENS) has been considered as a treatment modality for OA of the knee or hip. It can help with short-term pain relief, and no serious side effects have been reported.⁴⁷

Dosage

For conventional TENS, the frequency is 85 pps and the pulse width is 75 μ sec. The intensity is sensory, with placement of pads over the target tissue, dermatome, or nerve distribution. The duration of application is 15–30 minutes to 4 hours (until relief is obtained). The frequency of application is one to six times daily, depending on the patient's response and the intensity of pain. A review study noted that TENS has increased benefit when the highest intensity tolerated by the patient is applied, and when pads are placed at acupoint locations rather than nonacupoint locations.^{73a}

Precautions

Use TENS with caution in patients who have cardiac pacemakers, implanted cardioverter defibrillators, electrocardiography monitors, other electronic implants, skin allergic reactions, and impaired skin sensation, as well as in patients who drive or operate hazardous machinery and are currently taking pain medications.

Stimulation over the intercostal muscles should be avoided or closely monitored because, in one case report of a patient with cardiac disease, this stimulation led to respiratory failure. In addition, caffeine intake higher than 200 mg/day (approximately three cups of coffee per day) decreased the ability of the TENS to modulate pain.⁷⁴

Massage

Massage may lead to improvement in pain and function. A randomized controlled trial of Swedish massage therapy in patients with OA found significant improvements in pain, stiffness and physical function, pain perception, knee range of motion, and time to walk 50 ft.⁷⁵ Research to replicate these findings and further define the role of massage in the treatment of OA of the knee is ongoing; however, a 2012 study identified an “optimal practical dose.”⁷⁶ Research evaluating the role of massage in the treatment of other joints afflicted with OA is also needed.

Dosage

The dose of Swedish massage is 60 minutes per week for 8 weeks.

Precautions

Although the risk of local pain from excessive pressure or bruising does exist, massage is commonly performed and is generally not harmful. Massage likely has no serious risks.

Acupuncture

Acupuncture-associated analgesia is believed to work through the release of opioid peptides.⁷⁷ Numerous randomized controlled trials have been undertaken to assess the efficacy of acupuncture for treatment of pain associated with OA. In a 1975 study, 40 patients were randomly allocated to receive acupuncture either at standard points or at placebo or sham points.²⁰ Analysis before and after treatment showed a statistically significant improvement in tenderness and subjective report of pain in both groups.⁷⁸ In a 1982 study, 32 patients with OA of the hip, knee, or humeroscapular joint were randomly allocated either to receive weekly acupuncture or to take piroxicam, with checkup visits at 2, 4, 6, 12, and 16 weeks. The extent of improvement was equal in both groups at 2 weeks (30%); after that, however, the acupuncture group showed greater pain relief than the piroxicam group.⁷⁹ A systematic review of 11 randomized controlled trials of acupuncture for OA concluded that the most rigorously conducted studies showed that acupuncture is not superior to sham needling in reducing pain from OA.⁸⁰ The most recent Cochrane Review of acupuncture reported that although sham-controlled trials do have statistically significant benefits, the benefits do not meet the predefined thresholds for clinical relevance and the benefits are small.⁸¹ The investigators also noted that the benefits are likely the result of a placebo effect or participant expectations.⁸¹

Another randomized controlled trial, however, suggested that acupuncture may indeed provide relief for OA pain, unlike sham acupuncture.⁸² In this trial, 570 patients with knee OA were randomly allocated to receive 23 sessions of either true or sham acupuncture over 26 weeks or to participate in six 2-hour education sessions over 12 weeks (controls). Persons in the true acupuncture group showed an improvement in function at 8 weeks and a significant improvement in pain at 26 weeks compared with the sham and control groups, as

evidenced by scores on the Western Ontario and McMaster Universities Arthritis Index (WOMAC).⁸²

Acupuncture may serve as an adjunct to a conventional medical regimen by allowing a reduction in dosage of nonsteroidal antiinflammatory drugs (NSAIDs) and therefore potentially reducing the side effects occasionally seen with long-term NSAID use.⁸³ Each state has its own requirements for acupuncture licensure and certification. Patients should be referred only to a licensed or certified practitioner.

The 2008 OARSI recommendations for managing OA of the knee noted that acupuncture may be of symptomatic benefit in patients with knee OA.⁴⁷ In addition, although multiple sham-controlled trials showed minimal benefit over sham, acupuncture may still provide symptomatic relief for patients with OA who are wary of or unable to use pharmaceutical interventions.⁸⁴

Dosage

Acupuncture treatments vary depending on the patient's underlying conditions, the severity and location of pain, and the practitioner's assessment. However, most acupuncture treatments last between 15 and 30 minutes, with needles inserted. A common acupuncture regimen consists of treatment once to three times weekly.

Precautions

Acupuncture may cause bleeding or bruising at the site of needle insertion. Therefore, patients taking blood thinning medications may have a higher incidence of this side effect.

Acupuncture has been shown to improve both pain and function in osteoarthritis of the knee. Six or more treatments are often required before efficacy can truly be assessed.

Supplements

Glucosamine Sulfate and Chondroitin Sulfate

Glucosamine's primary role is as a substrate for glycosaminoglycans and

the hyaluronic acid backbone used in the formation of proteoglycans found in the structural matrix of joints.⁸⁵ Chondroitins are the main glycosaminoglycans in human joints and connective tissue, and they play a role in cartilage formation through the stimulation of chondrocyte metabolism and synthesis of collagen and proteoglycans.⁸⁶ Destructive synovial enzymes are inhibited by chondroitin.⁸⁷ Unlike other therapies used as symptom modifiers, such as NSAIDs, these supplements are potentially structure modifying.⁴⁷ Glucosamine sulfate and chondroitin sulfate are sulfate derivatives of glucosamine and chondroitin, and doubts regarding their absorption and metabolic fate have fueled skepticism about their therapeutic potential.⁸⁸ This dilemma has stimulated numerous studies.

In a 2001 double-blinded, randomized controlled trial,⁸⁹ 212 patients with knee OA were randomly assigned to receive either 1500 mg of glucosamine sulfate or placebo once daily for 3 years. Seventy-one of 106 patients who received placebo completed the trial, and radiographs of their knees showed progressive joint space narrowing. Sixty-eight of 106 patients who received glucosamine sulfate completed the trial, and they had no radiographic evidence of joint space narrowing. This study concluded that oral administration of glucosamine sulfate over the long term could prevent joint structure changes in patients with OA of the knee as well as improve symptoms.⁸⁹

Two randomized controlled trials looked at the effectiveness of chondroitin sulfate in OA.^{90,91} In one trial, 300 patients with knee OA were randomly assigned to receive either 800 mg of chondroitin or placebo once daily for 2 years.⁹⁰ Although the study found no significant symptomatic effect, results suggested that long-term chondroitin sulfate use may retard radiographic progression of the disease. A 2004 study of 120 patients receiving either the same dosage of chondroitin sulfate or placebo for 1 year provided some evidence that chondroitin sulfate may reduce pain and improve function associated with knee OA.⁹¹

To evaluate the benefit of glucosamine sulfate and chondroitin sulfate for OA, a meta-analysis combined with systematic quality assessment was performed.⁹² Fifteen double-blind, randomized, placebo-controlled trials were included in the analysis. The knee was the joint studied in all the trials, and in one study the hip was also evaluated. Glucosamine or chondroitin sulfate was taken orally in 12 of the studies, intramuscularly in 2 of the studies, and intraarterially in 1 of the studies. Glucosamine sulfate or chondroitin sulfate demonstrated a moderate to large effect on OA symptoms. However, methodological problems may have led to

exaggerated estimates of benefit. Overall, these compounds do appear to have efficacy in treating OA symptoms, and they are safe.⁹² Glucosamine may not be as effective in patients who are obese compared with patients of normal weight.

The Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT) compared 1500 mg of glucosamine hydrochloride alone and in combination with chondroitin in 1500 people with mild knee pain from OA. Using an end point of 20% reduction in pain, no significant benefit of each supplement individually or in combination was noted. Those individuals with more severe symptoms (moderate to severe OA) reported a 22% reduction in pain. Glucosamine hydrochloride was used in this trial. Most over-the-counter products contain glucosamine sulfate.⁹³

Glucosamine is believed to work, in part, by retaining fluid content within the joint cartilage, while chondroitin works, in part, by increasing the viscosity of the synovial fluid.

Glucosamine and chondroitin are sold as dietary supplements in most health food stores and in many pharmacies. They are often sold in combination; however, it is unclear whether the combination is superior to either treatment alone.⁹⁴ In December 1999 and January 2000, a health consultant firm purchased 25 brands of glucosamine, chondroitin, and combination products to test whether the products contained the amounts listed on their respective labels. Nearly one-third of the products did not contain the stated amounts of the supplements.⁹⁵ According to Vangsness et al.,⁹⁶ glucosamine and chondroitin sulfate have shown inconsistent but overall positive efficacy in decreasing OA pain and improving joint function. The safety of these compounds was equivalent to that of placebo. In addition, although the literature suggests that individual use of glucosamine sulfate, chondroitin sulfate, or glucosamine hydrochloride has therapeutic value, the effectiveness of monotherapy with these agents has not been proven.⁹⁶

Dosage

The dose of glucosamine sulfate is 500 mg three times daily, or 1500 mg/day. The dose for chondroitin sulfate is 400 mg two to three times

daily, or 800-1200 mg/day. Both are used for a minimum of 6 months to show benefit.

Precautions

Potential adverse effects include dyspepsia, nausea, and headache.

S-Adenosylmethionine

S-Adenosylmethionine (SAME) is a physiological molecule formed in the body from the essential amino acid methionine. It functions in a wide variety of anabolic and catabolic reactions in all living cells. Although the mechanism of action on the symptoms of OA is not fully understood, it may be related to the agent's ability to stimulate proteoglycan synthesis in OA cartilage.⁹⁷ The US Food and Drug Administration approved SAME for sale as a dietary supplement in 1999; however, it has been used since the mid-1970s, primarily in Europe to treat depression and arthritis.⁹⁸

To encourage production of S-adenosylmethionine in the body, patients with osteoarthritis who have low folic acid levels should consider increasing these levels through higher consumption of dark green leafy vegetables or supplementation.

A 1987 double-blind, randomized controlled trial compared 1200 mg of SAME with 1200 mg of ibuprofen taken by 36 patients with OA of the knee, hip, or spine, or a combination, for 4 weeks.⁹⁹ Morning stiffness, pain at rest and during motion, crepitus, swelling, and limitation of motion in the affected joints were assessed before and after treatment. The study found that both treatments were well tolerated and equally effective in lessening symptoms. The investigators thus concluded that SAME exerted a beneficial effect on the symptoms of OA.⁹⁹ Similar results were found in a trial comparing 1200 mg of SAME and 150 mg of indomethacin; SAME was better tolerated.¹⁰⁰ A later randomized, double-blind, crossover study comparing celecoxib with SAME in 56 patients with knee OA suggested that SAME may be as effective as celecoxib at reducing symptoms but may have a slower onset of action.¹⁰¹ *The Arthritis Foundation's Guide to Alternative Therapies* noted that SAME is a promising treatment worth trying for pain relief, but that more scientific evidence is needed to prove that it supports cartilage repair.¹⁰²

Dosage

The dose is 400–1600 mg daily; a common regimen is 600 mg twice daily.

Precautions

Watch for nausea and gastrointestinal distress. Ensure adequate intake of vitamin B₁₂ and folate through diet (green leafy vegetables) or supplementation to optimize S_{AMe} supplementation.^{103,104} Do not take close to bedtime because of the risk of insomnia.

Methylsulfonylmethane

Methylsulfonylmethane (MSM) is a dietary supplement commonly sold for the treatment of OA. The MSM metabolite dimethyl sulfoxide is found naturally in the human body. Because sulfur is necessary for the formation of connective tissue, MSM is thought to be useful in the treatment of OA. Animal studies have suggested that MSM may help decrease inflammatory joint disease,¹⁰⁵ but unfortunately, no published human trials are available. Overall, the literature on the sulfur-containing compounds S_{AMe} and MSM in OA appears to be limited. However, the literature shows a trend toward decreased pain and increased function with the consistent use of these compounds. The therapeutic benefit and safety of these compounds for long- and short-term use needs to be further researched, especially through randomized clinical trials.^{96,106}

Dosage

The dose is 1000–3000 mg three times daily.

Precautions

Watch for nausea, diarrhea, and headache. Although MSM is promoted as being nontoxic, clinical data are lacking, and further scientific study is needed to define the efficacy and safety of this supplement.

Pharmaceuticals: Nonopioid Analgesics

Acetaminophen

Acetaminophen acts by inhibiting prostaglandin synthesis in the central nervous system. It may relieve mild to moderate joint pain and may be used as initial therapy on the basis of its overall cost, efficacy, and toxicity profile.¹⁰⁷

Dosage

The dose is 325–1000 mg every 4–6 hours, up to a maximum of 4 g/day.

Precautions

Reactions are uncommon with normal therapeutic doses of acetaminophen but include nausea, rash, and minor allergic reactions, a transient drop in white blood cell count, liver toxicity, and prolongation of the half-life of warfarin. Patients with hepatic impairment or active hepatic disease must be monitored when acetaminophen is prescribed for the long term. Patients with viral hepatitis, alcoholism, or alcoholic hepatic disease are at greater risk for acetaminophen-induced hepatotoxicity.¹⁰⁸ Long-term acetaminophen use should be avoided in patients with underlying renal disease. Tobacco smoking may also potentially increase the risk for acetaminophen-induced hepatotoxicity.¹⁰⁸

Tramadol

Tramadol is a synthetic opioid agonist that inhibits reuptake of norepinephrine and serotonin. It should be considered for patients with moderate to severe pain in whom acetaminophen therapy has failed and who have contraindications to NSAIDs.⁹⁹

Dosage

The dose is 50–100 mg every 4–6 hours, up to a maximum of 400 mg/day.

Precautions

Watch for nausea, constipation, drowsiness, and, rarely, seizures.

Pharmaceuticals: Nonsteroidal Antiinflammatory Drugs

Nonsteroidal Antiinflammatory Drugs

Nonselective NSAIDs are a group of chemically dissimilar agents that act primarily by inhibiting the cyclooxygenase (COX) enzymes and thus inhibit the production of prostaglandins in peripheral tissues. Examples are aspirin, ibuprofen, naproxen, indomethacin, sulindac, and piroxicam.

Dosage

- Aspirin: 2.6–5.4 g in divided doses daily
- Ibuprofen: 300–800 mg three or four times daily; maximum, 3200 mg/day
- Naproxen: 250–500 mg twice daily; maximum, 1500 mg/day
- Indomethacin: 25 mg two or three times daily; maximum, 200 mg/day
- Sulindac: 150–200 mg twice daily; maximum, 400 mg/day
- Piroxicam: 20 mg daily or 10 mg twice daily

Cyclooxygenase-2 Inhibitor

COX-2-specific inhibitors act in the same manner as nonselective COX inhibitors, but their action is confined to inflamed tissues. Celecoxib (Celebrex) is the only COX-2 inhibitor currently available on the market.

Dosage

The dose of celecoxib (Celebrex) is 200 mg daily or 100 mg twice daily.

Precautions for All Nonsteroidal Antiinflammatory Drugs

Precautions vary with specific agent and include epigastric distress, nausea, vomiting, gastrointestinal bleeding (nonselective NSAIDs more than COX-2 inhibitors), prolonged bleeding (aspirin), headache,

dizziness, and renal toxicity. Epidemiological studies have shown that COX-2 inhibitors may increase the risk of myocardial infarction.¹⁰⁹

The choice between nonselective NSAIDs and COX-2-specific NSAIDs should be based on the risk of upper gastrointestinal bleeding.

Data from epidemiological studies demonstrate that among persons aged 65 years and older, 20%–30% of all hospitalizations and deaths resulting from peptic ulcer disease are attributable to NSAID use.¹¹⁰

Persons at increased risk of gastrointestinal bleeding are those aged 65 years or older, as well as those with a history of peptic ulcer disease, previous upper gastrointestinal bleeding, concomitant use of oral corticosteroids or anticoagulants, and, possibly, smoking and alcohol consumption.¹¹¹ Patients in this category may benefit from a COX-2-specific inhibitor or a nonselective NSAID with gastroprotective therapy (e.g., misoprostol, omeprazole, or high-dose famotidine).

Pharmaceuticals: Opioid Analgesics

Patients with OA who have tried acetaminophen, tramadol, and NSAIDs without success may consider opiates. Opiates bind to receptors in the central nervous system to produce effects that mimic the action of endogenous peptide neurotransmitters, specifically, the relief of intense pain. These agents should usually be avoided for long-term use, but their short-term use helps in the treatment of acute exacerbations of pain.¹¹² Commonly used opiates are fentanyl, meperidine, propoxyphene, acetaminophen plus propoxyphene, hydromorphone, long-acting morphine, oxycodone plus acetaminophen, and acetaminophen plus hydrocodone.

Dosage

Doses and routes vary.

Precautions

In addition to the potential for addiction to these agents, side effects include constipation, nausea, vomiting, sedation, urinary retention, and respiratory depression.

Pharmaceuticals: Topical Analgesics

In patients with OA of the hands or knees, topical analgesics may relieve mild to moderate pain.¹¹³ A cream may be used alone or in combination with an oral agent.

Capsaicin Cream

Capsaicin cream (Zostrix) is a commonly used topical agent. It exerts its pharmacological effect by depleting local sensory nerve endings of substance P, a neuropeptide mediator of pain.

Dosage

A thin film of capsaicin cream (0.025%, 0.075%) should be applied to the symptomatic joint four times daily.

Precautions

A local burning sensation is common but rarely leads to the discontinuation of therapy.

Diclofenac

Aside from capsaicin cream, diclofenac sodium is available as a topical solution. This product (Pennsaid) combines diclofenac with dimethylsulfoxide (DMSO). Pennsaid is indicated for the treatment of signs and symptoms of OA of the knee. Most studies have shown topical diclofenac to be equivalent to oral diclofenac in the treatment of OA of the knee.¹¹⁴⁻¹¹⁸ Pennsaid, in particular, has also shown similar effectiveness in treatment of OA of the knee, although further studies to compare Pennsaid with other formulations of diclofenac have yet to be done.¹¹⁴

Dosage

Diclofenac topical (Pennsaid 1.5% topical solution plus DMSO, Solaraze 3% gel, Voltaren topical 1% gel) is applied to the knee four times daily. It may also be used for other areas of body or joint pain. The Flector patch is applied directly to the area of pain. The skin patch

can be worn for up to 12 hours and then removed. Apply a new patch at that time if pain continues. Do not wear a skin patch while taking a bath or shower or while swimming.

Precautions

Although diclofenac is applied topically, it is absorbed systemically and has possible side effects. Aside from local irritation at the site of application, diclofenac topical solutions, like other NSAIDs, may increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke or increased gastrointestinal events such as bleeding, ulceration, and perforation of stomach or intestines.

Intraarticular Steroid Injections

Injections are useful in treating a joint effusion or local inflammation that is limited to a few joints. Injections should be limited to three or four per year because of concern about the possible development of progressive cartilage damage through repeated injections in weight-bearing joints.¹¹⁹

Other Pharmaceuticals: Diacerein

Diacerein (INN), also known as diacetylrhein, is a drug used in the treatment of OA. It works by inhibiting IL-1. A 2006 Cochrane Review found no significant difference between diacerein and NSAIDs.¹²⁰

Although diacerein may have a better risk-to-benefit ratio compared with NSAIDs, it also has an important side effect of diarrhea. In addition, diacerein may have a mild effect on the symptoms of OA and structure-modifying effects in patients with symptomatic OA of the hip, and further research is necessary to confirm the short- and long-term effectiveness and toxicity.^{47,120}

Dosage

The dose is 50 mg twice daily.

Precautions

Diacerein may cause diarrhea. It is also a long-acting drug with symptomatic effects appearing 4 weeks after beginning treatment.¹²⁰

Surgery

Surgical treatment is usually considered only after failure of nonsurgical treatments. The two categories of surgery are nonbiological and biological.¹¹³

Nonbiological Approaches

- Osteotomy: This conservative approach may provide effective pain relief and slow disease progression. Its greatest benefit is in patients with only moderately advanced disease.
- Arthroscopy: Removal of loose cartilage fragments can prevent locking and relieve pain. When joint space narrowing is substantial, this type of surgical procedure is of limited benefit.
- Arthrodesis or joint fusion: This alleviates pain and is most commonly performed in the spine and in small joints of the hand and foot. In the hip and knee, it is reserved for very young patients with unilateral disease.
- Arthroplasty or total joint replacement: This is the mainstay of surgical treatment of the hip, knee, and shoulder. It is the most effective of all medical interventions and can restore patients to near-normal function. It is limited in durability in persons with life expectancies exceeding 20 years and in those who wish to participate in high-demand activities.

Biological Approaches

- Biological restoration of articular cartilage uses resident hyaline cartilage, which is stimulated to repair its own defects.
- Biological restoration of articular cartilage is performed using one of three types of cartilage transplantation: osteochondral autografting, osteochondral allografting, and tissue engineering.

Therapies to Consider

Omega-3 Fatty Acids

Omega-3 fatty acids, the precursors for antiinflammatory prostaglandin production in the body, can be very supportive in the treatment of patients with OA. Multiple studies have shown efficacy of increased omega-3 fatty acids in the diet or by supplementation for reducing or alleviating symptoms of rheumatoid arthritis.¹²¹⁻¹²⁴ In different animal

(dog) studies, investigators found that dietary supplementation with omega-3 fatty acids from fish oil led to an increase in weight-bearing tolerance and a reduction in the need for the NSAID carprofen.^{125,126} An in vitro study showed that omega-3 fatty acids caused a reduction in the levels of mRNA for a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS)-4, ADAMTS-5, matrix MMP-3, MMP-13, COX-2 (but not COX-1), IL-1alpha, IL-1beta, and TNF-alpha, which are key contributors to the pathological process of OA. Investigators also found that eicosapentaenoic acid was most effective, followed by docosahexaenoic acid, and finally by alpha-linoleic acid. Arachidonic acid, an omega-6 fatty acid, had no effect.¹²⁷

Curcumin

Curcumin is the active ingredient in the spice turmeric. It has been used in various cultures around the world, particularly in India and Asia. Research on curcumin has found that it has many properties, which may explain the diversity of its traditional uses. These properties include anticancer, antiinflammatory, antioxidant, and hypolipidemic effects.¹²⁸ Curcumin has been researched for benefits in the treatment and management of cardiovascular disease, hypercholesterolemia, diabetes mellitus, insulin resistance, weight loss, and inflammatory conditions.¹²⁸ This supplement may be most beneficial for those with OA with other concomitant conditions, such as obesity, diabetes, heart disease, or autoimmune conditions.

In 2009, an in vitro study using articular chondrocytes found that curcumin acted as a strong inhibitor of inflammatory and catabolic mediators, nitric oxide stimulated by IL-1beta, prostaglandin E2, IL-6, IL-8, and MMP-3, produced by chondrocytes.¹²⁹

Avocado Soybean Unsaponifiables

Avocado soybean unsaponifiables (ASU) are extracts of unsaponifiable fractions from one-third avocado oil and two-thirds soybean oil.¹³⁰ In multiple animal and human in vitro studies, investigators found that ASU extract had an effect on various cytokines in articular chondrocytes and monocyte/macrophages.¹³¹ In a multicenter, randomized controlled trial, persons taking ASU had slightly lower need for NSAIDs and an improvement in functional disability. Improvement was greatest in patients with hip OA.¹³⁰ Most of the in vitro and in vivo studies have used an ASU product that is patented and sold in Europe (Piascledine

1300, Laboratoires Expanscience, France). Because this formulation is unique, the data obtained from its use cannot be extrapolated to all ASU extracts, and thus further studies examining various ASU extracts from multiple manufacturers and processes of extraction are needed.¹³¹

Boswellia serrata

Boswellia serrata, also known as H15 or indish incense, is a botanical used in traditional Ayurvedic medicine; in vitro, it decreases leukotriene synthesis.¹³² A double-blind pilot study evaluated the efficacy of H15 in 37 patients with rheumatoid arthritis. Treatment with H15 showed no measurable efficacy.¹³² A double-blind, randomized controlled trial found that *Boswellia* improved symptoms of knee OA. Treatment included a combination of herbs, rather than *Boswellia* alone.¹³³ A single-blind, randomized controlled trial in which *Boswellia* was taken along with *Withania*, *Curcuma*, and a zinc complex found that this combination led to improvement in pain and disability in OA.¹³⁴

Although the literature on this agent is promising, it is insufficient to support the use of *Boswellia* for OA. Taken in combination with other herbs, *Boswellia* may improve pain and function.

Ginger

Ginger root is an herb used extensively as a spice in many world cuisines. More recently, attention has focused on the possible medical benefits of ginger, including reduction of nausea and analgesic effects. One study suggested that ginger may be moderately effective in reducing pain from knee OA.¹³⁵ This 6-week multicenter, randomized controlled trial evaluated the effect of a highly concentrated standardized ginger extract in 261 patients in comparison with placebo. A moderate reduction of pain was observed in the ginger-treated group. Some mild adverse gastrointestinal effects were also observed in the ginger group, but the overall safety profile was good.

Magnet Therapy

A popular therapy for the treatment of various medical conditions is the application of a magnetic field. The biological effects of low-level magnetic fields have been studied since the 1500s. Explanations of these effects include increased circulation and decreased inflammation.¹³⁶ One double-blind, randomized controlled study¹³⁷ evaluated bipolar magnets for the treatment of chronic low back pain. The researchers concluded

that the application of magnets had no effect on patients' pain.¹³⁷ However, a later randomized controlled trial suggested that standard-strength magnetic bracelets may be effective in decreasing pain from OA of the knee and hip.¹³⁸ Although magnet therapy does appear to be harmless, its therapeutic use remains questionable. According to the OARSI guidelines for the management of hip and knee OA, five placebo-controlled, randomized controlled trials showed that improvement in function was small and efficacy for reduction in pain was not significant with pulsed electromagnetic field therapy.¹³⁹

Therapeutic Touch

In a 6-week, single-blinded, randomized controlled trial, therapeutic touch was evaluated for effectiveness in the treatment of OA of the knee. Thirty-one participants were enrolled and randomized to therapeutic touch, mock therapeutic touch, or standard care. The main outcome measures were pain and its impact, general well-being, and health status measured by standardized validated instruments, as well as the qualitative measurement of a depth interview. Twenty-five participants completed the study. The findings were that participants receiving therapeutic touch had significant improvements in pain, function, and general health status compared with both placebo and control groups.¹⁴⁰ Further studies with a larger sample size and further evaluation into treatment time and time for course of treatment are required.

Prevention Prescription

- Maintain appropriate weight.
- Exercise regularly with a combination of aerobics, resistance training, and stretching.
- Consider glucosamine and chondroitin sulfate if at high risk for osteoarthritis.
- Avoid excessive trauma to the joints.

Therapeutic Review

Therapeutic Modality

Nutrition

- Antiinflammatory diet: individualized  
- Weight loss: individualized program 

Exercise

- Aerobic exercise: Three times weekly 
- Resistance training/muscle strengthening: 1-hour sessions, three times weekly 
- Flexibility exercise: Two to three times weekly 

Mind-Body Therapy

- Telephone interventions: Twice weekly for 6 months 
- Group programs: Group course with experienced teacher twice weekly for at least 12 weeks 
- Yoga: 1 hour weekly for 8 weeks 

Physical Modalities

- Knee bracing: as needed 
- Heat applications: as needed 
- Cold applications: 20–30 minutes, reapplied every 2 hours 
- Transcutaneous electrical nerve stimulation: 15-minute to 4-hour session, once daily to six times daily 
- Swedish massage therapy: 60 minutes weekly 
- Acupuncture: 15–30 minute sessions, once weekly to three times weekly 

Supplements

- Glucosamine sulfate and chondroitin sulfate: Glucosamine sulfate, 500 mg three times daily; and chondroitin sulfate, 400 mg three times daily, both for a minimum of 6 months 
- S-Adenosylmethionine: 400–1600 mg daily; common regimen, 600 mg

twice daily 

- Methylsulfonylmethane: 1000–3000 mg three times per day 

Pharmaceuticals

- Acetaminophen: 325–1000 mg every 4–6 hours; maximum, 4 g / day 
- Tramadol: 50–100 mg every 4–6 hours; maximum, 400 mg / day 
- Nonsteroidal antiinflammatory drugs: Dose variable by drug 
- Opioid analgesics: Doses and routes variable 
- Capsaicin cream (topical): Thin film of cream (0.025%, 0.075%)
applied to the symptomatic joint four times daily 
- Diacerein: 50 mg twice daily 

Injections

- Intraarticular steroid injections 

Surgery

- Knee replacement

CHAPTER 66

Myofascial Pain Syndrome

Robert Alan Bonakdar, MD

Epidemiology

Myofascial pain syndrome (MPS) and similar terms ([Box 66.1](#)) refer to pain and associated sequelae developing from and aggravated by myofascial trigger points (TrPs). The actual prevalence of MPS varies, based on terminology and diagnostic criteria. However, myofascial pain is considered to be a leading cause of musculoskeletal pain, affecting up to 85% of the population at some point during their lives.¹ The prevalence of MPS also appears to be related to age and gender. Persons aged 30–60 years appear to have a 37% (male) and 65% (female) prevalence, whereas those older than 65 years have a prevalence rate higher than 80%.^{2,3}

Even with a high prevalence rate, MPS is often refractory and clinicians often characterize available treatment options as insufficient. In a recent survey of clinicians, the authors concluded:

Despite a variety of commonly prescribed treatments, the moderate effectiveness ratings and the frequent characterizations of the available treatments as insufficient suggest an urgent need for clinical research to establish evidence-based guidelines for the treatment of myofascial pain syndrome.⁴

Diagnosis

There are currently no definite criteria for the diagnosis of MPS. Classic criteria include those developed by Simons and Travell as noted in [Box](#)

[66.2](#).⁶ More recently an international survey of pain management providers was undertaken to create a preliminary set of diagnostic criteria.⁷ These are listed in [Box 66.3](#) and are similar to the initial criteria while noting the importance of stress as well as coexisting diagnosis. Due to issues with interrater reliability of palpatory diagnosis, some researchers have suggested the incorporation of imaging techniques, such as use of sonography, to aid in the objective diagnosis of MPS.⁸ However, routine imaging, including the use of techniques such as whole-body 18F-FDG positron emission tomography / computed tomography (PET / CT), has not been found to be consistently helpful in the diagnostic process.⁹

Pathophysiology

The actual mechanism for initiation of a TrP is not completely understood, but it likely arises from both local and central changes.¹⁰ Locally, leakage of factors such as acetylcholine, which cause neurogenic inflammation, interact with dysfunctional motor end plates, promoting shortening of sarcomeres and formation of precursor taut muscular bands. These bands, which are found commonly in the latent state in asymptomatic individuals, may become activated in response to predisposing factors ([Table 66.1](#)). These factors are believed to be the exclusive causes of active TrPs (thereby making MPS a secondary phenomenon). Once activated, TrPs are associated with multisystem dysfunction, especially vascular and neurological. Doppler ultrasound examination of active TrPs demonstrates constricted vascular beds and enlarged vascular volumes that create higher peak systolic velocities and negative diastolic velocities as compared with latent myofascial TrPs and normal muscle sites.⁵

Subsequent to sensitization of motor end plates, TrP activation appears to be further propagated neurologically by activation of mechanosensitive afferents, as well as their connection at the dorsal horn of the spinal cord. Once established, this process may have cortical ramifications such as thalamic asymmetry, which may create spontaneous or stimuli-generated tissue hypersensitivity in a progressive process known as *central sensitization*. Because of cortical sensitization, patients with MPS may exhibit phenomena including allodynia and spontaneous contralateral sensitivity initiated from a unilateral TrP.¹¹ The hypothesized mechanism for MPS generation is illustrated in [Fig. 66.1](#).

BOX 66.1 Synonyms for Myofascial Pain Syndrome

- Myofascial pain and dysfunction
- Trigger points syndrome
- Localized fibromyalgia
- Fibromyositis
- Muscular rheumatism
- Soft tissue syndrome
- Somatic dysfunction
- Tension myalgia

BOX 66.2 Classic and Confirmatory Signs of Active Trigger Points in Myofascial Pain Syndrome

- Palpable, taut muscular band containing a nodular structure
- Tenderness to palpation locally or in referred pattern replicating patient complaints
- Visual or tactile identification of local twitch response produced with needling or snapping (“guitar string”) palpation
- Decreased range of movement of the involved muscle
- Increased spontaneous electrical activity on electromyography
- Low skin resistance points found over trigger points, unlike in surrounding tissue (skin resistance may normalize after treatment of trigger points)
- Imaging of local twitch response induced by needle penetration of tender nodule
- Characteristic referred pattern of pain for specific muscles involved (as described by Simmons and Travell⁶)

BOX 66.3 Proposed Set of Diagnostic Criteria for Myofascial Pain Syndrome Based on International Survey

Myofascial pain syndrome can be diagnosed when the following criteria have been met^a:

- A tender spot is found with palpation, with or without referral of pain (“trigger point”)

- Recognition of symptoms by patient during palpation of tender spot AND at least three of the following^b:
 - Muscle stiffness or spasm
 - Limited range of motion of an associated joint
 - Pain worsens with stress
 - Palpation of taut band and /or nodule associated with tender spot
- Considerations:
- It is important to rule out other conditions that may manifest as local muscle tenderness.

^a These items were judged by more than 50% of respondents as “essential” to the diagnosis.

^b These items from palpatory findings and signs and symptoms were judged by more than 80% of respondents as “essential” or “associated with” the diagnosis. Items with conceptual redundancy were combined.

Rivers WE, Garrigues D, Graciosa J, Harden RN. Signs and symptoms of myofascial pain: an international survey of pain management providers and proposed preliminary set of diagnostic criteria. *Pain Med.* 2015;16:1794-1805.

Once initiated, MPS has classic features, typically linked to active TrPs that allow physical and electrophysiological identification and differentiation from other pain conditions, including fibromyalgia (see [Box 66.2](#)). In addition to physical signs, differentiation is sometimes possible between MPS and fibromyalgia on the basis of comorbidities seen in patients with fibromyalgia, including greater fatigue, sleep dysfunction, mood disturbance, headaches, and irritable bowel syndrome.¹² Although differentiating between these two entities is advantageous, coexistence of MPS with fibromyalgia is quite common, thus making distinct classification often difficult, and in some cases not possible.¹³ MPS is believed to be a secondary phenomenon, so in addition to proper diagnosis, initiating and propagating factors must be investigated and, if possible, corrected. Of key importance is the appreciation by the treating clinician of the possible and likely psychological and lifestyle triggers of MPS. Therefore, the contributing factors in MPS are quite broad and require a biopsychosocial assessment to determine proper treatment. Some of the more common medical and psychological triggers of MPS are listed in [Table 66.1](#).

TABLE 66.1

Predisposing and Coexisting Conditions Requiring Identification in Myofascial Pain Syndrome

Skeletal and soft tissue abnormalities	Trauma Repetitive stress injury Muscular strain or tear Ligamentous sprains Joint instability (spondylolisthesis) Osteoarthritis Facet joint abnormality Local inflammatory conditions (e.g., tendinitis or bursitis, epicondylitis, costochondritis) Craniofacial or temporomandibular joint (TMJ) dysfunction (e.g., TMJ syndrome, headaches of various origin) Leg-length discrepancies
Functional asymmetry	Postural and ergonomic dysfunction Pelvic girdle dysfunction? Prolonged immobility
Neurologically Mediated Reflex Sympathetic Dystrophy Syndrome	Neurologically mediated reflex sympathetic dystrophy Spinal and peripheral nerve entrapment: Cervical and lumbar radiculopathy Sciatic nerve, median nerve (carpal tunnel syndrome), others
Other rheumatological disorders	Polymyalgia rheumatica Polymyositis
Metabolic deficiencies	Calcium Magnesium Potassium Iron Vitamins C, B ₁ , B ₆ , and B ₁₂
Medical conditions	Anemia Hypothyroidism Hyperuricemia Hypoglycemia Celiac disease Chronic infections Visceral diseases
Psychological disorders	Chronic stress Sleep deprivation and dysfunction Depression Anxiety Somatization disorders

Integrative Therapy

As previously discussed, lifestyle factors can play a significant role in the initiation and propagation of MPS. Although prescription and interventional approaches can provide immediate relief, patient education on the importance of lifestyle and self-care approaches should be emphasized early in the process of creating a treatment plan. Shared decision making and motivational interviewing, as discussed elsewhere in the book, should be utilized to create an individualized treatment plan with steady transition from passive to active self-management approaches. This has also been borne out in the literature. Chan et al.

compared 6 weeks of clinic-based physical therapy alone or in combination with home exercise and self-massage.¹⁴ All parameters, including pain, neck disability, patient-specific functional scales (PSFS), and autonomic tone (heart rate variability), improved more significantly in the home treatment group, leading the researchers to note: “Treatment with physical modalities plus combination of self-massage and home exercise is more effective than the physical modalities alone.” This general adage can be applied to most of therapies discussed in the following text. An example of this type of plan with focus on nonpharmacological approaches is illustrated in [Fig. 66.2](#).¹⁵ In addition, examples of the transition from passive to active modalities are shown in [Table 66.2](#).

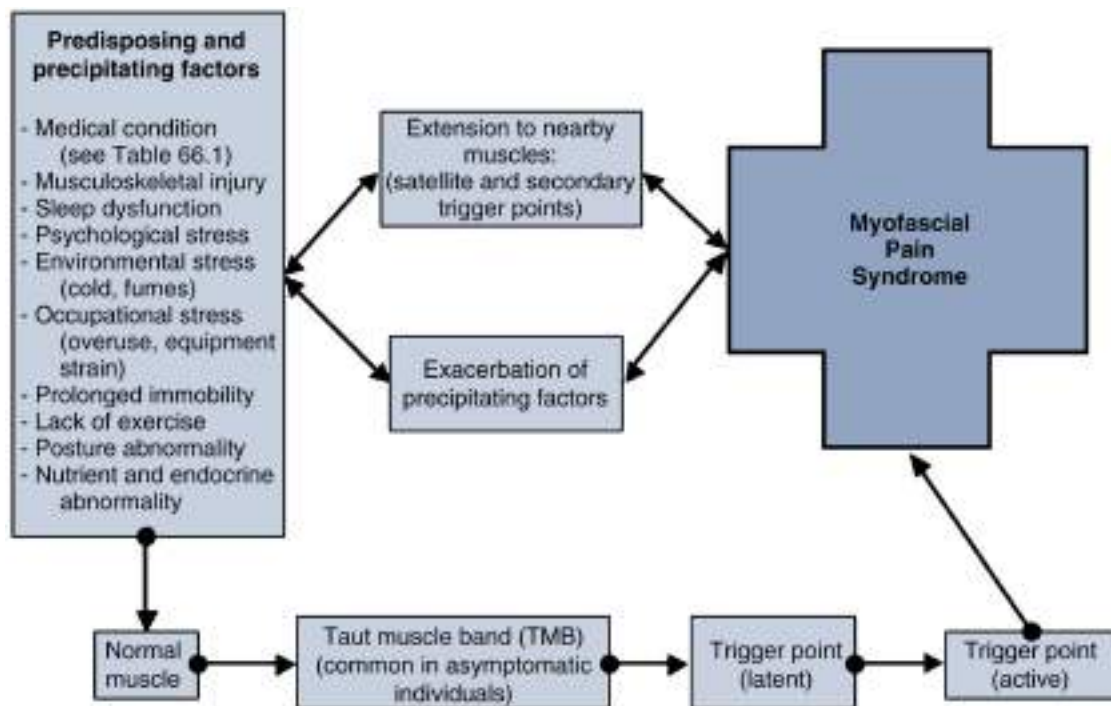

FIG. 66.1 Integrated mechanism for development of myofascial pain syndrome.

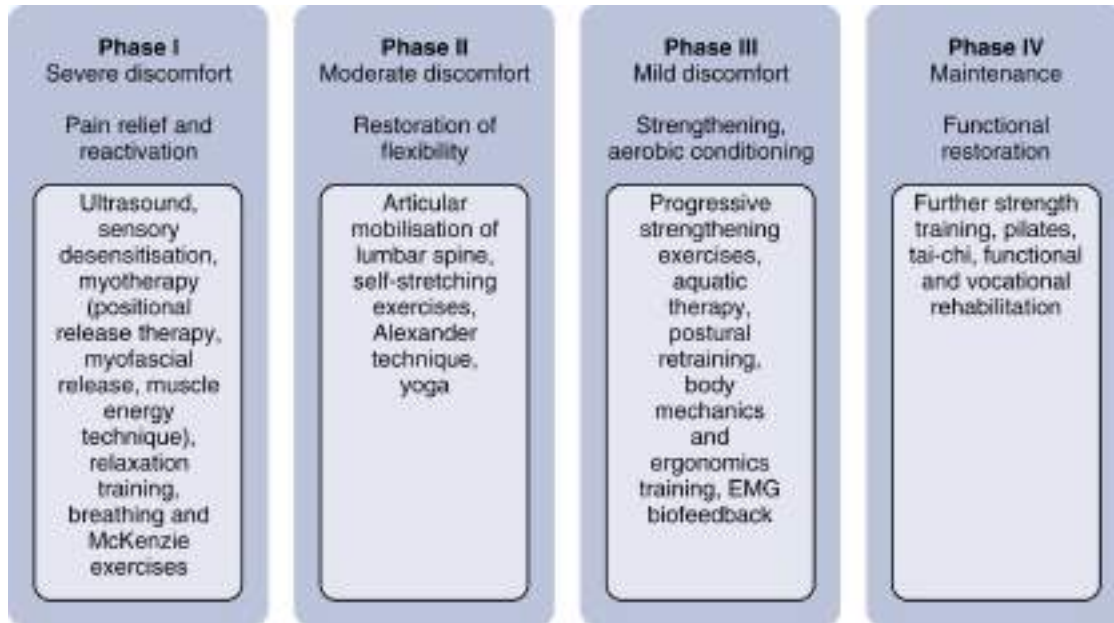

FIG. 66.2 Example protocol of integration and transition of physical therapies for myofascial pain syndrome treatment. (From Sharan D, Rajkumar JS, Mohandoss M, Ranganathan R. Myofascial low back pain treatment. *Curr Pain Headache Rep* . 2014;18:1-8.)

Exercise

Low physical activity level has been linked to the development and progression of MPS. Conversely, exercise is essential in myofascial rehabilitation through its physiological effect on tissues including improvement in tissue oxygenation, sensitivity, and range of motion, as well as cortical effects including modulation of neurochemicals, such as endorphins and serotonin. Exercises must be chosen carefully to diminish significant postexertional flaring (typically defined as more pain 2 hours after activity than at baseline). Flaring can be detrimental by potentially promoting both central sensitization and activity avoidance. To maximize the benefit of an activity regimen, a progressive and preferably guided program of active and passive movement, especially when combined with posture correction, is recommended. This type of exercise program, especially when combined with relaxation techniques, has demonstrated significant success in improving pain and functional status in patients with MPS¹⁶ (see [Chapter 91](#)).

TABLE 66.2**Transition from Passive to Active Modalities**

Modality	Passive	Active
Acupuncture	Clinic based acupuncture	Self-directed acupressure
Yoga/yoga nidra	Facility based yoga classes	Self-directed with video, exercising
Nonallopathic chiropractic care	Clinic based manipulations	Self-correcting exercises
Therapeutic medical massage	Clinic based treatments	Partner or self-treatment
Biofeedback	Clinic based biofeedback techniques	Self-directed biofeedback with video, heart rate variability monitors, meditative practices
Mind-body therapies (meditation, mindfulness)	Facility based classes	Self-directed

Adapted from Office of The Army Surgeon General Pain Management Task Force May 2010. Access on September 25, 2015 at <http://www.dvcipm.org/files/reports/pain-task-force-final-report-may-2010.pdf>

Exercise should be introduced or intensified slowly to reduce the risk of a postexercise flare in pain, which is defined as having more pain 2 hours after exercise than at baseline.

Sleep

Sleep regulation is an important factor in the progression of MPS. Several comparative studies found significantly reduced sleep quality in patients with MPS than in patients with other pain disorders.¹⁷ In addition, poorer sleep quality predicts higher comorbidity and poorer response to planned therapy. Even in patients without a pain condition who are placed in an experimental setting of frequently disrupted sleep for several nights, investigators report a significant drop in pain threshold and a rise in musculoskeletal discomfort and fatigue.¹⁸ The clinician should discuss sleep difficulties with patients who have MPS and describe strategies to correct sleep as a paramount goal in the treatment plan, such as stress management, sleep hygiene, and biochemical interventions (see [Chapter 9](#)).

Mind-Body Therapy

The clinician should assess past or ongoing psychosocial stresses or traumas that may be related to MPS. Several questionnaires (e.g.,

Perceived Stress Scale [PSS]) can help identify stresses or psychogenic attitudes that may be higher in MPS, including premorbid pessimism, future despair, and somatic anxiety.¹⁹ Treatment approaches can be effectively based on the symptoms and patient's preference. Several choices of mind-body therapy are described here.

Relaxation and Awareness Techniques

Relaxation techniques—breathing techniques (see [Chapter 92](#)), guided imagery (see [Chapter 97](#)), mindfulness-based stress reduction, yoga (see [Chapter 100](#))—are helpful in pain alleviation and, specifically, the stress-mediated component of myofascial pain through a decrease in autonomic arousal. A number of these techniques, such as yoga, have been researched for benefit specifically in MPS and can be seen as combination approaches that provide mindful exercise and relaxation in a coordinated manner.²⁰

Beyond pain relief, mind-body techniques influence sympathetic–parasympathetic (autonomic) balance and assist in diminishing several key physiological influences on myofascial pain, including vasospasm, muscle spasm, and adrenal gland–mediated dysfunction in tissue inflammation and nutrient uptake. Lastly, techniques such as biofeedback and mindfulness-based stress reduction, have an awareness component that can be highly effective in reducing predisposing factors, including poor posture, shallow breathing, and repetitive stress. Several studies have pointed out this benefit.

In one study, a randomized program of physical self-regulation with training in breathing, postural relaxation, and proprioceptive reeducation was taught to 44 patients with myofascial facial pain and compared with standard care. At 26-week follow-up, the two-time, 50-minute intervention demonstrated a significant reduction in pain ($p < .04$), as well as affective distress, somatization, obsessive-compulsive symptoms, tender point sensitivity, and sleep dysfunction.²¹

A useful question to ask patients with myofascial pain syndrome is where in the body they carry their stress (neck, back, stomach, or head). Have patients use this sign of stress as a “red flag” that, when it appears, encourages them to step back and see what in their life may be exacerbating their pain. Once the subconscious stressor enters the consciousness, the pain often improves because the body no longer

needs to sympathize.

In addition to being highly effective in decreasing the pain and sequelae of MPS, mind-body techniques can also be cost effective. In another study, a biofeedback-based program implemented in a primary care setting for functional disorders including MPS was measured against standard care (n = 70). Implementation of the program brought about significantly lower frequency and severity of symptoms, as well as lower medical costs, for the 6 months after the intervention (p < .001).²² The clinician should reinforce the importance of mind-body techniques in overcoming MPS, a condition that the patient may understand on mainly physical terms. In addition, various techniques should be reviewed to locate those most suitable for the particular patient's needs (see [Chapters 94](#) and [102](#)).

Biomechanical Therapy

Posture Correction

Any active treatment regimen must discuss, train for, and reinforce active postural correction.²³ Dysfunctional posture both at rest and during work activities increases tissue strain and asymmetry. If not corrected, poor posture is theorized as a leading factor in the development and maintenance of MPS. Evaluation by a well-trained clinician (including but not limited to physician, physical or occupational therapist, or body mechanics specialist, such as a Feldenkrais or yoga practitioner) can provide invaluable information on the presence and severity of such dysfunction. Baseline and follow-up evaluations by a biofeedback therapist can also be helpful in demonstrating physiological progress to the patient. Ongoing correction and monitoring can help patients with MPS realize the preventive capabilities of this often overlooked intervention. Tools that help reinforce postural correction, such as kinesiotaping and behavioral techniques, can successfully reduce the severity of MPS.^{24,25}

Massage Therapy, Manual Therapy, and Myofascial Release Techniques

Massage therapy and manual therapy (MT) have been shown to change several important components of MPS. In general, MT has demonstrated upregulation of modulatory neurochemicals, including oxytocin,

serotonin, and dopamine. Locally, MT has been shown to improve circulation near TrPs, allowing for improved oxygenation and substrate/metabolite exchange.²⁶

The efficacy of practitioner-provided MT in MPS has been demonstrated in several trials. The strongest evidence appears to be with compression type MT directly at TrPs, which has shown improved outcomes versus superficial massage or compression at non-TrPs.²⁷ In addition to local effects as noted, compression at MTrPs induces an increase in parasympathetic activity.²⁸

Several schools of myofascial release techniques have developed to address the key features of MPS with training resources and courses noted as in the resources section. Many of these techniques are based on Simmons and Travell's foundational work, *Myofascial Pain and Dysfunction: The Trigger Point Manual*.⁶ Myofascial release, as well as spray and stretch techniques, should be considered as a first-line approach to MPS²⁹ (see [Chapter 109](#)). As noted in the introduction, providing instructions on identification and home MT of TrPs has been shown to have an added benefit in improving TrP sensitivity and pain intensity. Providing passive and active MT works well with other active treatments (thermotherapy and topical therapy) in improving awareness and self-management of MPS.³⁰

Low-Level Laser Therapy

Low-level laser therapy (LLLT) has been used for several decades in Europe for pain management, and soft tissue conditions are among the conditions most effectively treated with this technique. The mechanism of action of LLLT is not completely elucidated, but it may be related to improvements in microcirculation, inflammatory response, and adenosine triphosphate production.^{31,32} In addition, direct laser treatment of TrPs is believed to increase serotonin production, and trials demonstrated increased excretion of serotonin byproducts after treatment.³³ One 4-week trial (n = 60) comparing LLLT with dry needling and placebo laser demonstrated a significant improvement in pain at rest and with activity, as well as a rise in pain threshold in the laser-treated group.³⁴ LLLT has the advantage of being noninvasive and thus well tolerated, especially in patients with high tissue sensitivity. The treatment regimen and device specifications vary widely; clinicians should review the available research on the efficacy of the lasers they are considering incorporating into their practices.

Peripheral Biostimulation

Similar to LLLT, more conventional avenues of biostimulation (e.g., electrical stimulation and ultrasound) have been applied to MPS because of their ability to increase tissue microcirculation and help correct the myofascial contraction-relaxation cycle. The mechanism of such techniques includes improvement in circulation, local analgesic effects, and correction of electrical disturbances found in TrP. Namely, TrPs typically demonstrate lower resistance and microvoltage abnormalities compared with surrounding tissue. In addition, electrostimulation has been shown to be partially inhibited by the use of naloxone, and thus its benefit is likely related in part to endorphin upregulation at the spinal cord and higher centers. Use of these techniques, including transcutaneous electrical nerve stimulation (TENS) and interferential and neuromuscular stimulation (NMS), has provided patient-dependent improvements in pain threshold and range of motion in several studies.^{29,35}

Definitive conclusions regarding parameters cannot be drawn from the literature due to variability in protocols and outcomes.³⁶ However, trends in the literature suggest that continuous ultrasound (3 MHz, 1W/cm²) may be more effective than pulsed treatment.³⁷

Also, for TENS as little as 10 minutes of treatment directly over TrPs, typically using a burst mode (pulse width, 200 μs; frequency, 100 Hz; and burst frequency, 2 Hz) at an intensity that is felt but which does not induce visible muscle contraction, has been shown to improve pain parameters in placebo-controlled trials.³⁸⁻⁴⁰

FIG. 66.3 Application of various types of biostimulation in myofascial pain syndrome. A, Interferential and neuromuscular stimulation. B, Individual trigger point electrostimulation. C and D, Low-level laser therapy. (A, RS 4i unit courtesy RS Medical, Vancouver, Wash. B, Electrotherapeutic point stimulation unit courtesy Acumed Medical Supplies, Toronto. C, Courtesy Theralase, Markham, Ontario, Canada. D, Courtesy Meditech International, Toronto.)

Several biostimulation modalities should be considered in the clinic setting to assess response. Many are cost effective and or covered by insurance, such as TENS. If one technique is successful, the patient

should be transitioned to home use. These include TENS as well as electrotherapeutic point stimulation (ETPS) devices. [Fig. 66.3](#) demonstrates the application of various types of biostimulation techniques that can help patients identify and locally address TrPs.

Central Biostimulation

Several recent pilot trials have utilized brain stimulation protocols in the setting of MPS. The rationale for this includes the potential ability to reduce central sensitization as well as modulation of neurochemicals related to MPS including brain-derived neurotrophic factor (BDNF). Two randomized, placebo-controlled trials found that five 20-minute treatments daily at 1 to 2 mA with anodal transcranial direct-current stimulation (tDCS) over the motor cortex (M1) or the dorsolateral prefrontal cortex (DLPFC) improved pain intensity versus usual care or TPI.^{41,42} A third placebo-controlled trial using 10 treatments with repetitive transcranial magnetic stimulation (rTMS) at 10 Hz also demonstrated reduced pain scores of 30% as well as higher levels of BDNF.⁴³ At this point, central stimulation is still evolving, with further research required to elucidate optimal parameters and areas of stimulation.

Hydrotherapy and Thermotherapy

As discussed earlier, the tissue of patients with MPS tends to have abnormal microcirculation, which can have negative ramifications, including buildup of inflammatory markers and a drop in tissue temperature and effective range of motion. The application of short-term intense heat (heating pad, diathermy, or warm hydrotherapy) and long-term use of low-intensity heat pads can help alter the thermal dysregulation and muscle spasm seen in MPS. Similarly, water immersion, by removing weight from the joints, facilitates reduction in muscle spasm and joint stiffness and thereby facilitates functional mobility. Because of the benign nature of these interventions, patients with MPS should undergo thermotherapy and hydrotherapy when available and, if possible, in combination with other therapies.²⁹

Biochemical Therapy

Topical and Transdermal Applications

Topical and transdermal medications can be a useful adjunct because of

their ability to disrupt hypersensitive signaling from the myofascial focus to the spinal cord and higher centers. Lidocaine in various topical formulations (cream, transdermal patch) is believed to block sodium channels that may increase pain signaling. Lidocaine 5% patches were tested in a 1-month, open-label trial in 27 patients with myofascial pain.⁴⁴ By the end of the trial, several key parameters, including average pain intensity, mood, sleep, walking ability, and enjoyment of life, were significantly improved. These results have been replicated in a larger randomized, placebo-controlled trial as well as in a trial noting that lidocaine patches demonstrated benefit similar to bupivacaine injections, with improved tolerability.^{45,46}

Antiinflammatory preparations (e.g., diclofenac patch) have also been shown to be helpful in MPS and related conditions, such as delayed-onset muscle soreness.⁴⁷ In a placebo-controlled study of 300 subjects with MPS of the upper trapezius, diclofenac patch demonstrated improved pain, cervical active range of motion, and neck disability at the end of 1 week.⁴⁸ Moreover, topical applications of diclofenac have demonstrated efficacy similar to that of oral administration with fewer adverse effects.⁴⁹

Botanical and nonprescription applications, including capsaicin and menthol, appear to have local pain-modulatory activity.^{50,51} Specifically, capsaicin can deplete sensory C-fibers of substance P, the principal neurotransmitter of nociceptive impulses, and thus potentially decrease central sensitization. Another popular topical agent is magnesium, which in some studies has been found to reduce local myofascial pain.⁵² Application of topical agents also provides active patient feedback on the location and sensitivity of myofascial pain. For patients without contraindications, such as allergies to the agents, a trial of standardized or compounded prescription topicals should be considered. For compounded formulations, local clinicians should contact local pharmacies (see resources) to help coordinate appropriate formulas.

Dosage

Lidocaine

Patients can apply up to three lidocaine 5% (Lidoderm) patches for up to 12 hours, or over-the-counter 4% patches for up to 12 hours. Patches can be cut to size, and they come in a carton of 30 patches.

Capsaicin

Patients can apply capsaicin in 0.025%, 0.035%, 0.05%, 0.075%, 0.1%, and 0.25% patch, cream, gel, and lotion formulation) to the painful area two to four times daily for 3–4 consecutive weeks to reduce pain sensitivity. As most patients will experience burning with use, it is recommended that over-the-counter or prescription lidocaine be placed on the area prior to capsaicin application. Patients should thoroughly wash hands after application and avoid contact with their eyes.

NSAIDs

All topical NSAIDs are currently approved for osteoarthritis. The diclofenac (Flector) patch is indicated for osteoarthritis and contains 180 mg of diclofenac; one patch is applied to the painful areas twice daily. Other FDA-approved antiinflammatory topical formulations include diclofenac sodium 1% gel (Voltaren) and diclofenac sodium topical liquid solution 1.5% w/w dimethyl sulfoxide (Pennsaid).

Compounded Products

Compounding pharmacies can prepare creams and gels with various NSAIDs combined with other agents (e.g., lidocaine, cyclobenzaprine, and capsaicin). A dime-sized amount of gel (approximately 1 g) is rubbed into the painful area two to four times per day based on the patient. A typical starting formulation could be ketoprofen 10%, lidocaine 5%, and cyclobenzaprine 2%. Patients should attempt a formula for several weeks before reassessing and considering switching or adding other agents.

Trigger Point Needling or Injection

Various needling and injection techniques have been endorsed for treatment of myofascial pain. The mechanistic rationale for the use of these techniques is based on several lines of evidence. The simplest technique, dry needling of primary TrPs, has demonstrated reversal of spontaneous electrical activity, one of the hallmark abnormalities noted in MPS.⁵³ Dry needle-evoked inactivation of a primary TrP in the shoulder region also improves pain sensitivity of satellite TrPs as well as range of motion in the zone of pain referral.⁵⁴ Additionally, certain types of dry needling may activate muscle afferents more effectively than superficial needling to produce segmental analgesia.⁵⁵⁻⁵⁹

Injection techniques that involve introduction of sterile water, saline solution, or various pharmaceutical agents (often termed “wet” needling) are conjectured to provide adjunctive benefit to needling, based on both the properties of the injected agent and the tissue pressure effects created by the volume of agent introduced. The superiority of various techniques, including dry needling and the injection of saline, anesthetics, corticosteroids, and botulinum toxin type A have not been clarified in the research because of variation in trial size and methodology.^{60,61} Several trials found no distinct advantage for TrP injection over dry needling.^{62,63} Furthermore, studies have both demonstrated and refuted the advantage of injection of active drug (e.g., lidocaine, botulinum toxin) over saline injection.^{64,65} The most recent systematic review of 20 randomized controlled trials involving 839 patients noted that both dry and wet needling can be recommended for short-term relief of TrP pain in the neck and shoulders, with wet needling appearing to be more effective in the medium-term.⁶⁶

Without a clear advantage of needling interventions, dry needling and acupuncture (see the following text) are initially recommended to evaluate their efficacy and patient tolerance. Injection of saline and other active agents should be reserved for more advanced or refractory cases and administered by clinicians with the proper understanding of the role of these agents in comprehensive management. Although injection therapy is potentially effective in short-term TrP management, it is often pursued without regard to the global needs of patients with MPS. To minimize a repetitive cycle of passive interventions, clinicians are admonished to address triggers and active treatment options for MPS (e.g., posture correction, home stretching, mind-body therapies) that are pursued in conjunction with injection therapy. All needle interventions with potential benefit are based on the experience of the practitioner in isolating TrPs. Adverse effects may be related to incorrect needle placement, reaction to the injected agent, or improper use of aseptic technique.

Pharmaceuticals

Currently, there are no FDA-approved medications indicated specifically for the treatment of MPS. Overall, when looking at their efficacy in the setting of temporomandibular disorder–associated MPS, one review noted that “...evidence in support of the effectiveness of these drugs is lacking.”⁶⁷ However, certain over-the-counter (OTC) and prescription

agents, including NSAIDs, corticosteroids, muscle relaxants, antidepressants, anticonvulsants, anxiolytics, and opiates, are utilized off-label in the treatment of MPS to provide symptomatic relief. In addition, several of these agents may provide improvement in common comorbidities including depression, headache, and insomnia. As some patients with MPS fail initial medication attempts, lack of response or tolerability to one agent, it is important to keep in mind that this may not imply the same for other agents. For example, in an elegant, stepped pharmacotherapy trial of patients with MPS, 43% showed $\geq 50\%$ reduction in pain intensity (mean doses of amitriptyline = 16 mg and nortriptyline = 25 mg). Nonresponse was predicted by higher age, comorbid medical illness, and more widespread pain spread. Subsequently, 36.8% of nonresponders demonstrated $\geq 50\%$ reduction in pain intensity with gabapentin therapy at a mean daily dose of 975 mg. Overall, 54.8% of all treated patients reported a significant pain reduction.⁶⁸

Muscle Relaxants

Evidence for the effectiveness of muscle relaxants (e.g., tizanidine hydrochloride, cyclobenzaprine) and medication with muscle relaxation properties, including benzodiazepines and tricyclic antidepressants, is variable in MPS.⁶⁹ A Cochrane Review examining the use of cyclobenzaprine in MPS found that based on the minimal available published research in this area and the difficulty in estimating risk versus benefit, evidence was insufficient to support the use of this drug in the treatment of MPS.⁷⁰ Although not routinely endorsed, muscle relaxants may be worth a short-term trial to assess improvement while initiating a multimodality program. In a randomized trial of temporomandibular disorder, cyclobenzaprine (10 mg/night) was compared with clonazepam (0.5 mg/night). Cyclobenzaprine was better than placebo and clonazepam when incorporated into a self-care and education program for the management of jaw pain. Unfortunately, no significant improvement in sleep was noted.⁷¹

Dosage

Cyclobenzaprine, 10 mg at bedtime taken for a limited course, may provide some pain relief for temporomandibular disorder.

Precautions

This drug is structurally related to tricyclic antidepressants. As with all tricyclics, caution should be used when utilizing this agent, especially in individuals with a cardiovascular history.

Nonsteroidal Antiinflammatory Drugs

The use of NSAIDs may be justified in the short-term treatment of acute myofascial strain. In one study, ibuprofen appeared to work as well without the addition of a muscle relaxant (800 mg of ibuprofen three times per day, with or without the use of cyclobenzaprine 10 mg three times per day).⁷² However, with the lack of long-term evidence and the potential increased toxicity of oral NSAIDs based on length of use, utilization on a regular basis should be avoided.

Dosage

Ibuprofen, 800 mg three times daily with meals for short periods of time, can help reduce the pain of myofascial strain.

Antidepressants

Antidepressants are often considered in the setting MPS because of their potential benefits in common mood and sleep comorbidities. The benefit of these agents for primary MPS in nondepressed individuals may not be significant, however, with the possible exception of amitriptyline and duloxetine. Amitriptyline was tested (at 75 mg/day) in a small (n = 31), 32-week placebo-controlled, double-blind, three-way crossover study trial versus the highly selective serotonin reuptake inhibitor citalopram (at 20 mg/day). Study participants taking amitriptyline had significantly reduced myofascial tenderness and headache intensity than participants taking placebo (p = .01 and p = .04, respectively). The researchers concluded that amitriptyline may elicit its analgesic effect in myofascial pain by reducing transmission of painful stimuli from myofascial tissue, as opposed to reducing overall pain sensitivity: "We suggest that this effect is caused by a segmental reduction of central sensitization in combination with a peripheral antinociceptive action."⁷³ Similarly, duloxetine, which is a serotonin-norepinephrine reuptake inhibitor (SNRI), has been noted to have benefit in the setting of a number of

chronic musculoskeletal pain disorders and may be worth considering in the setting of MPS.⁷⁴

Dosage

Amitriptyline, 75 mg at bedtime, can reduce myofascial pain and headaches.

Duloxetine, 60 to 120 mg/day can reduce chronic musculoskeletal pain and comorbid depression.

Other Agents

As previously noted, anticonvulsants such as gabapentin can often be helpful when other first-line prescription agents have not been helpful. Other agents, such as opioids, ketamine, and memantine, do not demonstrate clear benefit for MPS and in some cases may be detrimental to reducing disability.⁷⁵

Dosage

Gabapentin at 300–1800 mg/day, titrated gradually for refractory myofascial pain. Dose in the evening to reduce daytime drowsiness.

Diet and Dietary Supplements

Diet can have a significant effect on pain in general as well as myofascial pain syndrome.⁷⁶ There are numerous ways this can happen including proinflammatory or highly processed diets inducing changes at the microbiome and cellular level to increase inflammation and muscle spasm. A poor diet can add to the prooxidant status present in some cases of MPS. For example, research has noted that total antioxidant capacity (TAC), total oxidative stress (TOS), and oxidative stress index (OSI) values are impaired in those with MPS versus matched controls, implying that MPS may be partially related to increased oxidative stress.⁷⁷

In addition, specific nutrient deficiencies, which may be linked to background diet, have been implicated in the progression of MPS. Specifically, deficiencies of minerals (e.g., magnesium, calcium, and zinc)

and vitamins or enzymes (e.g., vitamin D, vitamin B₁₂, and coenzyme Q10) have been reported in some studies of those with MPS.⁷⁸ These deficiencies, such as with vitamin D, have been noted to increase pain sensitivity in general and may contribute to the overall burden of MPS.⁷⁹

The level and type of deficiency, however, have not been consistently elucidated. In one trial, significant deficiencies in zinc levels in patients with MPS versus controls were noted without similar deficiencies in other nutrients such as magnesium or folic acid. These results may have reflected the type of testing done, including traditional extracellular versus intracellular testing. Although typical electrolyte analyses (“panels”) may rule out gross abnormalities, levels of these electrolytes are usually normal in MPS. Clinicians should be aware of specialized testing, such as ionized or intracellular testing methods (e.g., NutraEval by Genova Diagnostic, SpectraCell by SpectraCell Laboratories) that may identify more occult deficiencies. The response to replacement of nutrients (e.g., magnesium in the setting of migraine) appears to be more highly correlated with intracellular or ionized fraction level, but not with total serum levels.⁸⁰⁻⁸² On the basis of identified or suspected nutrient abnormalities, clinicians should use focused dietary and nutrient supplementation with careful patient monitoring of symptoms.

Consider checking serum levels of vitamin B₁₂, 25-hydroxyvitamin D, coenzyme Q10, and electrolytes, as well as red blood cell magnesium levels in patients with myofascial pain syndrome.

Recommendations on the use of dietary supplements in MPS suffer from inconsistencies, as noted previously.⁸³ Especially in patients with refractory cases of MPS unresponsive to lifestyle change, clinicians should proceed with supplements that may possess properties beneficial for pain and comorbid symptoms. A stepwise approach in which dietary supplements are incorporated and evaluated on a 2- to 3-month trial basis (i.e., a therapeutic trial) is suggested. These supplements may include those helpful for muscle function (e.g., magnesium, malic acid, calcium, vitamin D, and coenzyme Q10), antiinflammatory action (e.g., essential fatty acids, white willow bark, and *Boswellia*), or comorbidities such as sleep or mood dysfunction (e.g., St. John’s wort, S-adenyl-L-methionine [SAMe], valerian, and melatonin). As with prescription medications, the use of dietary supplements should be monitored on a regular basis to ensure benefit and to minimize adverse reactions.

Bioenergetics

Traditional Chinese Medicine

The use of traditional Chinese medicine, specifically acupuncture, was one of the earliest attempted treatments of MPS. More recently, investigators have speculated about the correlation between acupuncture and myofascial TrPs. In 1977, Melzack et al.⁸⁴ postulated an approximately 70% correlation between these two entities, although this correlation has been disputed.⁸⁵ Because of the likely coexistence of these entities, a separate discussion of dry needling and localized acupuncture appears somewhat arbitrary. However, acupuncture offers treatment avenues based on meridian and energetic dysfunction, which may entail treatment at distal or reflex points (auricular therapy) and thereby provide additional therapeutic options.⁸⁶ The global assessment of the patient that is undertaken in Chinese medicine is especially helpful in MPS because of likely comorbidities that must be considered in the formulation of a treatment plan.

The specific type of acupuncture that should be pursued in MPS has not been elucidated. Several reports argue that deep needling may be more effective in decreasing MPS than superficial needling, although the two terms have not been well defined.^{57,58} Conversely, Japanese acupuncture treatment, which typically uses superficial needling, was also shown to be effective in MPS in controlled trials.⁸⁷ The depth, frequency, and duration of treatments should be tailored to the patient; treatments typically should take place one or more times per week initially, followed by a gradual decrease with functional improvement.

Prevention Prescription

- Encourage posture awareness with frequent repositioning and adaptive stretching to reduce strain.
- Consider an ergonomic evaluation if patients remain in one position for prolonged periods at work.
- Incorporate stress management techniques to identify and reduce stress buildup. Ask patients to pay attention to where they carry stress in the body and use this to learn from the body's symptoms.
- Incorporate a regular exercise and movement program. At a minimum, patients should exercise three times/week for 30 minutes each session while stimulating movement, range of motion, and tone

in all muscle groups.

- Encourage adequate quantity and quality of sleep.
- Encourage the consumption of a healthy diet rich in fruits and vegetables with adequate fluid content to ensure perfusion to muscles.
- Encourage maintenance of an ideal weight.

Therapeutic Review

Myofascial pain syndrome (MPS) is a disorder that affects up to 85% of the general population at some point and is primarily characterized by local and referred pain, as well as comorbidities affecting mood, sleep, energy, and functional status. Although numerous treatment options are available, no widely accepted treatment guidelines exist. Clinically, MPS is a condition that is often difficult to treat, and physicians often characterize available treatments as insufficient.⁴ Based on its complex nature, MPS is a condition that requires a biopsychosocial evaluation and incorporation of individualized, preferably active, treatment options geared at underlying propagating factors with a focus on long-term neurobehavioral and functional rehabilitation.

Exclusion and Treatment of Conditions That Mimic or Contribute to Myofascial Pain Syndrome

- See [Table 66.1](#).
- Symptom-focused laboratory testing should be considered, including 25-OH vitamin D₃, coenzyme Q10, carnitine, vitamin B₁₂, folate, methylmalonic acid, and, as appropriate, baseline thyroid-stimulating hormone, creatine phosphokinase, alkaline phosphatase, and complete blood count and electrolytes with intracellular magnesium to rule out modifiable causes of MPS and associated symptoms.

Removal of Exacerbating Factors

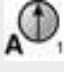

- Take measures to correct sleep dysfunction, including sleep hygiene and other interventions.
- Increase awareness of stress and environmental triggers (poor

posture, repetitive stress) by using periodic daily cues. 

Lifestyle Measures

- Incorporate stress management techniques 
- Biofeedback, preferred for baseline myofascial and autonomic measures and retraining efforts 
- Guided imagery, meditation 
- Exercise to decrease deconditioning and improve myofascial biomechanics. Mindful exercise (e.g., yoga, tai chi) is especially helpful in improving MPS. 

Biomechanical Interventions

- Posture evaluation and correction: Consider ongoing optimization with yoga, Feldenkrais, and physical therapy. 
- Manual and manipulative techniques, including massage, myofascial release, and spray and stretch: These should be considered in areas of distinct trigger points. Osteopathic manipulation is desired when functional skeletal asymmetry is provoking MPS. Refer to Simmons and Travell⁶ for detailed instructions. Several techniques can be taught to and successfully incorporated by the patient (e.g., compression massage with stretch). 
- Biostimulation: Low-level laser therapy, electrostimulation, hydrotherapy, and thermotherapy are recommended on a regular basis to assess reduction in symptoms, especially pain, with transition to home therapy. 

Bioenergetic Interventions

- Acupuncture is used to release trigger points and decrease autonomic arousal. 
- Other energetic treatments (e.g., healing touch, Reiki) should be used to assess for and treat energy imbalance. 

Nutrition

- Have patients increase their intake of fruits and vegetables, with a focus on appropriate levels of vitamins and minerals essential for musculoskeletal function. 
- Consider a trial of an antiinflammatory diet or elimination diet (see [Chapters 86](#) and [88](#)). 

Supplements

- Consider an 8- to 12-week trial of supplements for correction of myofascial pain and comorbid conditions (including identified deficiencies): Magnesium: starting with a chelated form if available for increased gastrointestinal tolerance; magnesium glycinate, 100–200 mg twice daily, advance as tolerated (other formulation doses vary; typically, starting at a low dose and advanced based on gastrointestinal tolerance) 
- Malic acid: 600 mg, one to two capsules daily 
- Carnitine: 2000 mg/day 
- D-Ribose: 5 g twice daily 
- Coenzyme Q10: 100–300 mg/day (dose increased based on response and serum levels) 
- B vitamins typically used: 50–100 mg of thiamine (vitamin B₁) and pyridoxine (vitamin B₆), 0.5–2 mg of folic acid and vitamin B₁₂ 
- Vitamin D₃: baseline 800–1000 units/day and based on individual level to maintain adequacy 

Pharmaceuticals

- Topical pharmaceuticals/compounded creams with ingredients based on patient presentation are applied to affected areas three times/day. Patients should be warned that some topical agents cause localized burning or rare allergic reactions. Systemic absorption negligible if these agents are used as directed.
 - Ketoprofen 10%–20% 

- Lidocaine 5% 
- Capsaicin 0.025%–0.075% 
- Cyclobenzaprine 5% 
- Oral pharmaceutical
 - If the response to other interventions is unsatisfactory, consider a trial of amitriptyline (up to 75 mg/day) for long-term treatment, as well as a trial of short-term antiinflammatory agents for acute exacerbations. 
- Needle-based injection therapy
 - If the patient's symptoms persist or worsen despite the preceding measures, consider needle-based intervention in a stepwise approach.
 - Acupuncture or dry needling 
 - Saline injection 
 - Anesthetic injection (e.g., a combination of 2% lidocaine and 0.05% bupivacaine in a 1:3 ratio upto a total of 8 mL) 
 - Botox injection 

All treatments should be well integrated, with the goal of improving patient awareness of biomechanical and stress triggers. Treatments should gradually move from passive (practitioner directed and supervised) to active (patient initiated), with improving awareness of the patient's ability to address and diminish the myofascial pain cycle.

Chapter 67

Chronic Low Back Pain

Russell Lemmon, DO, and Eric J. Roseen, DC

Introduction

Low back pain (LBP) is a tremendously common condition challenging patients, clinicians, and health care systems worldwide. The lifetime prevalence of LBP is reportedly as high as 84%; therefore, most adults will experience at least one episode.^{1,2} Back pain is the fifth most common reason to visit one's primary care physician and is the single most common reason adults in United States use complementary and integrative medicine (CIM).^{3,4}

Over the last several decades, the management of back pain has been associated with increased expense and disability.⁵ In 2008, annual direct costs of LBP were estimated at \$86 billion, similar to the costs associated with arthritis, diabetes, or cancer.⁶ Total direct and indirect costs (e.g., absenteeism, lower productivity) for LBP are thought to be even higher, an estimated \$625 billion in the United

States alone.⁷ In 2012, the World Health Organization (WHO) published the Global Burden of Disease Report, which ranked LBP as the 6th most burdensome condition in 2010, a notable increase from 1990 when it was ranked 11th.⁸

Additionally, the WHO's report also determined back pain to be the top cause of morbidity in the United States and worldwide.⁹ The societal problems associated with increased opioid use are also closely linked to chronic low back pain (CLBP), as it is the leading cause of opioid prescriptions for noncancer pain.^{10,11}

Despite its high prevalence and substantial global impact, back pain remains poorly understood. Effective management of acute back pain in the primary care setting is perhaps the most important factor to prevent progression to chronic back pain. Multiple evidence-based guidelines for the management of acute and chronic back pain are readily available to guide providers; however, adherence to such recommendations remains low.¹²⁻

¹⁹ LBP patients increasingly utilize high-cost, invasive interventions despite their risks and questionable benefits.^{20,21} A conservative approach, using a personalized combination of evidence-based conventional and complementary therapies, is consistent with current guidelines and is cost

effective and safer. Using these therapies in the context of the patient's psychosocial picture, preferences, and values are also vital and often overlooked components of effective treatment plans. This integrative approach is ideally suited to address the costly and complex condition of CLBP.

Pathophysiology

Acute low back pain (ALBP) is defined as pain in the lumbosacral region, with or without leg pain, which has been present less than 6 weeks.²² The condition is considered subacute when it has been present between 6 and 12 weeks. By extension CLBP is often defined as pain persisting for more than 12 weeks.

A recent National Institutes of Health (NIH) task force defined CLBP as pain persisting greater than 3 months and bothering at least half the days in the past 6 months.²³

A precise diagnosis for acute, subacute, or CLBP is often not possible, causing significant frustration for patients and providers alike. The vast majority of patients with ALBP can expect a favorable prognosis and a significant improvement within 6

weeks, regardless of the treatment given. However, recurrence rates are high (20%–35%), and approximately 5%–20% of patients will go on to develop CLBP.²⁴⁻²⁶ Intriguingly, a growing literature base is suggesting that the majority of back-related pain persists at a mild or fluctuating intensity after an acute episode.²⁷⁻²⁹ This evidence may help inform patient expectations and support longitudinal conservative management of patients experiencing recurrent or persistent LBP symptoms.

LBP origins and perpetuating factors vary tremendously among patients. Given that identifiable pathological causes are relatively uncommon, a broad biopsychosocial approach to back pain is more appropriate for understanding useful approaches to the treatment of “nonspecific” LBP than a traditional biomedical paradigm ([Fig. 67.1](#)).^{22,23,30} If specific pathology is unlikely, origins of pain may be linked to a neuromusculoskeletal dysfunction (e.g., tissue irritation, weakness, or imbalance) from one or many sources. However, pain may persist long after an injured tissue has healed. A chronic, recurring back pain experience is perhaps common, although associated pain and disability are rarely progressive. Contributing psychosocial factors (e.g., anxiety, depression, or work dissatisfaction) may perpetuate the pain

experience and should be identified early.

Specific Pathology

Definitive causes of LBP include disk herniation with suspected radiculopathy or spinal stenosis (5%), osteoporotic compression fracture (4%), and inflammatory arthropathies (3%) ([Table 67.1](#)). Other specific organic causes of LBP are cancer and infection (1%), cauda equina syndrome (<1%), and visceral pathologies (<2%) such as aortic aneurysm, pelvic, gastrointestinal, and renal pathology.^{12,22,31} These definitive causes are uncommon, and the vast majority of patients presenting with back pain will have nonspecific LBP of a less clearly understood origin.

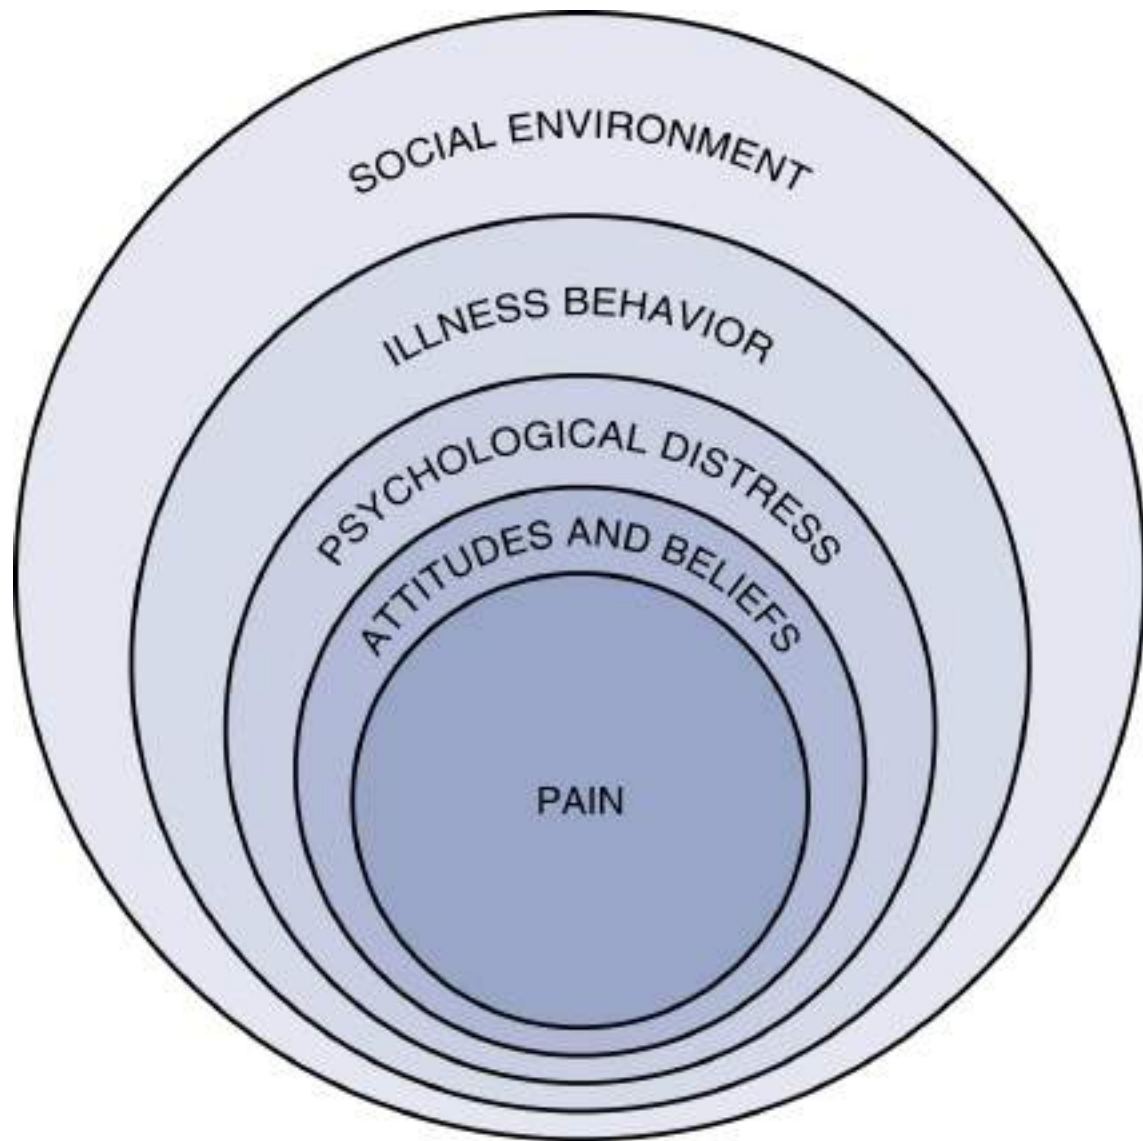

FIG. 67.1 Biopsychosocial model of pain. (From Main CJ, Williams AC. ABC of psychological medicine: musculoskeletal pain, *BMJ* 325:534-537, 2002.)

Neuromusculoskeletal Dysfunction

An estimated 80%–90% of all back pain is nonspecific and may emanate from ligaments, facet joints, muscle, fascia, nerve roots, the vertebral periosteum, or the outer portion of the disk.³¹ Despite sophisticated systems for evaluating these other causes of back pain, successful identification of a pain generator is often not consistent among or between providers who commonly evaluate back pain. Joint irritation, maladaptive movement patterns, muscle stiffness, spasm, and weakness commonly contribute to back pain and are often identified on examination. Peripheral and central neurophysiological mechanisms also play important roles in acute and chronic pain. Unfortunately, providers can rarely agree on the cause of one's back pain, and systems of identifying neuromusculoskeletal dysfunction (NMS) often have uncertain clinical relevance.

Psychosocial Factors

Psychological and social factors play a very important role in the prognosis of musculoskeletal conditions.^{32,33} Comorbid stress, anxiety, and depression have been linked with risk of chronicity. “Fear avoidance beliefs” and catastrophizing may cause maladaptive movement patterns or activity

avoidance that may cause spinal muscle deconditioning. The purpose of the biopsychosocial evaluation shifts from the characterization of a causative agent to the identification of inappropriate attitudes and beliefs, high levels of distress, and fear-avoidance behaviors that can impede recovery of function and place the patient at higher risk for developing chronic LBP. To effectively manage back pain, providers must address identifiable causes and perpetuating factors (see [Chapter 102](#)).

TABLE 67.1

Specific Conditions Causing Low Back Pain

Syndrome	Red Flags	Further Evaluation
Cauda equina syndrome	<ul style="list-style-type: none"> • Bilateral neurological symptoms • Fecal incontinence or urinary retention • Weakness in limbs and/or gait abnormality 	• Medical emergency; immediate magnetic resonance imaging and neurological referral
	• Saddle anesthesia	
Lumbar radiculopathy	<ul style="list-style-type: none"> • Severe lower extremity pain • Significant neurological deficits (indicator of nerve root compression) • Sensory (pain, numb, weakness, or diminished deep tendon reflexes) consistent with nerve root distribution • Significant neurological deficits (indicator of nerve root compression) 	• If no improvement with conservative treatment after 6 weeks, magnetic resonance imaging considered
Spinal cord stenosis	<ul style="list-style-type: none"> • Pain, sensory loss, or weakness in one or both legs • Pain worse with walking or standing • Pain relieved with sitting or lumbar flexion 	• Magnetic resonance imaging
Spasmodic torticollis	<ul style="list-style-type: none"> • Presence of four or more of the following: <ul style="list-style-type: none"> • Age younger than 40 years • Insidious onset • Improvement with exercise • No improvement with rest • Pain at night (with improvement on arising or walking) 	<ul style="list-style-type: none"> • HLA-B27 • Erythrocyte sedimentation rate • C-reactive protein
Cancer	<ul style="list-style-type: none"> • History of cancer • Age older than 50 years • Failure to improve with treatment 	<ul style="list-style-type: none"> • Erythrocyte sedimentation rate • Plain film radiographs • Magnetic resonance imaging

Table Continued.

Syndrome	Red Flags	Further Evaluation
	<ul style="list-style-type: none"> • Worsening pain especially at night, at rest, or when lying down 	
	<ul style="list-style-type: none"> • Urinary retention 	
Fracture	<ul style="list-style-type: none"> • Age older than 50 years • Osteoporosis • Significant trauma • Steroid use • Structural deformity 	<ul style="list-style-type: none"> • Plain film radiographs (cannot distinguish new from old compression fractures) • Computed tomography • Magnetic resonance imaging
Infection	<ul style="list-style-type: none"> • Fever • Immunosuppression • Intravenous drug use • Multiple comorbidities 	<ul style="list-style-type: none"> • Complete blood count • Erythrocyte sedimentation rate • C-reactive protein • Magnetic resonance imaging
	<ul style="list-style-type: none"> • Trauma 	

Evaluation

A thorough history and physical exam can guide care for patients with acute and chronic back pain. Applying three conceptual frameworks may be helpful for the evaluation and successful management: (1) rule out specific pathology, (2) differentiate patients with nonspecific LBP, and (3) identify psychosocial factors. Understanding these categories can help providers better understand a patient's pain and prognosis and help inform and individualize treatment.

History

While taking a patient history, it is helpful to think in terms of three basic diagnostic categories: nonspecific LBP, back pain with suspected radiculopathy or spinal stenosis, or back pain that is

a result of a specific pathology.¹² A thorough history is helpful for identifying red flag symptoms of serious, albeit rare, causes of LBP, such as cancer, infection, and abdominal aortic aneurysm.^{34,35} Other definitive causes of LBP include disk herniation with radiculopathy, spinal stenosis, compression fractures, and inflammatory arthropathies.

The history should begin with a description of the primary complaint in order to identify pain severity and functional limitations. The patient should be questioned about the pattern and nature of any lower extremity symptoms, as well as the presence of significant neurological deficits, gait abnormalities, or bowel or bladder dysfunction.

Attention to any history of trauma, immunosuppression, constitutional symptoms, substance use, comorbidities, and previous history of back troubles including spinal surgery is important. In addition, postures or spinal loading strategies (e.g., flexion, extension) that aggravate or palliate the patient's lumbar spine and/or extremity symptoms should be explored. Because most patients will benefit from conservative care and the incorporation of one or more integrative therapies, history is also very important for matching a treatment to a patient.

Physical Examination

During physical examination, emphasis should be placed on the observation of posture and gait, back inspection, palpation, range-of-motion testing, orthopedic maneuvers, and a comprehensive neurological evaluation. Observing transitional movements is informative; for example, a reverse lumbopelvic rhythm (bending knees to return from flexed position) suggests dynamic lumbar instability, which may benefit from stabilization exercises.³⁶ Active and passive range-of-motion testing, especially active repetitive flexion and extension, can help determine which tissues are pain generating. Particular attention should be paid to repetitive movements that centralize the pain or cause it to move from a more peripheral location (e.g., buttocks) to a more central location (midline of the lumbar spine). Orthopedic tests are particularly meaningful when they recreate a patient's chief complaint pain. For example, a series of six orthopedic tests are very reliable for identifying sacroiliac joint pain when three or more provoke familiar pain.^{37,38} Nerve tension tests, such as the straight leg raise and slump test, apply tension to the sciatic nerve and may recreate the chief complaint of leg pain in patients with nerve root

irritation.³⁹ The neurological examination should focus on the L4, L5, and S1 levels by evaluating myotomes (including heel and toe walking), dermatomes (light touch or pin prick sensation), and deep tendon reflexes (knee and ankle).^{12,15,17,18} Distribution of myotomes, dermatomes, and deep tendon reflexes are outlined in [Table 67.2](#).

TABLE 67.2

Common Radiculopathies

Level of Disk Herniation	Nerve Root Involved	Muscle to Be Tested	Area of Sensory Loss	Reflex
L3-4	L4	Tibialis anterior	Medial calf	Patellar
L4-5	L5	Extensor hallucis longus	Lateral calf	None
L5-S1	S1	Gastroc-soleus	Lateral foot	Achilles
Cauda equina syndrome	S2-S3-S4	External anal sphincter	Perirectal	None

Red Flags

Roughly 10% of patients will have examination findings suggesting a specific underlying cause, some of which warrant immediate further evaluation. Observing absence or presence of such red flag signs is an important part of an evaluation and can help identify rare causes of back pain, including cauda equina syndrome, cancer, fracture, or infection. [Table 67.3](#) lists constellations of red

flags concerning specific LBP pathologies and recommendations for further evaluation and referral.^{12,15,17,18,40} The minority of patients with LBP (2%) will have one of these serious underlying causes of back pain. The majority of specific LBP cases involve lumbar stenosis and disk herniation with correlating radiculopathy type leg pain. For most patients with suspected radiculopathy or spinal stenosis, conservative management aimed at alleviating pain and improving function is recommended, unless they present with progressive neurological symptoms. However, if the patient demonstrates persistent leg pain or neurological findings after 6 weeks of conservative care, surgical referral should be considered.³¹

Yellow Flags

Yellow flags are key patient characteristics that are linked with poor prognosis.^{33,41} Yellow flags have significant prognostic importance, and their presence should influence a patient's course of treatment. [Table 67.4](#) describes common yellow flags such as comorbid anxiety, depression, and stress. The presence of nonorganic signs ([Table 67.5](#)) is a very strong predictor for chronicity.³³ Additionally, patients who fear reinjury may avoid

movements or exercise and consider activity harmful (i.e., fear-avoidance beliefs). Such patients also have an increased likelihood of developing chronic back pain. Providers should choose words carefully for back pain patients and provide clear, concise patient education to patients with yellow flags. For example, such terms as stenosis and disk degeneration should always be coupled with thoughtful patient education and reassurance to avoid any strong, potentially negative, association a patient may have regarding their prognosis. Encouraging patients to participate in a healthy framing of back pain is key because the vast majority of patients will experience relief of pain and back-related disability.

TABLE 67.3

Historical Red Flags

Fever, weight loss, nausea	History of intravenous drug use
Saddle anesthesia	History of cancer
Recent trauma	History of immune suppression
Bowel/bladder incontinence/retention	History of chronic steroid use

Recent urinary tract infections

History of tuberculosis

Subgrouping

The broadly defined category of nonspecific back pain does not represent a uniform population of patients. Given the heterogeneous nature of nonspecific LBP, employing a “one size fits all” treatment approach is paradoxical and has led to unsatisfactory results.⁴² Attempts to subgroup patients with nonspecific back pain has been a research priority since the 1990s.⁴³ Several strategies have linked back pain subgroups to more specific treatments with the goal of improving clinical outcomes.⁴⁴

Developing subgrouping systems involves stratifying patients based on key individual patient characteristics such as prognostic factors, likely response to specific treatment, or suspected underlying causal mechanism, all of which can help tailor treatment. The subgrouping process is thought to result in better, more efficient care.⁴⁵

Three important examples of subgrouping strategies include (1) the Keele STarTback tool (prognostic factors), (2) treatment-based classification (TBC; likely responders) systems, and (3) the McKenzie

method of mechanical treatment and diagnosis (MTD; underlying causal mechanisms).^{44,46,47}

Keele STarTback Tool

Capturing a patient’s biopsychosocial profile is tremendously important in the primary care setting, but is often neglected in the evaluation of back pain. The Keele STarTback Tool is a brief (nine-item) questionnaire that separates patients into low, medium, and high risk for developing back pain disability. It measures, in part, the patient’s amount of worry and lack of hope toward improvement. Patients in the moderate or high-risk groups have been shown to have better outcomes if treatment is augmented by a cognitive behavioral intervention⁴⁸ (see [Key Web Resources](#)).

TABLE 67.4

Yellow Flags: Risk Factors for Disability and Chronic Low Back Pain

Psychosocial Factors	Occupational Factors	Interview Questions
• Inappropriate attitudes and beliefs	• Work status	• What do you believe is causing your back pain?
• Poor or maladaptive coping strategies	• Low job satisfaction	• What do you think will help your back pain?
• High levels of emotional distress	• High physical job demands	• Do you think your pain will ever get better?
• Fear-avoidance behavior	• Inability to modify work	• How do you deal or cope with your back pain?
• Depressed mood and social isolation	• High levels of job stress	• Have you been feeling worried, down, or blue?
• Resistance to change	• Working conditions	• How do your family, friends, and coworkers respond when you have pain?
• Family reinforcement of illness behavior	• Worker’s compensation claim or litigation	• Have you had time off work because of your back pain?
	• Health benefits and insurance	• When do you think you will return to work?

TABLE 67.5

Waddell's Nonorganic Signs^a

Sign	Description
Superficial or nonanatomical tenderness	Pain with light or superficial palpation of the skin, or widespread deep tenderness that is not localized to one skeletal or neuromuscular structure, does not follow an anatomic distribution, and often extends to the thoracic spine, sacrum, or pelvis
Pain on axial loading or simulated rotation	Pain with downward pressure applied to the top of the patient's head when standing, or back pain when the shoulders and pelvis are passively rotated as a unit with the patient standing relaxed with the feet together
Nonreproducibility of pain when patient is distracted	A positive physical finding elicited during the examination that is not present later in the examination when the patient is distracted and the finding is

	checked again (e.g., pain with a standard straight leg raise test, but not when the examiner passively extends the leg of a seated patient)
Regional weakness or sensory change	Regional, nonanatomical sensory change (stocking sensory loss, or sensory loss in an entire extremity or side of the body) or regional weakness (weakness that is jerky, with intermittent resistance such as cogwheeling or catching)
Overreaction	An exaggerated painful response to a stimulus that is not reproduced when the same stimulus is given later, or an exaggerated response to a stimulus that should not cause back pain (e.g., gently pinching the skin on the back in the area of pain)

^a Elicitation of one or more of these signs on physical examination suggests a nonorganic or psychological component to the patient's back pain.

Adapted from Chou R, Shekelle P. Will this patient develop persistent disabling low back pain? JAMA. 2010;303:1295-1302.

Treatment-Based Classification ([Fig. 67.2](#))

The TBC subgrouping strategy uses clinical prediction rules, which are specific clusters of signs and symptoms, to match patients to a particular treatment that they are more likely to respond favorably to. Essentially, TBC classifies patients into categories that help guide decision making when considering the many treatments available for back pain. Currently, TBC categories include specific therapeutic exercise (flexion, extension, and lateral shift patterns of bias), stabilization exercises, and spinal manipulation. Unfortunately, TBC does not include therapies where the specific characteristics of “treatment responders” are unknown (e.g., acupuncture, yoga). TBC’s clinical predication rules have been incorporated into a variety of clinical settings and have shown better clinical and cost outcomes when compared to usual care.⁴⁴

Which sub-group does the patient fit best?

Brennan et al 2006

Manipulation		Stabilization		Specific exercise	
Factors favoring	Factors against	Factors favoring	Factors against	Factors favoring	Factors against
More recent onset of symptoms Segmental hypomobility LBP only (no distal symptoms) Low FABQ scores (FABQW <19)	Symptoms below the knee Increasing episode frequency Peripheralization with motion testing No pain with mobility testing	Younger age Positive prone instability test Aberrant motions present Greater SLR ROM Hypermobility with spring testing Increasing episode frequency 3 or more prior episodes	Discrepancy in SLR ROM (>10 degrees) Low FABQ scores (FABQPA <9)	Strong preference for sitting or walking Centralization with motion testing Peripheralization in direction opposite centralization	Low back pain only (no distal symptoms) Status quo with all movements

FIG. 67.2 Treatment-based classification. (From Brennan, Fritz JM, Hunter SJ, Thackeray A, Delitto A, Erhard RE. Identifying subgroups of patients with acute/subacute “nonspecific” low back pain. Spine 31:623-631, 2006.)

McKenzie Method

The McKenzie method describes three syndromes:

postural (end-range stress of normal structures), dysfunction (end-range stress of shortened structures possibly due to scarring, fibrosis, or nerve root adhesion), and derangement (anatomical disruption or displacement within the spinal segment). Each distinct syndrome is addressed with specific static physical postures and repetitive movements.⁴⁷ A specific set of therapeutic interventions is suggested for each of these categories. The MTD classifies patients by evaluating the cause and effect relationship between a patient's historical pain behavior and their pain response to repeated test movements, positions, and activities.⁴⁷ This classification approach is most commonly used by physical therapists.

Imaging

A history and physical exam is adequate for making a diagnosis and determining a treatment plan for the vast majority of patients with LBP. The potential benefits of imaging in spinal pain are to advance the diagnosis, exclude urgent medical and surgical pathology, or guide evidence-based treatment. In most cases, imaging does not add useful information or value. Despite this, use of magnetic resonance imaging (MRI) in lower back pain

increased by 307% from 1994 to 2005, with no evidence of improved outcomes.⁴⁹

Early imaging in acute back pain has not been shown to improve either short- or long-term outcomes and is not recommended by several clinical guidelines.^{10,50}

Imaging has been shown to be costly, can be harmful, and findings most commonly do not correlate to the clinical course of LBP.⁵⁰ Avoiding the use of imaging in the early evaluation of LBP has been identified as one of the top five ways to improve value in primary care.⁵¹ Without red flag symptoms or concerning neurological findings, imaging prior to 6 weeks of symptoms should be discouraged.

Even after the acute period, patients should undergo imaging only if it may reasonably guide treatment decisions. There are several limitations associated with the use of radiographic and MRI testing that can lead to increased risks to patients. A major problem is the poor correlation between anatomic abnormalities and the underlying source of pain. For example, there is no known standard to identify diskogenic pain as the primary pain generating tissue. Simply identifying a disk

herniation on an MRI is not well correlated with the disk being the source of pain. Also, MRI findings of degenerative changes in lumbar facet joints are not predictive of a patient benefiting from a facet joint injection.⁴⁹ The same is true of degenerative changes in the sacroiliac joints. This makes interpreting imaging studies difficult and may overestimate their importance when trying to correlate information to the patient presentation. Potential harms of advanced imaging include unnecessary subsequent procedures and “labeling” a patient with a condition, such as degenerative disk disease, which may ultimately have no bearing on the course of their clinical symptoms. In some patients this labeling may cause avoidance of helpful activities out of fear that the activity will cause further damage.⁵² Direct harms related to radiation exposure are unlikely because computed tomography (CT) scans are seldom used in back pain evaluations, but worth considering for patients who receive repeated imaging studies. If the decision is made to proceed with imaging in LBP, plain radiographs are recommended initially. If there is a specific neurological concern or the patient is considering interventional treatments, an MRI may help guide treatment.

Integrative Therapy

Current “usual care” approaches to the diagnosis and treatment of chronic back pain are costly and often ineffective, leaving significant room for improvement. A 2009 study on cost of LBP noted, “National expenditures on spinal pain...increased 82% from 1997 to 2006. Paradoxically, mental health and physical functioning worsened for patients with spinal pain over this time frame.”⁵³ Patients are frustrated with treatment options and outcomes, and turn to complementary treatments for pain more often than for any other diagnosis.⁵⁴ LBP is an area where an integrative approach is clearly needed.

A wide range of treatments is available for LBP. Some complementary modalities are featured prominently in guidelines, such as exercise, spinal manipulation, and acupuncture.^{12,18} Even so, complementary therapies, as a whole, are likely underutilized options in treating spinal pain.

Lifestyle

Nutrition, exercise, and ergonomic awareness are important behaviors that may contribute to or perpetuate back pain. These elements are

foundational in providing a comprehensive treatment approach to chronic back pain. Nutritional choices can influence pain directly or indirectly. Some foods have known antiinflammatory properties, which may affect pain through altering cytokine and oxidant production.⁵⁵ Indirectly, food can affect pain through improving mood, energy level, sleep, and helping achieve a healthy weight. Both general exercise and specific therapeutic exercises have important implications for musculoskeletal conditions as well as for general health (see [Chapter 88](#)).

Helping patients recognize and change potentially destructive lifestyle habits is central to an integrative treatment approach. A tool that can be useful in this process is the concept of SMART goals ([Table 67.6](#)). This approach can help patients develop attainable goals related to their treatment, and these goals can be monitored at future office visits, allowing for focused discussion.

Self-Care Strategies

Education and self-management are cornerstones of widely used guidelines on the treatment of chronic back pain.^{12,18} Both the American College of Physicians (ACP) and National Institute for Health

and Care Excellence (NICE) guidelines recommend advising patients to stay active and giving information to support self-care.^{12,18} A 2012 systematic review concluded that moderate evidence exists that self-care provides a mild benefit in chronic back pain.⁵⁶ Self-care strategies are inclusive of patients taking an active role in the management of their pain, which is a vital step in effective treatment plans.

Self-management differs philosophically from traditional patient education. Goals of self-management programs include building self-efficacy, goal setting, and self-tailoring of information.⁵⁷ In addition to educating about a topic, self-management strategies give patients practical tools. Self-management education regarding LBP often includes information on acceptance of pain, staying active, activity pacing, and tools on how to effectively manage pain flares.

TABLE 67.6

SMART Goals (Using the Example of Wanting to Increase Exercise)

Specific: Walk 15 minutes every day before breakfast (avoid generic goals such as “exercise

more”).

Measurable: Track time spent walking on kitchen calendar for the next month.

Attainable: I currently am able to walk 15 minutes, but do so sporadically. Physically I am able to do this, and it is realistic to wake up 15 minutes earlier.

Relevant: Increasing exercise is a vital part of my pain treatment plan.

Time-sensitive: I will find my tennis shoes today and start walking tomorrow.

Biomechanical Interventions

Exercise Therapy

Regular routine exercise can help maintain good back health. Furthermore, physical exercise is one of the few proven treatments for CLBP, albeit with modest effects. Patients should choose activities they enjoy; no specific type of exercise has been shown to be clearly superior to reduce pain or improve back related function.^{58,59} Regular exercise supports general fitness and may successfully address perpetuating factors contributing to back pain such as sedentary lifestyle, obesity, and lumbopelvic instability.

Patients may benefit from professional guidance

with exercise when experiencing back pain. Exercise therapy refers to a broad range of techniques designed to improve strength, coordination, flexibility, range of motion, endurance, and aerobic capacity. These techniques can vary according to frequency, intensity, and duration. Exercise therapy is the most widely used nonpharmaceutical intervention for LBP. Exercise therapy is primarily provided by physical therapists although chiropractors and physicians frequently prescribe it.⁵⁸

The benefit of exercise therapy for acute LBP remains unclear. However, there is strong evidence that exercise therapy provides a small but significant benefit for short and long term pain compared to usual care in the CLBP population.⁵⁸⁻⁶⁰ Exercise is effective as a stand-alone or conjunctive therapy for LBP. Studies comparing different forms of exercises to one another in the CLBP population have not found clinically meaningful differences.⁵⁸ Individually designed, supervised, high intensity programs are recommended as they have been found to achieve better pain reduction and functional improvements than standardized group or home programs.⁵⁹ Adverse events associated with back exercise programs are rare.⁵⁸ If home programs are used, frequent patient follow-up to encourage

compliance is needed because adherence is typically poor.^{58,61}

There may be subgroups of patients with LBP that respond differently to various types of exercise therapy.⁵⁸ A common component of the TBC and the McKenzie methods of classification is the identification of patients whose symptoms “centralize” in response to specific postures or movements. The centralization phenomenon, which occurs when movement in a specific direction, such as lumbar flexion or extension, causes the patient’s pain to rapidly decrease or move from a peripheral location to a more central location in the axial spine.⁶² Likewise, movement in the opposite direction may peripheralize the pain or reverse the effect. Indications in the patient’s history that these movement patterns should be explored include constant pain that varies in intensity; pain often in seated positions; and movement restrictions are usually asymmetrical.

TBC also utilizes a clinical prediction rule by Hicks et al. to identify patients likely to benefit from lumbopelvic or core stabilization exercises.³⁶ Criteria that are supportive of benefit from core exercises include age < 40 years, passive straight leg raise range of motion > 90 degrees, aberrant movement pattern during trunk flexion, and a positive prone

instability test.³⁶ Exercises target the transversus abdominus, erector spinae / multifidus, quadratus lumborum, and oblique abdominal musculature. The major clinical practice guidelines recommend offering exercise therapy according to patient preference for CLBP. In addition, insights from the TBC and MTD may be helpful in identifying patients who are likely to benefit from specific forms of exercise (see [Chapter 93](#)).

Spinal Manipulation

Spinal manipulative therapy (SMT) involves high-velocity low-amplitude (HVLA) forces to spinal segments and supporting soft tissues. The result is thought to have local biomechanical effects (e.g., facet joint gapping, stretching of soft tissues) that stimulate a cascade of peripheral and central events resulting in pain relief and improved spine related function. The exact mechanism of action of spinal manipulation is unclear, although multiple potential mechanisms have been observed. The clinical effect is the likely sum of improved joint biomechanics and multiple peripheral and central nervous system mechanisms.^{63,64} In the United States, spinal manipulation is primarily performed by

chiropractic and osteopathic physicians, although physical therapists and physicians may also provide SMT.⁶⁵ Specific manipulative techniques differ slightly within and between professions although mechanisms and clinical effectiveness appear to be similar across providers who are properly trained and regularly perform SMT.

More than 100 randomized controlled trials have evaluated spinal manipulation for LBP, making it one of the most studied interventions for back pain.⁶⁶ Spinal manipulation is the only nonpharmacological therapy recommended for ALBP by the practice guidelines from the American Pain Society and ACP.¹² Additionally, all major international guidelines recommend spinal manipulation as a treatment option for subacute and CLBP.^{12,15,17,18} Spinal manipulation is likely effective in improving function and pain in both acute and chronic low back pain compared to sham manipulation, analgesic medications, or exercise therapy.^{60,66} Evidence suggests that spinal manipulation is as effective, but not more effective, than other nonpharmacological therapies.⁶⁷ Serious adverse events (e.g., disk herniation, cauda equina syndrome) associated with lumbar spine manipulation are very rare with an estimated risk of less than 1 in 1,000,000 manipulations.⁶⁸ Spinal

manipulation is likely most effective when provided in addition to standard medical care or as part of a set of guideline-recommended care.⁶⁹

The TBC system uses a clinical prediction rule to identify patients who are most likely to be manipulation responders. The prediction rule has been validated for use in patients with ALBP or an acute exacerbation of CLBP.^{70,71} The five criteria in the prediction rule are (1) duration of current episode < 16 days, (2) extremity symptoms not distal to the knee, (3) low fear-avoidance score (<19) as determined by the Fear Avoidance Beliefs Questionnaire work subscale, (4) palpation of ≥ 1 hypomobile lumbar segment, and (5) one or both hips with internal rotation range of motion > 35 degrees.⁷⁰ Patients who met four out of five criteria and received manipulation had more than a 90% likelihood of a successful outcome, defined by a 50% improvement in Oswestry Disability Questionnaire scores at 1 week.⁷⁰ In this subpopulation, the clinical benefit was also maintained at 4 weeks and 6 months.

LBP patients most likely to respond to manipulation:

1. Duration of current episode < 16 days
2. Extremity symptoms not distal to the knee

3. Low fear-avoidance
4. Palpation of ≥ 1 hypomobile lumbar segments
5. One or both hips with internal rotation range of motion > 35 degrees.

Clinical practice guidelines recommend that spinal manipulation be offered according to patient preference or when they have failed to improve with a short-course of advice and self-care. In addition, the clinical prediction rule is a useful decision support mechanism for identifying patients who are more likely to benefit from spinal manipulation. For individual patients who would prefer an alternative to HVLA manipulation a number of nonthrust manual therapies may be more appropriate.

Nonthrust Manual Therapy

Nonthrust manual therapies include a number of common techniques directed at the joints and soft tissues. Commonly, joint mobilization is a stretching of the joint without the presence of HVLA thrust. Nonthrust manual therapies also include passive procedures such as flexion distraction, strain-counter strain (see [Chapter 109](#)), myofascial release, instrument assisted soft tissue manipulation, and

craniosacral therapy. Active nonthrust therapies include muscle energy techniques. Chiropractors, physical therapists, and osteopathic physicians commonly perform nonthrust therapies.

A meta-analysis by Licciardone looked at six randomized controlled trials in subacute and chronic low back pain populations which used a combination of nonthrust manual therapies, all described under the umbrella of osteopathic manipulative therapy.⁷² In some of the trials HVLA spinal manipulation was also used. The authors concluded that these combined therapies significantly reduced LBP versus active treatments, sham, and no treatment control. Furthermore, these pain reductions were observed across short, intermediate, and long-term end points. Spinal mobilization provides better pain relief and greater increase in range of motion when compared to no treatment but is not significantly different from placebo.^{73,74} There is also moderate evidence to show that spinal mobilization produces benefits in both acute and chronic back pain populations.⁶⁶

Nonthrust manual therapies may be offered according to patient preference or when patients have failed to improve with a short-course of advice and self-care.

Massage

Massage refers to a broad range of techniques where a therapist will press, rub, and otherwise manipulate a body's soft tissues. Massage is typically performed in the outpatient setting, often in private community-based clinics. Massages are often of longer duration, lasting between 30 and 90 minutes and covering a range of body areas. Clinical guidelines recommend massage for subacute and chronic back pain patients.^{15,60} A 2008 Cochrane Review of massage in CLBP patients found similar improvement in pain and function when compared to exercise therapy. In addition, the review concluded massage provides better short-term outcomes when compared to several other common therapies, including spinal mobilization, relaxation therapy, physical therapy, acupuncture, and self-care education.⁷⁵ This evidence is mixed, as other reviews have concluded that there is not one superior physical modality in the treatment of CLBP.⁷⁴ In addition to short-term benefits, one clinical trial found massage provided long-term beneficial effects when compared to acupuncture and self-care in CLBP patients.⁷⁵ Patients with acute LBP have also shown short-term benefits from massage.⁷⁴

There is evidence to show that acupressure massage (gently pressing healing points) produces better results than Swedish massage (effleurage, petrissage, and tapotement) and that Swedish and Thai (stretching and deep massage) massage are equivalent.⁷⁵ It should be noted that minor pain or discomfort is experienced in a small percentage (<15%) of patients during or shortly after receiving massage.⁷⁶ It is important to work with an experienced and /or licensed massage therapist.

Mind-Body Interventions

The link between mind-body interventions and chronic pain is important to consider given the adaptive changes of the central nervous system in chronic pain. Using mind-body interventions directly addresses this component of central-mediated pain.⁷⁷ In addition, therapies targeted at a patient's psychosocial experience could be hypothesized to affect both pain perception and related psychological symptoms, such as depression or anxiety. Overall, this is an important category of therapies to discuss with patients as it may improve not only pain, but also mood-related symptoms, stress management, and illness-related coping skills. Psychotherapy, meditation, relaxation, imagery,

hypnosis, and biofeedback are among the modalities included within mind-body therapies. Collectively these modalities have been studied in many pain conditions, including LBP. A Cochrane Review on behavioral therapies in CLBP concluded that strong evidence exists for a moderate effect on pain relief and mild improvement in functional status with behavioral therapies.⁷⁸ A meta-analysis of cognitive behavioral therapy found improved pain and coping skills in patients with chronic pain.⁷⁹ There is evidence that mindfulness meditation can decrease pain intensity and stress levels^{80,81} (see [Chapter 100](#)).

Yoga

In the West, yoga is often conceived as a form of physical exercise; a set of postures (asanas) with variable difficulty connected by potentially rigorous transitions. However, yoga practice often incorporates additional components such as meditation (dhyana) and breathing (pranayama) and is commonly classified as a mind-body intervention by clinicians and researchers. Additional components may include yogic philosophy, diet, and lifestyle. This multifaceted

practice allows yoga to address multiple interrelated domains (i.e., physical, mental, emotional, social, cultural, spiritual), which may be important in managing CLBP. The multimodal nature of yoga parallels the biopsychosocial model. Yoga can be modified to an individual's fitness level and is therefore accessible to most individuals. Certain styles such as Iyengar yoga utilize props (e.g., straps, blocks) to facilitate postures and in some instances to augment the stretching experience. While the specific mechanisms by which yoga helps back pain are uncertain, several are plausible. Increased physical activity, enhanced body awareness, reduced maladaptive movements, correction of postural strain, and relief of physical and mental stress are all possible. Specific conceptual models have suggested how these multiple therapeutic mechanisms may overlay and synergistically enhance the therapeutic effect.⁸² Current evidence for yoga strongly suggest that yoga has an important role to play in the management of back problems for adults who are willing to practice it. There is good evidence that yoga is moderately effective for CLBP, based on the relatively large number of high-quality trials and their broadly consistent findings of reducing pain and improving back function.⁸³ Moreover, yoga for

back pain appears to be a safe intervention in the context of clinical trials with carefully selected postures and well-trained instructors with the most common adverse event being a temporary increase in musculoskeletal pain. Trials of yoga have used various different styles of yoga. In addition, they have used a variety of postures. Across studies, the postures have overlapped but have not been identical. Although no study has directly compared different styles of yoga for back pain or different sets of postures, the evidence suggests that a variety of styles and postures may be helpful for patients with nonspecific CLBP.

Tai Chi

Similar to yoga, tai chi is a low-impact exercise therapy potentially augmented by important mind-body components. Participants complete a series of whole body movements with focus and attention to movement patterns and quality.

Recent literature suggests tai chi may be beneficial for back pain, although it has not been included in clinical guidelines as a recommended therapy for CLBP. One trial of tai chi found reductions in pain and back-related disability when compared to usual

care.⁸⁴ Tai chi is generally considered safe for a wide range of individuals and may be an appropriate option for sedentary or elderly individuals.⁸⁵ Additionally, tai chi has been shown to improve balance, which may be important for some patients with back pain.

First-Line Pharmaceuticals

Acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs) are the initially recommended medications in treating CLBP.^{12,18} These medications are recommended as initial choices for pain by the WHO. Acetaminophen is generally considered to be the analgesic option with the fewest side effects, although it is not benign. In excess, it can cause hepatic failure. NSAIDs have been found to be effective in the short-term treatment of lower back pain, although the effect is thought to be small.⁸⁶ NSAIDs may cause gastrointestinal ulcers/bleeding, interfere with platelet aggregation, worsen renal function, and increase risk of cardiovascular events.⁸⁷ However they carry less risk than second-line medication choices, such as muscle relaxants or opioid medications.⁸⁶

Second-Line Pharmaceuticals

Tricyclic Antidepressants

Tricyclic antidepressant medications are recommended as adjunctive treatments for both nociceptive and neuropathic pain.⁸⁷ They are recommended as adjunctive agents for CLBP in the NICE guidelines.¹⁸ An additional benefit in some patients may be an aid in sleeping. As such, a common side effect is sedation. It is recommended to use tricyclics with caution in elderly patients.⁸⁸

Skeletal Muscle Relaxants

Muscle relaxant medications affect muscle spasm indirectly by acting on the central nervous system. The specific mechanism varies depending on the agent.⁸⁹ An older systematic review found muscle relaxants were effective for short-term pain relief with a high likelihood of adverse effects.⁹⁰ There was no evidence of effectiveness for CLBP. Muscle relaxants have similarities with benzodiazepine medications, including similar side effects, most notably dizziness and sedation.

Opioid Medications

The use of opioids is a source of increasing tension among physicians treating patients with chronic musculoskeletal pain. Effectiveness of opioids has been questioned when used in the setting of treating chronic, nonmalignant pain. The medications come with a long list of potential side effects, and the list continues to grow. In addition, opioid abuse and overdose has become a societal burden with increasing publicity and scrutiny of prescribing physicians. Although problematic, opioids may be indicated in the treatment of select patients due to few effective pharmacological options.

The NICE guidelines currently list weak opioids (codeine) as a second-line medication, especially in the short term.¹⁸ A 2010 Cochrane Review evaluated long-term opioid use for chronic pain. They found weak evidence of pain relief; however, an inconclusive effect on function was found.⁹¹

A systematic review on opioids for several types of chronic pain concluded that, on average, opioids result in a small magnitude of pain relief, but actually less functional improvement than other analgesics.⁹²

There are many adverse effects and precautions of opioids. They commonly cause constipation,

dizziness, and sedation. These side effects are so common that they cause large numbers of patients in clinical trials to withdraw due to medication intolerance.⁹³ In some patients they can actually cause hyperalgesia, worsening the pain syndrome.⁹⁴ Opioids lower testosterone levels in men.⁹⁵ Importantly, they carry a high risk of addiction and misuse.

Botanicals and Supplements

Devil's Claw

Devil's claw comes from the roots of the *Harpagophytum* species, a perennial plant native to southern Africa. Its healing properties have been known for centuries and have been traditionally used for a variety of symptoms. Currently, its most common use is in the treatment of pain. A 2007 review of the evidence found five systematic reviews on devil's claw, with strong evidence of effectiveness in LBP and osteoarthritis pain of the knee and hip.⁹⁶ This effect was not inferior to NSAIDs. The review concluded by stating "since there is strong evidence for devil's claw...the possible place in the treatment schedule before NSAIDs should be considered."⁹⁶

Dosage

Doses should be at least 50 mg of the harpagoside and effects are dose dependent.

Precautions

These are generally well tolerated, with few side effects. The most common side effect in trials is diarrhea. It is recommended to use cautiously in combination with anticoagulant medications.

Willow Bark

Willow bark is an herb containing salicin, which is related to aspirin. It has been used for centuries to relieve pain.⁹⁷ The mechanism of action is thought to be through the combined antiinflammatory effects of salicin and flavonoids, without affecting the gastrointestinal (GI) mucosa or blood clotting as seen with aspirin.⁹⁸ There is evidence of efficacy in CLBP similar to that seen in rofecoxib 12.5 mg.⁹⁷ Evidence of its efficacy in osteoarthritis is mixed.⁹⁷

Dosage

The effect is dose dependent, and the willow bark dosage used in studies was standardized to 240 mg of salicin.

Precautions

Willow bark has precautions similar to those using aspirin. Avoid use if a patient is allergic to aspirin. It can cause GI upset, headache, and can impair platelet function, but less so than aspirin. Caution should be used in patients with kidney disease.

Topical Capsaicin

Capsaicin is widely available a cream in various doses. It is useful as a short-term analgesic, and a review has shown that it is superior to placebo for acute episodes of CLBP.⁹⁹ Side effects can include a burning or stinging to the skin after it is applied, which tends to improve with repeated use. It is important to advise patients to wash their hands after using capsaicin to avoid inadvertently getting the product in their eyes, which can result in irritation and discomfort.

Vitamin D

The relationship between vitamin D deficiency and chronic back pain is intriguing, but not yet clear. Epidemiological studies have correlated low vitamin D levels and chronic musculoskeletal pain, with prevalence in one study exceeding 90%.^{100,101}

Vitamin D deficiency is known to cause osteomalacia and a resultant dull, achy pain, which can be either localized or widespread.¹⁰² Despite the high correlation and a plausible mechanism of contributing to pain states, a recent Cochrane Review found poor evidence to support vitamin D supplementation in chronic pain.¹⁰³ This finding was based on four studies, three of which were deemed of low quality. A smaller study, published since the Cochrane review on vitamin D supplementation, in veterans showed improved pain, sleep, and quality of life.¹⁰⁴ Clearly more research is needed in this area to guide future recommendations. At this time it seems reasonable to test vitamin D levels in patients with chronic musculoskeletal pain and institute a trial of supplementation with low levels given the safety of supplementation and the potential to have a positive impact on other aspects of health.

Acupuncture

Acupuncture stems from traditional Chinese medicine (TCM), with a history of more than 2000 years of use. TCM is holistic system encompassing acupuncture, herbal medicine, nutrition, meditative practices (qi gong), and movement (tai chi).

Acupuncture stimulates points on the body, usually

with needles, altering the flow of qi attempting to achieve this balance. Even though acupuncture represents one piece of TCM, it is often practiced as an independent therapy.

Recommending acupuncture may be uneasy for some physicians because the theoretical basis of yin, yang, and qi does not relate to a modern understanding of human physiology or pathology.

However, basic science research has uncovered multiple mechanisms of action that likely contribute to acupuncture's physiological effect, especially in the treatment of pain. Needling an acupuncture point stimulates the natural endorphin system, altering the pain sensation.¹⁰⁵ This endorphin stimulation is reversible with naloxone.¹⁰⁶

Serotonergic systems also seem to be involved centrally. Multiple chemicals released peripherally appear to influence acupuncture analgesia, including interleukins, substance P and adenosine.¹⁰⁵ A local anesthetic injected around a peripheral nerve at an acupoint blocks acupuncture's analgesic effect.¹⁰⁷ The gate control theory is also believed to play a role, with modulation of sensory input at the level of the dorsal horn of the spinal cord.¹⁰⁵ Taken together, acupuncture likely has mechanisms of action in the brain, spinal cord and at the periphery, making it a

unique therapeutic modality. It remains controversial how these mechanisms interact and how they could have persisting effects on chronic pain.

While the WHO lists more than 40 disorders effectively treated with acupuncture, pain is the most common reason acupuncture is used.¹⁰⁷ There is a growing literature base and multiple reviews supportive of using acupuncture for these multiple indications. From 1991 to 2009, nearly 4000 acupuncture research studies were published, with pain accounting for 41%.¹⁰⁷ Cochrane Reviews showing effectiveness of acupuncture have been published for L, as well as neck pain, headaches and osteoarthritis.¹⁰⁸ Several other literature reviews support the use of acupuncture in the treatment of CLBP.¹⁰⁹⁻¹¹¹ The NICE low back pain treatment guidelines list acupuncture as a primary therapeutic option.¹⁸

Injections

Patients who have persistent back pain after medications and physical therapy are frequently referred for injection therapies. The most common injections are epidural steroid injections, but others include facet joint injections, sacroiliac joint

injections, and prolotherapy. Injection therapies are common, and their use is growing in popularity. More than 1.5 million epidural procedures were performed in Medicare patients alone in 2006, more than double the amount 10 years prior.²⁰ The rate of facet joint injections has increased by 543%.²⁰ Despite the rapid rise in their use, injections therapies as a whole have very limited evidence of effectiveness. A 2008 Cochrane Review concluded that “no strong evidence exists to support any injection therapy.”¹¹²

Among the injection therapies, epidural injections have been the most studied. Patients with lumbosacral radicular pain are the most likely to have some benefit from epidural injections. Several systematic reviews have found low quality or fair evidence of short-term relief of radicular symptoms with epidural injections.¹¹³⁻¹¹⁷ This benefit is no longer seen after 6 weeks.¹¹⁶ Injections do not seem to impact the need for subsequent surgical intervention.¹¹⁷ For LBP patients without radiating leg pain, there is no evidence of benefit from an epidural injection. A 2013 review gives the following summary: “the evidence for epidural injections ranges from nil to possible based on the cause of chronic back pain. There is no evidence of efficacy...for long-term relief of back pain of any

etiology.”¹¹⁶ Adverse effects are relatively uncommon with epidural procedures, but as noted in two systematic reviews, these are not well reported in trials.^{113,117} The possibility of significant morbidity is real, however. This was highlighted by the widely publicized case reports of *Aspergillus* meningitis associated with contaminated epidural injection medications in 2012.¹¹⁸ Overall, epidural injections remain an option for patients with refractory radicular pain. In light that the relief will likely be short-lived, the treatment can be viewed as a bridge allowing for a patient to start rehabilitation-based therapies.

A randomized trial of epidural steroid injections for spinal stenosis found no difference in outcomes between the xylocaine alone and the xylocaine plus steroid groups. However, both groups showed improvement. The needle insertion alone may hold the therapeutic potential.¹¹⁹

Facet joint injections are sometimes performed on patients with perceived facet joint-mediated LBP. An inherent problem with the treatment is determining which patients are likely to benefit from the procedure. Finding facet joint degenerative changes on MRI is not predictive of benefiting from

a facet joint injection.⁴⁹ This leads to varied definitions and inclusion criteria in trials that test facet joint injections. That said, high-quality reviews to this point have not shown facet joint injections more effective than placebo interventions.^{112-114,117} Very few studies have evaluated sacroiliac joint injections, and to at this point there is no evidence of effectiveness.¹¹⁷

Prolotherapy

Prolotherapy is an injection therapy for painful ligaments, tendons, and joints. It involves the injections of an irritant solution, most commonly a solution containing dextrose. The goal of the treatment is to induce an inflammatory response in the affected tissues, and therefore stimulate the body's natural healing response. Prolotherapy is a promising therapy for certain musculoskeletal conditions, especially knee osteoarthritis.¹²⁰

Cochrane reviewed prolotherapy injections for CLBP, and did not find them effective when used as a standalone therapy.¹²¹ When combined with other therapies such as exercise and spinal manipulation, there is evidence of some pain relief from prolotherapy^{121,122} (see [Chapter 112](#)).

Surgery

Much like injection therapies, surgical therapies are also on the rise to treat CLBP in the United States. Spinal fusion rates more than doubled from 1998 to 2008.²¹ During the same time period, charges for spinal fusion more than tripled, outpacing many other surgical procedures in cost escalation.²¹ There is also significant geographic variation, as surgical therapy for LBP is more common in the United States than anywhere else in the world.¹²³

The evidence base regarding surgical therapies for LBP can effectively be divided into three clinical groups: those with radicular symptoms and a concordant herniated disk on imaging, those with severe neurogenic claudication from lumbar spinal stenosis, or those with nonspecific back pain, often with associated degenerative changes. Patients with radicular symptoms and an associated herniated disk seem to benefit from discectomy in the short term. A 2007 Cochrane Review and a subsequent systematic review concluded that good evidence exists for symptomatic improvement compared to nonsurgical treatment for up to 3 months.^{124,125} Long-term follow-up studies have shown inconsistent results, and there does not appear to be a benefit to surgery past 1 year.¹²⁵

Patients with severe neurogenic claudication from spinal stenosis may also benefit from surgical treatment. In patients with severe symptoms, conservative care is effective approximately 33% of the time, in contrast to 80% effectiveness of surgical decompression.¹²⁶ A challenging part of evaluating a patient with symptoms suspicious for spinal stenosis is correlating the symptoms to imaging findings. Although there are objective measures to determine the severity of spinal canal narrowing, the degree of severity has not been shown to correlate to any clinical measure. Specifically, there is poor correlation between MRI assessment of stenosis and walking distance, degree of disability, patient-reported pain, and the physician's clinical impression.¹²⁶ The best approach would be to not obtain MRI studies in patients with mild–moderate symptoms as the findings would not alter the initial treatment options.

For patients with chronic nonradicular LBP, surgical treatment is often performed in the United States, but not often indicated. Trials assessing spinal fusion for patients with CLBP presumably due to degenerative changes have revealed inconsistent results. However, spinal fusion has not been shown to have better results than intensive physical therapy or cognitive-behavioral programs.¹²⁵ Despite

this, degenerative CLBP continues to be the most common reason for spinal fusion.²¹ As a general rule of thumb, patients with primarily radicular symptoms are more likely to benefit from surgery or injection therapies than patient with primarily axial back pain. This clinical pearl can help guide imaging decisions as well. Patients who have nonradicular LBP without red flag symptoms are unlikely to benefit from interventional procedures, so results of an MRI are unlikely to provide clinical benefit.

Prevention Prescription

- Maintain a healthy weight.
- Stay active and physically fit.
- Reassurance. Nearly everyone experiences acute back pain at some point, but associated pain and functional limitations typically improve quickly.
- Encourage graded return to physical activity following an episode of acute back pain.
- Improve mental health resilience by practicing some form of stress reduction on a regular basis.

Therapeutic Review

Evaluation

- Red flag findings help identify serious, albeit

rare, causes of back pain.

- Yellow flag findings help identify patients with acute back pain with an elevated risk of developing chronic back pain.
- Avoid imaging in patients with acute or subacute symptoms when red flag symptoms are not present.
- For nonspecific back pain, consider patients' preferences and clinical subgrouping strategies in treatment planning.

Education and Self-Management

- Educate patients on the multiple facets of chronic pain and the need for patient engagement in treatment. 
- Provide resources to aid patients in starting a general exercise program or staying active. 
- Reassure patients of favorable outcomes and address psychosocial risk factors for chronic back pain (e.g., catastrophizing, fear-avoidance beliefs). 
- Provide resources for patients to improve self-management of pain flares. 

Mind-Body Interventions

- Consider a referral to a health psychologist with experience in improving pain-related coping skills, especially if yellow flag symptoms are present.

- Consider a referral for cognitive-behavioral therapy, especially if yellow flag symptoms are present.  A₁

- Encourage patients to develop a stress management practice, such as relaxation breathing or meditation.  C₁

- Encourage patients to try yoga through a program specifically tailored for those with back pain.  B₁

Pharmaceuticals

- Acetaminophen, 500–1000 mg, three to four times daily, up to a maximum of 3000 mg/day  B₁

- Nonsteroidal antiinflammatory medications  A₂

- Ibuprofen, 600–800 mg up to three times daily

- Naproxen, 500 mg two times daily

Botanicals

- Devil's claw, 400 mg supplements, two capsules three times daily. Most are standardized to 1.5%

- harpagoside.  A₂

- Willow bark, 240 mg of salicin, one to two times daily.  B₂

Biomechanical Modalities

- Spinal manipulation is recommended for acute, subacute and chronic low back pain; it is likely most effective when combined with therapeutic

exercise. One to two times per week for 4 weeks.

- Exercise therapy is recommended for subacute and chronic low back pain, two to three times per week for 4 weeks. 

- Consider massage therapy for four to eight visits for acute or chronic LBP. 

Bioenergetic Modalities

- Consider acupuncture as an adjunctive treatment, 6–12 treatment sessions. 

Interventional Treatments

- For patients with persistent radicular symptoms despite a minimum of 8 weeks of integrative therapy, consider further imaging with an MRI to evaluate for primary discogenic pain. If disc disease correlates to the persistent radicular leg pain, consider further evaluation for an epidural injection.

- Advise against interventional injection therapies or surgery for patients without radicular pain.

CHAPTER 68

Neck Pain

Alexandra Ilkevitch, MD, Taryn Lawler, DO, and J. Adam Rindfleisch, MPhil, MD

In many Eastern traditions, the neck is considered our center of communication, self-expression, and creativity. Metaphors related to the neck tell us something about its association with vulnerability. Something frustrating is “a pain in the neck,” and something depressing gives one a “lump in my throat.” We “stick our necks out for others” when we are being brave, and we “go for the throat” when we are being aggressive.

The neck houses our voice, our capacity to swallow, and the major blood vessels that are the lifelines between the heart and head. It has 37 separate joints and moves an average of 600 times per hour. It has evolved to be simultaneously rigid and flexible, and it houses separate flexor and extensor muscles for the head and cervical spine. It contains our cervical spinal cord, multiple nerve roots and joint facets, and the atlantoaxial joint. The neck is indeed a vulnerable part of the body. At any given year, 30%–50% of people in the United States are experiencing neck pain,¹ and two-thirds of people have neck pain sometime during their lives.² Not surprisingly, neck pain is one of the most common complaints primary care providers encounter.³ Even with a full biomedical course of treatment, neck pain often recurs.⁴ An individualized, relationship-centered, and holistic integrative approach can markedly improve outcomes.

Pathophysiology

Pinpointing the exact anatomical source of neck pain is often difficult. Most neck pain is the result of cervical paraspinal muscle spasm or other musculoskeletal factors, but clinicians must rule out various other causes, as noted in [Box 68.1](#).^{2,3,5} Most neck pain is localized to the posterior or

lateral aspects of the neck, over the suboccipital region, cervical spine, or attachment points of such structures as the trapezius muscles; that said, however, there are certainly some anterior neck pain sufferers. Due to lack of available research and evidence-based therapies for anterior neck pain, this chapter will focus on more common lateral and posterior neck pain.

Musculoskeletal neck pain can be traumatic or nontraumatic in origin.¹ Traumatic neck pain is most commonly associated with hyperextension syndrome (whiplash). As many as 40% of whiplash injuries are estimated to result in long-term symptoms.⁶ In countries where litigation for whiplash is uncommon, long-term sequelae of whiplash are almost unheard of, a situation that leads one to wonder about the role of mind-body and economic influences on pain outcomes.⁷

Nontraumatic neck pain, which is more common, can be related to a structural or degenerative disorder, but more commonly it is caused by soft tissue disorders. Twin studies revealed a link between genetics and a predisposition to development of nontraumatic neck pain.⁸ Common causes of soft tissue pain include poor posture, repetitive activity, and sports injuries. A strong connection exists between soft tissue neck pain and emotional or mental states, such as anxiety and depression.⁹ Myofascial trigger points—clusters of muscle fibers locked in a contractile state—are commonly present in soft tissue pain.

The pathophysiological basis of neck pain is complex, and our knowledge of the multitude of chemical and structural processes involved is far from complete. Pain begins with tissue irritation, which may be caused by infection, disk or joint deterioration, sustained use (or sustained immobility), psychological stress, or trauma. Irritation activates nociception. Muscle spasms often occur as the neck is voluntarily or involuntarily repositioned to avoid pain. Inflammation follows, and a vicious positive-feedback circle arises as inflammation leads to even more pain. As edema, structural changes, and harmful metabolites accumulate, they can cause ischemia of the tissues. If these alterations are not interrupted or reversed in time, long-term changes in neck structure may arise, and disability can result.

Integrative Therapy

The goals of an integrative approach to neck pain are three-fold:¹⁰

1. Understand the pain in a broader context. Move beyond an exclusively

physiological perspective to explore how emotions, occupation, social issues, relationships, past trauma, and other factors contribute. What burdens is a person “carrying” on his or her shoulders? Asking people their views on why they have pain can offer interesting insights.

2. Explore where the cycle of pathophysiology may be interrupted and how that could best be done. Identify the initial insult or insults causing the pain. Supplements or diet may help to lessen inflammation. A mind-body approach may alter the tendency to fear or avoid the pain and/or maintain tension. Manual therapy, acupuncture, or exercise may help patients alleviate any structural dysfunction and diminish the pain, as they learn to carry themselves differently. The key is to collaborate on a plan of action, with care taken not to overwhelm people with too many options. Trust your intuition as a provider.

3. Remain mindful of therapeutic complications and factors likely to cause pain recurrences. Pain can often be a powerful teacher. Why is this signal arising, and what changes are needed so that the signal will no longer be necessary? It is easy for a pattern to arise if the pain is masked, rather than truly treated. Some therapies (e.g., long-term narcotics) can lead to long-term problems and should be used cautiously, if at all.

BOX 68.1 Key Points to Remember in the Evaluation of Neck Pain

- Keep in mind that severe neck pain associated with fever is meningitis until proven otherwise.
- Consider a tumor or other mass lesion in a patient who has pain at night or whose pain does not improve when the body is supine, an elevated erythrocyte sedimentation rate, or lytic lesions found on imaging.
- Neck pain with associated neurological symptoms (e.g., dizziness, paresthesias, weakness, and/or bowel/bladder dysfunction) merits diagnostic imaging studies, most commonly computed tomography or magnetic resonance imaging of the neck.
- If neck pain is associated with joint pain in other areas, rule out a systemic rheumatic disorder, such as osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, or gout. Lyme disease should also be considered.
- Neck pain can be referred from a source in the head or arms. Consider dental disorders, temporomandibular joint disorders, and

rotator cuff injuries. For example, cervical spine disorders may lead to patient descriptions of the eyes being “pulled” or “pushed” if the sympathetic nerve plexuses that surround the arteries of the neck and innervate the eyes are irritated.

- Referred neck pain can arise from nearly any organ system. In addition to nervous and musculoskeletal causes, myocardial ischemia, gastrointestinal ulcers or hiatal hernias, and pancreatic inflammation are all in the differential diagnosis. Referred diaphragmatic pain and tumors of the apical lung must also be considered.
- Keep in mind that uncommon local sources of neck pain can include the carotid arteries, vertebral arteries, lymph nodes, and the thyroid.

Data from references [1–3](#) and 174.

Lifestyle

[Box 68.2](#) lists some of the risk factors for neck pain.^{[2,10,11](#)} Smoking, obesity, work activities, and substance abuse should all be given attention in an integrative visit.

Exercise and Movement

To assume that exercise for musculoskeletal neck pain would be beneficial seems logical. Patients with chronic neck pain demonstrate altered muscle activation patterns during the performance of tasks that may influence how rapidly their muscles become fatigued.^{[12](#)} There are many therapeutic disciplines that can help teach patients healthier movement patterns.

Physical Therapy

A good starting point for many neck pain patients is a course of physical therapy (PT), preferably done by a provider who specializes in spine care. A randomized controlled trial (RCT) by Tunwattanapong discovered that office workers had an improvement in chronic neck and shoulder pain as well as quality of life and function when they participated in a stretching program.^{[13](#)} However, in a 2015 Cochrane Review, Gross and colleagues found that stretching alone did not provide benefit for mechanical neck pain.^{[14](#)} In fact, O’Riordan et al.

concluded that multimodal approach may be best when it comes to PT for chronic neck pain with particular emphasis placed on active strengthening. Adding aerobic exercise and stretching provided further improvement in positive outcomes.¹⁵ More studies are needed.¹⁶

BOX 68.2 Risk Factors for Neck Pain

- Depression
- Drug abuse
- Increasing age
- Heavy physical work, manual labor
- High job demands
- History of headaches
- Lack of control-over-work situation
- Low job satisfaction
- Work with exposure to repetitive vibration or unusual postures
- Obesity
- Smoking (and frequent coughing)

Data from Devereaux MW. Neck pain. *Med Clin North Am* 93: 273-284, 2009; Teets RY, Dahmer S, Scott E. Integrative medicine approach to chronic pain. *Prim Care* 37:407-421, 2010; and Christensen JO, Knardahl S. Work and neck pain: a prospective study of psychological, social, and mechanical risk factors. *Pain* 151:162-173, 2010.

If PT does not provide satisfactory relief, many other movement-based disciplines are available. Some of the most common ones are described in the following text.

Alexander Technique, Feldenkrais, Pilates

Medical research continues to be limited regarding the potential benefits of the Alexander technique, Feldenkrais, and Pilates for neck pain, but these therapies are increasingly popular with patients with chronic pain, are effective for other musculoskeletal complaints, and tend to be safe.¹⁷⁻¹⁹ A 2013 pilot study showed preliminary evidence in favor of Pilates in reducing disability and pain related to neck pain.²⁰ A 2015 RCT found that patients practicing the Alexander technique for 5 weeks scored higher on physical function and general health measures, as well as satisfaction, with this modality compared to the other two intervention groups (local heat and guided imagery). There was no difference between the three groups in disability, analgesic requirements, or pain

levels.²¹

Yoga

A 2014 systematic review found that supervised Qigong, Iyengar yoga, and combined programs involving stretching, range of motion, and strengthening were all similarly efficacious for the patients with chronic neck pain (i.e., there was no superiority of one exercise modality over the other).²² However, Crow and colleagues conducted a systematic review in 2015 and concluded that Iyengar yoga was more effective compared to control interventions for short-term relief of chronic neck and low back pain.²³ The control interventions varied and included no treatment, educational materials on self-treatment, standard medical care, and home-based exercise.²³

TABLE 68.1

Examples of Various Osteopathic Manipulative Techniques

High-velocity low-amplitude (HVLA)	The physician uses an HVLA thrust to push through a joint in order to restore the range of motion of that joint.
Springing	The physician repetitively gently rocks or pulses against the restriction of a joint to restore the range of motion of that joint.
Muscle energy	The physician asks the patient to push or pull against the physician's resistance, in order to rebalance the muscles around a dysfunctional joint or increase range of motion.
Soft tissue techniques	The physician kneads, stretches, or applies inhibitory pressure to relax the soft tissues. ⁷⁵
Functional techniques	The physician monitors the soft tissues while small motions are applied to the joint to decrease resistance. These techniques often use the patient's breathing to cause the restriction in the joint to "release."
Strain-counterstrain	These techniques involve palpating tender points, and utilizing various body positions to take away the palpatory pain of these points. This position is held until the restriction releases (approximately 90 seconds). ⁷⁶
Myofascial release	In these techniques, the joint or tissue is taken to the position of most comfort. It is then held until the physician palpates a tissue tension release.
Facilitated positional release	In these techniques, the joint or tissue is taken to the position of most comfort. Traction or compression is applied to facilitate an immediate release of the tissue tension.
Still technique	This technique, thought to be developed by osteopathy's founder Dr. A.T. Still, is set up like facilitated positional release, but after traction or compression is applied, the joint is moved into the joint's restriction and is then returned to neutral. The goal is increased range of motion and restored joint function.
Cranial OMT	This gentle, manual technique emphasizes balancing of the primary respiratory mechanism, as well as the tensions of the cranial bones, dura, and overlying tissues. ^{162,163}
Lymphatic techniques	Gentle techniques aimed at promoting the movement of the lymphatic fluid are used to promote healing of several conditions.

Data from Chila AG, executive ed. *Foundations of osteopathic medicine*. 3rd ed. Baltimore, MD, 2011, Lippincott Williams & Wilkins, pp 513-527.

Moreover, participants of a 9-week weekly Iyengar yoga sessions appeared to have more body awareness, manifested as improved coping,

decreased pain, and increased sense of control over and acceptance of pain.²⁴ In a randomized controlled trial studying the same population, yoga was more effective than a home exercise program in several measures, including improvement in neck pain severity and related disability and life quality.²⁵

Cervical Support

Early mobilization was found to be superior to cervical collar use in the treatment of neck pain.²⁶ In another study of patients with an acute cervical radiculopathy, a semi-hard cervical collar combined with rest was comparable to physical therapy and superior to watchful waiting.²⁷ One small randomized controlled trial from Sweden found that cervical pillows could be useful for both neck pain and poor sleep.²⁸ Proper neck positioning during sleep is important. Prolonged flexion of the neck should be avoided; maintenance of the neck's natural lordotic curve is preferable. Cervical spine pillows may be useful. Evidence on whether traction is beneficial is insufficient.²⁹

Repetitive Strain

Certain movements and activities can put the musculoskeletal structures of the neck under chronic stress and tension. Examples are holding a phone between the shoulder and the ear (administrative work), carrying a heavy purse or backpack on one shoulder, staring at a computer monitor for long periods of time, and looking over the shoulder (farming, mechanical work). Bifocals may lead to awkward flexion of the neck as well. The effects of such postures should be brought to patients' attention. Many people "carry their stress" in their neck and shoulder muscles. Chronic stress can result in a constant readiness to duck or to dodge danger, and many people chronically tense the muscles used for these actions without realizing it.

Nutrition

Increase Essential Fatty Acids

Increasing intake of omega-3 fatty acids and reducing consumption of omega-6 fatty acids lower the levels of prostaglandins and leukotrienes that cause inflammation and can worsen pain^{30,31} (see [Chapter 88](#)). Several months may pass before patients derive a benefit from using an

antiinflammatory diet, and diet changes are most likely to be beneficial when neck pain has been chronic.

Increase Antioxidants

Elevations of serum free radicals can occur as a result of poor nutrition, excessive stress, and toxic environmental exposure. Foods rich in antioxidants, such as fruits and vegetables, seem to play a role in reducing pain by removing free radicals.³² Eating a combination of green, yellow, red, purple, and orange produce will guarantee that numerous beneficial antioxidants are consumed. High doses of supplemental antioxidants, such as vitamin E, have been the subject of some controversy and may be inadvisable in patients with heart disease or other chronic conditions.³³

Decrease Saturated Fats

Eating saturated fats, which come primarily from animal products such as red meat and dairy foods, can also contribute to inflammation and pain.³⁴ A transition to a vegetarian diet, or at least toward a significant reduction in saturated fat consumption, is worth recommending. Some patients may benefit from a trial of an elimination diet, specifically avoiding dairy and meat products (see [Chapter 86](#)).

Take care not to underestimate the impact of mental health on the course of neck pain. Encourage the use of at least one of the many mind-body therapies that may offer benefit.

Mind-Body Therapy

Pain perception does not necessarily correlate with the severity of an injury. Some people with structural neck abnormalities develop chronic pain, whereas others do not. Numerous landmark studies have shown magnetic resonance imaging (MRI) examinations of *asymptomatic* individuals indicating that up to 52% had one or more bulging disks, and the number went up to 80% in subjects aged more than 60.³⁵ Similarly, nearly everyone who is older than 70 years has some degree of cervical spondylosis, but not everyone in that age group has neck pain.² Pain is often centrally mediated, with abnormal intensification of sensation noted in the portions of the brain that govern a chronically painful part

of the body.¹⁰ Fortunately, the brain's plasticity allows for the possibility for "rewiring" the brain; sensory processing may be changed to someone's advantage. The key is to discern how to help someone with pain make that happen, and this is where mind-body approaches can come into play.³⁶

Emotions and Neck Pain

Emotional well-being plays an important role in whether pain arises.³⁷ A Stanford University study that evaluated both symptomatic and asymptomatic patients with abnormal MRI findings concluded that the severity of the MRI lesions did not predict the presence of pain; rather, pain severity correlated with whether patients had underlying psychological issues.³⁸ Pain is more likely to become chronic in people who tend to catastrophize,³⁹ or somaticize,⁴⁰ or feel a lack of control in decision making.⁴¹ Stress also plays a role. A British study of 12,907 people concluded that the association between perceived neck pain and mental stress was much stronger than the association between neck pain and repetitive occupational activities.⁴²

In his book, *The Mindbody Prescription: Healing the Body, Healing the Pain*, John E. Sarno, MD, suggested that unexpressed emotions are responsible for neck, back, and limb pain in most patients.⁴³ Sarno held that unexpressed anger, accumulated as a result of internal and external pressures, is of particular significance. After physical concerns have been appropriately ruled out, the following elements can be used to help people markedly decrease pain:

- *Learn about pain and its relationship to one's feelings.* Patients attend a series of lectures describing the relationship between pain and emotions.
- *Focus on emotions when pain strikes.* When patients become aware of the pain, they practice consciously shifting their focus toward the psychological, as opposed to physical, causes of their discomfort.
- *Maintain physical activity.* Patients must overcome fears that physical activity will worsen the underlying condition. This step is implemented after the pain has been decreased through exploration of emotional issues.
- *Discontinue physical or physiological treatments.* Sarno contended that focusing on physical causes of pain distracts the mind from the unexpressed emotions that are the pain's true cause. Medications are used sparingly for episodes of severe pain only.
- *Consider counseling.* Patients are encouraged to seek help from a

counselor in moving through the various emotional issues they encounter during the program.

Although outcomes research on the efficacy of Sarno's program is limited, the program has proved helpful for many people with chronic neck pain. Once potentially dangerous causes of pain have been ruled out, the risk of harm from participating in such a program is minimal. Many health care institutions offer pain management and coping groups, which may be similarly helpful (see [Chapter 102](#)).

Journaling

By writing about stressful events, patients may be able to reduce pain and inflammation. One study found that symptoms of asthma and rheumatoid arthritis improved significantly in people who wrote about stressful life events in a journal for just 20 minutes for 3 consecutive days.⁴⁴ To assume that other disorders may also respond to this approach is reasonable (see [Chapter 98](#)).

Hypnosis

Hypnosis has been found to be useful in helping patients manage chronic pain.^{45,46} In one study, 25 patients with head and neck pain were treated with acupuncture. After a washout period, they were treated with hypnosis. Both interventions were found to be helpful, but hypnosis scored slightly better, with an average reduction of 4.8 points on a 10-point symptom scale, compared with 4.2 points for acupuncture. Acupuncture was more appropriate for acute pain, whereas hypnosis appeared to work better for psychogenic pain. Subjects who also received healing suggestions through audiotape experienced less pain than those who did not⁴⁷ (see [Chapter 95](#)).

Interactive Guided Imagery

Interactive guided imagery (IGI) is based on the philosophy that insight and knowledge gained from the creation of internal images can be used to improve symptoms. One interactive guided imagery technique is to have a patient visualize an image representing a particular symptom. The patient is asked to have a dialogue with the image that arises and to explore why it is present and what it would "need" for healing to occur. The image can serve as a means by which the conscious mind can access the subconscious⁴⁸ (see [Chapter 97](#)).

Phillips found that that 78% of chronic pain patients reported an

emotionally charged “index image.” Recalling this image increased negative emotional response and pain levels.⁴⁹ Also, catastrophizing was found to be a predictor of higher future pain levels in patients who suffered from whiplash associated disorder.⁵⁰ Although further research is necessary, this may have important implications for techniques that help rewrite the image, such as IGI, hypnosis, neurolinguistic programming, motivational interviewing, and cognitive behavioral therapy.⁴⁹

Relaxation Exercises

Relaxation exercises, such as breathing techniques and progressive muscle relaxation, can reduce sympathetic stimulation, a potential contributor to muscle tension and pain. One study comparing relaxation, exercise, and ordinary activity for neck pain treatment did not find a benefit from either intervention in comparison with placebo.⁵¹ Nevertheless, perhaps these techniques can serve as a safe and potentially useful way to empower patients to decrease their neck pain (see [Chapter 94](#)). Autonomous sensory meridian response is an emerging relaxation modality in which heightened bodily sensations arise and are usually accompanied by a state of deep relaxation as well as temporary reduction in pain. More research is required.⁵²

Biofeedback

Biofeedback uses technology or instrumentation to help people gain awareness of and control over various body processes.⁵³ Functional MRI studies indicated that biofeedback training can allow people with pain to alter pain perception by controlling activation of the rostral anterior cingulate cortex and other brain locations.^{54,55} Severe chronic pain can be decreased. For example, sensors placed over the trapezius muscle can be used to train a patient to relax more efficiently. A small study of older patients with trapezius pain showed a 70% reduction in pain with biofeedback-assisted relaxation.⁵⁶ Another small pilot study found that a 10-week heart rate variability biofeedback training course for patients with chronic neck pain was correlated with improved perception of health.⁵⁷ Biofeedback is worth considering in patients with neck pain.

Bioenergetic Therapies

Acupuncture

The principle that energy flows through or over the surface of the body is common to several healing systems worldwide. Acupuncture, a 3000-year-old therapy based on the idea that the body contains multiple energy channels or meridians, maps out more than 350 major points. Needles are inserted at those points to improve the flow of energy (known in China as *qi*). Many of these points are located within or in close proximity to the neck.^{58,59}

Evaluations of acupuncture as a treatment for chronic neck pain show promise. A 2008 review by the Task Force on Neck Pain and Associated Disorders noted that acupuncture was superior to sham treatment, no treatment, and many other modalities for chronic neck pain.⁶⁰ A 2012 systematic review and meta-analysis by Furlan et al. had the following findings:⁶¹

- Acupuncture was better than no intervention for myofascial neck pain of unknown duration.
- Acupuncture was no better than sham acupuncture for posttreatment pain in individuals who had neck pain of both known and unknown etiology.
- Multiple studies compared acupuncture to pain medications for instant and short-term posttreatment pain relief and results were inconsistent. The same was true for acupuncture compared to manipulations. No difference in efficacy was found between acupuncture and mobilization or laser therapy for short-term neck pain relief after the treatment.

A 2015 systematic review and meta-analysis by Yuan and colleagues found moderate evidence in favor of acupuncture for treatment of chronic neck pain when compared to sham acupuncture. Pain was measured by visual analogue scale immediately after the treatment.¹⁶

Less evidence is available at this time to indicate whether acupuncture is useful for acute neck problems.⁶² Evidence regarding electroacupuncture and auricular acupuncture is also limited.¹⁶

Acupuncture has been found to be extremely safe when it is offered by a well-trained provider.⁶³

Other Energy Medicine Modalities

Many Eastern traditions hold that the neck houses the throat chakra, a wheel of energy that extends anterior and posterior to the body at the

level of the thyroid. Although therapies that purport to balance the human energy field, such as therapeutic touch and reiki, require further study, some interesting findings are beginning to emerge,^{64,65} especially regarding emotional responses to illness.

Authors of a 2014 review of nontouch human biofield modalities found that most of the evidence reviewed demonstrated a statistically significant improvement in at least one primary outcome. However, the preliminary nature and small size of the currently available trials warrants further investigation.⁶⁶ Harm is minimal, provided that patients do not defer potentially lifesaving biomedical therapies to focus on receiving energy medicine treatments. For more information about energetic therapies, see [Chapter 116](#).

Other Therapies

Practitioners are encouraged to look beyond the immediate sources of pain to see where the imbalance causing the pain originates. Awareness and appreciation of the body's fascial network, myofascial meridians, and the deep front lines (DFL) (myofascial connections that originate at the sole of the foot and extend all the way up to the prevertebral fascia, which attaches at the base of the occiput; psoas muscle is one of the many important muscles comprising DFL⁷⁶) may offer additional insight into the origins of neck pain.⁶⁷ These concepts can help illustrate how imbalances in lower parts of the body can contribute to neck discomfort.

Additionally, although currently there is no supporting evidence, the correlation between tight cervical myofascial structures and the function of the glands that are housed in the neck, specifically thyroid and parathyroid glands, may be a potential future subject worthy of investigation.

It is also important to mention the recent rise of interest in using therapeutic neurogenic tremors for various conditions including posttraumatic stress disorder and chronic pain, in a technique known as trauma and tension release exercise, or TRE, as described by Dr. David Berceli, Ph.D. in his book, *The Revolutionary Trauma Release Process. Transcend Your Toughest Times*.⁶⁸ Although the research is currently very limited, the subject definitely warrants further investigation given the low cost, ease of learning and utilizing the therapeutic tremor, and the potential to improve the patients' quality of life.⁶⁹

Manual Therapies

Manual medicine is another common approach to neck pain. Manual techniques are performed by various health professionals, including some osteopathic physicians, physical therapists, massage therapists, manual therapists, some specially trained occupational therapists, and chiropractors.⁷⁰ Spinal manipulation performed by chiropractors, in fact, is the most common complementary and alternative therapy provided in the United States.⁷¹

The nomenclature of biomechanical therapies can be confusing. Chiropractic and physical therapy manual techniques are typically broken into two groups. Manipulation refers to a technique that uses a high-velocity, low-amplitude (HVLA) thrust.⁷²⁻⁷⁴ Mobilization refers to techniques that incorporate lower-velocity, passive movements to the joints.⁷² Osteopathic providers use the term manipulation to describe more than 100 different techniques including but not limited to HVLA.⁷⁴ Osteopathic manipulation is categorized into several groups of techniques, as outlined in [Table 68.1](#).⁷⁵⁻⁷⁷ In this chapter, manipulation refers to the term as defined by chiropractors and physical therapists, and osteopathic manipulative treatment (OMT) refers to manipulation as defined by the osteopathic profession.

Safety

The safety of manipulation of the cervical spine has been questioned in the past. Most of these potential risks occur because of the rapid thrust, and therefore the safety of high-velocity manipulation techniques has been studied much more than mobilization or non-HVLA techniques. Common transient effects of cervical manipulation include local pain, headache, tiredness (fatigue), and radiating pain.^{78,79} Transient effects occur in 30%–61% of patients, begin within 4 hours of spinal manipulation, and usually resolve within 24 hours.^{78,79}

BOX 68.3 Contraindications to Manipulation (High-Velocity Manipulation or HVLA Osteopathic Manipulative Treatment) of the Neck

- Aneurysm or other vertebral artery structural anomaly
- Bone tumor
- Carotid or vertebrobasilar disease
- History of pathological fractures
- Vertebral infection

- Acute vertebral fracture
- Ligament rupture and instability
- Metastatic carcinoma
- Osteopenia or osteoporosis
- Anticoagulation therapy
- Previous surgery involving neck joints
- Rheumatoid arthritis of the cervical spine
- Unstable odontoid peg

Data from references [82-89](#).

Substantive reversible risks of manipulation are much less common. Worsening disk disease can occur with manipulation, but it occurs in fewer than 1 in 3.7 million patients,⁷⁸ though this adverse effect is more common with manipulation of the low back than in cervical manipulation. Because of this risk, manipulation is relatively contraindicated in patients with signs or symptoms of disk herniation until this disorder has been ruled out radiographically.⁸⁰

The most concerning risks of cervical manipulation are those that are nonreversible. The most common of these is iatrogenic stroke, although vertebral artery dissection can also occur. These complications are quite rare, and in a review of injuries caused by manipulative therapy between 1925 and 1993, only 185 cases of serious injury were reported.⁸¹

As noted in [Box 68.3](#),⁸²⁻⁸⁵ however, few contraindications exist, and manipulation seems to be significantly safer than other modalities (including antiinflammatory medications) commonly used for musculoskeletal conditions.⁸⁶⁻⁸⁹ A study by Rubinstein et al.⁹⁰ showed that the “benefits of chiropractic care for neck pain seem to outweigh the potential risks,” and recent study by Ekhardt et al. showed no change in vertebral artery blood flow after high velocity thrust, in healthy subjects, when done by trained physical therapists.⁸⁹

Research in Manual Therapies for Neck Pain

Chiropractors and physical therapists have performed more manual therapy studies than other health professionals, and this is true when it comes to studies of neck pain as well.⁹¹ Whether study findings are generalizable from one type of therapy to another is difficult to know because of the differences in categorization of the various types of manual therapies, the difficulties in creating sham manipulation, and the use of osteopathic manual manipulation (in the United States) as

adjuvant therapy.⁹²

Chiropractic and Physical Therapy Studies

Neck pain is the second most common reason (behind low back problems) for a patient to visit a chiropractor. Approximately 24% of visits to a chiropractor are for neck pain.⁹³ Chronic neck pain has been studied by chiropractors more than acute neck pain, and Gross et al. summarized the findings in multiple Cochrane Review meta-analyses. In these reviews, Gross et al. assessed whether manipulation or mobilization improved pain, function or disability, patient satisfaction, quality of life, and perceived effect in patients with neck pain (with or without headache or radicular symptoms). The 2004 meta-analysis of 33 trials showed that combined mobilization, manipulation, and exercise achieved clinically important improvements in pain, global perceived effect, and patient satisfaction in subacute and chronic neck disorders with or without headache.⁹⁴ A more recent review of 27 trials found only immediate- or short-term pain relief with a course of cervical manipulation or mobilization alone; however, a multimodal approach, including manipulation, seems to have the best long-term benefit.⁹⁵

Less literature is available on the use of manipulation and mobilization for acute neck pain.^{74,96} A small pilot study of 36 patients showed less pain intensity ($p < .05$) and a greater range of motion ($p < .05$) immediately following a single manipulation to patients with acute neck pain.⁹⁷

Some research showed that manipulation of the thoracic spine results in immediate improvement in neck pain,⁷² and a follow-up study showed that using thrust manipulation techniques in the thoracic spine resulted in greater short-term reductions in pain and disability than nonthrust mobilization in patients with neck pain. No additional side effects were noted in the thrust-treated group.⁹⁸ Previous studies had also shown significant improvements in patients with whiplash-associated disorders after thoracic mobilization was used.⁹⁹ Investigators proposed that techniques performed in the thoracic back may be an even safer option in patients with neck pain. However, further research must be done to assess long-term effects and to determine whether thoracic manipulation is most beneficial in isolation or in combination with some form of neck manipulation for the treatment of neck pain.⁷²

Osteopathy

There are few studies available in the osteopathic literature to assess the effects of OMT on patients with chronic neck pain. In one study, 17 patients with chronic neck pain were recruited. These patients were treated with OMT for a total of 4 weeks (twice weekly for 2 weeks and once weekly for the final 2 weeks). They were analyzed before treatment, at 2 weeks, and at 4 weeks for changes in pain and disability. Significant improvements were found in pain ($p < .001$) and disability ($p < .001$) over the treatment course in the group receiving OMT. Improvements in pain and disability were found to be significant in patients with chronic pain and in those with subchronic pain. Further follow-up was not done.¹⁰⁰

In a second, slightly larger study, 41 patients with nonspecific neck pain were divided into two groups. One group of 17 patients received ultrasound therapy only (every week for an average of 10 weeks), whereas a second group received ultrasound (every week for an average of 10 weeks) and OMT (every other week for an average of 10 weeks). Pain was measured at each of the treatments, 1 week after the treatments, and 3 months after the last treatment. The OMT used a combination of various techniques. Pain intensity decreased in both groups, with more improvement noted in the group receiving OMT ($p = .02$). No long-term follow-up was done.¹⁰¹

FIG. 68.1 Hand positions for suboccipital release. See [Box 68.4](#) for explanation of technique. (From Chaitow L. *Cranial manipulation theory and practice: osseous and soft tissue approaches*, New York, 1999, Churchill Livingstone, 119.)

Another study looked at OMT in patients with acute neck pain, in which 58 patients were randomized to receive either OMT (HVLA, muscle energy, and soft tissue techniques) or 30 mg intramuscular ketorolac (a known effective nonsteroidal antiinflammatory drug for musculoskeletal pain). Both groups showed a significant reduction in pain intensity ($p < .01$ for both groups), but patients receiving OMT reported a significantly greater decrease in pain intensity ($p = .02$).⁷⁴

A systematic review done in 2015 found OMT to be an effective treatment for chronic, nonspecific neck pain, in spite of the small sample sizes in the reviewed studies.¹⁰²

Gua Sha

A traditionally East Asian technique called gua sha, which involves the use of a smooth-edged spoon or other object to rub over the skin, resulting in petechial rash, has also been studied in relation to its efficacy for treatment of neck pain. One small RCT showed that a single gua sha treatment offered significantly more pain relief and functional improvement (95% confidence interval -43.3; -16.6 mm on visual analogue scale; $p < .001$) after 1 week than localized heating pad therapy.¹⁰³

In summary, the available literature indicates that manual therapies hold promise and are worth considering in the management of neck pain.

Strain-Counterstrain and the Suboccipital Release

Two techniques that the primary care provider can incorporate into his or her practice for the manual therapy of neck pain are strain-counterstrain and the suboccipital release ([Fig. 68.1](#) and [Box 68.4](#)). Strain-counterstrain is helpful for relieving trigger points and muscle spasms (see [Chapter 109](#)). The suboccipital cranial base release is beneficial for patients with suboccipital neuralgia and tension headaches. For challenging cases, appropriate referral is indicated. See [Table 68.1](#) for a detailed list of commonly used osteopathic techniques.

BOX 68.4 Suboccipital Release

The suboccipital release (also known as the cranial base release) is a manual soft tissue technique that can be incorporated into your daily practice. It is most useful for patients with cervical myofascial tension that has led to suboccipital neuralgia and headache. If you find it helpful, consider referring the patient to a cranial osteopathic practitioner.

The suboccipital release loosens soft tissues that attach to the base of the cranium. If hypertrophic and inflamed, these tissues can restrict cervical and cranial range of motion and cause pain.

- See [Fig. 68.1](#). The patient is supine on the table. Seat yourself at the head of the table with your arms resting on and supported by it.
- Rest the backs of your hands on the table. The pads of your fingertips, which are bent toward the patient's posterior neck, are positioned at

the base of the occiput in the suboccipital sulcus.

- Your fingertips serve as a fulcrum for the patient's occiput. The patient should allow the full weight of the head to rest in your hands. The resultant pressure will induce tissue release in the suboccipital space, under your fingertips.
- As relaxation proceeds and your fingers sink deeper into the soft tissues, apply gentle cephalic traction with your fingertips for a few minutes. This movement allows the arch of the atlas to disengage from the occiput. This portion of the technique is also known as an occipitoatlantal decompression. Cephalic traction should be started only after you are a few minutes into the technique, to allow for initial relaxation.
- This "release" of deep structures of the upper neck reduces tension, improves drainage of the sinuses, lymphatic and venous structures of the head and neck, increases circulation to the head, and helps reduce intracranial congestion.

Data from Chila AG, executive ed. *Foundations of osteopathic medicine*. 3rd ed. Baltimore, MD, 2011, Lippincott Williams & Wilkins, pp 513-527; and from Chaitow L. *Cranial manipulation therapy and practice: osseous and soft tissue approaches*. New York, 1999, Churchill Livingstone, pp 113-114.

Injections

1. Trigger point injections (TPIs): Although definitive evidence is lacking, some studies suggest that TPIs may help with the neck and shoulder pain regardless of medication injected. They can also be used as an adjunct therapy.¹⁰⁴ It is important to be aware of diagnostic criteria for trigger points and the less invasive strategies of treating them, such as stretching and massage.¹⁰⁵ Needling may be an important part of the TPI's therapeutic effect.¹⁰⁴ Providing ischemic compression to the trigger points postinjection for at least 30 seconds resulted in greater improvement in symptoms than with trigger points alone.¹⁰⁶
2. Botulinum toxin A: There is some favorable evidence for injection for treatment of musculoskeletal and myofascial neck pain.^{107,108} However, a 2011 systematic review did not find any evidence in favor of botulinum toxin A injections for chronic neck pain.¹⁰⁹ Larger, higher quality studies are necessary.¹¹⁰
3. Regenerative medicine: A growing field of medicine. There is currently no strong evidence to support the use of prolotherapy or platelet rich

plasma injections for patients with neck pain in the literature, but that may change with time. Please see the [Chapter 112](#) for an in-depth discussion.

4. Epidural steroid injections (ESIs): If noninvasive measures fail to relieve neck pain and improve daily function, ESIs may be considered in carefully selected candidates. There is good evidence that interlaminar ESIs may be helpful for patients with chronic neck and arm pain stemming from cervical disk herniation. Evidence is not as strong for diskogenic, axial, spinal stenosis, or postsurgical pain.¹¹¹ A 2015 systematic review by Manchikanti revealed positive evidence in favor of interlaminar ESIs for all of the neck pain etiologies listed previously.¹¹² Patients need to be aware of significant potential risks of ESIs.¹¹³

5. Facet joint injections: There is limited evidence, but fair evidence for medial branch blocks or radiofrequency neurotomy for patients with chronic neck pain.¹¹⁴

Surgery

Considering surgery, such as cervical fusion, is reasonable when patients have symptoms of radiculopathy, progressive myelopathy, neurological deficits that do not improve with other forms of treatment, or imaging-confirmed operable conditions.¹¹⁵ However, according to a 2010 Cochrane Review, the evidence supporting the use of surgery for chronic neck pain, resulting from degeneration radiculopathy, is not conclusive.¹¹⁶ The review found no benefit at 1 year postoperatively for patients with mild symptoms preoperatively, and the reviewers noted that additional research is required to confirm when surgery is most appropriate.

A 2015 meta-analysis by Wu found that in appropriate surgical candidates cervical disk arthroplasty yielded better outcomes compared to fusion in multiple parameters, including but not limited to neck disability index, visual analogue scale of neck and arm pain, and physical quality of life measures.¹¹⁷

Pharmaceuticals

Western medical therapy goes to great lengths to suppress inflammation and nociception. Steroids, cyclooxygenase-2 inhibitors, NSAIDs, and other medications are effective largely because they interfere with the inflammatory cascade. Muscle relaxants, opioids, and antidepressants are

used to alter nervous system signaling at various levels.

[Table 68.2](#) lists medications commonly used in the treatment of neck pain, along with recommended doses and precautions regarding their use.^{118-121,121a} In addition to the medications listed in the table, second-line medications such as antiepileptics (gabapentin,¹²² pregabalin),^{123,124} selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs) (duloxetine), and topical medications (lidocaine, diclofenac, magnesium, capsaicin,¹²⁵ compounded topicals, and essential oils) may also be considered separately or as adjunct treatments, although the overall evidence for the use of most of these remedies specifically for neck pain is limited.¹²⁴ Intravenous lidocaine infusion therapy may provide hours to weeks of relief and may also be considered for treatment of chronic pain refractory to more conservative measures, but more research is needed and no studies have yet looked at the neck pain population specifically.¹²⁶ Screening electrocardiogram is required.

Clinicians must also be vigilant about possible drug interactions with use of multiple agents (e.g., when combining opioids and SNRIs).¹²⁷

A 2007 Cochrane Review concluded that, for mechanical neck disorders, “Muscle relaxants, analgesics, and NSAIDs had limited evidence and unclear benefits.”¹²⁸

Between 1997 and 2004, the use of opioids for treating spinal disorders increased by 108%, but pain, poor quality of life, and percentages of disability claims did not show improvement.¹²⁰ Long-term narcotic administration downregulates endorphin receptors, which are partially responsible for the pain relief conferred by mind-body therapies such as hypnosis and guided imagery. In other words, long-term narcotic use can impede the symptomatic relief that comes from these therapies.

Use of inhaled or ingested cannabinoids for painful conditions is a highly controversial topic, is associated with significant side effects, and has not been investigated specifically in the neck pain population.¹²⁹

Pharmaceuticals should be considered only as stopgap approaches, to be used on a short-term basis as the root causes of pain are being sought. Research on long-term opioid use is becoming less supportive of chronic pain medication use.

TABLE 68.2

Pharmaceuticals Commonly Used to Treat Neck Pain

Medication	Example(s) and Dosage	Comments/Precautions
Tricyclic antidepressants (TCAs)	Amitriptyline: 10–25 mg at bedtime, titrated up by 10–25 mg every 3–7 days as tolerated to a maximum of 150 mg/day. Nortriptyline: 10–25 mg at bedtime, titrated up by 10–25 mg every 3–7 days as tolerated to a maximum of 150 mg/day.	<ul style="list-style-type: none"> - Modulation of ascending and descending pathways - Can give for 2–4 wk for pain reduction - Decrease dose if excess sedation or anticholinergic effects - Sedating - Consider checking serum levels if high doses used for long periods - Taper dose when stopping therapy
Muscle relaxants	Cyclobenzaprine: 5–10 mg at bedtime at three times/day	<ul style="list-style-type: none"> - Anticholinergic side effects - May cause anxiety and restlessness - Do not give with TCAs - More effective than placebo in back and neck pain¹⁰⁸
	Tizanidine: 2 mg every 4–6 h as needed up to 3 times daily, titrated by 2–4 mg per day every 1–4 days; give consistently with food or on empty stomach, up to 36 mg/day.	<ul style="list-style-type: none"> - Alpha 2 agonist - Centrally acting muscle relaxant - Sedating - Dry mouth - Hypotension - Effective compared to placebo in the patients with acute neck pain¹⁰⁹ - Taper dose when stopping therapy¹¹⁰
Other muscle relaxants	Baclofen, diazepam, carisoprodol, flunitrazepam, methocarbamol, metaxalone (Skeletal)	<ul style="list-style-type: none"> - Data is inconclusive or limited for musculoskeletal conditions¹¹⁰ - Carisoprodol has a high abuse potential¹¹¹
Nonsteroidal antiinflammatory drugs (NSAIDs)	Ibuprofen: 200–800 mg with food up to every 6 h to a maximum dose of 3200 mg Naproxen: Typically no more than 1000 mg per day in divided doses. Contraindicated in the setting of coronary artery bypass graft (CABG) surgery. Many other NSAIDs available.	<ul style="list-style-type: none"> - Can cause gastrointestinal bleeding, anticoagulation - No one NSAID known to be better than others.¹¹² Black box warning includes increased risk of serious cardiovascular thrombotic effects, risk of myopericardial infarction and stroke, and serious gastrointestinal bleeding, ulceration, and perforation
Acetaminophen	325–650 mg every 4–6 h as needed to a maximum of 3000 mg/day	<ul style="list-style-type: none"> - Use caution in liver disease - Compatible to NSAIDs for arthritis pain
Opioids	Hydrocodone 5 mg/acetaminophen 325 mg (other doses available): one to two tablets every 4–6 h as needed Aristonapine 500 mg/loxidine 50 mg: one to two tablets every 4–6 hours as needed	<ul style="list-style-type: none"> - Best to use short-term only - Significant addictive potential - Constipation common - Use caution with alcohol or sedatives - No clear benefits long term for quality of life, pain level, or disability¹¹³
Topical agents	Lidocaine patches or gel, diclofenac gel (NSAID class), OTC capsaicin, OTC essential oils—apply to the painful area, follow manufacturer's directions with regard to duration of use.	<ul style="list-style-type: none"> - Local and at large reactions may occur

Supplements

Omega-3 Fatty Acids

Ideally, as with any nutrients, essential fatty acids should be obtained through a healthy and varied diet, but this often proves difficult. Not many foods contain omega-3 fats in large amounts. Fish oil supplements decrease inflammation for many conditions, and although studies of its use specifically for neck pain are few, a reasonable approach is to give these supplements a try (see [Chapter 88](#)).

Dosage

The dose is 1–8 g fish oil daily, as tolerated.¹³⁰

Precautions

Doses of more than 3 g of fish oil a day may have an anticoagulant effect and should be used with caution in patients who are prone to bleeding disorders or who are taking anticoagulant or antiplatelet medications.¹³⁰

Phytoantiinflammatory Agents

Few studies have focused specifically on the role of herbal remedies in treating musculoskeletal neck pain. However, several trials have evaluated the overall antiinflammatory properties of herbal remedies and the use of these remedies for pain in general, [10,62,131](#) as well as for conditions such as osteoarthritis, [132,133](#) rheumatoid arthritis, [132](#) and low back pain. [133](#) Overall, these supplements are quite safe and well tolerated. Most of them work by altering levels of one or more compounds involved in the inflammatory cascade, including cyclooxygenase-2, lipoxygenase, nitric oxide, tumor necrosis factor-alpha, interleukin-1 and interleukin-6, and prostaglandin E₂. [130](#) For mild to moderate chronic pain, phytoantiinflammatory agents are worth considering, with the intent of decreasing pharmaceutical use and reducing the risk of adverse effects. As with conventional medications, these agents would ideally be used only in the short term while other approaches are used to reveal the root of the neck pain. [Table 68.3](#) lists some of the most commonly used phytoantiinflammatory agents, their dosage, evidence of their efficacy, and precautions related to their use. [62,125-150](#)

TABLE 68.3

Herbal Antiinflammatory Agents^a (Please refer to [Chapter 65](#) as well)

Botanical and Dose	Efficacy Evidence	Precautions
Avocado (<i>Persea americana</i>)/Soy isoprenylfate ^b 95, 96 300-600 mg/day	Decreased NSAID intake in people with knee and hip OA. Structural collagen growth. A 2014 Cochrane Review found a small improvement in OA symptoms and function. ¹³⁸	Seems to take 2 mo to reach full effect, and effects linger for 2 mo after patients stop taking them. Do not use in people with banana or chestnut allergies.
Harvestis TM 94, 95 (Elaeagnus argentea, Indian frankincense) Extract: 500 or 333 mg three times/day	Rated as possibly effective for osteoarthritis by Natural Standard, a producer of good-quality, evidence-based monographs. Conflicting research regarding efficacy for OA. A small 2014 study found benefit for pain threshold and tolerance. ¹³¹ Patients who were treated for 90 days with 100 mg of <i>Elaeagnus argentea</i> had a significant improvement in OA symptoms. ⁹⁵	No evidence of harm from any preparation. Rare GI effects.
Gal's claw ^{104,105,107-109} (<i>Chamaecrista nictitans</i> or <i>C. nictitans</i>) Densely branched. Most common in United States (along with yellow root). Capsules: 300-390 mg once or twice/day. Tincture: 1-2 mL, two or three times/day. Freeze-dried aqueous extract: 180 mg/day. Glycolic alcohol/dilute extract: 20 mg three times/day.	Rated as possibly effective for OA by Natural Standard. Freeze-dried extract decreased knee pain with activity in OA. Modest improvement with some trials in OA. Decreased need for drugs in OA. May also have anti-osteoporosis and immune-enhancing properties.	Studies have not shown harmful effects. May lower blood pressure. May inhibit CYP 3A4. May interfere with immunosuppressants. May work better if soluble alkaloids removed. May increase bleeding risk. Avoid in pregnancy. Not for children younger than 3 yrs.
Devil's claw ^{104,105,107-109,110,111} (<i>Harpagophytum procumbens</i>) Dried root: 1500-2400 mg in aqueous solution three times/day. Tincture: 0.2-1.0 mL (1:5) in 25% alcohol three times/day.	Rated by Natural Standard as having "good" level of scientific evidence for therapeutic use. Effective for back pain and osteoarthritis. A small observational study found pain relief in OA patients who took combination product containing Devil's claw, turmeric, and bromelain. ¹³¹	Rated as safer than analgesic medications; side effects rare. May raise GI tract acid levels; avoid in duodenal ulcer disease. May lower blood glucose and increase bleeding risk.

Table Continued

Botanical and Dose	Efficacy Evidence	Precautions
Glucosamine (<i>Glucosamine hydrochloride</i>) Powdered root: 500 mg; 1 g twice or three times/day Tablets (1 g/3 mL): 1.25–5 mL, three times/day	Rated as possibly effective for OA by Natural Standard A 2015 meta-analysis found reduction in OA pain and disability compared to placebo. ¹³⁸	Occasional mild GI effects Whole root consumption may increase stomach acid; theoretical increase in anticoagulation (no evidence in humans)
Physalis (<i>Physalis peruviana</i>) Mixture of roots (<i>Physalis peruviana</i>), common ash (<i>Persea menziesii</i>), and goldenseal (<i>Hydrastis virginica</i>) Tincture: 20–40 drops three times daily in a beverage; tablets for 2–4 wk to reach full therapeutic benefit	Risk in salicylates Studies of more than 180 subjects showed reduced drug dosing in rheumatological disease Improved gait in OA Compatible to celecoxib in one OA study A 2011 meta-analysis and more analysis concluded that Physalis was better than placebo for pain in musculoskeletal disorders and was as effective as NSAIDs. ¹³⁹	No adverse effects noted in trials Theoretical side effects similar to aspirin; avoid in patients with salicylate allergy No drug interactions known Should be avoided in pregnancy
Black hore (<i>Heracaria cicutaria subsp. nov.</i>) ¹⁴⁰ Standard powder or tincture 5 g/day	Rated as possibly effective for OA by Natural Standard	No contraindications
Thorned rose (<i>Rosa rugosa</i>) Black: 1.5–3 g/day, divided into several doses (can be made into tea; one heaping teaspoon is 4 g)	Rated as possibly effective for OA by Natural Standard Many mechanisms of action, including alteration of arachidonic acid metabolism Improved swelling, stiffness and walking time in RA Improved OA pain and disability but not other clinical parameters May lower LDL and raise HDL	Generally recognized as safe in doses of 2 g/day or less Can be taken in place of an NSAID Seems to protect stomach against NSAIDs
Willow bark (<i>Salix alba</i>) ¹⁴¹ Powdered bark: 1–3 g three to five times/day	Rated as possibly effective for back pain by Natural Standard Studies indicated benefit for neck pain Best evidence was for dose-dependent effect in 181 patients with back pain Anti-inflammatory effect was largely related to salicylate content	Theoretically, may have similar side effects to aspirin, but this has not been found Occasional nausea, rash, and ulcerating Caution with use in arthritic patients
Other herbal anti-inflammatory agents found possible effective by natural standard for OA or RA	Storage: sealed (RA) Staining: acidic (OA) Therapeutic value: <i>Zingiber officinale</i> (RA)	Please consult a reference for detailed side effect and safety profiles

CYP, cytochrome; GI, gastrointestinal; HDL, high-density lipoprotein; HIV, human immunodeficiency virus; LDL, low-density lipoprotein; NSAIDs, nonsteroidal antiinflammatory drugs; OA, osteoarthritis; RA, rheumatoid arthritis.

Evidence regarding the use supplements containing gamma-linolenic acid (GLA), such as evening primrose oil, black currant seed oil, and borage seed oil, for pain has been less convincing. Of the three, borage oil has the highest GLA content and should be tried first at a dose of 500–1000 mg twice/day.¹³⁰ Other promising supplements include stinging nettle, green-lipped mussel extract, *Geranium robertianum*, *Tripterygium wilfordii* (Hook F), and green tea.^{130,131}

^a Efficacy data are based primarily on studies of symptom control in RA, OA, or back pain. No studies focusing specifically on the treatment of neck pain were found.

Aromatherapy/Essential Oils

New and favorable evidence is emerging regarding the use of essential oils and aromatherapy for neck pain specifically (using a blend of peppermint, black pepper, marjoram, and lavender)¹⁵⁶ as well as other painful and nonpainful conditions. This holds true especially in the populations that are at high risk for side effects with pharmaceutical or invasive interventions such as the elderly.^{156–160}

Prevention Prescription

- Avoid tobacco and other substance use.
- Maintain a healthy body weight.
- Exercise regularly, and include exercises that strengthen the neck muscles.
- Ensure that the normal curve of the neck is maintained when sleeping.
- Take measures at work to minimize the risk of pain:

Avoid heavy lifting, or be sure to do it safely.

Try to cultivate a sense of control in the work environment, as neck pain is less likely when someone has higher job satisfaction.

- Pay close attention to posture.

Frequent backpack use can increase neck pain.

Make sure that posture is good when reading or using a computer.

Use a headset rather than holding a phone between the ear and shoulder.

- Eat a diet that will prevent or reduce inflammation.

Increase dietary intake of omega-3 fatty acids or supplement with fish oil or flaxseed oil.

Increase fruit and vegetable intake to 8–10 servings a day.

Avoid foods high in saturated fats.

- Maintain a healthy social support network.

- Decrease stress levels. Use stress-reduction techniques regularly, such as meditation, progressive muscle relaxation, journaling, and any others that prove helpful.

- Treat anxiety or depression, if they are present.

Therapeutic Review

Lifestyle Modifications Including Exercise

- Exercise should be encouraged to prevent and treat soft tissue neck

pain. 

- Postural therapies, such as Alexander technique, Feldenkrais, and Pilates therapy, can improve cervical muscle support. Iyengar yoga

may help. 

- Preserve the normal lordotic curve of the neck during sleep; cervical spine pillows may help. 

- Avoid repetitive strain (holding telephone on the shoulder, leaning over a desk, carrying heavy over-the-shoulder bags, looking over the shoulder). 

- Avoid smoking and use of tobacco products. 

- Work to maintain a sense of control in your work environment. 
- If your neck has been injured, avoid prolonged use of a cervical collar and instead work to regain full range of motion as early as possible.

Nutrition

- Increase intake of foods high in omega-3 fatty acids (cold-water fish, flaxseed products, nuts, green leafy vegetables). 
- Decrease intake of foods rich in omega-6 and trans-fatty acids (hydrogenated vegetable oils, margarine, processed foods). 
- Decrease saturated fat intake. 
- Eat foods rich in antioxidants, including a combination of colorful (green, yellow, red, purple, and orange) produce. 

Mind-Body Therapy

- Address underlying emotional issues that may be causing or exacerbating pain and spasm. 
- Reduce chronic stress and watch for indications of psychological causes of neck pain, such as depression and anxiety. 
- Journaling, self-hypnosis, biofeedback, and guided imagery are worth exploring, and hypnosis (with recorded guidance or when done by a trained therapist) may be more effective than acupuncture for neck pain. 

Bioenergetic Therapies

- Acupuncture is a well-studied, potentially beneficial, and safe adjunctive treatment if performed by a trained professional. 
- Therapeutic touch and other “hands-on” healing techniques are of potential benefit and quite safe. 

Biomechanical Therapies

- Consider manipulative therapies:

- A multimodal approach that includes manipulation and/or mobilization has good evidence of benefit, especially in patients with whiplash injury. 
- Be cautious with high-velocity, low-amplitude manipulation because it may have some sequelae. 
- Soft tissue manipulation and massage are other possibilities. 
- Suboccipital release and strain-counterstrain are useful techniques that can be easily performed in the office environment. 
- Invasive interventions (such as various injections or surgery) should be considered only in carefully selected patient populations, for example if there was no improvement with noninvasive options, or when there is a known nerve root or spinal cord disorder. 

Supplements

- Taking 1–8 g/day as tolerated of omega-3–rich oil capsules can help reduce inflammation. The risk of gastrointestinal upset and prolonged bleeding time increases with higher doses. 

Pharmaceuticals

- For chronic pain, if other approaches not effective, consider a tricyclic antidepressant (TCA), such as amitriptyline (10–25 mg at night, or a serotonin-specific reuptake inhibitor, such as fluoxetine (10–20 mg in the morning). Doses of these agents may be gradually increased as needed. 
- Consider prescribing a muscle relaxant for 2–3 weeks. Cyclobenzaprine (5–10 mg at bedtime) is a reasonable choice if the patient is not already taking a TCA. 
- Provide a nonsteroidal antiinflammatory drug, such as ibuprofen (200–800 mg every 6 hours) with food. 
- Consider the use of narcotics for severe pain on a short-term basis only: hydrocodone 5 mg/acetaminophen 325 mg tablets, one to two every 4–5 hours as needed. 

Botanicals

- Consider a phytoantiinflammatory agent to complement or replace pharmaceutical therapy (see [Table 68.3](#)). 

Aromatherapy

- Consider adding aromatherapy to your treatment plan.

CHAPTER 69

Gout

Fasih A. Hameed, MD, ABIHM

Pathogenesis and History

Gout is a painful deposition of uric acid crystals in the synovial tissues of the body. Acute attacks usually manifest as a painful monoarticular inflammatory arthritis, classically of the first metatarsophalangeal joint, although other joints as well as the kidneys may be affected. A polyarticular presentation is more common with increasing age and length of disease ([Fig. 69.1](#)).

Purines are ubiquitous in the body and in nature. As adenine and guanine, they form part of the “building blocks” of DNA and RNA. Uric acid is the product of purine metabolism by the enzyme xanthine oxidase. Uric acid is excreted primarily by the kidneys, but also excreted by the small bowel. The build up of uric acid crystals can result from overproduction, underexcretion, or a combination of the two. A 24-hour urine assay with >800 mg of uric acid supports the diagnosis of overproduction, whereas a value of <600 mg suggests underexcretion.¹

Due to the numerous diseases with a similar presentation, confirmation of the diagnosis should be made via aspiration of synovial fluid, examination of which will reveal needle-shaped monosodium urate crystals with negative birefringence. Care should be taken not to miss potentially devastating mimics, most notably septic arthritis.

Gout has been recognized since ancient times, with mentions by the Egyptians dating as early as 2640 BC. In the fifth century BC, Hippocrates referred to gout as “the unwalkable disease.” It has also been called “the disease of kings” due to the association with the intake of heavy foods and alcohol, apparently common in members of the ruling class. The name “gout” is derived from the Latin “gutta,” meaning “drop”—a reference to a drop of one of the four medieval “humors” once believed

to rule our health or lack thereof.²

New Clinical Significance

Though gout is often considered solely in terms of its presentation as an acute inflammatory arthritis, it is truly a systemic disease with significant associated metabolic comorbidities. Gout is linked to obesity, hypertension, dyslipidemia, insulin resistance, hyperglycemia, and coronary artery disease.³ Data from the National Health and Nutrition Examination Survey (NHANES III) demonstrated that metabolic syndrome was present in 62.8% of persons with gout but only 25.4% of those without gout.⁴ The Framingham study demonstrated an *independent* 60% increased risk of coronary artery disease in men with gout after controlling for other factors.⁵ The 12-year prospective Health Professionals Follow-up Study of 51,529 men showed those with gout had 55% increased risk of fatal myocardial infarction, 28% increased risk of *all-cause mortality*, and 38% increased risk of death from cardiovascular disease.⁶ These strong associations were independent of age, body mass index, smoking, family history, diabetes, hyperlipidemia, and hypertension. The implications of these data cannot be overstated. Gout is an independent risk factor for death from *all* causes.

One proposed mechanism of this relationship may involve a renal-mediated increase in blood pressure caused by hyperuricemia. In a rat model of gout, elevated uric acid caused increased blood pressure through activation of the renin-angiotensin system and inhibition of neuronal nitric oxide synthase. Blood pressure normalized with appropriate pharmacological management and reduction in uric acid levels. This causal relationship may warrant early administration of urate-lowering therapies in patients with gout and hypertension.⁷

Perhaps the most surprising development surrounding gout is the emerging data, which suggest it may be inversely associated with Alzheimer's disease.⁸ Further studies to clarify the potential neuroprotective role of elevated uric acid levels are needed.

FIG. 69.1 Radiographic forefoot abnormalities in tophaceous gout. Extensive bone destruction is seen at the great toe metatarsophalangeal joint with overhanging edges (*arrowhead*) and soft tissue swelling. Smaller erosions are present involving the first tarsometatarsal and second metatarsophalangeal joints (*arrows*). (From Firestein G: *Kelley's textbook of rheumatology*. 8th ed. Philadelphia, 2008, Saunders.)

Hyperuricemia can *cause* hypertension. Recent evidence supports early treatment of gout because elevated uric acid can be a risk factor for heart disease.

The association of gout with numerous metabolic diseases warrants aggressive lifestyle counseling and screening to prevent long-term morbidity ([Fig. 69.2](#)). All persons with gout should thus receive extensive education regarding the health implications of this disease. Comorbidities, once identified, should be promptly managed, and the patient should be made aware of the interconnectedness of his/her various diseases. These preventable diseases of “lifestyle” may result in significant health consequences even with prompt identification and treatment. It is therefore imperative that the patient be encouraged, through appropriate use of behavioral change models, such as appreciative inquiry and/or motivational interviewing, and empowered to make positive changes in his/her life.

Gout is a metabolic disease, which independently increases risk of all-cause and cardiovascular mortality. Like other metabolic diseases (e.g., diabetes), gout warrants aggressive lifestyle counseling and modification.

Integrative Therapy

Lifestyle

Understanding gout as a complex metabolic process, which independently increases the risk of all-cause mortality, underscores the need for a holistic lifestyle prescription as the primary treatment of gout

in all patients.

Weight Loss

Encourage weight loss and maintenance of a healthy body mass index. Adiposity is associated with hyperuricemia, whereas weight loss leads to reductions in gout incidence.⁹ Weight loss will also have the greatest benefit on mediating the numerous comorbidities associated with gout. All patients with gout should be encouraged to control weight through exercise and diet modification. Emphasis should be placed on the associated increased risk of cardiovascular and all-cause mortality in persons with gout.¹⁰

Nutrition

Decrease consumption of red meat and most seafood. Persons consuming higher amounts of beef, pork, and lamb have a 41% increased risk of gout. Those consuming higher amounts of seafood have a 51% increased risk of gout.¹¹ Given the potential cardiovascular benefits of omega-3 fatty acids found in oily fish, patients can be counseled and may consider moderate intake of small, sustainably caught, cold-water fish (e.g., sardines). The low purine diet is generally no longer recommended.

GOUT RISK AND A HEALTHY EATING PYRAMID

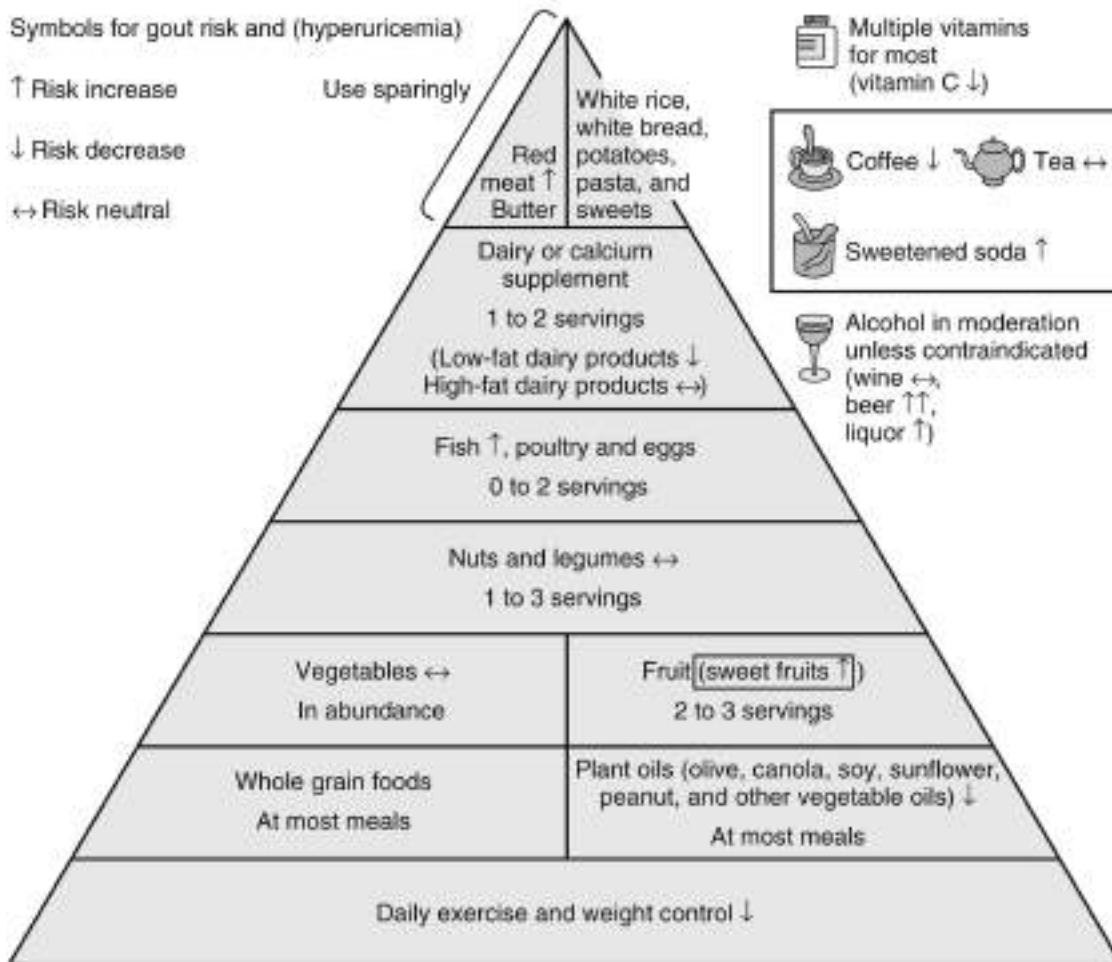

FIG. 69.2 Gout pyramid. (From Choi HK. A prescription for lifestyle change in patients with hyperuricemia and gout, *Curr Opin Rheumatol* 22:165-172, 2010.)

Increase intake of omega-3 fatty acids. Patients wishing to absolutely avoid the purines associated with fish should be encouraged to increase dietary intake of plant sources of omega-3s such as flax, purslane, walnuts, and leafy greens. Supplementation may also be encouraged (see the following section, Omega-3 Fatty Acids).

Increase intake of vegetables, legumes, nuts, and vegetable proteins. Purine-rich vegetables, which were once thought to contribute to gout, are now understood to have no impact on the incidence of gout.¹¹ Furthermore, increased intake of vegetable protein was actually associated with up to 27% lower incidence of gout.¹¹ Additionally, there are numerous cardiovascular and metabolic benefits associated with the aforementioned foods, which are particularly relevant given the negative

impact of gout on these conditions.

Due to new evidence, experts are no longer advocating the avoidance of purine-rich vegetables or an overall purine-restricted diet. Avoidance of animal meat seems to have a larger impact than purine intake.

Decrease intake of sugar-containing beverages and fructose. Sugar intake was independently associated with elevated uric acid levels in men.¹² Additionally, there is a direct relationship between intake of fructose-containing soft drinks and hyperuricemia as well as gout.^{13,14}

Diet soft drinks do not appear to affect uric acid levels, but their use should be discouraged due to an association with metabolic syndrome.¹⁵ Sweet fruits may increase uric acid levels, but the health benefits of these foods outweigh the associated risks, which can easily be countered through numerous other dietary modifications (i.e., less meat, alcohol, refined sugars).

Limit alcohol to no more than one to two drinks per day, and drink wine rather than beer or liquor. Alcohol intake has been positively correlated with gout. Beer has the strongest association—each 12-ounce beer consumed increases the risk of gout by 50% compared to non-beer-drinkers. Distilled spirits have a smaller but still significant association, whereas wine does not appear to be strongly associated with increased risk of gout.¹⁶ Numerous studies have demonstrated the health benefits of moderate alcohol consumption.¹⁷ Nonetheless, it is probably not advisable to recommend intake of alcohol to those currently abstinent. Persons wishing to imbibe should consider wine the healthiest option.

Increase intake of low-fat dairy, up to two servings per day. Low-fat dairy intake, specifically milk and yogurt, appears to have a protective effect on the incidence of gout.¹¹ Interestingly, a randomized controlled trial (RCT) of milk confirmed its urate-lowering effect.¹⁸ The mechanism is likely related to the milk proteins casein and lactalbumin.¹⁹ Low-fat dairy also has the advantage of protecting against metabolic syndrome.¹⁵

Drink water. Though there are no studies to quantify or confirm the effect, adequate hydration is often considered a mainstay of treatment and prevention. The rationale is that a dehydrated state will concentrate uric acid and lead to precipitation. Patients should be advised to drink a minimum of 48 ounces of water per day.²⁰

Consider coffee. Coffee appears to reduce uric acid levels by a

mechanism not linked to caffeine content.²¹ Modest intake of coffee may be considered as part of a therapeutic prevention program. Abrupt increases in consumption may trigger an acute gouty attack and should therefore be discouraged.

Alkalinize urine. A study of an acidic versus alkaline diet found a direct correlation between urine pH and uric acid excretion. This occurred despite the lower purine content of the acidic diet.²² Patients may therefore be encouraged to follow an alkalinizing diet, low in animal protein and rich in vegetables.

Supplements

Vitamin C and Bioflavonoids

Vitamin C supplementation was once thought to exacerbate gout. Recent data, however, have reversed that belief. Vitamin C most likely decreases serum uric acid levels through competitive binding of proximal tubule uric acid reuptake channels and may also increase uric acid clearance through a modest improvement in global glomerular filtration.²³ Recent studies show an inverse relationship between vitamin C intake and uric acid levels.²⁴ A double-blind RCT showed supplementation with 500 mg per day of vitamin C significantly lowered uric acid levels compared to placebo, although a later study had conflicting results.^{25,26} A 20-year, large prospective study in the *Annals of Internal Medicine* confirmed an inverse relationship between vitamin C intake and the incidence of gout, with as much as a 45% reduced incidence in those ingesting >1500 mg of vitamin C per day.²⁷

While it is probable that vitamin C can prevent and aid in the treatment of gout by reducing uric acid levels, there may be an additional benefit conferred by increasing intake of citrus foods and by taking supplements with the citrus bioflavonoid hesperidin. Hesperidin is found in citrus foods as well as plants from the family *Lamiaceae* (mint family), such as the common herb rosemary. An extract of rosemary demonstrated antinociceptive effects in an animal model of gout and hesperidin was identified as a chief contributor to this effect.²⁸

Dosage

It is recommended that all patients increase their intake of citrus foods.

Patients may also consider increasing intake of herbs from the family *Lamiaceae*, especially rosemary. Interested patients should also take 500 to 1500 mg of a high-quality vitamin C with citrus bioflavonoids including hesperidin.

Vitamin C is likely *protective* against gout, though supplementing may not have a dramatic effect on uric acid levels.

Eicosapentaenoic Acid and Gamma-Linolenic Acid

Though purine-rich seafood has been shown to increase uric acid levels and gout,¹¹ eicosapentaenoic acid (EPA), found in certain fatty fish, and gamma-linolenic acid (GLA) have been shown to suppress inflammation in monosodium urate-induced arthropathies such as gout.²⁹ EPA and GLA appear to work via complementary mechanisms. Besides decreasing the inflammation of acute gouty arthropathy, omega-3 fatty acids have also demonstrated cardiovascular benefits.³⁰ This is significant given the association of gout with cardiovascular mortality. In those wishing to avoid the purine intake associated with fish, supplementation with EPA and/or GLA may be encouraged. GLA is an omega-6 fatty acid found in evening primrose oil, borage oil, and black currant seed oil.

Dosage

Though the ideal dosing has not been determined, consider supplementing with 500 mg of EPA and/or 3000 mg of evening primrose oil (GLA).

Cherry

Consumption of cherries and cherry juice should be encouraged. Studies indicate that intake of 280 g (two servings) of Bing sweet cherries lowers plasma urate levels and increases urine urate levels in healthy volunteers.³¹ There is also a trend toward decreased C-reactive protein and nitric oxide with cherry intake, which suggests that cherries may help inhibit inflammation. Indeed, a double-blind, placebo-controlled trial of cherry juice in long-distance runners showed that those who ingested cherry juice seven days before running reported less post-run pain than those who ingested placebo juice.³²

Dosage

Approximately half-pound of cherries or an equivalent amount of cherry juice consumed daily.

Quercetin

In addition to displaying antiinflammatory properties, the flavonoid quercetin inhibits xanthine oxidase.³³ Quercetin can also play a role in the treatment and prevention of cardiovascular diseases by reducing blood pressure and oxidized low-density lipoprotein.³⁴ Quercetin may thus be of some clinical use in patients with gout. No human clinical trials have been performed to date, though a study in animals showed a positive effect.³⁵

Dosage

Food sources of quercetin include onions, apples, berries, grapes, green and black tea, citrus fruits, capers, tomatoes, broccoli, and leafy greens. Encourage adequate intake of these foods. Consider supplementation with up to 500 mg twice daily.

Bromelain

Use of a proprietary bromelain-containing product was clinically equivalent to diclofenac in a double-blind RCT of patients with acute pain from osteoarthritis of the hip.³⁶ Similar benefits may be conferred to persons with gout, though no studies have yet been performed.

Dosage

Encourage daily consumption of pineapple, which is the source of bromelain. Alternatively, supplementation with 500 mg once or twice daily may be considered.

Botanicals

Hibiscus (*H. sabdariffa*)

Hibiscus calyx has mounting evidence demonstrating blood pressure lowering qualities, which are believed to be due to an ACE-inhibitor-like effect.³⁷ Hibiscus tea increased uric acid excretion and clearance in healthy volunteers but did not affect serum uric acid levels.³⁸

Dosage

Patients with gout and borderline hypertension may wish to try hibiscus 1.5-g calyx as tea taken two to three times daily. This can be purchased in the bulk herb section of most progressive grocery stores. Hibiscus tea is also readily available in Mexican grocery stores where it is known as “Jamaica.”

Physical Medicine

Acupuncture

Acupuncture alone appears to be an effective treatment for acute gouty attacks. A trial of acupuncture versus western treatment with allopurinol and indomethacin found acupuncture to be superior (93% vs. 80% effective, $p < .01$). The acupuncture group also had greater reductions in serum uric acid and fewer adverse effects.³⁹ This trial was limited due to its small size ($n = 60$) and use of allopurinol during acute attack—a practice which is generally not employed by Western physicians, but is not necessarily contraindicated. Nonetheless, the outcomes were impressive, and given the lack of significant side-effects, acupuncture can be recommended as a viable option for management of acute gouty attacks. Physicians trained in acupuncture may want to try the daily surround treatment, which is similar to the Tendinomuscular meridian treatment described by Dr. Joseph Helms.⁴⁰ Referral to a licensed practitioner of traditional Chinese medicine (TCM) may also be considered.

Ice

In contrast to most arthritides, application of ice to inflamed gouty joints causes significant pain relief. Though most arthritic conditions benefit from heat application, patients with gout prefer ice.⁴¹ Frequent use of

topical ice during painful attacks should be encouraged. This difference may also help distinguish gout from other inflammatory mimics (e.g., rheumatoid arthritis) and thus help aid in diagnosis.

Response to therapeutic application of ice may help distinguish gout from other inflammatory arthritides.

Rest

Patients will inevitably resist movement of a painful joint, and this should be allowed within reason until symptoms are resolving.

Traditional Chinese Medicine

There are numerous trials of TCM demonstrating clinical effectiveness. A small trial ($n = 67$) of blood-letting cupping plus Chinese herbs versus a control group of diclofenac found both treatments to be effective in improving acute gouty arthropathy.⁴²

The traditional Chinese herbal formulation “Simiao pill” or “Si Miao,” which is a combination of herbs commonly used in the treatment of gout, was clinically superior to Western medicine control in a randomized trial of three distinct formulations.⁴³ Simiao pill traditionally consists of a specific blend of the following individual herbs: *Phellodendron chinense*, *Atractylodes lancea*, *Achyranthes bidentata*, and *Coix lacryma-jobi*. This formulation of Simiao pill was also found to have in vivo uricosuric and nephroprotective effects in hyperuricemic rats.⁴⁴

Dosage

Based on specific formulation, generally between three and seven tablets taken three times daily.

Pharmaceuticals: Acute Treatment

Nonsteroidal Antiinflammatory Drugs

Despite the relative lack of high-quality large randomized control trials, nonsteroidal antiinflammatory drugs (NSAIDs) are considered the first-

line agents for an acute gouty episode. Indomethacin has historically been favored, but given the lack of data or rationale for its use, any high-dose regimen should suffice.⁴⁵

Dosage

Indomethacin 50 mg three times daily, naproxen 500 mg twice daily, or ibuprofen 600 mg three times daily as needed for 5–10 days.

Precautions

Standard NSAID precautions should be reviewed, and therapy should be tapered as soon as clinical improvement is noted. Aspirin should be avoided due to the potential uric acid raising effect of salicylates.

Colchicine

Alexander of Tralles, a sixth-century Byzantine physician, was the first to use *Colchicum autumnale* for the treatment of gout. Though this plant, autumn crocus, is no longer recommended due to significant toxicity, its active derivative colchicine is still widely used for acute gout attacks, though no head-to-head studies have been conducted to show it offers benefit over any other acute method of treatment. The older methods of hourly high-dose treatments and intravenous colchicine are no longer recommended due to risk of toxicity and unnecessary side effects as well as lack of significant benefit over oral dosing.

Dosage

Oral colchicine 1.2 mg followed by 0.6 mg 1 hour later (total dose 1.8 mg), initiated as soon as possible in gouty flair.⁴⁶ Some patients may wish to use daily colchicine 0.6 mg for suppression, though use of the other preventive methods should be preferentially encouraged as colchicine has no effect on uric acid.

Precautions

Do not use in cases of end-stage renal disease. Potentially severe drug–drug interactions do exist. Check specific interactions before prescribing.

Glucocorticoids

Oral, intravenous, or intraarticular steroids may be useful in cases where NSAIDs or colchicine are contraindicated.

Dosage

Oral prednisolone 35 mg was equivalent to twice-daily naproxen 500 mg in a double-blind RCT.⁴⁷ This dose can be tapered over 7–10 days as clinical improvement ensues. In monoarticular cases, intraarticular injection of 10–40 mg triamcinolone can be effective, although data is limited.⁴⁸ Intravenous glucocorticoids can be used in patients unable to take oral prednisone or in polyarticular crisis.

Precautions

Standard steroid precautions should be observed. Take oral steroids with food as early in the day as possible. If split doses are used, advise taking second dose with lunch rather than dinner to avoid insomnia.

Pharmaceuticals: Prevention

New guidelines were published by the European League Against Rheumatism (EULAR) in 2016. The EULAR guidelines suggest treating to a uric acid target of <5 for severe gout. Otherwise, the goal of treatment should be <6 ([Figure 69.3](#)). The American College of Physicians' gout guidelines do not recommend treating to uric acid levels, but simply treating to reduce recurrent flares.^{48a,48b}

ACE Inhibitors Versus Diuretics

Although diuretics have been blamed for precipitating many a gouty crisis, their negative effect is actually less than that of hypertension itself.⁴⁹ At low doses, thiazide diuretics have a relatively small effect on the serum uric acid levels and addition of an ACE inhibitor or ARB can offset this increase. That being said, the uric acid-lowering effects of ACE inhibitors may warrant consideration of these as first-line agents for hypertension in patients with gout.

2016 EULAR RECOMMENDATION FOR THE MANAGEMENT OF HYPERURICEMIA IN PATIENTS WITH GOUT

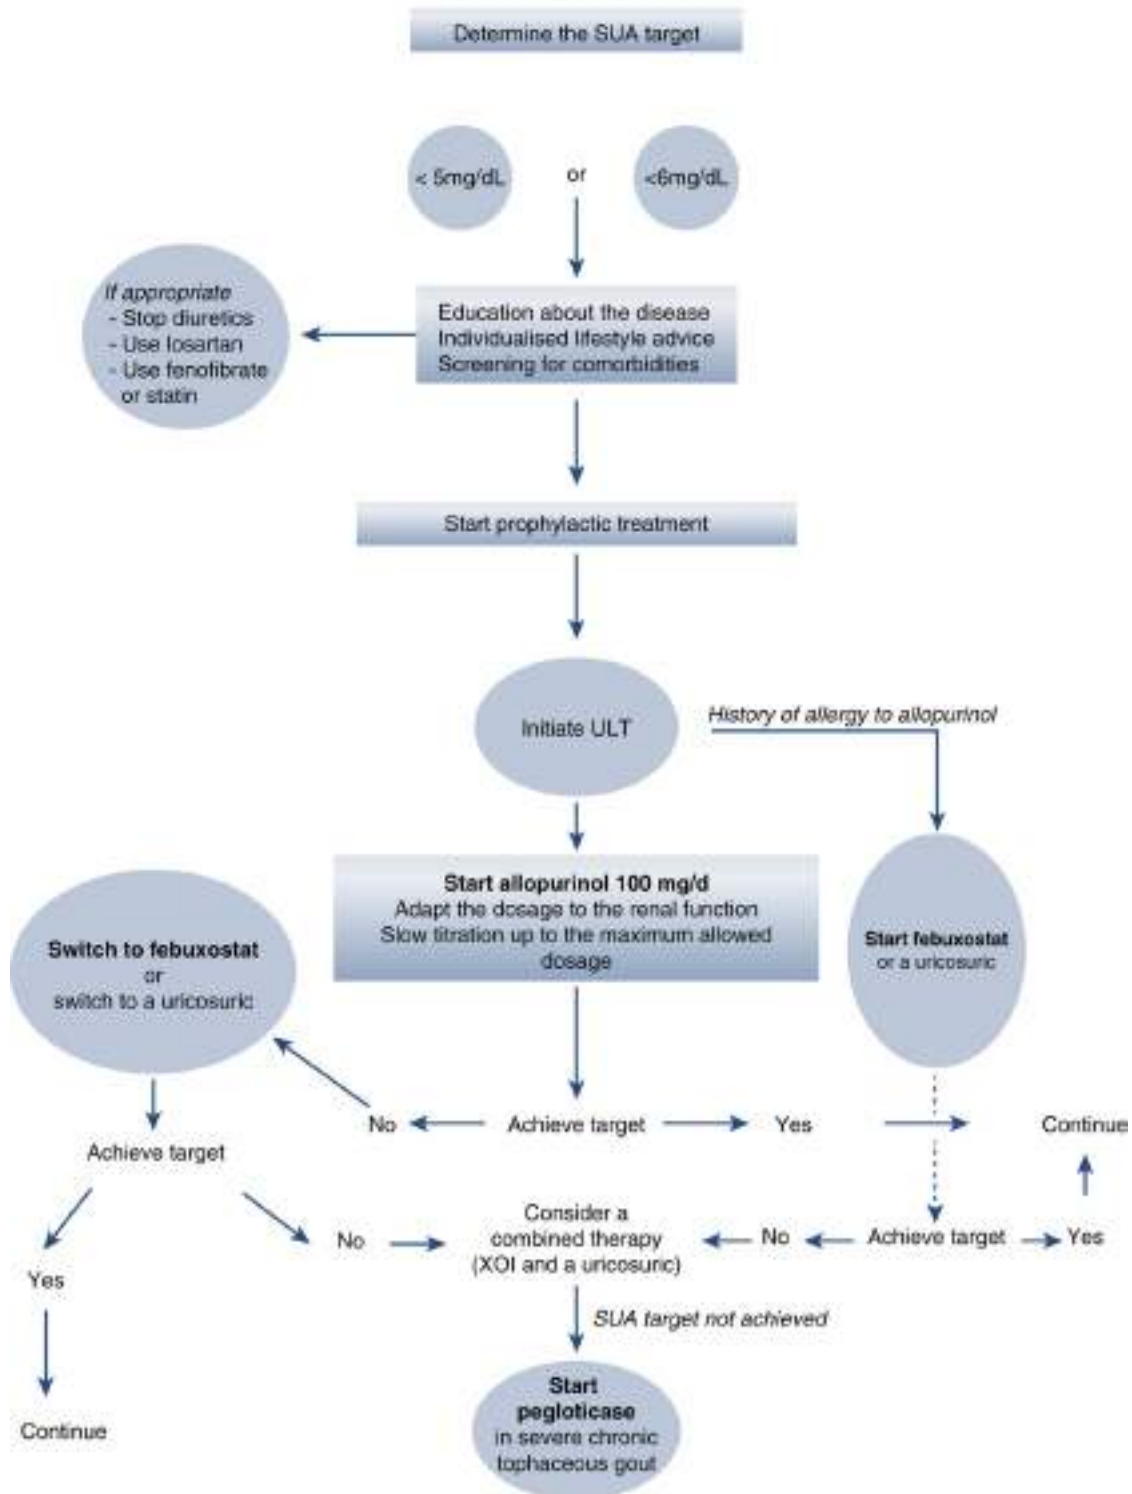

FIG. 69.3 Management of hyperuricaemia in patients with gout according to the European League Against Rheumatism recommendations. At this stage, combined allopurinol and a uricosuric is also recommended. SUA, serum

uric acid; ULT, urate-lowering therapy; XOI, xanthine oxidase inhibitor. (From Richette P, et al.: 2016 updated EULAR evidence-based recommendations for the management of gout, *Ann Rheum Dis* 0:1-14, 2016.)

Probenecid

Probenecid is a uricosuric drug and therefore helpful in cases of underexcretion. It is the “gold standard” in elderly patients on thiazide diuretics.¹ Uricosuric agents should be avoided in persons susceptible to nephrolithiasis such as those with tophaceous disease or urate overproduction.

Dosage

Starting dose of probenecid is 250 mg twice daily. Titrate up to effective dose, usually 500–1000 mg twice daily.

Precautions

Probenecid is less effective at glomerular filtration rates less than 60 mL/min. Avoid use in persons prone to nephrolithiasis and in those with cystinuria.

Allopurinol

Allopurinol inhibits xanthine oxidase activity. Unlike probenecid, it is useful in all causes of hyperuricemia. Due to theoretical risk, allopurinol is generally not started during an acute attack. Patients on allopurinol should not, however, stop the medicine if an acute attack does occur.

Dosage

Allopurinol can be started 100–300 mg daily and titrated up until normal uric acid levels are achieved. Most patients can be adequately treated with 300 mg daily, although the maximum daily dose is 900 mg, and treatment should be titrated to achieve a uric acid level less than 6.⁵⁰ To reduce the risk of precipitating a gouty attack, low-dose colchicine may be started simultaneously.⁵¹

Precautions

Up to 5% of patients will experience side effects including rash, leukopenia, thrombocytopenia, diarrhea, or drug fever. The allopurinol hypersensitivity syndrome (AHS) is a rare (less than 0.1% of patients) but potentially fatal adverse reaction consisting of erythematous rash, fever, hepatitis, eosinophilia, and acute renal failure.

Alternatives

Febuxostat is a newer xanthine-oxidase inhibitor that may be used in place of allopurinol.⁵⁰ At starting doses, it may be more effective than allopurinol at reducing uric acid levels.⁵² However, it is significantly more expensive and does not confer additional benefit if allopurinol is titrated to doses sufficient to achieve target serum uric acid levels.

Titrate urate-lowering therapies to achieve serum uric acid levels less than 6.

Therapies to Consider

Botanicals

There are numerous new ethnobotanical studies of traditional antigout agents, many of which are yielding promising results and confirming the wisdom of indigenous healing systems.

In mice, in vivo trials of the Ayurvedic gout treatments *Coccinia grandis* (Ivy gourd) and *Vitex negundo* (five-leaved chaste tree) demonstrated significant decreases in serum uric acid levels. Impressively, *Coccinia grandis* in particular showed urate reductions nearly equivalent to those of allopurinol (3.90 +/- 0.07 mg/dL vs. 3.89 +/- 0.07 mg/dL).⁵³

Polynesians used noni (*Morinda citrifolia*) juice for treatment of a variety of ailments, including gout. Noni was found to have in vitro inhibition of xanthine oxidase,⁵⁴ but no clinical trials have been performed to date.

Populus nigra (black poplar) and *Betula pendula* (Silver Birch) were found to have the highest level of xanthine oxidase inhibition in a study of traditional Czech herbal folk remedies for gout.⁵⁵

In a similar study of 120 traditional Chinese antigout treatments, the

following herbs demonstrated the most pronounced xanthine oxidase inhibition: *Cinnamomum cassia* (Chinese cinnamon), *Chrysanthemum indicum*, leaves of *Lycopus europaeus* (bugleweed, gypsywort), and the rhizome of *Polygonum cuspidatum* (Japanese knotweed).⁵⁶

Supplements

In vitro studies have shown folic acid is a weak inhibitor of xanthine oxidase.⁵⁷ More potent effects on

Prevention Prescription

- Encourage weight loss and maintenance of a healthy body mass index.
- Decrease consumption of red meat and excessive seafood.
- Increase intake of vegetables, legumes, nuts, and vegetable proteins.
- Decrease intake of sugar-containing beverages and fructose.
- Limit alcohol to no more than one to two drinks per day and drink wine rather than beer or liquor.
- Increase intake of low-fat dairy, up to two servings per day.
- Maintain adequate hydration.
- Consider drinking coffee, one to two cups a day.
- Increase food intake of vitamin C and consider supplementing with 500 mg per day.
- Increase intake of cherries; half-pound per day should be adequate.
- Increase intake of omega-3 fatty acids or take a supplement.

Therapeutic Review

Lifestyle Modification

- Encourage weight loss 
- Maintain hydration 
- Limit intake of beer and liquor 

Nutrition

- Decrease consumption of red meat and most seafood 
- Increase intake of vegetables, legumes, nuts, and vegetable proteins 
- Decrease intake of sugar-containing beverages and fructose 
- Increase intake of low-fat dairy, up to two servings per day 
- Consider coffee, one to two cups a day 

Supplements

- Increase intake of vitamin C through foods; consider supplementing with 500 mg daily 
- Eat more cherries: up to half-pound daily 
- Supplement with EPA and/or GLA: EPA 500 mg daily and/or evening primrose oil 3000 mg daily 
- Eat more pineapple or take bromelain supplements 500 mg daily 
- Eat more apples, grapes, onions, and tea or take quercetin supplements 500 mg twice daily 

Botanicals

- Hibiscus tea can be used for borderline blood pressure and may lower uric acid levels 

Physical Medicine

- Acupuncture can help relieve a gouty attack 
- Ice and rest painful joints 

Pharmaceuticals

Acute Treatment

- Use NSAIDs for first-line treatment unless contraindications exist 
- Consider colchicine, but use only a low-dose regimen: 1.8 mg divided over 1 hour 

- Use glucocorticoids in patients unable to take NSAIDs or colchicine

Prevention

- Use probenecid for inadequate uric acid excretion. Start 250 mg twice daily 
- Use allopurinol for all causes of uric acid excess. Start 100–300 mg daily 
- Titrate urate-lowering therapies to achieve serum uric acid levels less than 6.0 

inhibition have been traced to the activity of a common folate contaminant pterin aldehyde.⁵⁸ Nonetheless, few in vivo trials have been conducted. Daily doses of folate 1000 mcg failed to lower serum uric acid concentrations in five hyperuricemic subjects.⁵⁹ Therefore, we do not recommend that folate be prescribed for gout unless stronger evidence emerges to support its usefulness.

Niacin has a small uric acid-raising effect, which is doubtful to be of negative clinical significance.⁶⁰

CHAPTER 70

Carpal Tunnel Syndrome

Gautam J. Desai, DO, FACOFP, Dennis J. Dowling, DO, and Joshua W. Harbaugh, OMSIV

Pathophysiology

Carpal tunnel syndrome (CTS) is a compressive neuropathy of the median nerve that affects women roughly three times as often as men and usually develops after the age of 30 years.^{1,2} Symptoms typically include pain, numbness, tingling, weakness of the thumb and first finger, and involvement of the palm and other fingers except the fifth. Wasting of the thenar eminence may be visible. Activities that may precipitate CTS include repetitive stress activities involving the wrist such as mechanical work, gardening, house painting, meat wrapping, and typing.³ Trauma, both recent and remote, should be explored, and one of the “keystone” bones of the carpal floor, the lunate, has been implicated in ventral compression of the median nerve against the flexor retinaculum when it is subluxed or displaced.⁴ CTS is also commonly seen in persons involved in the occupations listed in [Table 70.1](#).^{5,6}

The carpal tunnel contains nine flexor tendons and the median nerve. The tunnel is created by the three sides of the carpal bones and the flexor retinaculum.⁷ Any development that leads to tunnel narrowing or increased pressure within the limited space may cause CTS. These conditions may include edema, bony overgrowth, or inflammation of the tendons. The pressure compresses the median nerve and the small blood vessels that feed the nerve, with resulting ischemia and decreased nerve conduction. Initially, the compression and ischemia result in pain, numbness, and tingling. Chronic compression may result in more prolonged symptoms and signs such as weakness and wasting of the thenar eminence.^{8,9} Some conditions that may be associated with CTS are listed in [Table 70.2](#).^{10,11} At times, the origin may be multifactorial, both functional (overuse) and structural (osteoarthritis).

Clinical Manifestations and Diagnosis

Patients typically present with sensory or motor changes along the distribution of the median nerve, which includes the thumb, index finger, middle finger, and radial half of the ring finger.⁸ Sparing of pain and numbness in the thenar eminence is usually seen in CTS as the palmar branch of the median nerve, innervating this region, diverges proximal to the carpal tunnel and travels over the flexor retinaculum, although there are reported cases of concurrent compression of this nerve in CTS.^{12,13} Patients may experience greater pain at night or after sleeping. Some patients find relief of symptoms by shaking their hands, which may temporarily relieve ischemia.¹⁴ Pathognomonic physical findings may be absent early in the course of CTS; as pressure increases within the carpal tunnel, however, patients may demonstrate weakness of the thumb, which causes difficulty with writing or holding objects. Thenar eminence atrophy may be present on physical examination in advanced CTS.¹⁵ Other nerve and vascular compressive syndromes that can cause the same or similar symptoms and signs should also be explored. These disorders can occur separately or concomitantly with CTS in what are known as double-crush and triple-crush syndromes. These syndromes can include cervical root impingement, thoracic outlet syndrome, cubital tunnel syndrome, ulnar neuropathy, pronator syndrome, median nerve neuropathy of the forearm, brachial plexopathy, anterior interosseous nerve syndrome, and Raynaud phenomenon.¹⁶

The National Institute of Occupational Safety and Health defines CTS as having two or more of the following criteria:

- One or more of the following symptoms affecting at least part of the nerve distribution of the hand: paresthesia, hyperesthesia, pain, and numbness
- One or more of the following symptoms: physical findings of median nerve compression including a positive Hoffman-Tinel sign or a positive Phalen test result, diminished sensation to pinprick in the median nerve distribution, and electrodiagnostic findings indicating median nerve dysfunction across the carpal tunnel.¹⁷

The exact location of nerve entrapment can be diagnosed with electrodiagnostic studies; however, results of nerve conduction studies may be normal in clinically symptomatic patients.¹⁸

Integrative Therapy

Lifestyle

Behavior Modification

Elimination of aggravating factors and repetitive motions may help reduce symptoms of CTS, but many patients do not have the opportunity to change occupations. Patients may obtain some relief by using their hands less forcefully, taking frequent breaks, and performing stretching and strengthening exercises. The practitioner should query the patient about hobbies that require repetitive motion as well, because patients may not associate those hobbies with their symptoms. A wrist splint worn during waking hours may provide additional symptom relief, but most patients cannot tolerate daytime splinting. Occasional use of the same splints while sleeping may also bring about some relief during the waking hours.^{19,20} Splints should be individually adjusted (most have a metal stay within a sleeve on the volar surface) to maintain an angle of the wrist that avoids excessive flexion or extension. One study looked at wrist positioning and resultant pressure within the carpal tunnel, finding that the lowest pressure was in slight extension (2 ± 9 degrees) and ulnar deviation (2 ± 6 degrees).²¹ Many braces available off the shelf place the wrist into too high a degree of extension.

Exercise

A 10-month aerobic exercise program demonstrated a reduction in symptoms of CTS, but whether these results were related to the natural course of the disease or to the therapy is unclear.²² Although performing aerobic activity for cardiovascular health is certainly in the patient's best interests, such exercise has not been proven to be of benefit for CTS treatment, so no evidence supports its use. Stretching of the flexor tendons, the major occupants of the tunnel, may have some benefit in reducing compression of the median nerve (see [Fig. 70.2](#)).

Ergonomic Keyboards

Results of studies comparing the use of ergonomic keyboards for amelioration of symptoms of CTS have been mixed.^{23,24} One small study ($N = 37$) confirmed swelling and changes in the median nerve after 30 minutes and 60 minutes of typing; however, the changes resolved after a period of rest, thus only offering speculation of a link between

keyboarding and CTS while also not addressing long-term symptoms.²⁵ If a patient believes that using such a keyboard will help, it may be worth the higher price to try the device to determine if it has no adverse effects. No evidence exists for its use. The position in which patients place their hands may have more to do with effectiveness than the keyboards themselves. Patients should avoid resting their wrists on the surface while extending their wrists to reach their fingers to the keyboard. Pianists and touch typists classically hover their hands above their respective keyboards.

Pharmaceuticals

Acetaminophen

Acetaminophen has a limited role in CTS owing to a lack of its antiinflammatory properties. Acetaminophen appears to display analgesic and antipyretic effects by inhibiting the isoenzymes cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2) in the central nervous system. This inhibition does not seem to extend into the periphery, thereby eliminating any antiinflammatory properties.²⁶ However, because it has a relatively safe profile, acetaminophen remains a good choice for relief of mild to moderate pain in CTS, especially in patients who have concomitant osteoarthritis.

Dosage (Adult)

The recommended dose of acetaminophen (Tylenol) is 500 mg every 4–6 hours; the maximum dose is 3000 mg/day.²⁷

Precautions

Acetaminophen should be used with caution in patients with a history of liver disease and in patients who consume more than three alcoholic beverages daily.²⁸ In addition, consideration should be given to the appropriate dosage of acetaminophen when patients are taking other concomitant medications that are similarly metabolized by the liver. At recommended dosages, acetaminophen is considered safe in pregnancy.

Nonsteroidal Antiinflammatory Drugs

Median nerve compression caused by inflammation of the flexor tenosynovium can cause patients a great deal of pain.²⁹ Nonsteroidal antiinflammatory drugs (NSAIDs) exert pain-relieving and antiinflammatory properties through prostaglandin inhibition by inhibition of COX-1 and COX-2 isoenzymes.²⁸ In general, all NSAIDs have similar efficacy regarding analgesia and antiinflammatory effects. However, these effects remain to be proven adequate for control of symptoms of CTS, despite common use of NSAIDs in the treatment of this condition. In a study comparing the efficacy of NSAIDs, oral steroids, diuretics, and placebo, only steroids achieved a significant improvement in signs and symptoms of CTS.³⁰

TABLE 70.3

Common Nonsteroidal Antiinflammatory Drugs Used for Pain Relief

Generic Name	Brand Name ^a	Recommended Adult Dose	Route	Maximum Daily Dose
Aspirin	Bayer Aspirin	325–650 mg every 4–6 h	Oral or rectal	3600 mg
Salsalate	Salflex	500–1000 mg every 8–12 h	Oral	3000 mg
Ibuprofen	Motrin and Advil	200–400 mg every 4–6 h	Oral	2400 mg
Diffusal	Dolobid	500–1000 mg every 12 h	Oral	1500 mg
Choline magnesium	Tricosal	500–1000 mg every 8–12 h	Oral	3000 mg salicylate
Naproxen sodium	Aleve and Anaprox	220–550 mg every 8–12 h	Oral	1500 mg
Naproxen	Naprosyn	250–500 mg every 12 h	Oral	1500 mg
Ketoprofen	Oradis KT	12.5 mg every 6–8 h; second dose may be taken after 1 h if needed	Oral	75 mg
Fenoprofen	Nalfon	300–600 mg every 6–8 h	Oral	3200 mg
Flurbiprofen	Ansaid	200–300 mg in 2–4 divided doses	Oral	300 mg
Oxaprozin	Daypro	600–1200 mg/day	Oral	1800 mg
Ibuprofen	Indocin and Indocin SR	25–50 mg, 2–3 times/day	Oral	200 mg
Diclofenac	Voltaren	50 mg every 8 hours; 75 mg every 12 h	Oral	150 mg
Etofenac	Lodine	200–400 mg every 6–8 h	Oral	1200 mg
Nabumetone	Relafen	500–1000 mg, 1–2 times/day	Oral	2000 mg
Meloxicam	Mobic	7.5 mg/day	Oral	15 mg
Piroxicam	Feldene	10–20 mg/day	Oral	20 mg

^a More than one brand may exist for an agent.

Data from references [18](#), [19](#), and [22](#).

Dosage

Common NSAIDs and dosages are listed in [Table 70.3](#).

Precautions

NSAIDs must be used with caution in patients with a history of gastrointestinal bleeding, ulcers or perforation, hypertension or other cardiac disorders aggravated by fluid retention, asthma, renal insufficiency, or coagulation defects, as well as in pregnant patients.^{26,28,31}

Diuretics

A rise in tissue pressure in the carpal tunnel is theorized to lead to perineural edema.³² Diuretic therapy has been employed in efforts to rid the body of excess fluid accumulation and ameliorate CTS. Although case reports exist regarding successful use of furosemide to alleviate symptoms of CTS associated with iatrogenic fluid administration, larger comparative studies refute the benefit of diuretic use in CTS.³³ In a study comparing bendrofluazide (a thiazide diuretic not available in the United States) with placebo, no improvements in CTS symptoms were seen.²³ Diuretics should not be used in treatment of CTS.

Corticosteroids

The human body endogenously produces glucocorticoids. At supraphysiological doses of exogenous corticosteroids, an antiinflammatory response is seen. Modified cellular transcription and protein synthesis lead to local inhibition of leukotriene penetration, suppression of the humoral response, and a reduction in lipocortins, thus diminishing the inflammatory response.²⁸ In CTS, corticosteroids may offer relief and can be given orally or directly injected into the carpal canal.⁹ Short-term oral steroid therapy with conventional treatment, such as splinting, has reduced symptoms in patients with CTS. In a study comparing the use of NSAIDs, diuretics, oral steroids, and placebo, only the group receiving oral prednisolone demonstrated significant relief of CTS symptoms.³⁰

Corticosteroid injection, administered on the radial side of the palmaris longus tendon, has shown short-term efficacy in providing CTS symptom relief.^{34,35} In a study comparing surgical decompression with local steroid injection, patients receiving steroid injections had better symptom relief 3 months after treatment than patients who had undergone surgery. At 6 months and 12 months, however, the percentage of patients in whom relief of symptoms was maintained after

injection began to decline, whereas the level of relief in the surgically treated group remained constant.³⁵ Steroid injections are most beneficial to patients with mild to moderate CTS, thus delaying the need for surgery. Injection may be repeated 3 weeks after the initial dose, but the need for a third dose in less than 1 year indicates a need for surgical treatment.³⁴

Dosage

A standard dosage for oral steroids in CTS has not been determined. A study comparing two prednisolone regimens—2 weeks of 20 mg/day followed by 2 weeks of 10 mg/day versus 2 weeks of 20 mg/day followed by 2 weeks of placebo—for long-term improvement found no difference in treatment response with respect to the duration of steroid therapy.³⁶ Hence, the lower dosage should be used to minimize adverse effects.

Injection therapy consists of methylprednisolone acetate, 40 to 80 mg mixed with 1 mL of 1% lidocaine,³⁷ or 6 mg of betamethasone combined with 1% lidocaine.³⁵

Precautions

Long-term oral steroid use has been associated with immunosuppression, hyperglycemia, hypertension, Cushing syndrome, osteoporosis, and electrolyte disturbances. Injection of steroids must be performed by a skilled practitioner trained in CTS injection to avoid nerve atrophy and necrosis, which may be created by entry of corticosteroid into the median nerve sheath.^{28,31,34} The use of corticosteroids in pregnancy is controversial. Although drug monographs indicate corticosteroids to be relatively safe in pregnancy (safety category B), animal studies have indicated possible long-term developmental abnormalities. More research using corticosteroids during pregnancy is needed.³⁸

Botanicals

Patients using dietary supplements should be advised to choose brands that have been certified for content and purity. Testing for content and

purity is not a mandatory requirement for dietary supplements. Trusted organizations that voluntarily test product purity are the United States Pharmacopeia (USP), the Association of Analytical Communities (AOAC), and Consumer Labs (consumerlabs.com). [Table 70.4](#) provides a list of sample USP-verified brands.⁴¹

Ginger (*Zingiber officinale*)

Ginger, also known as *African ginger*, *black ginger*, *cochin ginger*, and *imber*, is a mixture of several compounds, which include gingeroles, beta-carotene, capsaicin, caffeine, curcumin, and salicylate.⁴² However, these chemical entities seem to vary according to the form of the herb. Ginger is most often used for relief of nausea, vomiting, motion sickness, dyspepsia, flatulence, migraine headache, rheumatoid arthritis, osteoarthritis, and pain. Although the exact mechanism remains unknown, investigators have speculated that some of the constituents in ginger may inhibit COX-1, COX-2, lipoxygenase pathways, tumor necrosis factor-alpha, prostaglandin E2, and thromboxane B2.⁴³ Each of these inhibited mechanisms plays a role in inflammation. A randomized, placebo-controlled, crossover study was conducted comparing the efficacy of ginger, ibuprofen, and placebo in patients with osteoarthritis. Although ibuprofen was found to be the most effective at treating pain, both ibuprofen and ginger had a significant pain-rating reduction in comparison with placebo.⁴⁴ Ginger may be of benefit in patients who have both CTS and osteoarthritis. Patients with nausea and vomiting of

pregnancy and CTS may benefit from the anti-nausea properties of ginger as well.

Dosage

In osteoarthritis management, Eurovita Extract 33, a specific ginger extract, is often used. The dosage of this formulation is 170 mg orally three times daily or 255 mg twice daily.⁴³

Precautions

Because of possible inhibition of platelet aggregation, ginger should be used with caution in patients who are concurrently undergoing anticoagulant therapy or have coagulation disorders. Common adverse reactions with ginger are gastrointestinal discomfort, heartburn, and diarrhea. The use of ginger during pregnancy is relatively safe when it is orally ingested for medicinal purposes. Although some concerns have been expressed about ginger and its involvement in altering fetal sex hormones, and one case report of a spontaneous abortion exists, the overall risk of fetal malformation does not appear to be higher than the baseline (1%–3%).⁴³

Willow Bark (*Salix alba*)

Willow bark, also known as white willow bark, brittle willow, and simply willow, is a dietary supplement from the Salicaceae family. It is most often used by patients to treat headache or pain caused by osteoarthritis, myalgia, gout, and dysmenorrhea. Although components of willow bark include flavonoids and tannins, its pain-relieving properties are attributed to the salicin glycosides present in the compound. After ingestion of willow bark, the salicin glycosides are converted in the intestine to saligenin, which is then metabolized to produce salicylic acid. At this point, elimination becomes the same as for aspirin (acetylsalicylic acid).⁴³ As with aspirin, willow bark demonstrates analgesic, antipyretic, and anti-inflammatory properties. Platelet aggregation may be inhibited by willow bark, but to a lesser extent than by aspirin. Studies comparing willow bark, diclofenac, and placebo in patients with osteoarthritis and rheumatoid arthritis found willow bark to be no better than placebo for pain relief.⁴⁵ Although no studies have

evaluated willow bark use for CTS, this substance can be regarded as having efficacy similar to that of aspirin and other NSAIDs in pain management.

Dosage

Willow bark should be dosed according to the salicin content in the supplement: salicin, 120–240 mg orally in two to three divided doses daily.⁴³

Precautions

Safety concerns about using willow bark are similar to those for salicylate therapy. Willow bark may cause gastric irritation, nausea, vomiting, and bloody stools. It should be used with caution in patients who are also taking antiplatelet medications or other salicylate-containing products. Insufficient evidence exists for using willow bark in pregnancy. Pregnant women are advised to avoid it.

Arnica (*Arnica montana*)

Also known as arnica flower, leopard's bane, and mountain tobacco, arnica is used to treat inflammation and as an immune system stimulant. The boost in immune response is thought to decrease healing time in bruises, aches, and sprains. The primary active constituents in arnica are sesquiterpene lactones.⁴³ Although the exact mechanisms are not completely understood, the antiinflammatory effects seen with arnica seem to differ mechanistically from those of NSAIDs. A specific sesquiterpene lactone, helenalin (which is implicated in inflammation), inhibits nuclear transcription factor NF-kappaB.⁴⁶ Helenalin has also been shown to inhibit platelet function. In a randomized, placebo-controlled study using arnica to control pain and swelling in patients who had undergone surgical repair of CTS, no difference in swelling was seen in patients receiving arnica and in those receiving placebo. However, a significant reduction in pain was seen 2 weeks after surgery in patients receiving arnica.⁴⁷ Arnica may be useful in patients who have undergone surgical treatment for CTS, but the potential side effects and toxicity, as well as the difficulty in obtaining standardized doses, may be obstacles to its use.

Dosage

Unless diluted, arnica is toxic when taken by mouth. Although no standard or well-studied doses or arnica preparations are available, the usual homeopathic preparations are diluted to 1:10 and 1:100 strengths. Serial dilutions continue until the desired strength is reached. For example, a 1:100 solution that is diluted 30 times is said to be 30C potency.⁴⁷ Caution should be exercised because of the difficulty in obtaining a standardized dose and the possible side effects.

Precautions

Arnica in homeopathic doses is generally safe.

Arnica belongs to the Asteraceae/Compositae family. Patients allergic to other members of this family will also be allergic to arnica. Additional members of the Asteraceae/Compositae family include ragweed, chrysanthemums, marigolds, daisies, and many other herbs.⁴³

Supplements

Vitamin B₆ (Pyridoxine)

Vitamin B₆ is required by the body for many functions, including metabolism of amino acids, carbohydrates, and lipids. Vitamin B₆ is also a coenzyme in various metabolic reactions, such as transamination of amino acids, conversion of tryptophan to niacin, synthesis of gamma-aminobutyric acid, metabolism of serotonin, norepinephrine, and dopamine, and the production of heme for hemoglobin. It is also required in myelin sheath formation.⁴³ Clinically, vitamin B₆ is used to offset neuropathy caused by certain medications, such as isoniazid. Vitamin B₆ was first thought to be an effective treatment in CTS on the basis of low tissue levels seen in deceased patients with CTS. Investigators now know, however, that pyridoxine levels decline in deceased or infarcted tissue.⁴³ Two studies involving a total of 50 subjects with CTS demonstrated no benefit for vitamin B₆ in comparison with placebo.⁴⁸

Mild deficiencies in vitamin B₆ are relatively common. Sources of this

vitamin include potatoes, milk, cheese, eggs, fish, carrots, spinach, and peas. Vitamin B₆ is useful in treating general deficiency and neuritis. Patients with CTS receiving benefit from pyridoxine therapy are thought to have an underlying deficiency or neuropathy. More studies are needed to assess the effectiveness of vitamin B₆ in CTS, but the supplement may be useful in patients with an underlying deficiency.

Dosage

For vitamin B₆ deficiency, 2.5–25 mg/day orally is taken for 3 weeks, with a maintenance dose of 1.5–2.5 mg/day thereafter. For neuritis, the dose is 10–50 mg/day orally.⁴³

The U.S. Recommended Dietary Allowance (RDA) values for vitamin B₆ are as follows:

- Men: 19–50 years old, 1.3 mg; 51 years old and older, 1.7 mg
- Women: 19–50 years old, 1.3 mg; 51 years old and older, 1.5 mg. Some researchers think that the RDA for women 19–50 years old should be increased to 1.5–1.7 mg.
- Pregnant women: 1.9 mg; lactating women: 2 mg.⁴³

Precautions

Adverse reactions associated with vitamin B₆ therapy include abdominal pain, nausea, vomiting, increased serum aspartate aminotransferase values, and decreased serum folic acid concentrations. This vitamin has been shown to cause sensory neuropathy at doses exceeding 1000 mg. It should be used with caution in patients concurrently taking phenytoin, phenobarbital, or levodopa. Pyridoxine may increase the metabolism of these drugs and thereby reduce the plasma levels of phenytoin, phenobarbital, or levodopa.

Biomechanical Therapy

Massage Therapy

A small study ($N = 16$) showed a short-term benefit of pain reduction and functionality improvement in patients treated with four weekly massages by a therapist (not further defined) as well as daily self-massage.⁴⁹ The type of massage described resembled pétrissage and effleurage-type

stroking and was focused on the hand and forearm. No group received sham massage, so whether the benefits resulted from direct action of the massage on the carpal tunnel and surrounding tissues to mobilize fluid or from neurotransmitter release in the central nervous system is unclear. Because teaching a patient to massage his or her own hand and forearm has minimal cost, a trial of this modality may be of benefit.

Yoga

In another small study, a group of patients taking part in a highly individualized and methodical yoga program (Iyengar approach) demonstrated significant reduction in pain and significant improvement in grip strength compared with a control group offered a wrist splint in addition to continuation of the current treatment.⁵⁰ No significant difference was reported in the median nerve motor and sensory conduction time between the two groups. The yoga regimen, for which the group met twice weekly for 8 weeks, was designed to focus on improving strength and balance in each joint in the upper body, and it also covered a relaxation technique. Although a larger study with long-term follow-up is needed, yoga may be an option for patients who are able to afford such a program, as well as for those who may be unable or unwilling to use other approaches or treatment options for CTS.

Physical Therapy and Occupational Therapy Modalities

Wrist Splinting

Splints that prevent excessive flexion or extension of the wrist are inexpensive options shown to be moderately effective in the treatment of CTS and should be a first-line choice for most patients with mild to moderate CTS.^{51,52} Although full-time splint use may produce better results, most patients generally do not tolerate daytime use of the appliance, thus nighttime splinting is recommended. Splints that keep the wrist in a neutral position may be more beneficial than those placing the wrist in extension. Patients should try a noncustom orthotic first, which is less expensive than the custom-fitted counterpart. Generally, negative effects are not associated with splint use, other than the initial discomfort of wearing a new appliance. Splinting may be used in combination with other therapies. Commonly splints, along with stretches, are utilized, and one study revealed a 4-week trial of a nighttime cock-up splint along with lumbrical intensive stretches

improved symptoms and function in CTS compared to other splinting and stretching regimens.⁵³ Another study demonstrated splinting to be superior to steroid injection of the carpal tunnel in patients with mild and moderate CTS, in terms of both symptomatic relief and improvements in sensory and motor nerve conduction velocities.⁵⁴ These results were obtained with near-nightly use of the splint for 1 year, a regularity and duration that may be more difficult to obtain in a nonstudy patient population. Patients in whom CTS is unresponsive to this therapy after 3 weeks of use must be reexamined; in addition, patients with thenar wasting on initial presentation may benefit from another treatment modality. Pregnant patients may be especially good candidates for splinting.

Ultrasound Therapy

Ultrasound therapy may benefit patients with mild to moderate CTS, although the cost and frequency of treatments may be a barrier. One study demonstrated an improvement in symptoms and motor distal latency in wrists receiving ultrasound treatment that was not seen in wrists receiving sham ultrasound.⁵⁵ The investigators postulated that the antiinflammatory and tissue-stimulating effects of ultrasound could be responsible for the results. However, studies are limited and more research is required.⁵⁶ Long-term benefits of ultrasound therapy are unknown.

Osteopathic Manipulative Treatment

Randomized controlled studies of osteopathic manipulative treatment (OMT) for the treatment of CTS are scarce. Palpatory examination was noted to be 92% sensitive, but only 75% specific, when compared with electrodiagnostic studies for determining CTS.⁵⁸ However, cadaver studies demonstrated an elongation of the transverse carpal ligament after treatment with OMT (nonthrust techniques designed to stretch the transverse carpal ligament) directed at the wrist, in conjunction with static loading (weights).^{59,60} Whether these results may be applied to living patients remains to be seen, although animal studies have shown minimal change in postmortem biomechanical properties of ligaments after freezing.^{61,62} Thus, these findings may possibly be relevant. The female cadaver wrists tended to be smaller and had greater elongation of the transverse carpal ligament, especially when OMT was done first, followed by static loading.

Osteopathic physicians practice many specialties, and many serve as primary care physicians and can easily perform OMT in the office, as shown in [Fig. 70.1](#), during the first presentation of the complaint. The patient can be instructed in self-stretching exercises (shown in [Fig. 70.2](#)), which can be done at home at no cost and often with increasing relief of symptoms. One small study ($N = 16$ wrists) demonstrated a reduction in symptoms with OMT,⁶³ and another reported magnetic resonance imaging evidence that OMT and self-stretching enlarged transverse and anteroposterior dimensions of the carpal canal.⁶⁴ However, three of the four patients undergoing this treatment had symptoms of CTS after trauma, which may respond differently than CTS from other causes, such as repetitive motion. A quasi-single blinded pilot study revealed statistically significant improvements in symptoms and function on a self-reported pain scale specific to CTS, the Boston Carpal Tunnel Syndrome Questionnaire (BCTQ), after 6 weeks of OMT ($F = 11.0$; $p = .004$). The improvements tended to be more pronounced on the treated side. There was also a decrease in symptom-specific diagramming scores after 6 weeks of treatment, and this was also statistically significant ($F = 4.19$; $p = .0002$). The patient estimate of overall improvement of symptoms was statistically significant for the treated side. No statistically significant changes in electrophysiological function of the median nerve, cross-sectional area of the median nerve, or transverse carpal ligament bowing were observed. The transverse carpal ligament length was increased in length following the treatment period and was also statistically significant, but no side-to-side difference was detected. The authors concluded that OMT resulted in patient-perceived improvement in symptoms and functions associated with CTS. However, median nerve function as measured by electrophysiological studies and the morphology at the carpal tunnel did not change, possibly indicating a different mechanism by which OMT had been effective.⁶⁵ Large randomized trials including sham OMT are needed before OMT can be clearly stated as being beneficial for CTS. However, given the low risk of adverse events with OMT, as well as the low cost, a patient can be treated by a combination of approaches, including self-stretching and wrist splints. Before more invasive approaches (i.e., injection, surgery) are considered, a trial of OMT may be of benefit. Additionally, the holistic philosophy of osteopathic medicine mandates taking into account the person as a whole, considers other potential aggravating factors, and seeks ways to reduce or remove these factors.

FIG. 70.1 A, The physician's thumbs apply pressure away from the center of the wrist, while the fingers below simultaneously apply an upward force to create a spreading effect. B, Once an initial stretch has been achieved and held, the physician can then gently extend the patient's wrist farther (by pushing patient's fingers with his or her knee) and create more of a spread by moving his or her thumbs farther away from the center of the wrist. The goal is to increase the length of the transverse carpal ligament and widen the carpal canal, thereby reducing the amount of pressure on the median nerve. (From Sucher BM. Myofascial release of carpal tunnel syndrome. *J Am Osteopath Assoc.* 93:92-101, 1993.)

FIG. 70.2 A, The patient is instructed to stand near a wall, place the affected hand's palm flat against the wall (fingertips down), and, with the other hand, add a downward force to the thumb of the affected hand. With this maneuver, the elbow is compressed by pressure from the iliac crest, and the pressure can be gently increased as stretching occurs. B, The patient can also perform a similar technique while seated, by placing the palm (fingertips down) on the inside of one thigh and the olecranon process on the other side and then bringing the legs together as the free hand exerts downward pressure on the thumb. The patient should be taught this stretching maneuver in the office and should perform it 5 to 10 times a day. (Adapted from Sucher B. Myofascial manipulative release of carpal tunnel syndrome: documentation with magnetic resonance imaging. *J Am Osteopath Assoc.* 93:1273-1278, 1993.)

Surgery

The three basic types of surgical procedures for carpal tunnel release, all of which attempt to visualize and cut the transverse carpal ligament, are as follows:

- Traditional open (approximately a 5-cm incision)
- Mini-open (approximately a 2.5-cm incision)

- Endoscopic (one or two portals)

Relief of symptoms is similar with all three types, but patients undergoing endoscopic surgery performed by an experienced surgeon will likely return to work sooner than those undergoing traditional open surgery.⁸ A 2005 randomized controlled trial demonstrated open surgery to be superior in terms of symptom relief, but not grip strength, compared with a single steroid injection for CTS over a 20-week period.⁶⁶ Although most patients report satisfaction with surgical outcomes, some caveats apply:

- Hand strength may take months to recover.
- The surgical scar site may be tender for up to a year after the operation.
- Attorney involvement (in cases of Workers' Compensation) may predict a worse surgical outcome.⁶⁷

Before considering surgical intervention, one must carefully rule out reversible causes of CTS, and referral to a specialist to be certain of the diagnosis may be warranted. Patients with mild CTS symptoms should especially be made aware of the risks and benefits of surgery. Pregnant patients should not be considered candidates for CTS surgery because their symptoms will probably improve after delivery.

If surgical intervention is being considered, the patient should be referred to a surgeon experienced in carpal tunnel syndrome and should undergo electromyography before the surgical procedure to be certain of the diagnosis.

Bioenergetics

Therapeutic Touch

Therapeutic touch has not been shown to be better than sham therapeutic touch in the treatment of CTS.⁶⁸

Traditional Acupuncture

Although the National Institutes of Health issued a consensus statement supporting the use of acupuncture in the treatment of CTS,⁶⁹ randomized controlled trials are required.⁷⁰ In 2004, the modality was approved as a treatment for CTS in Massachusetts for Workers' Compensation cases. Acupuncture may be regarded as an adjunct to other therapies or as an

alternative to surgery for mild cases of CTS. One barrier is the cost of acupuncture.

Laser Acupuncture

Laser acupuncture is probably not of benefit in the treatment of CTS.²³

Traditional Chinese Medicine

A retrospective, single-case series of 11 patients with CTS who were treated with jackyakamcho-tang (shaoyaogancao-tang), an herbal formulation that has been used for spasmodic muscles and pain in Eastern countries, demonstrated an analgesic effectiveness of approximately 72%.²⁰ However, this study had many limitations, and approximately 11% of the patients treated also had adverse effects.

Therapies to Consider

Many models of health care outside the traditional Western model likely offer beneficial treatments for many ailments of the Western world, such as CTS. Some involve a detailed and highly individualized assessment of the patient, and treatment is often multifaceted, with a combination of products (traditional Chinese medicine) that are not easily found or identified in the United States without some advanced knowledge. Ayurvedic medicine, for example, takes into account a balance of the life energies as well as the constitution of the individual, and the treatment offered varies from patient to patient, thus making it difficult to perform randomized controlled trials to study its effects. As we continue a push toward evidence-based medicine, potential therapies for CTS treatment and other disorders will emerge.

Prevention Prescription

- Avoid repetitive hand motions, especially those with forceful thrusting.
- Avoid prolonged gripping.
- Avoid prolonged positioning of the wrist in extremes of flexion or extension.
- Avoid gripping vibrating workplace tools for a prolonged time.
- Avoid isolated finger motions, such as typing, for a prolonged time.

- Schedule rest and stretching breaks every 1–2 hours.

Therapeutic Review

If a patient presents with mild to moderate symptoms of carpal tunnel syndrome (CTS), has no thenar flattening, and has had symptoms for less than 1 year, a stepwise approach is appropriate. Most therapies can be combined with nighttime splinting. If a patient has unremitting numbness or pain or a history of symptoms lasting longer than 1 year, a thorough examination should be conducted to ensure a correct diagnosis, and then referral to a surgeon specializing in CTS release may be the most appropriate therapy.

If a patient presents with thenar atrophy, this indicates long-standing neurological compromise, so more aggressive diagnostic and therapeutic options should be given priority.

Lifestyle Changes

- Have the patient reduce activities that bring on symptoms. 
- Take frequent breaks to rest hands.
- Perform stretching or strengthening exercises for the hands (see [Fig. 70.2](#)).

Splint Therapy

- The patient should wear a splint as often as possible, even during the day if tolerated. 
- Start with a rigid over-the-counter appliance first, ensuring proper fit and prevention of wrist flexion.
- Better results may be achieved with the wrist held in neutral position rather than extended.
- Reconsider therapy if no benefit is seen after 3 weeks.

Yoga

- A patient who is willing to try yoga, despite the cost of an individualized program, may see some benefit from it. 

Ginger

- The dose of eurovita extract 33 is 170 mg three times daily or 255 mg twice daily. 
- Ginger may be of benefit in patients with both osteoarthritis and CTS, as well as in pregnant patients with CTS and nausea or vomiting.
- Ginger should be used with caution in patients taking anticoagulants.

Osteopathic Manipulative Treatment

- Osteopathic manipulative treatment (OMT) can be done in combination with other therapies. 
- In addition to OMT in the office (see [Fig. 70.1](#)), patients can do self-stretching exercises at home (see [Fig. 70.2](#)) 5 to 10 times daily until symptom resolution or for 2–3 weeks, at which point reassessment is warranted if no improvement has occurred.

Oral Steroids

- Prednisolone is taken at 20 mg/day for 2 weeks. 
- The use of steroids in pregnancy is controversial.

Steroid Injection

- Injection of methylprednisolone acetate, 40 mg mixed with 1 mL of 1% lidocaine, into the carpal canal by a physician trained in this procedure may offer some relief of symptoms. It may also delay the need for surgery. 
- Use of more than three doses in 1 year suggests a need for surgical intervention.

Ultrasound

- Although costly and time consuming, ultrasound may be beneficial in patients with mild to moderate CTS. It can be combined with splint therapy, OMT, or medications. 

Traditional Acupuncture

- Acupuncture can be used as a possible alternative to surgery for mild CTS. 
- It may be costly and is usually not covered by medical insurance.

Surgery

- Surgery is likely most useful for patients with unrelenting pain or numbness, thenar atrophy, or treatment failure with other modalities.

- The clinician must be certain of the diagnosis and must choose a surgeon who has performed many CTS procedures.
- Referral to a CTS specialist for evaluation is recommended before surgery is suggested to the patient.
- Surgery is not advised for pregnant patients with CTS, which will probably resolve with delivery.
- Indications for surgery are unrelenting pain, thenar eminence atrophy, loss of motor function with diminished finger strength, and failure of other treatments.

CHAPTER 71

Epicondylitis

David Rabago, MD, Sarah James, DO, and Aleksandra Zgierska, MD, PhD

Pathophysiology

Lateral epicondylitis (LE) and medial epicondylitis (ME) are common, painful, debilitating soft tissue disorders. LE (tennis elbow) involves primarily the extensor carpi radialis brevis and common extensor tendon at its proximal insertion; pain is experienced over the lateral epicondyle. LE affects up to 7 out of 1000 persons per year in general medical practices.^{1,2} Both conditions are well known as sport-related injuries, but they have their greatest effect on workers who perform repetitive stressful hand tasks.³ The prevalence of LE among industrial workers is up to 30%; auto industry workers have a chronic lateral epicondylitis (CLE) prevalence of 16%.⁴ ME (golfer's elbow) is much less common and is associated with less functional impairment.² The most common causes of LE and ME may be low-load, high-repetition activities such as keyboarding, although formal data are lacking.⁵ The cost of time away from work attributed to these disorders is significant.

The understanding of the pathophysiology underlying LE and ME is evolving and remains controversial. Both LE and ME were traditionally seen as inflammatory conditions. The terms *lateral epicondylitis* and *medial epicondylitis* are often used indiscriminately to refer to both acute injury and chronic overuse elbow injury. However, most overuse tendon injuries, including LE and ME, show minimal histopathological evidence of inflammatory cells.⁶⁻⁹ Rather, they are chronic degenerative conditions. Therefore, *epicondylitis* is the preferred term.^{10,11} The current understanding identifies overuse of or trauma to elbow extensor or flexor tendons, microtearing, and failed tendon healing as the key mechanisms of injury. The result is weakened, fibrosed, and, finally, calcified and necrotic tendon insertions at the lateral or medial epicondyle.^{7,12}

Although inflammation may be present early in the disease process, biopsy studies have shown an absence of inflammatory mediators and cells, as well as dramatically disorganized collagen ([Figs. 71.1](#) and [71.2](#)). However, tenocyte hyperplasia and hypertrophy provide indirect evidence of upregulated inflammatory mediators in the long term suggest that elements of the inflammatory response may still play a role in the progression or continuation of tendon disrepair. Tendinopathy has been used as a general term for this class of injury.^{12,13} LE and ME are clinical diagnoses. Exam findings for LE include pain with gripping and resisted extension of the wrist with the elbow extended, and reduced grip strength.^{14,15} Tenderness is often elicited just distal and anterior to the lateral epicondyle but can also be present at the lateral supracondylar ridge, over the annular and radial collateral ligaments related to the radial head and the muscle bellies of the wrist extensors just distal to these ligaments. However, these tests have not been validated.¹⁶ Exam findings for ME include pain and tenderness near the origin of the wrist flexors on the medial epicondyle of the humerus, and sometimes on the ulnar side of the forearm, radiating to the wrist and occasionally to the fingers.

Lateral epicondylosis and medial epicondylosis are examples of overuse tendinopathies, which often require 3 to 12 months for complete healing.

Integrative Therapy

The treatment of epicondylosis has been assessed in more than 100 randomized controlled trials (RCTs) and in critical reviews, most addressing LE. The results of these reviews can be disheartening, given that no therapy was found to be definitively better than conservative treatment, in the long term. Existing studies often suffer from limitations such as small sample size, poor evaluation over longer periods (12 to 24 months), and inconsistency of diagnostic criteria, treatment protocols, and outcome measures. Key issues, such as quality of life, the cost and benefit of various therapies, and return to work parameters, have not been studied. Very few studies compare a given intervention with either watchful waiting or physical therapy designed specifically for epicondylosis; this is a critical issue given that up to 90% of patients will

fully recover by 1 year with a combination of time, relative rest, and conservative therapy. Although better research is sorely needed, recommendations can be made based on both clinical trial data and clinical experience.

Lifestyle

Healing Context

An integrative approach for the treatment of LE and ME focuses on pain relief, preservation of movement, muscle conditioning, and prevention. Most patients respond well to conservative treatment. The clinician should explain the pathophysiology of epicondylitis to the patient and should establish realistic expectations about treatment and expected time to full recovery. Many patients are surprised by both the nature of the condition (noninflammatory) and the lengthy period often required for complete healing. Most patients attain complete recovery in 3 to 6 months regardless of treatment.⁷ However, some patients with LE and ME suffer from symptoms that are refractory to initial therapy. In a general practice trial of watchful waiting, 20% of patients who had elbow pain for more than 4 weeks did not experience resolution of the pain and disability within 1 year.¹⁷

FIG. 71.1 Histology of a normal tendon. (From Wilson JJ, Best TM. Common overuse tendon problems: a review and recommendations for treatment. *Am Fam Physician*. 72:811-818, 2005. Copyright 2005 American Academy of Family Physicians.)

FIG. 71.2 Histology of a damaged tendon. Note the collagen disorientation and separation. (From Wilson JJ, Best TM. Common overuse tendon problems: a review and recommendations for treatment. *Am Fam Physician.* 72:811-818, 2005. Copyright 2005 American Academy of Family Physicians.)

Relative Rest

The pain of LE and ME is likely caused, and is certainly exacerbated, by activities that overuse the extensor and flexor tendons ([Fig. 71.3](#)). Pain from LE can be decreased by limiting wrist extension; ME-related pain can be decreased by limiting wrist flexion and pronation.

Patients whose work activity necessarily exacerbates pain should be transferred to more benign tasks, lighter or shorter duty, or should be given medical leave. Because relative rest makes good clinical sense, but is unstudied, the duration and extent of rest or leave, as well as the effect of short breaks, should be monitored clinically.

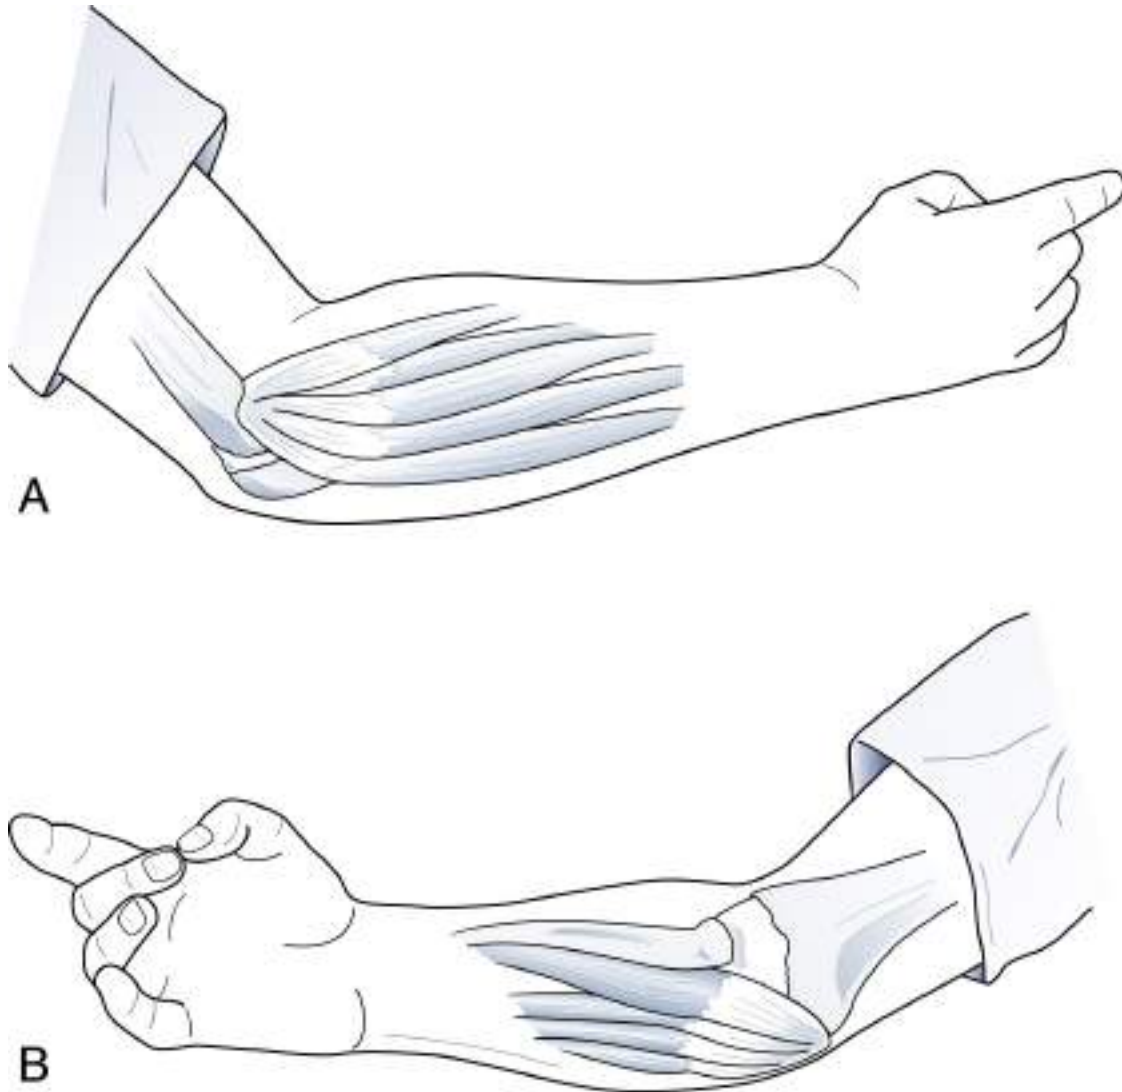

FIG. 71.3 A, Lateral epicondylitis. B, Medial epicondylitis.

Ice

Because the role of inflammation in tendinopathies is unclear, the importance of icing, a traditional antiinflammatory technique, is also uncertain. However, cryotherapy is probably effective in the acute phase (first 7 days), especially in the setting of trauma. Results from a systematic review performed in 2004, evaluating icing treatment for soft tissue injury, showed that application of ice through a wet towel for 10 minutes every 4 to 6 hours was effective.¹⁸

Mind-Body Therapy

Psychosocial Stress

The severity of epicondylitis has been found to be related to the intensity of work environment stress.³ Patient education about stress relief techniques, and workplace assessment to reduce psychosocial stressors, may affect the level of pain of LE and ME. It may also help prevent further tendinopathy when these measures are combined with other therapies.

Evidence suggests that acupuncture alleviates lateral epicondylitis pain in the short term.

Bioenergetic Therapy

Acupuncture

Acupuncture is based on the idea that patterns of energy flow (qi) through the body are essential for health. Disruptions of this flow are believed to be responsible for disease.

Acupuncture may alleviate or reduce epicondylar pain through activation of endogenous opioids.¹⁹ Reviews and RCTs have shown that needle acupuncture is significantly more effective than sham acupuncture for the treatment of LE,²⁰ acupuncture may increase the duration of pain relief and the proportion of people with at least 50% pain reduction after only one treatment,²¹ and that acupuncture increased the proportion of subjects who reported good or excellent result from treatment (22 out of 44 with acupuncture compared with 8 out of 38 without acupuncture).²² Acupuncture is a reasonable therapeutic option if pain and disability are refractory to more conservative treatment.

Precautions

Acupuncture must be performed by a trained specialist. Only one study reported harm resulting from needle acupuncture.²³ The investigators noted that one patient withdrew from the study because of needle pain. Given that needle acupuncture has provided pain relief in the short term period and is a very low risk procedure, it is a reasonable treatment option for patients in whom more conservative

management has failed.

Pharmaceuticals

Nonsteroidal Antiinflammatory Drugs

Nonsteroidal antiinflammatory drugs (NSAIDs) target the inflammatory process thought to play a role in the early stage of LE and ME. A systematic review of the use of topical NSAIDs (diclofenac and benzydamine) for lateral elbow pain in adults found that pain was significantly improved after 4 weeks of NSAID use in comparison with placebo.²⁴ However, no differences in grip strength or range of motion were reported. Another study noted significant improvements in pain and function after iontophoresis and diclofenac.²⁵ A systematic review of oral NSAIDs found that diclofenac significantly reduced short-term pain compared with placebo, but the studies reviewed did not assess function or long-term pain.²⁶

Nonsteroidal antiinflammatory drugs and corticosteroid injections have been shown to relieve acute epicondylar pain, but not improve long-term outcomes.

Although beneficial in the short term, use of NSAIDs is controversial because the role of inflammation is not fully understood; inflammation may have an efficacious role in soft tissue healing. In addition, studies have assessed the use of NSAIDs in the acute phase, when spontaneous healing is most likely. Acetaminophen has not been studied, but it may provide relief of mild to moderate pain without gastrointestinal risk.

Dosage

Topical diclofenac 3% gel is applied twice daily for 1 to 2 weeks. The regimen for topical diclofenac with iontophoresis is as follows: 3% gel, 150 mg using a 4- to 8-mA intensity for 20 sessions of 25 to 30 minutes each.

The dose of oral diclofenac is 75 mg twice daily for 1 to 2 weeks. The dose of oral ibuprofen is 600 mg every 6 hours for 1 to 2 weeks.

Precautions

Topical NSAIDs may cause skin irritation. Oral NSAIDs may cause abdominal pain and diarrhea, and patients have an increased risk of gastrointestinal complaints (relative risk, 3.0 to 5.0).²⁷

Corticosteroid Injections

Corticosteroid injections also target inflammation and have traditionally been a mainstay of conventional therapy for LE and ME. Clinical trial data support their use on a limited basis for pain and disability from LE and ME, although the effects may be relatively short lived; clinical trial and systematic review data suggest that the effectiveness of these injections is limited to 6 months or less. One review concluded that steroid injections were effective on a short term basis (2 to 6 weeks) compared with placebo, elbow strapping, physical therapy, and NSAIDs, but not in the long term.²⁶ A methodologically strong study compared steroid injections with physical therapy and watchful waiting; at 6 weeks, the injection-treated group was most improved, but at 1 year, the other two groups experienced a higher rate of complete symptom relief.²⁸ A systematic review and clinical trial both reported that corticosteroid injection use was associated with limited effectiveness at 1 year and even overall long term negative effect in the intermediate (13–26 weeks) and long terms (≥ 52 weeks).^{29,30} Corticosteroid injections may have a role in a small set of patients whose work or sport activity requires rapid, short-acting relief of pain, and who are clearly informed of potential lesser long term effects, or harm, compared to other therapies. Patients can be reinjected at 4 to 6 weeks, to a maximum of three injections.²⁴

Dosage

The dose is 1 mL of 40 mg/mL methylprednisolone in 2 to 3 mL of 1% lidocaine.

Precautions

One systematic review found that 17% to 27% of patients in two RCTs suffered some skin atrophy. A more common adverse event is postinjection pain, experienced by approximately half of patients.³¹ The theoretical outcome of tendon rupture was not reported in two separate

reviews, and this complication seems to be rare.²⁶

Other Injection Therapies

Two other injection-based therapies, prolotherapy and platelet-rich plasma (PRP), directly address the hypothesis that tendinopathic pain and functional loss result from degenerative effects. Both have received attention in small but well done RCTs. In both cases, patients had a therapeutic solution injected at the attachment of the common extensor tendon with optional injection of surrounding ligamentous attachments. A peppering injection technique is often employed. Although the precise mechanism of action for both techniques is not well known, both purport to heal damaged, degenerative tendons at the tissue level. As such, both therapies attempt to address the contemporary understanding of LE and ME as degenerative conditions, and have been categorized as “regenerative” therapies, although their mechanisms of action are not well understood.

PRP is a concentrated solution of autologous platelets that delivers growth factors directly to areas of degeneration and is hypothesized to enhance tissue healing.^{32,33} Autologous blood is drawn and is centrifuged at the point of care to separate the portion with the greatest abundance of platelets. Studies reported that PRP for LE could result in improved quality of life through decreased pain and function, and PRP could modify the disease course at the level of the damaged tendons.^{30,34} Promising early clinical trial and anecdotal evidence have resulted in increasingly common use of PRP in clinical practice.^{32,33} One RCT showed that at 52 weeks, subjects with LE who received PRP injection reported a 66% effect size compared to baseline values, whereas study participants who received steroid injections reported only a 17% improvement ($P < .05$) in disease-specific quality of life.³⁰ However, a recent controversial systematic review has challenged the positive conclusions of several positive PRP studies³⁵ and has drawn sharp criticism.³⁶

The efficacy of prolotherapy, an injection-based therapy reported to enlarge and strengthen ligaments, has been evaluated in systematic and descriptive reports.^{37,38} Prolotherapy is used for the treatment of various soft tissue conditions including LE and ME. While the mechanism of action is not well understood, it is thought to involve inflammation, which initiates a local physiological reaction favoring anabolic processes, recruitment of growth factors, and direct sensorineural effects.³⁹ The net effect is hypothesized to strengthen and revitalize tendon and ligament

tissue at the bony insertion. Injectants include hypertonic dextrose and morrhuate sodium. In one RCT, subjects with severe refractory LE responded well to three prolotherapy treatments. Compared with participants receiving blinded saline injections, subjects treated with prolotherapy experienced pain reduction (absolute effect size between groups of 68%; $P < .01$) and improved isometric strength ($P < .05$) compared with control saline injections by 16 weeks, and these effects were maintained at 52 weeks.⁴⁰ A more rigorous study confirmed these findings using hypertonic dextrose alone.⁴¹ Both were of a small sample size; a larger study is under way (see [Chapter 112](#)).

Both prolotherapy and PRP injection appear to be safe when performed by an experienced injector and are reasonable treatment options for patients in whom more conservative management has failed. Neither therapy is typically covered by third-party payers; costs for each vary considerably.

Dosage and Precautions

There is currently no formal dosing for either PRP or prolotherapy. Both therapies require specific injection techniques. Obtaining these services is best done in consultation with physicians who are experienced at performing these procedures. Both procedures are performed in an outpatient setting without significant analgesia, similar to corticosteroid injections. Both solutions are injected at tender points at the attachments of the common extensor tendon and radial collateral ligament. PRP injection therapy is performed in a single treatment session, whereas prolotherapy is more typically performed in a minimum series of three treatment sessions that are separated by approximately 4 weeks each.

Biomechanical Medicine

Physical Therapy

Exercise and physical therapy make sense clinically and are well accepted. Eccentric exercises preferentially load tendons and promote the formation of new collagen. These exercises were reported to be beneficial in one small RCT comparing exercise for epicondylar pain at 8 weeks

with ultrasound and friction massage,²⁶ as well as in other tendinopathies.^{42,43}

Exercise and physical therapy are reasonable conservative modalities, although their overall long-term efficacy is unclear.

One review and one well-done RCT reported that exercise, stretch, and mobilization were effective therapies and yielded significant improvement compared with wait-and-see, placebo, and ultrasound approaches.^{44,45} Unfortunately, the physical therapy protocols vary, and studies do not describe them in detail. Examples of exercises and recommendations for their use are shown in [Fig. 71.4](#).

Osteopathic Manipulation

Practitioners of osteopathic medicine understand the human body as a coherent unit of mind and body that is capable of self-regulation and self-healing. Structure and function are assumed to reciprocally interrelated⁵¹; achievement of normal body mechanics is viewed as being central to maintaining good health.⁴⁷ Osteopathic manipulative treatment (OMT) is aimed at improving the body's physiological and homeostatic processes that have been inhibited by a somatic dysfunction, which can be myofascial, vascular, neurological, cartilaginous, or bone-related. The osteopathic view of LE and ME is that they may be not only be a tendon enthesopathy but also include articular, myofascial, and/or vascular/lymphatic elements leading to pain at the lateral or medial elbow. The goal of osteopathic OMT is to remove joint and muscle restriction, as well as to address any associated tissue texture changes. Treatment is usually directed at the affected extremity⁴⁸ but can include manipulation of the ipsilateral cervical and thoracic spines and ribs.^{49,50} Treatment of the radial head, interosseous membrane, or ulnar somatic dysfunction has been reported to improve lateral elbow pain and function.⁵¹ Limited objective and descriptive data suggest that OMT alone is effective for epicondylitis, as well as in combination with routine care.^{52,53}

Lateral Epicondylitis Physical Therapy

Start exercises with set **A** and proceed slowly through the set. Advance to exercises with weights when pain begins to decrease, usually after 7-10 days.

A. Active range of motion and strengthening

1. Place forearm on table with hand off edge of table, palm down.
2. Move hand upward.

Hold position for 15 seconds.
Return to starting position.
Perform 1 repetition every 4 seconds.
Perform 1 set of 12 repetitions twice per day.

After 7-10 days, or as range of motion improves and pain diminishes, advance to step 3:

3. With other hand, grasp at thumb side of hand and bend wrist downward gently.
Perform 1 set of 4 repetitions twice per day.

B. Exercise with weight

1. Place forearm on table, palm down, weight in hand.
2. Use other hand to raise wrist fully upward.
3. Release wrist and slowly lower weight.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

C. Exercise with weight

1. Support forearm on table or armchair, hand palm down holding weight.
2. Rotate hand to thumb up.
Return to starting position.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

D. Exercise with weight

1. Support forearm on table or knee.
Hold weight in hand, thumb up.
2. Lift weight upward.
Return to starting position and repeat.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

Medial Epicondylitis Physical Therapy

Start exercises with set **A** and proceed slowly through the set. Advance to exercises with weights when pain begins to decrease, usually after 7-10 days.

A. Stretch exercise

1. Grasping fingers of one hand with other hand, pull hand back gently. Keep injured elbow straight.

Hold position for 15 seconds.
Perform 1 set of 4 repetitions twice each day.
Rest 30 seconds between repetitions.

B. Exercise with weight

1. Grasp weight with hand. Place forearm on table with hand off edge of table, palm up as shown.
2. Move wrist upward. Return to starting position.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

C. Exercise with weight

1. Support forearm on table or armchair. Position hand palm up with weight in hand as shown.
2. Rotate hand to thumb up. Return to starting position.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

D. Exercise with weight

1. Support forearm on table or knee. Hold weight in hand, thumb up.
2. Lift weight upward. Return to starting position and repeat.

Start with 1/2-lb weight, advance to 1-lb weight.
Perform 1 repetition every 4 seconds.
Perform 3 sets of 10 repetitions once every other day.
Rest 1 minute between sets.

FIG. 71.4 Physical therapy for lateral epicondylitis.

Precautions

OMT is typically performed by osteopathic physicians (doctor of osteopathy [DO]) or MDs who have received additional osteopathic training. Obtaining these services is best done in consultation with physicians who are experienced with these procedures. OMT is performed in an outpatient setting without analgesia. The patient should be made aware that following treatment, muscle soreness or increased localized pain may occur for 24 to 72 hours. However, the pain usually decreases rapidly with maintenance of function and overall pain improvement.⁵⁴

Orthoses (Braces)

Orthotic devices (e.g., brace, splint, cast, or strap) are thought to decrease the pain of LE or ME by removing the damaging load from the lateral and medial epicondylar tendon attachments. A systematic review of five RCTs assessing various orthotic devices was unable to provide a general recommendation for their use.⁵⁵ However, the notion of reducing stress and strain at the tendon insertion makes sense and is generally accepted; clinically, many patients respond well to a simple and inexpensive elbow strap or wrist splint combined with relative rest. Complete immobilization with any orthotic device should be avoided because of the risks of deconditioning and muscular atrophy.

Precautions

Local deconditioning should be avoided.

Surgery

A 2005 review found no RCTs that evaluated surgical intervention for LE or ME.²⁶ However, data from case series have demonstrated the efficacy of surgery in patients with symptoms refractory to more conservative

therapy. The goal of surgery is to excise abnormal tissue or release the affected portions of the extensor or flexor tendons. Findings from one case series, consisting of 1300 patients that underwent surgery for refractory epicondylar pain (1000 for LE and 300 for ME), showed that 85% of patients experienced complete pain relief and strength return, 12% had partial improvement, and 3% had no improvement.¹² Surgery is a reasonable option for patients with significant pain for whom more conservative therapy has failed.

Precautions

Precautions include postoperative concerns such as infection and nerve damage. In the study cited previously, however, reported complications were rare.¹²

Prevention Prescription

Lifestyle

- Stop smoking.
- Reduce stress.

Avoid Exacerbating Activities

- Reduce or avoid the lifting of objects with the arm extended.
- Reduce repetitive gripping.
- Decrease overall tension of gripping.
- Avoid extremes of wrist bending and full extension.
- Work or train with the elbow in a partially flexed position.
- Use wrist supports when weight training.
- Enlarge the gripping surface of tools or rackets with gloves or padding, use a hammer with extra padding to reduce tensions and impact, and hold heavy tools with two hands.

Ergonomic Evaluation

- Evaluate repetitive motion activity, duties, equipment, and techniques, especially in work situations.
- More complete information on ergonomic evaluation of computer,

laboratory, and industrial settings is available through the Centers for Disease Control and Prevention (see [Key Web Resources](#)).

Exercise

- Use stretching and strengthening exercises once daily, along with frequent periods of short rest.

Therapeutic Review

Lifestyle

- Prevention: Most of the techniques listed in the Prevention Prescription box also off-load affected tendons and may speed healing.
- Establish a time course of healing; most patients recover in weeks to months, but recovery may take up to 1 year or longer.
- Relative rest: Remove or reduce repetitive, heavy activity affecting wrist flexors or extensors. 
- Use ice during the first 2 to 4 weeks of pain. 

Mind-Body Therapy

- Stress reduction techniques and workplace evaluation are recommended. 

Bioenergetic Therapy

- Needle acupuncture may be used. 

Pharmaceuticals

- Nonsteroidal antiinflammatory drugs and corticosteroid injections have good efficacy for pain control in the early stages of lateral epicondylitis and medial epicondylitis, but they do not change outcomes in the long term. 
- Topical diclofenac, 3% gel, may be applied twice daily for a duration of 1 to 2 weeks. 

Topical diclofenac may be applied with iontophoresis, using 150 mg at

4 to 8 mA for 25 to 30 minutes, for 20 sessions.

- Oral ibuprofen, 600 mg, may be taken every 6 hours for no more than 2 weeks. 
- Injection: Methylprednisone, 40 mg in 1 mL of lidocaine, may be injected weekly for up to four treatments. 

Physical Therapy and Preventive Exercise

- Various exercises may be performed in sets of repetitions with and without weights from twice daily to every other day (see [Fig. 71.4](#)).

Orthotics

- Simple wrist splints and elbow straps may be used in conjunction with relative rest. 

Prolotherapy

- Prolotherapy appears to be safe when performed by an experienced injector and is a reasonable treatment option for patients in whom more conservative management has failed. 

Platelet-Rich Plasma

- Platelet-rich plasma injection appears to be safe when performed by an experienced injector and is a reasonable treatment option for patients in whom more conservative management has failed. 

Surgery

- Surgery is a reasonable option for patients with severe pain that is refractory to conservative care.

CHAPTER 72

Atopic Dermatitis

Amanda J. Kaufman, MD, ABIHM

Atopic dermatitis (AD) is a pruritic, hereditary skin disease affecting 15%–25% of children; in 30% or more, it will persist into adulthood.¹ The heavy impact of atopic dermatitis on quality of life and medical care costs has led to an explosion of basic science and clinical research. Great strides have been made to understand the pathophysiology of the disease and study the impact of treatment modalities. Causes stem from genetic mutations that impair the skin barrier, which allow greater permeability for allergens and pathogens, enhancing Th2 immunity. Atopic dermatitis is also an outward manifestation of inner imbalances including nutrient deficiencies, food allergies, and other intestinal dysbiosis. It is essential to take the time for a thorough history and examination to best guide each individual on their treatment options. Interest in the integrative approach stems from seeking to address the underlying causes rather than suppressing the immune system enough to overcome the symptoms.

Pathophysiology and Diagnosis

The diagnosis of atopic dermatitis requires three major and three minor features.¹ Major features are as follows:

- Pruritus
- Typical morphology and distribution
- Flexural lichenification in adults
- Facial and extensor involvement in infants and children
- Chronic or chronically relapsing dermatitis
- Personal or family history of atopy (asthma, allergic rhinitis, atopic dermatitis)

The 22 minor features in the following list illustrate the varying degrees, extent, and distress that patients endure:

- Itch caused by sweating
- Xerosis
- Eczema (perifollicular accentuation)
- Recurrent conjunctivitis
- Wool intolerance
- Keratosis pilaris
- Palmar hyperlinearity
- Pityriasis alba
- White dermatographism
- Susceptibility to cutaneous infection (*Staphylococcus aureus*, herpes simplex virus, and other viruses)
- Nipple dermatitis
- Dennie-Morgan lines
- Elevated immunoglobulin E (IgE)
- Immediate (type I) skin test reactivity
- Food intolerance
- Cataracts (anterior-subcapsular)
- Cheilitis
- Facial pallor or erythema
- Hand dermatitis
- Ichthyosis
- Keratoconus
- Orbital darkening

Genetic, immunologic, and environmental risks collide to influence the course of disease and provide opportunities to mediate the clinical course. The stratum corneum permeability barrier is made up of the cornified envelope, fatty acids such as ceramides, and keratin proteins tightly bound by filaggrin (FLG). FLG mutations and/or impaired ceramide levels result in abnormal permeability and poor water retention. This abnormal skin barrier allows penetration of allergens and microbes that trigger an inflammatory cascade as they stimulate proinflammatory type 2 helper T (Th2) cells excessively.¹ Epidermal cells communicate to sensory neurons through cytokine thymic stromal lymphopoietin (TSLP) to promote itching.² This cytokine also promotes Th2 cells and the “atopic march” from AD to asthma and allergic rhinitis.

Among environmental exposures, Phthalates also stimulate TSLP; higher exposure in utero and in early life confers additional risk of AD.^{3,4}

Improving the skin barrier is essential in treatment and prevention.

Emollient use has been shown to cut AD risk in half among high-risk infants.

Light stimuli and contact irritants such as sweating, wool, and detergents cause itching. Skin damage caused by scratching releases inflammatory cytokines and further stimulates itch. Reduced barrier function allows entry of *S. aureus*, *Malassezia* yeasts, *Candida* organisms, and *Trichophyton* dermatophytes, thereby inducing local inflammation. Herpes simplex virus (HSV) can cause eczema herpeticum, with vesicles throughout vulnerable skin, usually with a bacterial superinfection. During a flare, the skin of patients with atopic dermatitis has reduced microbiome diversity with predominance of pathogenic bacteria, especially in the skin areas most often affected.⁵ During recovery, the microbiome diversity is restored.

Food allergies, especially to eggs, soy, milk, wheat, fish, shellfish, and peanuts, are implicated in one-third to one-half of children with AD. Aeroallergens can also increase peripheral eosinophilia and serum IgE levels, which lead to an increased release of histamine and vascular mediators. These features induce edema and urticaria and thus cause persistence of the cycle of itch, scratch, and rash.

Food allergies, especially to eggs, soy, milk, wheat, fish, shellfish, and peanuts, are implicated in one-third to one-half of children with atopic dermatitis.

The relationship between psychological stress and atopic disorders is bidirectional.⁶ Psychosocial stressors increase both self-reported and objective measures. The lack of sleep and physical suffering cause irritability and worsen mood disorders. Self-reporting of itch severity is increased when depression scores are elevated, similar to the relationship with pain scores.

Integrative Therapy

Atopic dermatitis is improved through an integrative approach focusing on improving the barrier function and reducing the itch-scratch cycle. Least invasive therapies are presented first, followed by those with a greater potential for harm. Outcomes are better when time is taken for

education and self-determination of the great variety of available treatment options.⁷ Akin to asthma therapies, developing an eczema action plan ([Fig. 72.1](#)) where the regimen can be amped up to provide control and then relaxed as the flare resolves reduces use of pharmaceuticals and improves patient satisfaction.⁸

Lifestyle and Supportive Care

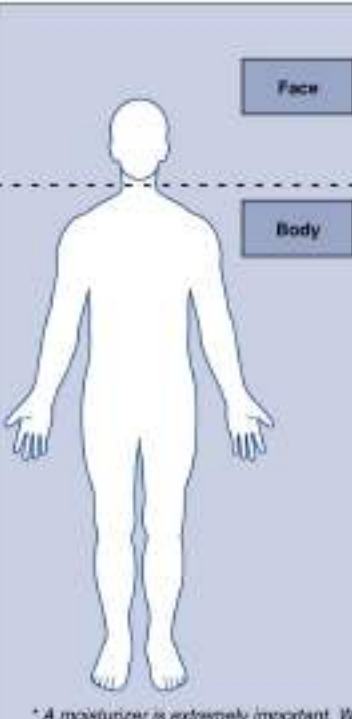

Hydration

Rehydration of the stratum corneum improves barrier function and reduces the effects of irritants and allergens. Soaking in a lukewarm bath for 10–20 minutes daily is ideal, or lukewarm showers may be taken. If even plain water is irritating during acute flares, one cup of salt or baking soda added to the water will reduce the sting.

Bleach Baths

Evidence is growing that all atopic dermatitis treatments improve skin microbiome diversity and reduce the dominance of *S. aureus*. Dilute bleach baths have been used successfully with this goal in mind and have improved symptom control.⁹ In the original study, 31 children aged 6 months–17 years were treated with cephalexin, 50 mg/kg (maximum 2 g daily) divided three times daily for 14 days, and were then randomized to bathing in a dilute bleach solution (approximately one-half cup to a bathtub of water) twice weekly for at least 5 minutes (then rinsing off) and applying mupirocin ointment intranasally for the patient and for all household members twice daily for the first 5 consecutive days of each month or placebo. The mean Eczema Area and Severity Score (EASI) of 19.7 was reduced by 10.4 points at 1 month and by 15.3 points at 3 months compared with 2.5 and 3.2 points in the placebo group. These reductions were in exposed areas, but not in head and neck lesions, although the head and neck can also be carefully exposed to the bleach solution. Follow-up studies have demonstrated equal effectiveness to baths only and have validated the ease of use.¹⁰

ECZEMA ACTION PLAN

		Clear	Mild-mod	Severe
Face	AM	Moisturizer*	Moisturizer*	Moisturizer*
	PM	Moisturizer*	Moisturizer*	Moisturizer*
Body	AM	Moisturizer*	Moisturizer*	Moisturizer* <i>Call your doctor if not improving after 2 weeks</i>
	PM	Moisturizer*	Moisturizer*	Moisturizer* <i>Call your doctor if not improving after 2 weeks</i>

* A moisturizer is extremely important. We recommend applying the moisturizer at least twice per day for any patient with eczema.

FIG. 72.1 Eczema action plan.

Mild Soap or Soap Substitutes

Use mild, neutral-pH soap (Dove, Aveeno, Basis) minimally if needed for the face, axillae, and groin. Alternatively, hydrophobic lotions or creams such as Cetaphil can be applied without water, rubbed until foaming, and wiped away with a soft cloth. Even use of the emollient itself can be effective for washing. Other guidelines include avoiding sodium laurel sulfate and bath oils or additives; use shampoo only on hair; avoid baby wipes as much as possible.¹¹ Invite new parents to leave the protective vernix on newborn skin.

Moisturizers Following Bathing

Follow bathing by lightly patting the skin with a towel and immediately applying an occlusive emollient over the entire skin surface to retain moisture. Application within 3 minutes improves hydration, whereas beyond 3 minutes, the surface dries due to evaporation. Emollient use from birth prevents AD. One hundred twenty-six high-risk infants were

randomized to daily emollient use or none; emollient use resulted in a 50% risk reduction at age 6 months.¹¹ Parents in the United Kingdom were given a choice of sunflower seed oil with a high linoleic:oleic acid ratio, double base gel (Dermal laboratories), or liquid paraffin 50% in soft white paraffin. Parents in the United States were given a choice of sunflower seed oil, Cetaphil cream, or Aquaphor ointment. Virgin coconut oil had excellent effects of reduced TEWL; it additionally reduces colonization with *S. aureus* and thus provides an added benefit.¹² Ceramide-containing emollients are effective. One formulation (EpiCeram) showed improvement nearly equal to that with fluticasone cream after 28 days of use.¹³ Urea, alpha-hydroxy acid, and lactic acid products have long been used for their exfoliation and moisturizing properties. However, studies are limited.¹⁴

Wet Dressings

Wet dressings are useful for severely affected skin. The constant moisture is therapeutic, the cooling sensation with evaporation reduces itching, and the mechanical barrier prevents scratching. Additional use of very dilute steroids such as 1:3 mometasone furoate 0.1% ointment for body and 1:19 mometasone furoate 0.1% ointment for the face under a mask are effective with less use of steroids.¹⁵ Two recent reviews discuss how effective this can be for the most severely affected patients.^{16,17} Apply a wet cloth with either plain water or Burow solution to recalcitrant lesions, and periodically rewet the compress. Wet dressings increase penetration of corticosteroids. Burow solution can be made 1:40 by dissolving one Domeboro packet or tablet in a pint of lukewarm water. Children can wear cotton pajamas dampened in the affected areas with other clothing worn over them to prevent them from getting too cold. The eczema company (see [online resources](#)) carries a variety of clothing and wet wrap products.

Wet dressings are highly effective and well tolerated, especially in severe disease. Hospital care can be replicated at home by using wet dressings as much as possible on the weekends.

Avoidance of Allergens

Eliminate known allergens. Eliminate smoke exposure for children with allergies. Dust mite control measures may be helpful in patients with documented sensitivity to dust mites. In children with animal allergies, consider removing animals from the home. A dog living in the home at the time of birth is associated with a 50% decrease in the incidence of atopic dermatitis at age 3 years.¹⁸ However, parents caring for a dog are less likely to be severely allergic to dog dander.

Loose-Fitting Clothing

Wear loose-fitting clothing made of cotton, silk, or other natural, smooth fibers. Avoid wool. Launder new clothes before wearing to remove formaldehyde and other chemicals. Use liquid detergent, ideally without fabric softeners or optical brighteners, and consider an extra rinse cycle to more completely remove detergent.

Humidity

Controlled humidity and temperature may reduce triggers of cold, heat, and dry air.¹ Humidify in the winter with a goal of 30%–40% humidity. Air conditioning in the summer decreases sweating as a trigger and prevents the growth of mold.

Nutrition

Prevention Through Breastfeeding or Hydrolyzed Formula in Infancy

Exclusive breastfeeding for the first 6 months of life reduces atopy, although results of some studies have been inconclusive. One study on breastfeeding among atopic mothers noted that dairy avoidance greatly reduced the risk of atopy in their children.¹⁹ Debate exists on the role of food avoidance even in high-risk infants. Some experts point to populations in whom very young babies are given tastes of adult food and subsequently have a lower incidence of life-threatening allergies. In the LEAP trial, 640 babies at high-risk for peanut allergy (severe eczema, egg allergy, or both) were randomized to consuming peanuts three times weekly or avoidance until age 60 months.²⁰ They were also tested by pin-prick testing for peanut protein allergy prior to randomization. Among

the 530 with negative prior testing, 13.7% among controls developed peanut allergy versus 1.9% in the consumption group ($p < .001$). Among the 98 participants with positive prior testing, 35.3% of controls developed peanut allergy versus 10.6% in the consumption group ($p = .004$). There were no significant differences in adverse events. The theory is that when we are first exposed to a protein through the healthy gut, versus first seeing it topically, we are less likely to develop an allergy. This is even more important in those with AD as their impaired skin barrier is more likely to be sensitized from peanut antigen in house dust.²¹

For those infants who cannot breastfeed, hydrolyzed formulas have been found effective for the prevention of atopic dermatitis. A 6-year follow-up to a study of 2252 newborns with a familial history of atopy, who were randomized to various hydrolyzed formulas versus standard cow's milk formula when breastfeeding was insufficient, revealed a significant risk reduction for allergic disease.²² The relative risk of development of atopic eczema was 0.79 for partially hydrolyzed whey formula, 0.92 for extensively hydrolyzed whey formula, and 0.71 for extensively hydrolyzed casein formula. A meta-analysis and a more recent study also found that partially hydrolyzed whey formulas appear to be as good at preventing atopic disease as extensively hydrolyzed formulas, and they cost less.^{23,24}

Allergy Elimination Diet

A study attempting to show a benefit to an allergy elimination diet in a broad sample of children with atopic dermatitis found a benefit only to an egg-free diet in infants with suspected egg allergy positive for specific IgE to eggs.²⁵ By the age of 5 years, many of these food allergies resolve. The most common foods causing positive oral challenges are egg, soy, milk, wheat, fish, shellfish, and peanuts. Elimination diets can be stressful on parents, especially exhausted breastfeeding mothers. However, many parents will become aware of their own allergies through the process. Parents often desire testing to guide them; however, testing is not as reliable as a clinical response. The skin in atopic dermatitis can develop a wheal with a needle prick alone.¹ Serum-specific IgE/IgG tests have significant false-positive rates.²⁶ For example, in the LEAP study, all consumers of peanut had increases in their peanut IgG. The gold standard for diagnosis is a placebo-controlled, double-blind oral food challenge because history, prick tests, and specific IgE do

not correlate well with clinical reactivity, especially in delayed eczematous skin reactions.^{1,26} Diagnostic elimination diets, such as those described in this text (see [Chapter 86](#)), should be used. A review of the serum radioallergosorbent test (RAST) and enzyme-linked immunosorbent assay (ELISA) and their inherent challenges provides further detailed guidance.²⁷

Oolong Tea

With consuming Oolong tea three times a day (made from five tea bags daily), 63% of patients had significant objective improvement, and the response persisted at 6 months in 54% of patients.²⁸ The antiallergenic properties of polyphenols are thought to produce the effect. Consuming five to six cups of green tea or green tea extract, at 200–300 mg three times daily, may provide similar results.

The main difference among green, oolong, and dark tea (all *Camellia sinensis*) is the length of fermentation of the leaf. Green is the shortest and dark the longest.

Mind-Body Therapy

Psychosocial stressors trigger flares of atopic dermatitis, and this connection prompted studies on the effectiveness of mind-body interventions. A Cochrane Review states that at least some patients may benefit from biofeedback, massage therapy, and hypnosis.²⁹ A study on the benefits of support groups found improved quality of life scores, especially personal relationships and leisure scores.³⁰ A study of a structured education program on coping skills in children with atopic dermatitis and their parents showed that the intervention improved psychological scores beyond what would be expected with disease improvement.³¹ Dr. Ted Grossbart, a Harvard Medical School (Boston) psychologist, created a mind-body program for skin disorders, and his e-book is available for free (see [Key Web Resources](#)). Many therapies with known effectiveness in similar conditions have not been studied. Given the low risk of side effects and the known benefits of mind-body therapies for other measures of well-being, these approaches are worth exploring.

Supplements

Vitamins

Vitamin D and E supplementation with vitamin D₃ (1600 units) and vitamin E (600 units synthetic all-rac-alpha-tocopherol) were compared to placebo for 60 days, reducing objective scoring measures by 64.3% ($p = .004$).³² In various studies, vitamin D supplementation had a greater effect in the winter in those with darker skin and in those with higher BMIs.³³ Higher serum vitamin D levels are correlated to milder disease and lowers IgE to microbial antigens.³⁴ Higher cord blood levels of vitamin D reduced risk of AD in children followed to age 5 years.³⁵

Dosage

Vitamin D₃ 2000–5000 IU daily (consider testing for adequacy) and vitamin E 400 IU as mixed tocopherols. Many practitioners recommend supplementation with antiinflammatory supplements such as 5000 IU of vitamin A daily and 20 mg of zinc per daily. Vitamin B₁₂ cream, 0.07% used twice daily, was found to be effective and well tolerated in adults and children with eczema in small studies.³⁶

Essential Fatty Acids

Linoleic acid is a precursor to ceramide. Docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) primarily function through their antiinflammatory effects. The primary sources of DHA and EPA are salmon and other cold-water fish. Good sources of gamma-linolenic acid (GLA) include borage oil (23% GLA), black currant seed oil (17% GLA), and evening primrose oil (8%–10% GLA).³⁷

Supplementing DHA/EPA, or getting breastmilk with adequate levels, prevents AD and improves objective measures.³⁸ An 8-week study of 53 adults randomized to DHA (5.4 g daily) or isoenergetic saturated fatty acids revealed significant improvement in the DHA-treated group.³⁹ Another small study of evening primrose oil with 2 g of linoleic acid and 250 mg of GLA for 3 months showed significantly improved inflammation in AD.⁴⁰

Dosage

For children, a combined total of 2000 mg of DHA, EPA, and GLA is likely effective compared with the doses recommended in single-agent trials. For adults, use 2–4 g daily of EPA/DHA and/or borage oil 500 mg–1 g daily or evening primrose oil 1–2 g daily.

Precautions

Adverse effects of supplements are few, and they are primarily gastrointestinal.

Probiotics

A lack of microbiome diversity in the gut is associated with a myriad of illnesses. Greater diversity with known beneficial flora on the skin such as lactobacilli and *Bifidobacterium species* prevents and improves symptoms in AD. Vaginal birth, breast-feeding, and a greater number of siblings increases rates of colonization with lactobacilli, and decreased rates of clostridia.⁴¹ The opposing conditions are associated with more clostridia and an increased risk of AD. Prenatal and postnatal use of *Lactobacillus rhamnosus* GG among atopic mothers reduces the prevalence of atopic dermatitis in their infants by 50%, with a number needed to treat of 4.5.⁴² To prevent atopic dermatitis, women with a history of atopy should consider supplementation with *L. rhamnosus* when they are pregnant and breast-feeding. Supplementation after diagnosis also provides improvement.

Dosage

For adults, the dose is 20–50 billion CFUs daily of a combination probiotic containing *L. rhamnosus*. For infants and children, the dose is 5–10 billion CFUs daily.

Precautions

Patients with extreme immune compromise or those with indwelling catheters should use caution with regard to taking these live organisms.

Encouraging the presence of lactobacilli and a diverse microbiome, either through lifestyle circumstances or supplementation, improves outcomes.

Botanicals

Much of the long heritage of herbal treatment of atopic dermatitis has not been studied, although several compounds have had small, successful trials, and no safety concerns exist. Ensuring the quality of the compound used is essential to achieve these treatment effects.

Glycyrrhetic Acid

Derived from licorice root, glycyrrhetic acid has antiinflammatory actions when it is used topically. Two percent glycyrrhetic acid cream used in a 5-week study noted significant improvements in objective disease scores and itch.⁴³ Atopiclair is a hydrophilic cream containing hyaluronic acid, telmesteine, *Vitis vinifera* (grape), and 2% glycyrrhetic acid. Two vehicle-controlled, randomized studies of 218 adults and 142 children with mild to moderate atopic dermatitis found highly significant response rates.^{44,45} Atopiclair cream is available by prescription (100-g tube) and over the counter.

Dosage

These products are applied to effected area two to three times daily as needed.

Precautions

Atopiclair cream contains a nut oil and thus should not be used in patients with a nut allergy.

Other Botanicals

Studies demonstrate the effectiveness of an extract of St. John's wort (*Hypericum perforatum*). This botanical has antimicrobial activity and may have beneficial immunological effects. A study of 28 patients found significant clinical improvement when this extract was applied as a cream compared with its vehicle.⁴⁶ Oregon grape root (*Mahonia*

aquifolium) has antimicrobial properties and inhibits proinflammatory cytokines.⁴⁷ A 10% cream used in 42 adult patients three times daily over 12 weeks demonstrated significant clinical improvement. Twenty-one patients with mild atopic dermatitis who were 5–28 years old were randomized to 0.3% *rosmarinic acid* emulsion twice daily or vehicle.⁴⁸ These patients had significantly reduced erythema and transepidermal water loss. Honey has been used to reduce inflammation and promote healing; small studies have shown it is helpful.⁴⁹ Chamomile is regarded as gentle and safe, and it has antiinflammatory and antibacterial properties. Cold, wet packs with chamomile tea are traditionally used for bacterial superinfections.⁵⁰ Herbavate, a topical preparation that contains the oil extracts of *Calotropis gigantea*, *Curcuma longa*, *Pongamia glabra*, and *Solanum xanthocarpum* in a cream base, showed promise in an open-label 4-week pilot study.⁵¹ These extracts have been used in Indian traditional medicine and Ayurveda.

It is easy to find combination products online or in health food stores. One example is Four Elements Herbals' product Look No X E Ma!, which contains almond oil, calendula, chamomile, licorice and comfrey root decoction, beeswax, shea butter, borax, evening primrose oil, and vitamin E (www.fourelementsherbals.com).

Familiarize yourself with the products available from your local herbalist or compounding pharmacist. Use of more than two topical products can be cumbersome for patients, although many products can be compounded together for ease of use. Many commercially available products contain several agents in combination.

Conventional Modalities

Coal Tar

Coal tar preparations have antipruritic and antiinflammatory effects and were used before the development of topical corticosteroids. Research shows coal tar activates the aryl hydrocarbon receptor (AHR), restoring filaggrin expression to wild-type levels.⁵² They work well on chronic and lichenified lesions.¹ Tar shampoos can be used for scalp involvement. Adverse effects include contact dermatitis, folliculitis, and photosensitivity. One review found that most studies reported favorable profiles of effectiveness with few side effects (including staining and

odor) and also noted that these preparations are cost effective.⁵³

Immunotherapy

Allergen immunotherapy is typically indicated for patients with allergic rhinitis or allergic asthma, although it has shown promise for atopic dermatitis. A meta-analysis of eight small, heterogeneous trials (385 subjects) was encouraging.⁵⁴ These included studies targeting house dust mites (8), animal dander (2), molds (1), and pollen (2). Clinically, there are some pediatric allergists performing peanut immunotherapy.

Immunization and Childhood Diseases

Concerns have been raised about the effect of immunizations on atopic dermatitis. Analyses concluded that both natural infection and immunization protect against childhood atopic dermatitis.⁵⁵ With varicella, infection has a decreased odds ratio of 0.55 for development of atopic dermatitis.⁵⁶ Children who are infected with wild-type varicella zoster infection, as opposed to vaccine, who develop atopic dermatitis have fewer doctor visits for atopic dermatitis (odds ratio, 0.17). In a study of 2184 infants with atopic dermatitis and a family history of atopy, exposure to vaccines (diphtheria, tetanus, pertussis, polio, *Haemophilus influenzae* type b, hepatitis B, mumps, measles, rubella, varicella, bacille Calmette-Guérin, meningococci, and pneumococci) was not associated with an increased risk of allergic sensitization to food or aeroallergens.⁵⁷ On the contrary, immunizations against varicella and pertussis and cumulative numbers of vaccine doses were inversely associated with eczema severity.

Ultraviolet Light

Ultraviolet (UV) light may be helpful for some patients, although this technique is less popular because of the acceleration of photoaging and increased risk of skin cancer. Many small studies and its popularity among patients support the use of sun and sea-water bathing.⁵⁸ A study of narrow-band UVB showed a statistically significant advantage when light therapy was accompanied by synchronous bathing in a 10% Dead Sea salt solution.⁵⁹ In one study, narrow-band UVB and medium-dose UVA1 dosed three times a week were equally effective.⁶⁰

Pharmaceuticals

Antimicrobials

Despite the role of bacteria in AD, use of antibiotics has not been found effective as treatment for atopic dermatitis.⁶¹ This reflects that it is not the eradication of the infection that is effective but the return of a diverse microbiome. Lesions that are not responsive to corticosteroids may need treatment for subclinical bacterial superinfection.⁶² Also consider testing for HSV with a smear or culture. Dermatophyte infections can contribute to head and neck lesions.⁶³

Dosage

- Mupirocin or bacitracin ointment twice daily for 7–10 days; cephalexin, 250 mg four times daily for 7 days; or dicloxacillin, 250 mg four times daily for 7 days.
- For HSV, acyclovir 800 mg orally five times daily for 7–10 days.
- For *Candida albicans* or *Malassezia furfur*, ketoconazole used topically or taken orally 200 mg twice daily for 10 days.

Antihistamines

Antihistamines may be useful to reduce scratching. Oral antihistamines may be mostly useful for their sedative properties.¹ Doxepin cream can cause sedation if it is used over large areas of the body.

Dosage

- Doxepin cream 5%, a thin layer applied up to four times daily
- Diphenhydramine, 12.5–50 mg orally every 6 hours
- Hydroxyzine, 10–50 mg orally every 6 hours; or loratadine, 10 mg orally daily

Topical Corticosteroids

The standard medical treatment of atopic dermatitis consists of topical corticosteroids. Interestingly, measured effects of topical steroids and topical calcineurin inhibitors (discussed in the following section) are reduction of transepidermal water loss and improved barrier function.⁶⁴

These drugs are typically used twice daily for up to 2 weeks during an acute flare and then once to twice daily on weekends to maintain remission. Because this disease is more common in young children, concerns arise that long-term use may suppress the hypothalamic-pituitary-adrenal (HPA) axis, cause growth retardation, and have other side effects. Despite these concerns, no other medication is as effective during an acute flare, and its use only during these times does not appear to pose a risk.

For quick control of flares, consider using a higher-potency product and then reducing the strength for maintenance or switching down to an herbal preparation. Use only class IV and V corticosteroids on the face, axilla, groin, and intertriginous areas.¹ For children, use class III agents when a more potent agent is desired and titrate downward. For the eyelids, use a class V or VI agent for 5–7 days. Apply a thin layer directly after bathing, followed by emollient use. Ointments are generally recommended, although not in warm, humid climates, in which their occlusiveness can cause sweat retention dermatitis and acne. Gels can be used for weeping lesions and on the scalp and bearded skin. A full list of potencies of topical steroids is available in [Chapter 73](#).

Dosage

- Class I (superpotent): clobetasol ointment 0.05% twice daily (also available as a gel)
- Class III (upper midstrength): triamcinolone 0.1% ointment twice daily
- Class IV (midstrength): hydrocortisone valerate 0.2% ointment twice daily
- Class V (lower midstrength): desonide 0.05% ointment twice daily
- Class VI (mild): hydrocortisone 1% ointment twice daily

Precautions

Prolonged use of steroid creams can cause skin atrophy or acne, and prolonged use of potent steroids carries a risk of growth retardation in children.

If systemic steroids are warranted, use in conjunction with an

aggressive topical regimen and give as a 14-day taper to avoid a rebound flare.

Topical Immunomodulators

Tacrolimus ointment and pimecrolimus cream, inhibitors of calcineurin, are additional nonsteroidal options for treatment of atopic dermatitis. These agents decrease T-cell activation and cytokine release while inhibiting mast cell and basophil degranulation. They have been studied largely as steroid-sparing agents for use after control of an acute flare to maintain remission. Investigators and clinicians were hopeful to find an agent to provide control without the risks of skin thinning and effects on the HPA axis.

After case reports of skin cancer and lymphoma with use of these agents appeared, the U.S. Food and Drug Administration issued a black box warning noting that although a causal relationship had not been established, these agents should be used with caution. Continued study has not demonstrated an increased risk of malignancy.⁶⁵ Patients with atopic dermatitis have an increased risk of lymphoma, and this risk increases with severity of disease. Experts comment mistaking cutaneous T-cell lymphoma for severe AD might account for the increased risk in these patients. Avoid the use of topical immunomodulators in immunocompromised patients or in those with a known neoplasm. If AD does not respond to usual treatments, perform a biopsy to rule out (CTCL) or other causes. Encourage sun protection to reduce photocarcinogenesis.

A meta-analysis of tacrolimus use in children found it safe and effective, with no statistical difference between tacrolimus 0.03% and 0.1% preparations and a good response compared with vehicle, 1% hydrocortisone acetate, and 1% pimecrolimus (odds ratio: 4.56, 3.92, and 1.58, respectively).⁶⁶ Use creams as infrequently as possible to maintain remission. Use only on lesional skin and without occlusive dressings. Use only in children who are older than 2 years old. Adverse effects include burning on application and photosensitivity.

Dosage

Tacrolimus 0.03% ointment is applied twice daily in patients older than 2 years, including adults with mild disease. For adults, tacrolimus 0.1%

ointment is applied twice daily, or pimecrolimus 1% cream is applied twice daily. Typical use is twice daily for no longer than 6 weeks and then reduce to daily or every other day use. Tacrolimus used three times weekly has been proven effective in children to maintain remission.⁶⁷

Other Immunomodulators

Cyclosporine can be used, but only by a provider experienced in its use. *Leukotriene inhibitors* (e.g., montelukast) are not effective monotherapy for atopic dermatitis, but they may reduce itching.

Therapies to Consider

Traditional Chinese Medicine

Several trials of traditional Chinese medicine herbal blends for atopic dermatitis have shown promising results. A Cochrane Review concluded that although the studies were small, they showed some evidence of effectiveness.⁶⁸ A five-herb concoction was studied in children with moderate to severe disease for 12 weeks, and although no significant difference was noted in clinical severity scores, the treatment group used one-third less corticosteroid and had significantly improved quality of life index scores at the end of treatment and 4 weeks later.⁶⁹

Traditional Japanese Medicine (Kampo)

A case report on treatment with kampo, traditional Japanese medicine, had color pictures showing resolution of flexural lichenification and provided an excellent review of the likely immunomodulatory effects of this therapy.⁷⁰ A trial of shiunko, an herbal mixture commonly used in kampo for atopic dermatitis, lowered bacterial counts in the areas treated in four of seven patients.⁷¹ A trial involving 95 patients using kampo showed promise, with a moderate to marked effect in more than half and no effect in just 4 patients.⁷²

Homeopathy

Homeopathic studies have largely not shown an effect of this therapy in atopic dermatitis, although results from one small study in children were promising. An open-label trial of 27 children using a homeopathic cream

of Oregon grape root (*M. aquifolium*), pansy (*Viola tricolor hortensis*), and gotu kola (*Centella asiatica*) revealed complete resolution in 6 children and marked improvement in 16.⁷³

Prevention Prescription

- Moisturize the skin. Apply emollients daily to newborn skin for the first 3 months of life, especially if at high risk for atopic dermatitis.
- Bathe in lukewarm water up to every day; if the water is irritating, add one cup of baking soda or salt to the water. Consider bathing in dilute bleach water (half cup per tubful) twice weekly for 5–10 minutes, then rinse off.
- Barely pat dry and then apply emollients to lock in moisture. Good choices include sunflower seed oil, virgin coconut oil, Cetaphil cream, Aquaphor ointment, paraffin, and creams containing creamed.
- Prevent break down of the skin barrier. Use soap minimally; when needed, use a mild, pH-balanced soap such as Dove, Aveeno, or Basis. Avoid sodium laurel sulfate and baby wipes when possible.
- Wet dressings using dilute corticosteroids such as such as 1:3 mometasone furoate 0.1% ointment for body and 1:19 mometasone furoate 0.1% ointment for the face can quickly gain control of recalcitrant lesions.
- Do not scratch! Pat, firmly press, or grasp the skin.
- Avoid triggers. Eliminate cigarette smoke exposure. Wear smooth, natural fibers that do not rub the skin. Avoid wool.
- Avoid fabric softeners and other chemicals in laundry detergent, use liquid detergent, and consider an extra rinse cycle.
- Humidify air in the winter. Dehumidify air in the summer.
- Reduce exposure to dust mites if sensitive; avoid rugs in bedrooms, wet mop floors, use mattress covers, and launder bed clothes weekly in hot water.
- Consider an allergy elimination diet if a food allergy is suspected.
- Discover ways to control emotional stress. Seek low-stress work environments. Mindfulness meditation, massage, or learning self-hypnosis may be helpful. Consider reading *Skin Deep* on www.grossbart.com.
- Pursue an antiinflammatory diet with frequent sources of omega-3

fatty acids such as cold-water fish, walnuts, and flaxseed. Drink green or oolong tea.

- Consider essential fatty acid supplementation, adding docosahexaenoic acid and eicosapentaenoic acid 2 g daily if your fish intake is inadequate and gamma-linolenic acid in the form of borage oil, 500 mg daily, or evening primrose oil, 1–2 g daily.
- Consider vitamin D₃ 2000 IU daily and vitamin E 400 IU daily for adults and half that for children aged less than 8 years.
- Pregnant women with strong history of atopy should consider taking *Lactobacillus rhamnosus* GG prenatally and while breastfeeding. Continue giving it to the infant until age 2 years. Other conditions where lactobacilli colonization may need encouragement include birth by C-section, bottle feeding, and antibiotics use. Others may also find this useful. Dosage is 25–50 billion CFU for adults, 5–10 billion CFU for children.
- Encourage a diverse microbiome. Avoid antibacterial products, avoid antibiotics in animal products, and consume fermented foods and beverages.
- If you cannot breastfeed, consider hydrolyzed formulas for atopy prevention for at least the first 4 months of life.
- Natural chickenpox (varicella) infection and childhood immunizations have been shown to reduce AD.
- Moderate amounts of sunshine may be useful and allow you to obtain vitamin D.
- Reduce exposure to plastics, food packaged in plastics, and topical skin care products containing phthalates.

Therapeutic Review

Avoidance of Triggers

- Reduce exposure to known allergens. 
- Wear smooth, comfortable, breathable clothing. 
- Use liquid detergents and fully rinse clothing to avoid disturbance of barrier function. 

Improvement in Barrier Function

- Hydrate by bathing daily and applying an emollient such as sunflower oil, virgin coconut oil, Cetaphil cream, Aquaphor ointment, double base gel (Dermal Laboratories, Hitchin UK), or liquid paraffin 50% in soft white paraffin. This can prevent half of AD in infants. 
- Bathing with one-half cup of bleach added significantly reduces AD. 
- Wet dressings with very dilute corticosteroids are effective for severe disease. Apply a 1:3 of their typical corticosteroid, use bandages or clothing over, and keep damp. 
- Ceramide-containing creams, such as *EpiCeram* or *TriCeram*, may have added benefit over other emollients. 
- Virgin coconut oil reduces *Staphylococcus aureus* colonization. 

Nutrition

- Avoid known food allergies. (The most common foods triggers of atopic dermatitis are egg, soy, milk, wheat, fish, shellfish, and peanut.) 
- When breastfeeding atopic mothers avoid dairy it prevents AD in their babies. 
- Infants at high risk who cannot exclusively breastfeed should use hydrolyzed formula (broken down proteins) in the first 4 months of life. Examples of hydrolyzed formulas include Nutramigen LIPIL, Pregestimil, and Alimentum Advance. 
- Infants with AD or egg allergy benefit from beginning peanut ingestion three times weekly after age 4–6 months to prevent peanut allergy. 
- Drink three cups of strong oolong tea daily. 

Mind-Body Therapy

- Support groups 

- Coping skill educational program 
- Psychotherapy 

Supplements

- Vitamin D₃: 2000 daily for adults, 1000 IU daily for children aged less than 8 years, or consider supplementing to keep normal serum levels 
- Vitamin E: 600 IU daily 
- Docosahexaenoic acid/eicosapentaenoic acid: 2–4 g daily 
- Gamma-linolenic acid: such as borage oil 500 mg daily 
- *Lactobacillus rhamnosus*: 20 billion CFUs daily for an atopic mother prenatally and postnatally for prevention of atopic dermatitis in the infant 

Botanicals

- 2% glycyrrhetic acid (Atopiclair or others) applied three times daily 
- Topical formulations of *Hypericum perforatum* (St. John's wort), Oregon grape root, rosmarinic acid, honey, or chamomile applied twice daily 

Other Creams

- Vitamin B₁₂: 0.07% cream used twice daily 
- Coal tar preparations applied twice daily to chronic or lichenified lesions 

Pharmaceuticals

Antihistamines

- Doxepin cream: twice daily to affected areas 
- Diphenhydramine: 12.5–50 mg orally every 6 hours 
- Hydroxyzine: 10–50 mg orally every 6 hours 

- Loratadine: 10 mg orally daily 

Antimicrobials

- Consider ketoconazole, 200 mg twice daily for 10 days, for head or neck involvement. 
- Consider skin culture or smear for herpes or empirical antibacterial treatment for recalcitrant lesions. 

Corticosteroids

- Triamcinolone 0.1% ointment: twice daily for up to 2 weeks for flares, then up to twice daily on weekends to maintain remission. 
- Hydrocortisone 1% ointment: used on thin skin at higher risk for adverse events (face, neck, axilla). 

Topical Immunomodulators

- Tacrolimus 0.03% ointment: twice-daily short-term use for patients older than 2 years. 
- Tacrolimus 0.03% ointment: three times weekly to maintain remission in patients older than 2 years. 
- Tacrolimus 0.1% ointment: twice-daily short-term use in patients older than 15 years. 
- Pimecrolimus 1% cream: twice daily for short-term use.

CHAPTER 73

Psoriasis

Apple A. Bodemer, MD

Pathophysiology and Clinical Background

Psoriasis is a chronic inflammatory skin disease characterized by abnormal differentiation and hyperproliferation of the epidermis. Its most common clinical presentation is as thick bright red to pink plaques with silvery scale ([Figs. 73.1](#) and [73.2](#)). Psoriasis is fairly common, affecting approximately 2% of the general population. It has a bimodal age distribution, with peak onsets between 20 and 30 years and 50 and 60 years.

Psoriasis is generally regarded as a disorder of the immune system that is driven by abnormally activated T helper cells that stimulate proinflammatory cytokine production and overproduction and abnormal maturation of the outer layer of skin cells. Activation of these T cells can occur through specific interactions with antigen-presenting cells (APCs) or nonspecific super-antigen interactions (guttate psoriasis triggered by streptococcal antigens). APC activation requires costimulatory signals. Once activated, psoriatic T cells produce a type 1 helper T cell (Th1)-dominant cytokine profile that includes interleukin-2 (IL-2), tumor necrosis factor-alpha (TNF-alpha), interferon (IFN)-gamma, and IL-8. These cytokines attract and activate neutrophils, which are responsible for much of the inflammation seen in psoriasis.

While genetics play an important role in the development of psoriasis, behavioral and environmental factors clearly influence the course of the disease. A family history can usually (but not always) be elicited. If one parent has psoriasis, the risk for having the disorder is approximately 14%. This figure increases to 41% if both parents have psoriasis. Several

genetic foci and human leukocyte antigens (HLAs; histocompatibility antigens) have been identified to be linked to the development of psoriasis.

Environmental factors implicated in triggering psoriasis or psoriatic flares include physical trauma (isomorphic or Koebner phenomenon), infections (e.g., streptococcal pharyngitis), hypocalcemia, stress, and medications (lithium, beta-blockers, antimalarials, IFNs, rapid tapers of systemic corticosteroids). Paradoxically, psoriasis and psoriatic lesions have been described to develop in patients treated with anti-TNF drugs for inflammatory bowel disease.¹ The effect of pregnancy on psoriasis is not consistent; half of the women with psoriasis worsen during pregnancy, while the other half improve. Patients infected with human immunodeficiency virus (HIV) tend to have a more severe disease. Other factors associated with psoriasis include rapid weight changes, higher body mass index, alcohol consumption, vitamin D deficiency, and tobacco use. Smoking has been clearly implicated in the onset and severity of psoriasis, with the incidence of psoriasis decreasing after successful smoking cessation.² Additionally, people with psoriasis are at a greater risk for developing coronary artery disease (CAD) and metabolic syndrome.

The Koebner phenomenon occurs when skin trauma or irritation triggers a skin reaction such as a psoriatic plaque. Treatment of itching is important because scratching can trigger flares through this mechanism.

Clinically, psoriasis may manifest in several ways ([Table 73.1](#)). In addition to skin findings, nail abnormalities are often present. These include pits, oil slicks, subungual hyperkeratosis, and onycholysis. The incidence of nail psoriasis is not known, but it does occur in the majority of people with the disorder at some point and is more common in people who also have psoriatic arthritis.³

The incidence of psoriatic arthritis effects is not clear and estimates vary widely. Generally, skin lesions precede the joint disease by up to 10–20 years; however, the joint disease may be the first manifestation 10%–15% of the time. The five classifications of psoriatic arthritis are summarized in [Table 73.2](#). Psoriatic arthritis can be extremely disabling and thus warrants more aggressive systemic treatments, such as methotrexate or newer biological immune response modifiers (see later

discussion of systemic pharmaceuticals).

Integrative Therapy

Skin Care

Gentle skin care can help minimize pruritus and skin trauma and can thus prevent the Koebnerization of psoriatic lesions. It can be helpful to bathe in cool-to-tepid water using only gentle cleansers (e.g., Cetaphil soapless cleanser, Aquanil). Additionally, frequent and regular application of thick emollients—especially while the skin is still damp—will help keep psoriatic skin hydrated and more manageable. Natural oils such as coconut oil, avocado oil, almond oil, or olive oil can be very helpful and soothing. Colloidal oatmeal in the form of an emollient or bath (e.g., Aveeno) may also help soothe itching and irritation associated with psoriasis.

FIG. 73.1 Auspitz sign. Pinpoint bleeding areas where scale was lifted from psoriatic plaque. (From Weston WL, Lane AT, Morelli JG. *Color textbook of pediatric dermatology*. 4th ed. Philadelphia: Mosby; 2007.)

FIG. 73.2 Psoriatic plaque. Note the sharp demarcation and silvery scale. (From van de Kerkhof PCM, Schalkwijk J. Psoriasis. In: Bologna JL, Jorizzo JL, Rapini RP, eds. *Dermatology*. 2nd ed. Philadelphia: Mosby; 2008.)

Oatmeal baths can be made by placing whole oats in a blender and grinding them into a fine powder. Add water to a half cup of the oat flour to make a loose slurry that can be poured into a bath. A thicker paste can be made and patted onto psoriatic lesions as a poultice.

Ultraviolet Radiation

Psoriasis typically improves during the summer months, when there is more exposure to ultraviolet radiation (UVR). People have been taking advantage of this response to UVR for many years in many forms. Well-controlled clinical exposure in the form of phototherapy offers more predictable clinical results and will be discussed in the pharmaceutical section.

Climatotherapy and Balneophototherapy

Climatotherapy means to relocate to a climate more favorable for treatment of a condition. *Balneophototherapy* is treatment with water and sun, usually in a spa setting. Dead Sea climatotherapy has long been touted as beneficial for patients with psoriasis. Patients visit resorts at the Dead Sea for 2–4 weeks and expose themselves to both the water and sun. One study of 740 German patients treated at the Dead Sea found a 70% complete clearance of symptoms after 4 weeks at one of the clinics.⁴ Several reviews have found this to be effective from a clinical as well as a cost standpoint and have found improved quality of life for patients with psoriasis as well.⁴⁻⁶ One proposed explanation for the success of this approach is that the elevation of 400 m below sea level and the thick haze present in the area increase the thickness of the atmosphere. This could attenuate shorter ultraviolet B (UVB) wavelengths and allow a larger proportion of longer-wave UVB to reach the patients' skin. Additionally, the water has a high mineral content. In vitro studies indicated that Dead Sea water had an antiproliferative effect on exposed cells.⁷ These clinics and solariums offer patients an extended retreat from stressful lives; the relaxation likely plays a role in the outcomes as well.

TABLE 73.1
Subtypes of Psoriasis

Subtype	Characteristics	Associations
Chronic Plaque	Erythematous plaques with silvery scale Typically involving the scalp, knees, elbows, low back, umbilicus, and gluteal cleft Pruritus variable Nail findings common	Most common; accounting for approximately 90% of all cases of psoriasis
Guttate	Diffuse salmon-to-red "drop-like" papules and plaques with fine scale Typically involving the trunk and extremities	Second most common type (2%) Most common in children and young adults Affecting children and young adults Associated with group A <i>Streptococcus</i> infections Tends to resolve with eradication of the infection Possibly persistent in "strep" carriers Best prognosis for remission
Inverse	Affecting predominantly the axillae, groin, and submammary area Less scale than in other types	Prone to secondary bacterial or yeast infections
Erythrodermic	Erythema with scaling over more than 80% of the body surface area	Potential complications include high-output cardiac failure, renal failure, and sepsis
Pustular	Confluent pustules on an erythematous base von Zumbusch type: generalized with acute fever, chills, nausea, headache, and joint problems Annular type: subacute or chronic; systemic symptoms possible Acrodermatitis continua of Hallopeau: distal fingers; fingernails possibly floating away on lakes of pus and permanent nail destruction common	Life-threatening Potential complications include high-output cardiac failure, sepsis, and hypercalcemia Systemic symptoms are less common than with the Hallopeau type

Palmoplantar Pustulosis | Pustules of the palms and soles with yellow-brown macules

| Commonly associated with sterile inflammatory bone lesions

TABLE 73.2
Classification of Psoriatic Arthritis

Type	Characteristics	Associations
Asymmetric Oligoarticular	Digits of the hands and feet are affected first Inflammation of the flexor tendon and synovium occurring simultaneously Usually affecting fewer than five digits	“Sausage digit” (involvement of both the DIP and PIP of one digit)
Symmetric Polyarthritis	Clinically identical to rheumatoid arthritis Possibly affecting the hands, wrists, ankles, and feet Involvement of the DIP Rheumatoid factor negative	Erosive changes seen on radiographs
DIP Arthropathy	Unique to psoriasis Affecting only 5%–10% More prominent in men	Nail involvement with chronic paronychia
Arthritis Mutilans	Osteolysis leading to telescoping of the finger with an “opera-glass” hand More common in early-onset disease More common in men	Osteolysis (dissolution of the joint) “Pencil-in-cup” deformity on radiographs
Spondylitis With or Without Sacroiliitis	Occurring in 5% of patients with psoriatic arthritis More common in male patients Asymmetric involvement of vertebrae	Morning stiffness of the lower back is the most characteristic symptom

DIP, distal interphalangeal joint; PIP, proximal interphalangeal joint.

Data from Hammadi AA, Gorevic PD. *Psoriatic arthritis*. www.emedicine.com/med/topic1954.htm. Accessed 28.08.06.

Studies looking at the safety of this type of therapy have found increased actinic damage but not an increase in skin cancers compared to patients with psoriasis treated by other means.^{8,9} Nevertheless, recommending protection of exposed, noninvolved skin is prudent.

Nutrition

Antiinflammatory Diet

Healthy dietary choices are important for overall health.

Antiinflammatory or Mediterranean-style dietary approaches have been found to enhance many aspects of health—especially in the setting of inflammatory diseases. A recent study asked 62 patients with mild-to-severe psoriasis to complete questionnaires that were created to assess their adherence to a Mediterranean-style diet. The Psoriasis Area Severity Index (PASI—a well-established tool for evaluating the severity of psoriasis with higher numbers indicating more severe disease) and C-

reactive protein (CRP) levels (a general marker of systemic inflammation) were found to be negatively correlated with consumption of extra virgin olive oil (EVOO), vegetables, fruit, legumes, fish, and nuts and positively correlated with the consumption of red meat. The strongest negative correlations were with EVOO and fish.¹⁰ More information about these dietary approaches can be found in [Chapter 88](#).

Elimination Diet/Gluten-Free Diet

Some patients with psoriasis have experienced improvement on a gluten-free diet.¹¹ Elevated markers for celiac disease (immunoglobulin A [IgA] antibodies to gliadin, tissue transglutaminase, and endomysium) have been found in some patients with psoriasis, and in those people, disease severity appears to correlate with circulating levels of these markers.¹²⁻¹⁴ A positive family history of celiac disease / gluten sensitivity or presence of gastrointestinal (GI) symptoms may suggest sensitivity to gluten. Testing for markers of gluten intolerance may help identify those patients who are most likely to benefit from a gluten-free diet. Please find more information about how to eliminate gluten from the diet in [Chapters 31](#) and [86](#).

Weight Loss

Low-calorie diets that promote weight loss have been found to be beneficial in overweight and obese patients with psoriasis.^{15,16,18} Naldi et al. conducted an intervention study that looked at over 300 obese people with psoriasis who were unresponsive to systemic therapies. They were randomized to either a 20-week qualitative and quantitative dietary and exercise program focused on weight loss or to an informational session about the importance of weight loss for control of psoriasis. At the end of the 20 weeks, there were significant improvements in PASI scores in the intervention group as compared with the control group.¹⁸ There is also evidence that bariatric surgery in obese patients with psoriasis results in improvement of psoriasis—at least in the short term—which also supports that weight loss can benefit psoriasis.^{19,20} Additionally, it appears that weight loss can improve responses to systemic medications.^{21,22} It is important to work closely with obese patients toward weight loss goals and to help them find the support they might need. An emphasis should be placed on long-term dietary and exercise patterns to improve overall health and minimize not only the skin and joint effects of psoriasis but also cardiovascular and

metabolic risks as well.

Supplements

Fish Oil

Rates of psoriasis and other inflammatory conditions are low in populations that consume high levels of fish oils that are rich in omega-3 fatty acids such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). In vitro evidence supports the theory that omega-3 fatty acids improve psoriasis by inhibiting the inflammatory cytokines IL-6 and TNF-alpha, as well as by decreasing levels of leukotrienes.²³ Collier et al. examined the effect of consumption of oily fish on chronic plaque psoriasis compared with whitefish. These investigators found that people who ate oily fish (6 oz/ day for 6 weeks) had significant improvement in their PASI score.²⁴

Bittiner et al. conducted a double-blinded placebo-controlled study of patients supplemented with 10 fish oil capsules (1.5 g EPA each) compared with 10 olive oil capsules for 12 weeks and found significantly less itching, scaling, and erythema in the group treated with fish oil.²⁵

Other randomized and double-blinded studies that investigated dietary intake of omega-3 fatty acids have not found significant benefit.^{26,27}

Some evidence indicates that fish oils can minimize side effects of other systemic therapies. Fish oils may help decrease triglyceride levels and improve cholesterol profiles in patients treated with retinoids.²⁸ Additionally, fish oils may help reduce the risk for nephrotoxicity associated with cyclosporine.^{29,30}

Dosage

Doses vary depending on the source. Flaxseed; walnuts; and cold-water fish, such as mackerel, lake trout, herring, sardines, albacore tuna, and salmon, are all rich natural sources of omega-3 fatty acids. Supplements that contain 1000–4000 mg EPA and DHA should be provided daily.

Precautions

Some types of fish may contain high levels of mercury, polychlorinated

biphenyls (PCBs), dioxins, and other environmental contaminants. Fish listed by the American Heart Association as having the highest mercury levels are shark, swordfish, tilefish, and king mackerel. PCBs are found in high concentrations in farmed salmon. Choosing wild-caught salmon, trimming fat before cooking, and avoiding over-grilling can help decrease exposure to PCBs. Though there has been concern about the risk for blood thinning with fish oil supplementations, studies have shown that there was no significant increase in bleeding incidents with up to 4 g/day EPA + DHA.³¹ Nevertheless, it is prudent to be cautious in patients already taking blood thinners.

Curcumin

Curcumin is the active component of turmeric. It has been shown to inhibit proinflammatory molecules and pathways important in psoriasis, including TNF, proinflammatory ILs (IL-1beta, IL-6, IL-8, and IL-12), and the nuclear factor (NF)-kappaB signaling pathways.^{33,34} Studies evaluating clinical use are limited, but clinical studies have found it to be safe at doses up to 8–12 g/day, with the only side effects being reversible GI problems (nausea and diarrhea).³⁵

Dosage

The dose is 1500 mg three times a day.³⁶

Vitamins and Minerals

Vitamin D

The role of vitamin D in the development or exacerbation of psoriatic flares is not yet clear, but it appears that there may be an inverse correlation between vitamin D levels and severity of chronic plaque psoriasis.³⁷ There is one study that found benefit with high-dose vitamin D supplementation for 6 months in patients with psoriasis and vitiligo who were also vitamin D deficient. The doses were very high (35,000 IU of cholecalciferol [D₃]), and participants were required to be on a low-calcium diet with a minimum of 2.5 liters of oral fluids daily. Serum 25-hydroxyvitamin [25(OH)] D₃, parathyroid hormone (PTH), total calcium,

ionized calcium, urea, and creatinine were carefully monitored, and PASI scores were followed. Significant clinical improvement was seen in all nine patients with psoriasis.³⁸ While this protocol may be extreme and further studies need to be conducted to better understand the potential utility of this treatment, determining the vitamin D level and moderate supplementation of vitamin D deficiencies is prudent.

Dosage

The dose is 600 IU/day for supplemental uses.³⁹

Administer 1000–2000 IU/day for treating vitamin D deficiency and titrate on the basis of serum levels.

Precautions

Recent research suggests that doses up to 10,000 IU/day are safe.⁴⁰ Higher than 10,000 IU/day, a person should be under the care of a physician and should be monitored for signs of vitamin D toxicity from hypercalcemia (headache, nausea, vomiting, abdominal pain, increased urination, and thirst).

Zinc

Zinc is a cofactor in many reactions important for skin health and immune function and has also been shown to have antiinflammatory properties. Some investigators have suggested that patients with psoriasis have decreased epidermal zinc levels.⁴¹ One group compared plasma levels of zinc in 35 patients with psoriasis with those in age- and sex-matched controls. No significant differences in zinc levels were found, but they did note a trend toward lower plasma zinc levels, independent of serum albumin and alkaline phosphatase levels, in patients with more extensive psoriasis.⁴² Subsequent studies have not reproduced this finding, and most clinical studies examining zinc supplementation for treatment of psoriasis have not shown benefit.⁴³ However, some clinicians who use zinc supplements for patients with psoriasis strongly believe that it can be beneficial.

The formulation of zinc may influence biological activity and may partly explain some of the conflicting results in the literature.

Effervescent preparations of zinc, zinc picolinate, and methionine-bound zinc are more bioactive than other formulations such as zinc gluconate

and zinc sulfate.

Dosage

The dose is 30–50 mg of elemental zinc per day.⁴⁴

Foods rich in zinc include oysters, beef, poultry (dark meat), pork, beans, and nuts.

Precautions

Minor side effects include nausea, vomiting, and a metallic taste in the mouth. At even higher doses, zinc toxicity can manifest as watery diarrhea, irritation and erosion of the GI tract, acute renal tubular necrosis, interstitial nephritis, and a flulike syndrome.

*At doses higher than 30 mg/day, zinc can induce a copper deficiency. Furthermore, 2 mg of copper should be added for every additional 30 mg of elemental zinc.

Inositol

Lithium is known to worsen psoriasis and depletion of inositol is known to occur in people taking lithium. Inositol supplementation for people taking lithium has been shown to reduce some of the side effects of lithium without diminishing its clinical usefulness. In 2004, Allan et al. conducted a randomized placebo-controlled crossover study and found that PASI scores were improved when patients taking lithium (300–1200 g/day) also took inositol (6 g/day) for 10 weeks. These investigators did not see a worsening of bipolar disorder, but this outcome was not formally evaluated in this study.⁴⁵

Dosage

The dose is 6 g/day.

Precautions

Inositol appears to be safe. However, patients who have bipolar disorder should undergo close monitoring of their psychiatric state during inositol supplementation.

Topical Botanicals

Indigo Naturalis Extract

Indigo naturalis (qing dai) is used by traditional Chinese medicine (TCM) healers to treat various inflammatory skin conditions. It has been used orally for psoriasis in TCM, but long-term use is associated with GI side effects and risk for liver damage.⁴⁶ Topical *Indigo naturalis* extract has shown promise in clinical studies evaluating its usefulness in both chronic plaque psoriasis and in nail psoriasis with no significant side effects.⁴⁶⁻⁴⁸ *Indigo naturalis* has been shown to have antiproliferative effects, to inhibit TNF-alpha-dependent inflammatory pathways, and to downregulate inflammatory markers seen in psoriatic skin.^{46,49,50}

Dosage

Apply 3%–5% oil, ointment, or cream once to twice a day.

Precautions

People may experience mild itching at the beginning of treatment, but that should go away after a few days. Contact sensitization could theoretically occur.

Capsaicin

Itching is a common complaint in psoriasis. The neuropeptide substance P has been shown to be elevated in psoriatic skin⁵¹ and is known to elicit itching when it is applied to normal skin.⁵² This compound also upregulates the expression of adhesion molecules important in the activation and recruitment of leukocytes.⁵³ Capsaicin is an extract of chili peppers that acts by depleting substance P locally in the skin. A double-blinded placebo-controlled study looking at the potential use of capsaicin four times daily for 6 weeks found that the treatment group tended to have better global improvement, greater pruritus relief, and reductions in psoriasis severity scores; however, none of the differences reached statistical significance.⁵⁴

Dosage

Apply 0.025% or 0.075% capsaicin cream three or four times / day.

Precautions

Patients typically experience burning during initial applications. The burning disappears with consistent use. Patients must be careful to wash their hands after application and to avoid rubbing capsaicin into their eyes.

Aloe Vera

Aloe vera is a succulent plant whose thick leaves contain an inner pulpy mucilaginous gel. Compounds in aloe vera have been found to have antiinflammatory and antiitch properties, as well as pain reduction and wound healing effects. Although results from controlled studies have been variable, topical aloe extract seems to reduce the desquamation, erythema, and infiltration associated with psoriatic plaques. One small study of patients with mild psoriasis compared the application of a 0.5% extract in a hydrophilic cream three times a day for 4 weeks with a placebo and found improvement of psoriatic plaques in the treatment group.⁵⁵ Another double-blinded placebo-controlled study with right-left comparisons in 40 patients found a slightly better response in the placebo group.⁵⁶ Although aloe is very safe, topical sensitization can occur.

Glycyrrhetic Acid (Licorice)

Cortisol is inactivated by the enzyme 11beta-hydroxysteroid dehydrogenase. This enzyme is inhibited by glycyrrhetic acid, a compound found in licorice. Through this mechanism, topical glycyrrhetic acid has been shown to potentiate the action of hydrocortisone.⁵⁷ Glycyrrhetic acid is available in 1% and 2% formulations and appears to be safe when it is used topically. No studies have specifically investigated the use of this compound in psoriasis.

Systemic Botanicals

Milk Thistle (*Silybum marianum*)

Although milk thistle has not been suggested to play a role in psoriasis treatment, this botanical has been purported to protect against methotrexate-induced hepatotoxicity. Milk thistle has been shown to act as an antioxidant by scavenging free radicals and inhibiting lipid

peroxidation. Investigators have also suggested that it may protect against DNA injury and increase hepatocyte protein synthesis.⁵⁸

Dosage

The dose is 140 mg (70% silymarin) two or three times / day.

Precautions

Diabetic patients taking silymarin require careful monitoring of blood glucose because this botanical may cause hypoglycemia secondary to increased insulin sensitivity.⁵⁹

Topical Pharmaceuticals

Keratolytics

Keratolytics are compounds that break down the outer layers of the skin and can decrease the thickness of psoriatic plaques. This class of compounds includes salicylic acid (2%–10%), urea (20%–40%), and alpha-hydroxy acids (glycolic and lactic acids). Along with providing added comfort, thinner plaques allow for enhanced penetration of other topical medications. Keratolytics can be applied once to several times a day as long as they do not cause irritation.

Precautions

Salicylic acid should not be applied extensively on the body, especially in children. Systemic absorption can lead to salicylism, which is characterized by tinnitus, nausea, and vomiting.

Topical Steroids

Corticosteroids are considered first-line therapy for mild-to-moderate psoriasis. They have antiinflammatory, immunosuppressive, and antiproliferative properties. These activities are mediated by alterations in gene transcription. The efficacy of an individual topical corticosteroid is related to its potency and its ability to be absorbed into the skin.⁶⁰

Dosage

[Table 73.3](#) provides information on potencies of different topical steroids.

Precautions

Topical corticosteroids are associated with tachyphylaxis—decreased efficacy with continued use. Intermittent treatment schedules and combination with other topical medications minimize this problem. Local side effects are more common with higher potency and include skin atrophy, acne, and localized hypertrichosis. Systemic absorption can occur with frequent or long-term use over large areas and can cause side effects similar to those of oral steroids (e.g., hyperglycemia, adrenal suppression, mood changes, weight gain).

Calcipotriene (Dovonex)

Vitamin D receptors are present on many different cells, including keratinocytes and Langerhans cells. The bioactive form (1,25-dihydroxycholecalciferol) has been shown to inhibit keratinocyte proliferation and promote keratinocyte differentiation.⁶¹ Calcipotriene is a synthetic analog of the naturally active form of vitamin D. It is locally metabolized very rapidly thus leading to less interference with calcium metabolism.⁶¹ It can safely be combined with other topical and systemic treatments.

Dosage

Apply 0.005% cream, ointment, or lotion once or twice daily.

Precautions

Self-limited irritant dermatitis is the most common complaint and can be minimized by combination with topical steroids. Photosensitivity can develop in patients who receive UVB after calcipotriene is applied, so calcipotriene should be used after phototherapy sessions. Hypercalcemia is the most significant potential risk, but this is not a problem as long as the dose is kept at less than the recommended 100 g/week.⁶²

Tazarotene Gel

Tazarotene is a topical retinoid (vitamin A derivative) that decreases epidermal proliferation and increases keratinocyte differentiation.

TABLE 73.3

Potencies of Topical Steroids

Class	Brand Name	Generic Name
1: Superpotent	Clobex lotion, 0.05%	Clobetasol propionate
	Cornax cream/solution, 0.05%	Clobetasol propionate
	Diprolene gel/ointment, 0.05%	Betamethasone dipropionate

	Prednisolone	

From The National Psoriasis Foundation: *Potencies of topical steroids*.

www.psoriasis.org/treatment/psoriasis/steroids/potency.php. Copyright 2006 National Psoriasis Foundation/USA.

Dosage

The dose is 0.05% or 0.1% gel.

Precautions

Local skin irritation and pruritus are common side effects, so concomitant use with topical steroids is common.⁶⁰ Tazarotene may be teratogenic, so it should be used extremely carefully by women of childbearing age.

Tar

Tar-based products are either derived from coal or wood (pine, birch). A precise mechanism of action is difficult to determine because of the large number of compounds present, but tar has antiinflammatory, antiproliferative, and antiitch properties.

Dosage

The dose is 1%–5% crude tar or 10%–20% tar extract (LCD; liquor carbonis detergens).⁶³

Precautions

Side effects are infrequent and include local irritation or allergic reactions, folliculitis or acne-like eruptions, and increased photosensitivity. Prolonged use of high concentrations in sun-exposed areas may result in an increased risk for skin cancer. If the formulation is too strong or irritating, it can worsen psoriasis via Koebnerization.

Anthralin

Anthralin is a synthetic derivative of chrysarobin from the bark of the araroba tree of South America. The mechanism of action is not well understood, but it has been shown to inhibit cell growth and promote cell differentiation.⁶⁰

Dosage

A 0.5%–1% preparation is applied for 10–30 minutes and is then washed off. Repeat once or twice daily.

Precautions

Irritation to normal skin can be minimized by protection with petrolatum or zinc oxide paste around psoriatic plaques. Anthralin is messy and can stain hair, skin, nails, clothing, and bedding a brownish-to-purplish color. The hair discoloration can be minimized by using neutral henna powder to coat the hair.

Phototherapy

Ultraviolet B

UVB consists of radiation and includes wavelengths between 290 and 320 nm. UVB is known to decrease DNA synthesis and to have immunosuppressive effects. Langerhans cells (the main APCs in the

epidermis) are extremely sensitive to UVB, and exposure limits antigen presentation to T lymphocytes. UVB also stimulates keratinocytes to secrete various cytokines that can further alter the immune response and limit inflammation.⁶⁴ Narrow-band UVB (nb-UVB), with wavelengths between 308 and 313 nm, has proven to be much more effective than full-spectrum UVB in the treatment of psoriasis.^{65,66} The 308-nm excimer laser offers an additional option for limited plaque psoriasis. This has been found to be effective and safe and may require fewer treatments than other phototherapy options.⁶⁷

Dosage

Treatment protocols are based on determining a minimal erythema dose (MED)—the dose of UVB that elicits barely perceptible erythema. Once an MED is defined, treatments are started at approximately 70%–75% of the MED and are given three times a week with the goal of maintaining minimally perceptible erythema. Once the skin is clear, some practitioners simply stop phototherapy, but others recommend tapering. There are no defined guidelines for accomplishing a UVB taper, and some people may require a maintenance dose.

Precautions

Potential short-term side effects of UVB include erythema, xerosis, pruritus, and higher frequency of herpes simplex outbreaks. Longer-term side effects consist of photoaging and possibly increased risks for skin cancers. The carcinogenetic risk for UVB appears to be much less than that associated with ultraviolet A (UVA) combined with psoralen (PUVA; see next section). One small study examining people who had had more than 100 treatments with UVB showed an increase in skin cancer in this group.⁶⁸ Other larger studies have not found this association.⁶⁹ Additionally, a study specifically examining the correlation between nb-UVB and skin cancer found no significant association.⁷⁰

Ultraviolet A and Psoralen

Systemic Pharmaceuticals

Methotrexate

Methotrexate is a folic acid antagonist that blocks dihydrofolate reductase—an enzyme necessary for making building blocks for DNA synthesis—and leads to cell cycle arrest. It also has immunosuppressive effects and acts as a potent antiinflammatory as well.⁷³ Methotrexate is particularly useful in patients with psoriatic arthritis.

Dosage

Methotrexate is available as a 2.5-mg pill or as solutions of 2.5 or 25.0 mg/mL. Typically, a 5- to 10-mg test dose is given, and complete blood count and liver function values are measured 7 days later. A dose of 10–15 mg/week is usually enough to control psoriasis. Methotrexate is given weekly either as a single dose or divided into three doses given 12 hours apart.⁷³

Precautions

Multiple side effects are associated with methotrexate. The most common is gastrointestinal upset, and the most dangerous is pancytopenia. Both can be decreased by adding 1 mg of folic acid daily. Other significant concerns are hepatotoxicity, pulmonary fibrosis, induction of malignancy, and teratogenicity. The concern for induction of malignancy is much greater when methotrexate is combined with PUVA; the risks for skin cancer and lymphoma appear to be increased (see the earlier section on PUVA). These potential complications require frequent monitoring with a complete blood count as well as renal and liver function tests. Liver biopsy to evaluate for fibrosis is indicated after a cumulative dose of 1.5–2.0 g. Additionally, the dose needs to be adjusted if the creatinine clearance value is less than 50 mL/minute.

Cyclosporine

Cyclosporine was initially isolated from the soil fungus *Tolypocladium inflatum*. It inhibits IL-2 gene transcription and leads to decreased T-cell proliferation and activation. Cyclosporine also inhibits the transcription

of various proinflammatory cytokines.⁷⁴ It is useful in all types of psoriasis, but because of its rapid effect, cyclosporine is particularly useful in widespread pustular or erythrodermic psoriasis. Rebound typically occurs when cyclosporine is discontinued, and bridging with another medication can be helpful when weaning off of this medication.⁷³

Dosage

Treatment should start at 5.0 mg/kg per day and slowly taper by 0.5 mg/kg per day, until the minimum dose required to prevent recurrences is achieved (typical doses range from 2 to 4 mg/kg per day).

Precautions

Potential side effects include renal dysfunction, hypertension, hypertrichosis, gingival hyperplasia, gastrointestinal upset, neurological effects (headache, tremor, paresthesias), electrolyte imbalances, sleep disturbances, acneiform eruptions, hypertriglyceridemia, decreased seizure threshold, and bone marrow suppression. Monitoring consists of measurements of blood pressure; renal function parameters, including urinalysis, complete blood count, liver function tests; and blood chemistry analyses, including magnesium, potassium, and uric acid.

Because cyclosporine is metabolized by the cytochrome P450 3A4 enzyme system, it has many potential drug interactions. The clinician should review a complete medication and herbal list with each patient before cyclosporine therapy is initiated.

Acitretin

Acitretin is an oral retinoid with antiproliferative and antiinflammatory effects. It can reduce lymphocyte proliferation and decrease arachidonic acid metabolism, thus leading to decreased neutrophil activation and inflammatory mediators. Acitretin has been especially useful for rapid control of pustular psoriasis.

Dosage

The dose is 10, 25, or 50 mg/day and is taken orally with food.

Precautions

Acitretin, like all retinoids, is highly teratogenic. It can cause drying of the skin and mucous membranes, which some investigators have suggested to be improved by adding 800 units of vitamin E daily.⁷⁵ Decreased night vision may occur, as well as pseudotumor cerebri, especially if acitretin is given with tetracycline antibiotics. Arthralgias, myalgias, bony changes (hyperostosis), poor wound healing, and gastrointestinal symptoms are all potential side effects. Serum cholesterol and triglyceride values may be elevated in 25%–50% of patients, and lipids must be monitored throughout therapy. Liver transaminase values may be elevated in up to 33% of patients, but toxic hepatitis is very rare.⁷⁶

Monitoring should include pregnancy tests, fasting lipid panels, liver function tests, complete blood count with platelets, renal function tests, and creatine phosphokinase concentrations.

Ultraviolet A and Psoralen

This treatment is not used as commonly anymore because of the better safety profile and increased availability of nb-UVB. This is included in the discussion because it is still available and is often used as a research tool.

UVA radiation (320–400 nm) alone is not effective for the treatment of psoriasis.

However, when it is combined with a topical or systemic photosensitizing agent (e.g., psoralen), PUVA becomes a powerful tool for the treatment of psoriasis. Psoralens are furocoumarins found in a wide variety of plants, including lime, parsley, fig, and celery. Synthetic furocoumarins primarily consist of 8-methoxypsoralen (8-MOP) and 5-MOP (available in Europe). Psoralens can be taken orally or used topically. Once absorbed, these compounds incorporate into DNA and cause cross-linkage when DNA is exposed to UVA and ultimately lead to cell cycle arrest. Additionally, psoralens can interact with reactive oxygen species to cause cell membrane damage.

Dosage

The systemic dose of 8-MOP is 0.6–0.8 mg/kg 1–3 hours before UVA treatment. For a bath PUVA, the regimen is as follows: 15–20 minutes of immersion in 0.5–5.0 mg 8-MOP per liter of water followed by immediate UVA exposure. The topical dose is 0.01%–0.1% 8-MOP as a cream, lotion, or ointment before UVA exposure. The initial dose of UVA is commonly based on skin type, but ideally should be determined by a patient's specific minimal phototoxicity dose (MPD).

Treatments are given 2–4 times a week, with no more than twice a week during dose changes to allow for appropriate evaluation of overdose. The dose may be increased by 30% if no erythema is noted at the next treatment. Doses should be held stable if minimal erythema is present. If evidence of a burn is noted, therapy should be stopped until symptoms resolve.

Precautions

Because psoralens persist for approximately 24 hours, patients must wear protective eyewear and practice sun avoidance with strict photoprotection. Oral psoralens can cause nausea and vomiting, sunburn, and persistent pruritus. These agents should be used extremely carefully or not at all in patients with liver or renal disease because slower metabolism and excretion can lead to extremely prolonged photosensitivity.

The dose-related risk for skin cancer with PUVA therapy is well known. The risk particularly applies to squamous cell carcinoma and is greatest in fair-skinned people. Subsequent systemic immunosuppressive therapy may lead to a further rise in the risk for squamous cell carcinoma. The risk for development of basal cell carcinoma of the trunk or extremities is moderately higher.⁷¹ An association between PUVA and melanoma has also been identified. One study that examined melanoma diagnosed in patients 15 years after their first PUVA treatment found a higher than expected rate. Patients who received 250 or more treatments appeared to be at the highest risk.^{71,72} Additionally, when PUVA is combined with methotrexate, there may be an increased risk for lymphoma.⁶⁹

Biological Immune Response Modifiers

Biological immune response modifiers are directed specifically at neutralizing cytokines and blocking costimulatory messages important for the activation of T cells. There are a number of these medicines, including adalimumab (Humira), certolizumab pegol (Cimzia), golimumab (Simponi), infliximab (Remicade), and ustekinumab (Stelara).

All of the biological immune response modifiers require a thorough baseline evaluation. This includes history and physical examination (with special attention to hepatic, neurological, or cardiac disease, infection, and malignancy), complete blood count, chemistry screen with liver function tests, viral hepatitis screening, and screening for latent tuberculosis. Patients require annual tuberculosis screening and blood chemistry with liver function testing every 2–6 months. Patients are generally advised to have any necessary vaccinations before they begin treatment with biological immune response modifiers.⁷⁷

Phosphodiesterase 4 Inhibitor

Apremilast (Otezla) is a new oral option for treating psoriasis. It acts by inhibiting phosphodiesterase 4 (PDE4) within the cell to block inflammation. The dose must be titrated over several days to 30 mg twice a day. Some GI upset with loose stool/mild diarrhea can occur for the first couple of weeks but resolves with continued treatment. Although this is a very new drug, it appears to be very safe, and unlike other biologics, no laboratory monitoring is required.⁷⁸

Mind–Body Therapy

It is well understood that patients with psoriasis experience greater stress as a consequence of their disease. A large survey study including members of the National Psoriasis Foundation documented that psoriasis had profound emotional, social, and physical effects on quality of life.⁷⁹ Additionally, emotional factors—particularly stress—have been shown to have a strong correlation with the onset and exacerbation of psoriasis.⁸⁰

How stress affects psoriasis is beginning to be understood more clearly. Garg et al. showed that injury to the epidermis promotes higher levels of keratinocyte growth stimulators, such as substance P and vasoactive intestinal peptide, and increases neural proliferation, which stimulates Langerhans cell activity. These researchers suggest that

psychological stress may change the level of tolerance for physical insult or may prolong epidermal recovery time. This effect could lower the threshold for disease initiation and/or interfere with treatment.

Fortune et al. examined 112 patients with psoriasis before they started PUVA phototherapy and compared the stress level with the time to clearance of symptoms. These investigators found that high-level worry was the only significant predictor of the time taken for PUVA to clear psoriasis. Patients in the high-level worry group cleared 19 days later (1.8 times slower) than patients in the low-level worry group. Severity of disease, rates of positive family history, and levels of alcohol intake at the onset of the study were not significantly different between the two groups.⁸¹ This suggests that improving stress levels may enhance results from more conservative or traditional therapies. Other studies looking at various psychogenic interventions support this as well.^{82,83}

Improving stress levels may enhance results from more conservative or traditional therapies.

Meditation

A small study found that patients who listened to a mindfulness meditation–based stress reduction tape during PUVA or UVB therapy for psoriasis cleared 1 month earlier in the UVB plus relaxation tape group compared with the UVB only group and 6 weeks earlier in the PUVA plus relaxation tape group compared with the PUVA only group.⁸⁴ Another small study looked at symptoms of psoriasis as rated by dermatologists after treatment with 12 weeks of meditation ($n = 5$) or meditation plus imagery ($n = 4$) compared with controls ($n = 9$). A significant difference was noted between the treatment groups and the control group, but imagery did not yield more improvement than meditation alone.⁸⁵ The study was very small and had flaws; nevertheless, the results suggested that some patients may be able to decrease symptoms of psoriasis with meditation (see [Chapter 100](#)).

Hypnosis

A 3-month randomized blinded controlled trial looked at the efficacy of active (suggestion of disease improvement) versus neutral (no mention of disease) hypnosis for the treatment of psoriasis in patients classified as highly or moderately hypnotizable. Although the groups were very

small, highly hypnotizable patients showed significantly greater improvement regardless of their assigned treatment group.⁸⁶ This observation suggests that patients who are highly hypnotizable may benefit from adding hypnosis to their treatment plan (see [Chapter 95](#)).

Therapies to Consider

Traditional Chinese Medicine

According to TCM, the main cause of papulosquamous skin disorders is an inadequate supply of nutrients to the skin. The inadequacies include external pathogenic wind-heat and wind-cold, accumulation of blood-heat resulting from dietary or emotional influences, qi stagnation and blood stasis from retention of pathogenic wind, damp, and heat, and yin deficiency of the liver and kidneys.

Topical Preparations

Xu Yihou discusses topical therapies only briefly in his text *Dermatology in Traditional Chinese Medicine*.⁸⁷ He recommended combinations that emphasize gentle, nonirritating ointments used to decrease the scale and thickness of psoriatic plaques. An abundance of combination topical TCM preparations are available. Many actually contain corticosteroids, which would explain their efficacy.⁸⁸ Additionally, reports exist of contamination with heavy metals, toxins, and other pharmaceuticals. Such contamination can have significant adverse effects, as exemplified by the report of salicylate toxicity after the use of an herbal preparation containing oil of wintergreen over a large body area with occlusion.⁸⁹

Systemic Herbs

A full description of all the Chinese herbs and combinations that can be useful for patients with psoriasis is beyond the scope of this chapter. Tse reviewed clinical trials in both the English and Chinese literature that pertained to the use of Chinese herbal medicines for psoriasis from 1966–2001. He found only seven poorly performed controlled trials but was also able to gain information from the 20 noncontrolled trials he identified. Of the 174 different herbs used in these trials, Tse specified 10 herbs that were commonly encountered and discussed their potential mechanisms of action. They were *Rehmannia glutinosa* (dried root), *Angelica sinensis* (root), *Salvia miltiorrhiza* (root), *Dictamnus dasycarpus* (root cortex), *Smilax glabra* (underground stem), *Oldenlandia diffusa*

(whole plant), *Lithospermum erythrorhizon* (root), *Paeonia lactiflora* (root), *Carthamus tinctorius* (flower), and *Glycyrrhiza uralensis* (root).⁹⁰

Precautions

Many herbal preparations are not well regulated, and the risk for hepatotoxicity can be significant, either from the herbal components themselves or from contaminants.⁹¹

Acupuncture

As with the prescription of herbs, the acupuncture points used depend on the individual patient's pattern of psoriasis. The main points discussed by Xi Yihou focused on correcting blood-heat (BL18, BL23, BL12, and BL15) and wind-dryness from blood deficiency (BL17, BL19, BL12, BL13, and BL20). He also provided guidance on selecting points on the basis of the location of the disease: LI4, LI11, TB6, and GB20 are useful for the scalp and arms; SP6, SP10, and GB34 treat the trunk, buttocks, or genital area; SP6, SP10, and ST36 treat the lower limbs; and GV14, LI11, SP6, and SP10 are good for generalized lesions.⁸⁷

In one case series, 61 patients with psoriasis not responsive to more conventional therapies were treated with acupuncture. After an average of nine sessions (range, 1–15), 30 patients experienced complete or almost complete clearance of the skin lesions, 14 had two-thirds clearance, eight experienced one-third clearance, and nine had minimal or no improvement.⁹²

Precautions

Acupuncture is quite safe, but because the needles are inserted into the skin, the Koebner phenomenon could potentially occur. Clearly, more work is needed in this area if we are to gain a better understanding of its usefulness in the treatment of psoriasis.

Assessment of TCM as a system is very difficult within a Western framework. The classification of disease in TCM is based on a different point of view, and because each patient is evaluated and treated

individually with various combinations of herbs and acupuncture, creating standardized protocols to measure treatment outcomes is difficult.

Homeopathy

Like TCM, the system of homeopathy looks at psoriasis as the local expression of a systemic disturbance. Each patient is evaluated individually, and treatments are given on the basis of a constitutional approach. Because each patient is viewed as having a unique imbalance, the specific remedy chosen depends greatly on the patient. Though research is limited, homeopathy can be effective for treating psoriasis.⁹³ The practitioner must be well trained and have a deep understanding of homeopathy. Certification is not uniformly required, so one should look for practitioners who are accredited by one of the following organizations: Council for Homeopathic Certification (CHC), American Board of Homeotherapeutics (ABHt), Homeopathic Academy of Naturopathic Physicians (HANP), and North American Society of Homeopaths (NASH).

Precautions

With homeopathic treatments, patients may experience an exacerbation of symptoms before resolution. This exacerbation is known as a healing crisis.

Prevention Prescription

We currently do not have a way to prevent psoriasis. Although some situations are known to exacerbate psoriasis, flares are often unpredictable. Some choices patients and clinicians can address include the following:

- Maintain a balanced lifestyle.
- Minimize stress.
- Maintain a stable weight.
- Avoid alcohol overuse.
- Avoid tobacco.

- Eat a well-balanced diet.
- Keep your skin well hydrated.
- Treat skin infections early.
- Avoid medications known to exacerbate psoriasis (i.e., lithium, beta-blockers, antimalarials, IFN, and rapid tapering of systemic corticosteroid dosage).

Therapeutic Review

General Measures

- Gentle skin care: avoid hot water for bathing and use gentle cleansers and thick emollients and colloidal oatmeal 
- UV exposure—climatotherapy and balneophototherapy 

Nutrition and Supplements

- Antiinflammatory diet: see [Chapter 88](#) 
- Low caloric diet for weight loss 
- Fish oil or oily fish: this is also useful as an adjuvant to decrease side effects of systemic retinoids and cyclosporine. Consider 2–3 g/day of DHA + EPA. 
- Curcumin: 150 mg three times a day 
- Zinc: no good evidence has indicated a benefit in psoriasis; however, some clinicians do report a benefit. The dose is 15–30 mg/day. 
- Inositol: this may be useful in patients with lithium-induced psoriasis. The dose is 6 g/day, with monitoring of psychiatric disease in patients with bipolar disorder. 

Topical Botanicals

- *Indigo naturalis* extract: 3%–7% oil, ointment or cream once to twice a day. 
- Capsaicin for itching: 0.025% or 0.075% cream applied three or four times/day. Patients may experience stinging or burning during initial

applications. 

- Aloe vera: 0.5% extract in a lipophilic cream may help decrease scaling and redness. 
- Glycyrrhetic acid 1%–2% formulation: this may enhance the effect of topical steroids by inhibiting their degradation. 

Systemic Botanicals

- Milk thistle: 140 mg (70% silymarin) two to three times/day 
Best used as a hepatoprotective agent in patients taking hepatotoxic medications such as methotrexate

Topical Pharmaceuticals

- Keratolytics, to decrease scale and plaque thickness:
 - Salicylic acid (2%–10%) twice daily 
 - Urea (up to 40%) twice daily 
 - Alpha-hydroxy acids (glycolic and lactic acids) twice daily 
- Topical steroids: see [Table 73.3](#). The clinician should pay attention to the location treated and watch for side effects. 
- Calcipotriene (Dovonex): 0.005% cream, lotion, or ointment twice daily, limited to no more than 100 g/week 
- Tazarotene gel (Tazorac): 0.05%–1% gel applied at bedtime 
- Tar: 2%–20% preparations 
- Anthralin: 0.5%–1% preparation applied for 10–30 minutes once or twice daily, to protect normal skin from irritation 

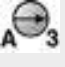

Phototherapy

- nb-UVB or UVB 

Systemic Pharmaceuticals

- Methotrexate: 10–15 mg/week; a single weekly dose or divided into three doses given 12 hours apart 
- Cyclosporine: started at 5.0 mg/kg per day, with dosage tapered by

0.5 mg/kg per day to the lowest required dose 

- Acitretin (Soriatane): 10, 25, or 50 mg daily 
- Biological immune response modifiers:
 - Adalimumab (Humira): 40 mg/subcutaneously every other week 
 - Certolizumab pegol (Cimzia): 400 mg/week subcutaneously once a month 
 - Etanercept (Enbrel): 50 mg once or twice a week subcutaneously 
 - Golimumab (Simponi): 50 mg subcutaneously once a month 
 - Infliximab (Remicade): 5 mg/kg over 2–3 hours intravenously on weeks 0, 2, and 6 and then every 8 weeks thereafter 
 - Ustekinumab (Stelara): 45 or 90 mg as a subcutaneous injection on weeks 0 and 4 and then every 12 weeks thereafter 
- Oral PDE4 inhibitor:
 - Apremilast (Otezla): 30 mg orally twice a day 

This is a very new drug, and though safety and efficacy studies are very promising, there is not as much experience with this type of drug.

Mind–Body Therapies

- Meditation: great for stress reduction or minimization 
- Hypnosis: most potential benefit for hypnotizable patients 

Therapies to Consider

- TCM 
- Homeopathy

CHAPTER 74

Urticaria

Apple A. Bodemer, MD

Pathophysiology

Urticaria, also known as hives, is a common problem affecting approximately 20% of people at some point in their lives. It is characterized by wheals—discrete areas of swelling, erythema, and pruritus that are often surrounded by a pale halo. Individual lesions typically wax and wane over the course of 24 hours, but recurrent crops can appear for weeks. *Acute urticaria* refers to outbreaks of wheals occurring for at least 2 days a week for up to 6 consecutive weeks. When the process lasts for 6 weeks or longer, it is considered *chronic urticaria*. Patients who have less frequent outbreaks are classified as having *recurrent urticaria*.¹ The skin findings and symptoms of urticaria are the result of increased inflammatory and vasoactive mediators such as histamine, prostaglandins, leukotrienes, proteases, and cytokines. These mediators are primarily found in mast cells and basophils. Although the main physiological event is mast cell degranulation, any mechanism that elevates these mediators can result in urticaria.

Mast cell degranulation can occur through both immunological and nonimmunological pathways. Immunological mechanisms include allergic mast cell degranulation, which is a type I hypersensitivity process initiated by antigen-mediated cross-linking of immunoglobulin E (IgE) receptors. Additionally, autoantibodies either to IgE or to the high-affinity IgE receptor (FcεRI) can bind to mast cells and result in degranulation.

Nonimmunological processes cause degranulation without interacting with the IgE receptor. This category involves compounds that can directly bind to mast cells to elicit degranulation, such as opiates and radio contrast media, as well as other compounds that can induce the

production of factors that bind to other receptors on the mast cell to cause degranulation. C1 esterase inhibitor deficiency can lead to higher levels of inflammatory and vasoactive mediators that are important in urticaria. This deficiency causes uninhibited activation of the complement system that leads to an increase in bradykinin—a vasoactive inflammatory mediator.² Some compounds, such as aspirin, can alter the balance of prostaglandin and leukotriene synthesis and others, including nettle plants, can directly implant vasoactive mediators into the skin.³

Determining the causative factor for urticaria is often very frustrating. No specific cause is ever identified in 50%–80% of patients. The most commonly implicated causes of acute urticaria are infections (especially viral infections of the upper respiratory tract), drugs (such as penicillins, sulfonamides, salicylates, nonsteroidal antiinflammatory drugs, and opiates), and foods (particularly shellfish, fish, eggs, cheese, chocolate, nuts, berries, and tomatoes) or food additives (including annatto—a yellow dye, as well as other colorants, butylated hydroxyanisole [BHA], and butylated hydroxytoluene [BHT]). Chronic urticaria can be caused by these same agents but is more likely to be secondary to physical stimuli (e.g., dermatographism, pressure, vibration, heat, cold, exercise, sun, and water), stress, autoimmune diseases (most commonly thyroid disorders), and other chronic medical diseases, such as connective tissue disease, cryoglobulinemia or cryofibrinogenemia, rheumatoid arthritis, amyloidosis, or cancer ([Table 74.1](#)).^{1,4,5}

The most important factor in a good evaluation is the medical history. Particular attention should be given to coexisting physical symptoms such as fever, unexplained weight changes, nausea/vomiting, weakness, fatigue, arthralgias/arthritis, etc. Thorough questioning about events surrounding urticarial flares may help patients recognize associations between stimuli and symptoms. Detailed diaries of a patient's activities, exposures, and ingestants can be invaluable in helping identify factors associated with urticarial outbreaks. Random screening laboratory tests have been proved to be of little value,⁶ but for selected patients, laboratory investigations directed by the history and physical findings should be considered. Tests may include complete blood count with differential, urinalysis, liver function tests, erythrocyte sedimentation rate, stool examination for ova and parasites, antinuclear antibody titer, screening for hepatitis B and C, thyroid function, thyroid antibody titer, and age-directed screen for malignant disease.⁷

Interestingly, there have been a few case studies and case series that demonstrate resolution of urticaria that either did not respond or only

partially responded to conventional antihistamine therapy when low vitamin D levels were treated.^{8,9} It has been suggested that the effects of vitamin D in urticarial and other inflammatory conditions is mediated by cathelicidin—a vitamin D responsive antimicrobial peptide that also plays a role in regulating inflammation.¹⁰ While more and better studies will hopefully clarify this issue in the future, it seems clear that testing for low vitamin D levels and supplementing when appropriate is warranted in people who have chronic urticaria.

Understanding the difference between urticaria and urticarial vasculitis is important. Urticarial vasculitis looks identical to other forms of urticaria, but individual lesions typically last for more than 24 hours and may be purpuric. Patients often complain more of burning sensation than itching.¹¹ Additionally, systemic symptoms such as arthralgia, gastrointestinal pain or digestive disturbance, pulmonary obstructive disease, or renal disease may be present.¹² Urticarial vasculitis has been associated with connective tissue diseases (most commonly systemic lupus erythematosus), infections (viral hepatitis), and, rarely, with medications or hematological disorders. The evaluation and treatment of urticarial vasculitis are beyond the scope of this chapter.

TABLE 74.1**Histamine-Rich and Histamine-Releasing Foods**

Data from Wantke F, Gotz M, Jarisch R. Histamine-free diet: treatment of choice for histamine-induced food intolerance and supporting treatment for chronic headaches. *Clin Exp Allergy*. 23:982-985, 1993.

Integrative Therapy

General Principles

When a cause of urticaria is recognized, treatment can be as simple as avoiding the causative agent. In many cases of urticaria, however, the trigger is never identified. Even if the trigger is known, some patients may be unable to avoid the exposure. In these situations, many options are available for the management of urticaria.

The patient must be educated that a causative agent may never be found and that urticaria can be a chronic disease. He or she should understand that the skin reaction itself is not dangerous but is often very frustrating and difficult to live with. Chronic idiopathic urticaria can be a very unsatisfying disorder to manage, and the health care practitioner may become easily frustrated with the patient. Practitioners must not let this happen and should be open and supportive of the patient, with the recognition that urticaria is most frustrating for those who live with it.

General conservative measures can increase comfort during an exacerbation. They include staying in a cool, calm environment, wearing loose, comfortable clothing, and taking lukewarm to cool baths with added baking soda, cornstarch, or colloidal oatmeal (Aveeno). Many topical preparations can help calm the itching associated with urticaria, including menthol-containing products, aloe, and topical steroids.

Nutrition

Dietary Limitations

In the setting of acute urticaria without a clear trigger after ingestant and activity diaries have been analyzed, an elimination diet may be useful (see [Chapter 86](#)). Although food is a rare cause of chronic urticaria (approximately 1% of all cases), it may still be helpful to try eliminating histamine-rich and otherwise antigenic foods from the patient's diet (see [Table 74.1](#)).¹³⁻¹⁵ Magerl et al. conducted a prospective trial, in which 140 people with difficult to control chronic urticaria were put on a pseudoallergen free diet. (A pseudoallergen is a compound that elicits an

inflammatory reaction without activating an antigen-specific immune response). Thirty-nine people had a strong to partial response to the diet after 3 weeks, and an additional nine were able to substantially reduce their medication without worsening of their condition.¹⁶ The diet prescribed eliminated all processed foods, artificial additives, dyes, antibiotics, preservatives, phenols, and foods naturally rich in aromatic compounds (such as tomatoes, artichokes, peas, mushrooms, spinach, rhubarb, and olives).

Antiinflammatory Diet

Research on the role of an antiinflammatory diet in patients with urticaria is lacking. Intuitively, it seems that if general inflammation can be minimized, urticaria—which is driven by inflammatory mediators—should improve. However, many antiinflammatory diets focus on foods rich in omega-3 fatty acid, including fish and nuts, which are known to cause or exacerbate urticaria in some patients. This type of diet should be tried only in patients who have already determined that their urticaria is not exacerbated by the recommended foods (see [Chapter 88](#)).

Botanicals

Many different botanicals have been reported to be useful for the treatment of urticaria. They vary with sources, including canthaxanthin, field scabious, Japanese mint, kudzu, peppermint, alfalfa, bilberry extract, cat's claw, chamomile, echinacea, ginseng, licorice, nettle, yellow dock, and sarsaparilla. Many of these remedies have no evidence of efficacy from controlled studies. This section focuses only on the botanicals for which at least some in vitro evidence supports potential mechanisms of action to explain their possible benefit for patients with urticaria.¹⁷

Quercetin

The bioflavonoid quercetin can be found in many foods, including red wine, black tea, green tea, onions, apples, berries, citrus fruit, and brassica vegetables. Its antiinflammatory effects are thought to be mediated by inhibition of leukotriene and prostaglandin synthesis, as well as by inhibition of histamine release from mast cells and basophils.^{17,18} Although theoretically, quercetin should help ameliorate symptoms of urticaria, no studies looking specifically at its use in

urticaria could be found.

Dosage

The dose is 500 mg by mouth twice daily before meals.

Precautions

None are known.

Quercetin works by stabilizing mast cells, and butterbur inhibits histamine and leukotrienes. These botanicals may work synergistically on the allergic type of reaction seen in urticaria.

Butterbur (*Petasites hybridus*)

Butterbur lowers serum levels of histamine and leukotrienes.¹⁹ It also decreases priming of mast cells in response to contact with allergens.²⁰ One study found butterbur to be as effective as cetirizine (Zyrtec) for allergic rhinitis, without associated sedation.²¹ No studies have been conducted specifically on the use of butterbur for treatment of urticaria. However, because of its positive mechanism of action on the mediators of this condition, butterbur should be considered for patients who are intolerant of the sedating side effects of antihistamines.

Dosage

The dose is 50 to 100 mg of extract twice daily with meals (extract should be standardized to contain a minimum of 7.5 mg of petasin and isopetasin).

Precautions

The major concern with butterbur is its hepatotoxic pyrrolizidine alkaloid content. Any formulation used should be labeled as free of pyrrolizidine alkaloids. This herb should not be used in patients with liver disease, and liver function parameters should be monitored in any patient who uses it over a long period.

Sarsaparilla

The sarsaparilla root contains quercetin. Please refer to the earlier section on quercetin for more details.

Dosage

The dose of dried root is 1–4 g, or one cup of tea, three times/day. The dose of liquid extract (1:1 in 20% alcohol or 10% glycerol) is 8–15 mL, three times/day.

Precautions

Gastrointestinal irritation or temporary kidney impairment may occur when sarsaparilla is used in excessive doses.

To prepare sarsaparilla tea, simmer 1–4 g of dried sarsaparilla in 8–12 oz of water for 5–10 minutes.

Stinging Nettle (*Urtica dioica*)

The leaves of the stinging nettle contain flavonoids, including quercetin, rutin, and kaempferol. Please refer to the earlier section on quercetin for more details.

Dosage

The dose is 300 mg three times/day (up to seven times/day).

Precautions

Possible side effects include gastrointestinal complaints, sweating, diarrhea, and rash. Stinging nettle may worsen glucose control in patients with diabetes, lower blood pressure, and act as a diuretic.²²

Peppermint

Luteolin-7-orutinoside from the peppermint leaf may inhibit histamine.²³ Additionally, menthol volatile oil, found in peppermint, is useful as a

soothing topical preparation for itchy skin.

Dosage

The dose of peppermint oil is 0.2–0.4 mL three times / day between meals. Enteric-coated tablets are available.

Precautions

Topical use of peppermint oil can cause contact dermatitis and hives. Oral peppermint can relax the gastroesophageal sphincter and possibly worsen symptoms of gastroesophageal reflux disease. Some people have peppermint sensitivity leading to burning mouth syndrome or pruritus ani. Other side effects of peppermint that may be seen at very high doses include cramping, diarrhea, drowsiness, tremor, muscle pain, slow heart rate, and coma. Additionally, peppermint oil appears to inhibit several cytochrome P-450 enzymes, thus resulting in several potential drug interactions. Pure menthol is toxic and should never be ingested.

Menthol-Containing Products for Topical Use

- Aveeno Skin Relief Moisturizing Lotion: menthol and colloidal oatmeal
- Sarna Anti-Itch Lotion: 0.5% menthol and 0.5% calamine
- Gold Bond Medicated Body Lotion: 0.15% menthol (Extra Strength has 0.5% menthol)
- PrameGel: 0.5% menthol and 1% pramoxine
- Watkins Menthol Camphor Ointment: 2.8% menthol and 5.3% camphor
- Eucerin Itch-Relief Spray: 0.15% menthol

Ginkgo biloba

Ginkgo biloba contains ginkgolides, which are strong inhibitors of platelet-activating factors. Some early evidence indicates that platelet-activating factor may be implicated in some cases of cold-induced urticaria.²⁴ No studies have looked at the use of *Ginkgo biloba* in urticaria, but this

botanical may be useful in some patients with cold-induced urticaria.

Dosage

The dose is 120 mg/day of standardized extract.

Precautions

Because of its antiplatelet activity, *Ginkgo biloba* may potentiate other anticoagulants and concomitant use requires extreme caution. Other side effects may include gastrointestinal upset and dizziness.

Valerian Root

Valerian has long been used as an anxiolytic and may be useful in patients in whom urticaria is induced by high levels of emotional stress. No studies have specifically evaluated its use for the treatment of urticaria.

Dosage

The dose is 200 to 300 mg/day for generalized anxiety.

Precautions

No known contraindications exist. Possible side effects may include upset stomach, headache, and itching.

Pharmaceuticals

Antihistamines

The four known histamine receptor subtypes are H₁, H₂, H₃, and H₄. H₁ receptors are found throughout the body and are involved in evoking pain and pruritus, vascular dilatation, vascular permeability, bronchoconstriction, and stimulation of cough receptors. H₂ receptors are widely distributed as well and have functions similar to those of the H₁ receptors, with increased activity in the gastrointestinal system leading to higher secretion of gastric acid and mucus. In allergic processes, H₂ receptors act indirectly by altering the cytokine milieu. H₃ and H₄

receptors have been described, and their expression appears to be limited to neural and hematopoietic tissues, respectively.²⁵

Antihistamines are the mainstays of treatment for patients with urticaria. Pharmacological control is typically initiated with H₁-receptor antagonists. These agents can be broken down into the first-generation, more sedating drugs (chlorpheniramine, diphenhydramine, hydroxyzine, and promethazine) and the newer, less sedating medications (fexofenadine, cetirizine, levocetirizine, loratadine, and desloratadine). Because additional factors are involved in the development of urticaria, antihistamines may not completely control symptoms, but they can be expected to improve symptoms in most patients. Antihistamines should be used on a regular basis, rather than as needed, to reduce inflammation and prevent symptom development.²⁶

Many studies on various antihistamine medications have shown that efficacy is equivalent for the sedating and nonsedating classes.²⁷ No specific drug works consistently better, but some patients may have a better response to one than to another. If one agent does not adequately control symptoms, switching medications or adding a second antihistamine is appropriate. In fact, combining two nonsedating agents is not an uncommon practice and can be very useful. Additionally, some patients may have good response to a combination of H₁ and H₂ antagonists.^{28,29} Histamine-2 receptor blockers include ranitidine, cimetidine, famotidine, and nizatidine.

The tricyclic antidepressant doxepin has potent antihistamine properties that make it useful for patients with chronic urticaria.³⁰ Doxepin is very sedating and therefore is best used either in patients who have symptoms primarily at night or in combination with nonsedating antihistamines during the day.³¹

Dosage of First-Generation H₁-Receptor Antagonists

The dose of hydroxyzine is 50 mg at bedtime or up to four times per day. The dose of diphenhydramine is 25–50 mg every 6–8 hours. The dose of chlorpheniramine is 4 mg every six hours. The dose of promethazine is 12.5–25 mg every 6–8 hours.

Dosage of Second-Generation H₁-Receptor Antagonists

The dose of loratadine (Claritin) is 10 mg once or twice daily. The dose of desloratadine (Clarinex) is 5 mg once or twice daily. The dose of cetirizine (Zyrtec) is 10 mg daily or twice daily. The dose of levocetirizine

is 5 mg once or twice daily. The dose of fexofenadine (Allegra) is 60–180 mg once or twice daily.

There is some evidence that desloratadine and levocetirizine can be used up to four times the recommended daily use without harm and with increasing benefit.³²

Dosage of H₂-Receptor Antagonists

The dose of ranitidine (Zantac) is 150–300 mg twice daily. For famotidine (Pepcid), the dose is 20–40 mg one or twice daily. The dose of cimetidine (Tagamet) is 200–400 mg once or twice daily.

Dosage of Doxepin

The dose of doxepin is 10–75 mg, taken at bedtime.

Precautions

The possible side effects of first-generation H₁-receptor antagonists include central nervous system depression, cardiac arrhythmias, electrolyte imbalance, dry mouth, constipation, blurred vision, dysuria, and drug interactions.

Second-generation H₁-receptor antagonists have no significant adverse effects. Loratadine may interact with some antidepressant medications.

The side effects of H₂-receptor antagonists are generally mild and reversible. Common side effects include constipation, diarrhea, fatigue, headache, insomnia, muscle pain, nausea, and vomiting. Cimetidine has some antiandrogenic activity, and high doses may rarely lead to breast enlargement in men or impotence. Cimetidine is an H₂ blocker that is typically used to block stomach acid production, but it can be used for patients with recalcitrant urticaria. Its use in patients with urticaria is considered “off-label.”

Doxepin is extremely sedating and has the potential for causing significant drug interactions. Other possible side effects are cardiac conduction disturbances (QT prolongation), orthostatic hypotension, and anticholinergic effects (dry mouth, blurry vision, constipation, urinary retention).

The tricyclic antidepressant doxepin has potent antihistamine

properties that make it useful for patients with chronic urticaria.

Leukotriene Inhibitors

Leukotrienes are secondary inflammatory mediators in the pathogenesis of urticaria. Inhibitors of these compounds include zafirlukast, montelukast, and zileuton. These agents are used successfully in patients with asthma and, theoretically, should work for patients with chronic urticaria as well. While case reports have shown somewhat mixed results,^{33,34} these medications appear to be especially helpful for NSAID-exacerbated urticaria.^{35,36} These agents are most useful when they are combined with traditional histamine receptor antagonists.³¹

Dosage

The dose of zafirlukast (Accolate) is 20 mg twice daily. For montelukast (Singulair), it is 10 mg daily. The dose of zileuton (Zyflo) is 600 mg up to four times/day.

Precautions

Use these agents cautiously in patients with liver disease and consider potential drug interactions.

Corticosteroids

Corticosteroids are very effective for rapid resolution of urticarial symptoms. Because side effects can be significant, the use of these drugs should be limited to occasional short, tapering dosages for severe exacerbations. These agents should be used cautiously and sparingly, with reliance on other therapies for maintenance control. Short, rapidly tapered dosages of corticosteroids are generally safe and well tolerated, but repetitive tapered dosages or long-term use can lead to significant side effects and complications.

Dosage

The dose of prednisone is 40–60 mg/day for 2–3 days, then tapered over 1–2 weeks. Some patients may need longer, slower tapers.

Precautions

Common side effects include euphoria or depression, gastrointestinal distress, hypertension, sodium and fluid retention, impaired wound healing, higher risk of infection, osteoporosis, and skin atrophy. Growth retardation may occur in children. More serious side effects include adrenocortical insufficiency, cataracts, glaucoma, Cushing syndrome, hyperglycemia, and tuberculosis reactivation.

Cyclosporine

Cyclosporine is a strong immune suppressant that can be useful for patients with severe debilitating urticaria that has been recalcitrant to other therapies. It blocks the transcription of interleukin-2, which is required for T-cell activation. Among other effects, cyclosporine blocks the release of histamine from mast cells. Side effects are severe and significant, so appropriate monitoring is essential. Long-term treatment with cyclosporine is not ideal, although some patients may require long-term, low-dose therapy. Fortunately, many patients experience a period of improvement, or even remission, after 4–12 weeks of treatment.³⁷

Dosage

Many dosage regimens have been described. All use cyclosporine at doses at or less than 5 mg/kg/day for various durations. One regimen described specifically for chronic and debilitating urticaria is as follows: 3 mg/kg/day divided into two doses for 6 weeks, followed by 2 mg/kg/day divided into two doses for 3 weeks, followed by 1 mg/kg/day divided into two doses for 3 weeks.³⁸

Precautions

Cyclosporine is contraindicated in patients with uncontrolled hypertension, severe renal disease, serious infections, or a current or prior history of malignant disease.

Potential side effects include renal dysfunction, hypertension, hypertrichosis, gingival hyperplasia, gastrointestinal upset, neurological effects (headache, tremor, paresthesias), electrolyte imbalances, acneiform eruptions, hypertriglyceridemia, bone marrow

suppression, and sleep disturbances. Monitoring includes urinalysis, complete blood count, liver function tests, and blood chemistry analysis including magnesium, potassium, and uric acid.

Because cyclosporine is metabolized by the cytochrome P-450 CYP3A4 enzyme system, it has many potential drug interactions. The clinician should review a complete medication and herb list with each patient before initiating cyclosporine therapy.³⁹

Omalizumab (Xolair)

Omalizumab was approved in 2014 for treatment of chronic urticaria in people aged 12 years and older. This humanized anti-IgE monoclonal antibody binds to free IgE, blocking it from interacting with IgE receptors on mast cells and basophils, which effectively blocks degranulation of these cells. This decrease in the blood level of free IgE also leads to downregulation of IgE receptors, further decreasing opportunity for degranulation and thus symptoms of urticaria.⁴⁰ Typically, people see benefits within the first month of treatment, if not in the first week.

Dosage

The typical initial dose is 300 mg via subcutaneous injection every 4 weeks. If a person responds, tapering to 150 mg every 4 weeks and monitoring for recurrence of symptoms is suggested.

Precautions

This medication appears to be very safe. Resistance rates appear to be low, and there is no laboratory monitoring required. As with any of the biological medications, hypersensitivity reactions can occur including anaphylaxis, injection site reaction, and, ironically, hives.

Mind-Body Techniques

Background

Several studies have shown that psychological stress can trigger or exacerbate flares of urticaria.^{41,42} Up to 81% of people with chronic urticaria report stress as an aggravating factor.⁴³ Additionally, people

with chronic urticaria have been found to have a higher incidence of depression and anxiety.⁴⁴⁻⁴⁶ Additionally, people with chronic urticaria are more likely than controls to suffer from posttraumatic stress disorder (PTSD).⁴⁷ Although the mechanism is not well understood, the release of neuropeptides is thought ultimately to lead to elevations of histamine or greater sensitivity to histamine.⁴⁸ Human skin mast cells have been shown to release histamine in response to stimulation from various neuropeptides, including substance P, vasoactive intestinal polypeptide, and somatostatin.⁴⁹ Much more work needs to be done before we have a clear understanding of the relationship between the neural impact of stress on inflammation and urticaria. Though quality studies are lacking for the usefulness of most mind-body approaches for this condition, it does seem clear that stress management should be addressed in people who suffer from chronic urticaria, and their treatment plan should address stress and overall psychological health.

Hypnosis

Most information on the effectiveness of hypnosis is in the form of case reports. The flare reaction to histamine prick testing has been shown to be significantly reduced with hypnosis.^{50,51} One study evaluating the use of relaxation techniques among patients who were classified as hypnotizable and unhypnotizable found that both groups experienced improvement in symptoms; however, only patients classified as hypnotizable had fewer clinical lesions.⁵² In spite of the limited evidence, hypnotherapy may be a beneficial alternative—either alone or in combination with other therapies—for some patients with urticaria.

Hypnosis is a therapy that should be encouraged for treatment of chronic urticaria. The evidence is promising, and the potential for side effects is minimal.

Traditional Chinese Medicine

Within the framework of traditional Chinese medicine (TCM), urticaria is thought to be caused primarily by wind-heat, which obstructs energy channels and networks and causes red inflammation on the skin. When excess wind is present in the body, it can wander through the skin and cause itching. Wind-heat can arise through several different mechanisms. Invasion of pathogenic wind is often combined with pathogenic cold or

heat. Emotional disturbances and irritability cause heat accumulation in the heart and blood that makes one more susceptible to invasive wind. Damage to the spleen and stomach (resulting from a diet that is unhygienic or heavy in fish, seafood, or spicy foods) impairs the function of these organs and leads to increased dampness. When dampness accumulates internally, it can be transformed into wind-heat.

Each situation leading to the accumulation of wind-heat can be specifically treated with various herbal concoctions that are beyond the scope of this chapter. Acupuncture can also be used alone or in combination with cupping and/or herbal remedies. The main general acupuncture points used for urticaria vary according to the source, but generally include PC6 Neiguan, GB20 Fengchi, and ST36 Zusanli⁵³ or LI11 Quchi, SP10 Xuehai, SP6 Sanyinjiao, and S36 Zusanli.⁵⁴ Because TCM treatments are highly individualized for each patient and vary based on the specific symptoms, the general acupuncture points may differ significantly from patient to patient. Cupping involves placing a cup filled with warm air on the surface of the skin. As the cup cools, skin is drawn in and suction is created, which theoretically removes stagnant blood and wind thought to contribute to chronic urticaria. This can be done at specific acupuncture points. The assistance of a well-trained TCM physician should be sought, especially if one is interested in pursuing TCM herbal therapies.

Wide variation exists from state to state regarding certification, so when choosing an oriental medical doctor (OMD), one should ask whether the person has passed the National Certification Commission for Acupuncture and Oriental Medicine herbal examination. If someone is interested in acupuncture alone, the American Academy of Medical Acupuncture is a good additional source of well-trained practitioners.

Homeopathy

Like TCM, homeopathy views urticaria as the local expression of a systemic disturbance. Each patient is evaluated individually, and treatments are given on the basis of the constitutional approach. Because each patient is viewed as having a unique imbalance, the specific remedy chosen depends greatly on the patient. Two patients with urticaria may be successfully treated with vastly different therapies. Approximately 20 remedies are commonly employed to help patients with urticaria, including natrum muriaticum (a derivative of sodium chloride), apis mellifica (derived from the honey bee), urtica urens (derived from the stinging nettle plant), silica, kali carbonicum (derived from potassium

carbonate), pulsatilla (from the pasqueflower), sulphus (sulfur), sepia (cuttlefish), and byronia (wild hops).

To give a patient an appropriate cure, a practitioner must be well trained and have a deep understanding of homeopathy. Certification is not uniformly required, so one should look for practitioners who are accredited by one of the following organizations: the Council for Homeopathic Certification (CHC), the American Board of Homeotherapeutics (ABHt), the Homeopathic Academy of Naturopathic Physicians (HANP), and the North American Society of Homeopaths (NASH).

Precautions

With homeopathic treatments, patients may experience an exacerbation of symptoms before resolution; this exacerbation is known as a healing crisis.

Prevention Prescription

If a cause is identified in a particular patient, recurrences can be limited by having the patient

- Avoid exposure to known triggers.
- Limit stress.
- Eat a healthy, balanced diet with a low-histamine content.

Therapeutic Review

This is a summary of therapeutic options for urticaria. Laboratory investigation should be directed by the patient's medical history and physical findings. Particular attention to associations with systemic disease is warranted in patients with chronic urticaria.

General Measures

- Identify and avoid any precipitating factors, if possible. Activity and ingestant diaries may be particularly useful in this endeavor.  **A** ₁
- Use topical measures, including a cool, calm environment, loosely

fitting, comfortable clothes, baths with cornstarch, colloidal oatmeal (Aveeno), or baking powder. 

Nutrition

- Avoid allergenic foods, pseudoallergens, and foods high in histamine (see [Table 74.1](#)). 
- Consider an elimination diet (see [Chapter 86](#)). 

Botanicals and Supplements

- Quercetin: 400 mg orally twice daily before meals 
- Butterbur (Petadolex): 75 mg orally twice daily 
- Sarsaparilla: 1–4 g as dried root or tea three times daily; liquid extract (1:1 in 20% alcohol or 10% glycerol): 8–15 mL three times daily 
- Stinging nettle: 300 mg three times daily 
- Peppermint: 0.2–0.4 mL oil three times daily between meals or equivalent in enteric-coated tablets 
- *Ginkgo biloba* for cold-induced urticaria: 120 mg per day standardized extract 
- Valerian root for stress-related urticaria: 200–300 mg per day 

Pharmaceuticals

- Antihistamines: H₁-receptor blockers alone or in combination with H₂-receptor blockers 
- First generation
 - Hydroxyzine: 50 mg one to four times daily
 - Diphenhydramine: 25–50 mg every 6–8 hours
 - Chlorpheniramine: 4 mg every 6 hours
 - Promethazine: 12.5–25 mg every 6–8 hours
- Second generation
 - Loratadine (Claritin): 10 mg once or twice daily
 - Desloratadine (Clarinex): 5 mg once or twice daily up to 20 mg a day

- Cetirizine (Zyrtec): 10 mg once or twice daily
- Levocetirizine: 5 mg once or twice daily up to 20 mg a day
- Fexofenadine (Allegra): 60 to 180 mg once or twice daily
- H₂-receptor antagonists
 - Ranitidine (Zantac): 150–300 mg twice daily
 - Famotidine (Pepcid): 20–40 mg one to twice daily
 - Cimetidine (Tagamet): 200–400 mg one to four times daily
 - Doxepin: 10–75 mg before bed
- Leukotriene inhibitors 
 - Zafirlukast (Accolate): 20 mg twice daily
 - Montelukast (Singulair): 10 mg daily
 - Zileuton (Zyflo): 600 mg up to four times daily
- Corticosteroids: 40–60 mg/day for 2–3 days, then tapered over 1–2 weeks 
- Cyclosporine: 3 mg/kg/day for 6 weeks, 2 mg/kg/day for 3 weeks, and 1 mg/kg/day for 3 weeks. Appropriate monitoring is essential. 
- Omalizumab (Xolair): 300 mg subcutaneous injection once every 4 weeks 

Mind-Body Therapy

- Relaxation and stress management: Good for everyone! 
- Hypnosis, especially for people classified as hypnotizable 

Traditional Chinese Medicine

CHAPTER 75

Aphthous Stomatitis

David Rakel, MD

Recurrent aphthous ulcers (RAUs), also called aphthous stomatitis and canker sores, are the most common oral mucosal lesions, affecting 20% of the population in North America. They appear as recurrent ulcers with circumscribed margins with erythematous halos and gray or yellowish floors ([Fig. 75.1](#)).

RAUs affect the nonkeratinized or poorly keratinized mucosa of the mouth and oropharynx. No specific test is available for RAUs, and diagnosis is made from the patient's history and clinical findings.

Pathophysiology

RAUs appear to be multifactorial in origin, with a strong component of immune mediation. Histologically, there is an increase in immunoglobulin (Ig)E-bearing lymphocytes along with an increase in the number of mast cells and tumor necrosis factor-alpha (TNF-alpha) in the prodromal stages.¹ Cytotoxic action of lymphocytes and monocytes seem to cause the ulceration, but the exact trigger is not clear.

The three main clinical variations are as follows²:

- **Minor aphthous ulcers:** Commonly less than 5 mm in diameter, these are the most common form (80%). Typically one to five ulcers may be present at any one time, and they usually heal without scarring in 7 to 14 days.
- **Major aphthous ulcers:** These ulcers, which are less common, are larger and deeper than minor aphthous ulcers, tend to have irregular edges, and are more painful. They affect the lips, soft palate, and oropharynx and can take up to 6 weeks to heal, often leaving a considerable scar. Major and minor RAUs can be associated with Behçet's syndrome and human immunodeficiency virus (HIV) infection.

FIG. 75.1 Recurrent aphthous ulcers. The ulceration seen on the labial mucosa is surrounded by a characteristic erythematous halo. (From Zitelli BJ, Davis HW. *Atlas of pediatric physical diagnosis*. 5th ed. St. Louis, 2007, Mosby.)

- Herpetiform RAUs: Measuring 1 to 3 mm in diameter, herpetiform RAUs often occur in groups of 10 to 100 that commonly coalesce to form large, irregular areas of ulceration. These are not as deep as major aphthous ulcers. They heal without scarring in 7 to 14 days and, despite their name, are not associated with the herpes or any other virus.

Minor and major RAUs usually begin in childhood or early adolescence and have a tendency to resolve naturally later in life. Herpetiform RAUs appear later in life compared to minor and major RAUs, usually in the third decade ([Box 75.1](#)).

Integrative Therapy

Lifestyle

Toothpaste

Sodium lauryl sulfate is a common detergent used in toothpastes that has been shown to precipitate RAUs.²¹ Other ingredients may also affect RAUs, so a good question to ask patients with newly developed RAUs is whether they have recently changed toothpaste. *CloSYS*, *Tom's of Maine*, *The Natural Dentist*, *Burt's Bees*, and *Squigle* are examples of brands of toothpaste that do not contain sodium lauryl sulfate.

Nutrition

Several nutritional deficiencies have been associated with RAUs. Vitamin B₁₂, iron, and folic acid have been the most studied nutrients and have been found to be commonly deficient in patients with RAUs.³ Laboratory evaluations for red cell folate, serum vitamin B₁₂, and ferritin levels should be included in any evaluation of RAUs.

Vitamins B₁,⁴ B₂, B₆, and B₁₂ have also been found to be deficient in some patients with RAUs.⁵

Laboratory evaluation for red cell folate, serum vitamin B₁₂, and ferritin levels, as well as a complete blood count, should be ordered in the evaluation of recurrent aphthous ulceration. HIV infection should be considered if the patient is at risk for this infection.

BOX 75.1 Etiology of Recurrent Aphthous Ulceration

The origin of recurrent aphthous ulceration seems to be multifactorial and can include one or several of the following factors:

- Familial and genetic basis
- Nutritional deficiencies: vitamins B₁, B₂, B₆, and B₁₂, folic acid, iron
- Stress
- Stopping smoking
- Menstruation
- Food allergies (cow's milk and gluten most common)
- Sensitivities to toothpastes (sodium lauryl sulfate)
- Medications
 - Antineoplastic (methotrexate, daunorubicin, doxorubicin, hydroxyurea)
 - Angiotensin-converting enzyme inhibitors (captopril most common)

Antimicrobials

Metformin

Barbiturates

Griseofulvin

Nonsteroidal antiinflammatory drugs (NSAIDs)

Sulfonamides

Quinidine

Penicillamine

- Physical trauma

- Systemic conditions

Celiac disease

Crohn's disease

Human immunodeficiency virus infection

Neutropenia and other immune deficiencies

Neumann bipolar aphthosis

Behçet's syndrome

MAGIC (mouth and genital ulcers with inflamed cartilage)

Diet

A few patients with RAUs have gluten-sensitive enteropathy and improve considerably with a gluten-free diet.⁶ The diagnosis is usually made by jejunal biopsy or by assay of tissue transglutaminase IgA with a positive antiendomysial antibody. Although no evidence in the literature shows that gluten-free diets help patients with RAUs who do not have gluten sensitivity,⁷ anecdotal observations indicate that some patients without gluten sensitivity may benefit from a gluten-free diet.⁸ For the patient with recurring ulcers, a 2- to 4-week therapeutic trial of gluten avoidance is a reasonable option to assess effect.

The role of food allergies in the pathogenesis of RAUs is controversial. Several foods—milk, chocolate, coffee, nuts, strawberries, pineapple, citrus fruits, tomatoes, azo dyes—and food additives—monosodium glutamate (MSG), benzoic acid, tartrazine (yellow dye no. 5), and cinnamaldehyde—have all been suggested as a cause of RAUs^{9,10} (see [Chapter 86](#)).

Honey

Honey has been found to be helpful in healing stasis ulcers of the legs as

well as preventing mouth ulcers in patients receiving radiation therapy. In 40 patients with head and neck cancer who were receiving radiation, those who took 20 mL of honey 15 minutes before therapy and at 15 minute intervals at the time of therapy, and then again 6 hours after therapy, developed significantly fewer mouth ulcers than the saline treated control group.¹¹

Supplements

Glutamine

Glutamine, the most abundant amino acid in the body, is essential for maintaining intestinal function, immune response, and amino acid homeostasis during times of severe stress. Glutamine supplementation has been found to improve nutritional and immunologic status and reduce complications in critically ill patients.¹² However, not everyone benefits from supplementation. Those who have the greatest nutritional deficiency are thought to have the best clinical response.¹³

Supplementation with glutamine is beneficial during times of skeletal muscle wasting because most of glutamine is produced in skeletal muscle, and glutamine depletion raises the incidence of oral and gastrointestinal ulcerations. This amino acid has been found to reduce the duration and severity of oral stomatitis in patients undergoing chemotherapy.¹⁴

Dosage

Glutamine can be purchased in powder form. The patient should mix 4 g of powder in water, swish in the mouth, and swallow four times daily. If glutamine is used with chemotherapy, it should be taken on the day of chemotherapy and then used for 4 days after completion of each treatment.

Precautions

Grittiness of the oral solution may be unpleasant. Glutamine is otherwise well tolerated. It may cause mania in patients with bipolar disease.

Vitamin B₁₂

A randomized, double-blind trial using 1000 mcg of sublingual vitamin B₁₂ taken daily before sleep for 6 months in 58 patients with RAU showed that those in the treatment arm of the trial had significant reduction in ulcer formation, and 74% (compared with 32% in the placebo group) reported “no aphthous ulcer status” after 6 months. The response was not predicted by the baseline serum vitamin B₁₂ levels; study subjects with normal B₁₂ levels still responded to therapy.¹⁵ Metformin can cause B-vitamin deficiency. Consider supplementing if patients on this medicine have RAU.³⁰

Dosage

The dose of vitamin B₁₂ is 1000 mcg sublingually daily for ulcer prevention.

Precautions

Vitamin B₁₂ therapy is safe. The body excretes any excess into the urine, with the resulting classic bright yellow coloration seen with vitamin B supplementation.

Botanicals

German Chamomile (*Matricaria recutita*)

Chamomile is used for its antiinflammatory properties in the treatment of dyspepsia, leg ulcers, and oral mucositis. When used as a mouthwash, it has been found to prevent oral mucositis associated with radiation therapy and chemotherapy.¹⁶

Dosage

Make an oral rinse with 10 to 15 drops of German chamomile liquid extract in 100 mL warm water, and use three times daily.

Precautions

The plant has allergic potential but is otherwise safe.

Licorice (*Glycyrrhiza*)

Licorice, which has antiinflammatory action, has been used as a mouthwash and is available in oral disks.¹⁷ A randomized, double-blind study using a *Glycyrrhiza* oral patch compared with placebo patch showed significantly faster resolution of ulcers in the *Glycyrrhiza*-treated group at 8 days.¹⁸

Dosage

To use licorice as a mouthwash, mix half of a teaspoon of licorice extract with a quarter cup of water, swish, gargle, and expel the mouthwash four times daily for symptomatic aphthous ulcers.

A product called CankerMelt contains 30-mg *Glycyrrhiza* extract. The disk is applied to the ulcer and allowed to dissolve over time; then a new disk is applied every 6 hours.

Precautions

If the mouthwash is not swallowed, side effects are rare. Licorice can cause sodium retention and hypokalemia if it is swallowed. Care should be taken with the use of licorice in patients with hypertension because licorice ingestion can worsen the condition.

Although research is limited, many patients find pain relief due to the tannins found in tea leaves (*Camellia sinensis*). A brewed black or green tea bag can be applied to the ulcer as needed.

Homeopathy

Several homeopathic remedies have been used historically to treat RAUs. Unfortunately, all of the evidence for their use is anecdotal. A classical homeopath would look for a constitutional remedy that fits the whole patient. Symptomatic remedies that may help are as follows:

- *Mercurius solubilis* is indicated if the RAUs are associated with foul breath and increased salivation.
- *Borax* is indicated if the RAUs are brought on by citrus or acidic foods. The mouth usually feels dry even though some saliva may be present.

- Arsenicum album is indicated in patients with RAUs that are brought on by stress and eased with hot drinks.

Dosage

All the preceding remedies are best given initially at a potency of 6X or 6C four times daily (the X and C refer to the potency, which is the extent of dilution of the remedy). They should be discontinued when the RAUs begin to improve (see [Chapter 115](#)).

Mind-Body Therapy

Stress, both emotional and physical, triggers RAUs. Emotional and environmental stress may precede 60% of first-time aphthous ulcer cases and be involved in 21% of recurrent episodes.⁸ The pathogenesis may involve the known alteration of the immune response from stress, the depletion of B vitamins, or may be unknown.

Meditation and stress reduction techniques, such as guided imagery and hypnosis, have been shown to be useful in the management of RAUs.^{19,20}

Pharmaceuticals: Antiinflammatory Agents

Amlexanox

The only prescription medication approved by the U.S. Food and Drug Administration (FDA) for treatment of aphthous stomatitis is amlexanox (Aphthasol) 5% paste. It accelerates healing through an unknown mechanism that inhibits release of inflammatory mediators (histamine and leukotrienes) from mast cells, neutrophils, and mononuclear cells. This agent has no direct analgesic properties.

Dosage

Apply 0.5 cm to the sore with fingertip four times daily after meals and at bedtime. Start at the onset of symptoms and stop with resolution. If no resolution has occurred in 7 days, reevaluation is warranted.

Amlexanox is dispensed in a 5-g tube.

Precautions

This agent may cause minimal burning on application. Rash, diarrhea, nausea, and worsening stomatitis have been reported in less than 1% of cases.

Triamcinolone and Dexamethasone

Steroids such as triamcinolone and dexamethasone reduce inflammatory mediators but do not decrease the frequency of RAU occurrence.

Dosage

For triamcinolone acetonide: 0.1% in carboxymethyl cellulose paste (Kenalog in Orabase), apply 0.5 cm to the sore two or three times daily. Start at the onset of symptoms and stop with resolution. If no resolution has occurred in 7 days, reevaluation is warranted. This agent is dispensed in a 5-g tube.

For dexamethasone (Decadron) oral solution: 0.5 mg/5 mL, rinse the mouth with one teaspoon (5 mL) for 2 minutes and spit out, three times daily after meals and once at bedtime.

Precautions

Thrush may occur.

Pharmaceuticals: Analgesic Agents

A helpful approach is to avoid spicy, salty, and vinegar containing foods that may irritate and increase pain of the ulcers. The following analgesic agents may also be useful:

Viscous Lidocaine (Xylocaine 2% solution)

This agent provides anesthetic properties that diminish pain while eating.

Dosage

To use viscous lidocaine (Xylocaine 2% solution), swish 15 mL and expel, every 3 hours or before meals, as needed for pain relief. Do not use more than eight doses daily. This agent is dispensed in 50-, 100-, and 450-mL bottles.

Precautions

Care should be taken not to ingest large amounts of viscous lidocaine because of its potential for cardiotoxicity. Benzocaine gel (10% to 20%) is a safer alternative, particularly for use in children.

Pharmaceuticals: Mouthwashes

Chlorhexidine Gluconate

Chlorhexidine gluconate 0.12% oral solution (Peridex or Periogard oral rinse) is a mouthwash that has been shown to reduce the incidence, duration, and discomfort of RAUs.²² It does not, however, appear to be as effective as the other pharmaceutical topical agents.²³

Dosage

Swish 15 mL for 30 seconds and expel, twice daily. Chewing sugarless gum after using this mouthwash can help reduce tooth discoloration.

Precautions

This agent can cause stinging when it is first used, reversible discoloration of the teeth and tongue after 1 week of use, transient disturbances of taste, and burning sensation of the tongue.

Tetracycline–Fluocinolone Acetonide–Diphenhydramine Mouthwash

For more severe cases, a formula containing tetracycline, fluocinolone acetonide, and diphenhydramine can be used. Tetracycline is thought to work through antimicrobial and antiinflammatory mechanisms. Fluocinolone and diphenhydramine work through antiinflammatory and anesthetic mechanisms. This mixture has been found to be very helpful in severe cases of RAUs resulting from immunosuppressant therapy.

Dosage

Mixing this formula requires the help of a pharmacist. Most pharmacies are able to comply with these directions. The following should be mixed together to make a total of 150 mL:

- Tetracycline: At a concentration of 500 mg per 5 mL (which a pharmacist makes by dissolving a 500 mg capsule in 5 mL of water) for a total of 60 mL
 - Diphenhydramine syrup (Benadryl): 12.5 mg/5 mL for a total of 60 mL
 - Fluocinolone acetonide 0.01% solution (Synalar) for a total of 30 mL
- Swish 10 mL and expel four times daily until the ulcers resolve. Do not use for more than 7 days at a time.

Precautions

Tetracycline should not be given to children younger than 9 years because it stains the teeth. Fluocinolone, like most steroids, can cause thrush if it is used for extended periods.

For severe cases, a trial of tetracycline–fluocinolone acetonide–diphenhydramine mouthwash is indicated before using systemic therapy.

Systemic Pharmaceuticals

For cases resistant to topical therapy, consider the following systemic pharmaceuticals, in descending order as discussed in the following.

Colchicine

Colchicine has been used for stomatitis associated with Behçet's disease.²⁴ It has also been found to be beneficial for RAUs in patients without this disorder and is even more effective when combined with systemic steroids.²⁵

Dosage

The dose is 0.6 mg orally twice daily. It may be increased to three times

daily as tolerated with regard to gastrointestinal side effects.

Precautions

The most common side effects are gastrointestinal, consisting of diarrhea, nausea, and cramping. Colchicine can also cause thrombocytopenia and aplastic anemia.

Systemic Steroids

No good studies have been conducted on the use of systemic steroids for RAUs. These agents should be used cautiously in immunocompromised hosts.

Dosage

The dose of prednisone is up to 40 to 60 mg/day for 5 days. If longer use is needed, taper the dosage over 10 to 14 days.

Precautions

In patients with HIV infection, adverse reactions include cushingoid facies, thrush, reactivation of herpes simplex virus, and accelerated progression of Kaposi sarcoma.²⁶

Thalidomide

Thalidomide has efficacy in healing oral aphthae. In two trials involving difficult cases, thalidomide completely healed 48% to 55% of ulcers, compared with 7% to 9% in patients receiving placebo. This effect was temporary, however; many of the patients treated had recurring symptoms.²⁷

Dosage

The dose is 200 mg/day orally.

Precautions

Because of the potential for teratotoxicity and irreversible peripheral neuropathy, this treatment should be used only for the most serious,

intractable cases.

Because of the elevation of tumor necrosis factor-alpha (TNF-alpha) in recurrent aphthous ulceration, some people with resistant cases related to autoimmune conditions may benefit from a TNF inhibitor drug such as infliximab, etanercept, or adalimumab. These medications also pose a significant risk resulting from inhibition of immune function.²⁸

Cautery With Silver Nitrate

The use of silver nitrate sticks to provide chemical cautery was found to reduce pain significantly compared with placebo, but it did not reduce healing time. The study involved only one application. Clinicians contemplating this therapy should consider pretreating the ulcer with 2% viscous lidocaine and then painting the ulcer with the silver nitrate stick until it turns completely white.²⁹

Therapies to Consider

Traditional Chinese Medicine

Chinese medicine views RAU as a condition caused by heat in the stomach; it can also be caused by yin deficiency or toxic heat. Treatment is with topical watermelon frost or internally with formulas that cool stomach heat and clear toxic heat, such as dao chi pian or niu huang jie du pian. Although no reliable studies on the use of traditional Chinese medicine in the treatment of RAUs have been conducted, referral to a Chinese medicine practitioner is a valid approach if other treatments are not indicated or are unsuccessful.

Prevention Prescription

Have patients:

- Avoid oral trauma from biting, dental procedures, brushing, and eating of rough foods.
- Avoid toothpaste that contains sodium lauryl sulfate.
- Ensure adequate nutrition by consuming seven to nine servings of fruits and vegetables daily.
- Avoid trigger foods; cow's milk protein and wheat (gluten) are

most common.

- Consider a B 100 complex vitamin daily for recurring cases.
- Help patients learn how to change their interpretation of stressful information and events to reduce physical consequences (see [Chapters 94](#) and [100](#)).
- Avoid the use of medications associated with recurrent aphthous ulcers (see [Box 75.1](#)).

Therapeutic Review

The most important issue in dealing with recurrent aphthous ulcers (RAUs) is to exclude systemic conditions, particularly Behçet's syndrome (mouth, genital, and eye ulcers). Because the origin of RAUs is multifactorial, a simple list of treatments is not applicable; a good history helps focus on the triggers and can lead to a specific treatment plan. The following is a guide to the most common causes and treatments of RAU.

Laboratory Evaluation

- Identification of nutritional deficiencies should be the first step in treating RAUs.
- Order laboratory measurements of serum ferritin, red cell folate, and serum vitamin B₁₂. Replace these nutrients if the patient is deficient.
- Giving 250 mg of vitamin C with iron is often helpful to assist with iron absorption.

Nutrition

- If you suspect celiac disease, assess the patient for tissue transglutaminase immunoglobulin A and antiendomysial antibodies.
- Identify any foods that trigger the RAUs and consider elimination (see [Chapter 86](#)).
- Consider using honey, 20 mL before, during, and after radiation therapy of the head and neck to reduce the severity of mouth ulcerations. 

Supplements

- B vitamins (vitamins B₁, B₂, B₆, B₁₂)
 - Because the cost and potential harm of B vitamins are low, a 3-month trial of one B 50 complex vitamin pill daily can be used to see whether the frequency of RAUs is reduced. A B 50 complex vitamin contains approximately 50 mcg or mg of each B vitamin.
 - Vitamin B₁₂, 1000 mcg sublingually daily for 6 months, has been found to reduce the incidence of ulcers. 
- Glutamine
 - Mix 4 g of powder in water, swish, and swallow four times per day.
 - This is best for RAUs resulting from severe disease or injury or in patients undergoing chemotherapy. 

Botanicals

- Licorice (*Glycyrrhiza*) mouthwash: Mix half teaspoon of licorice extract in a quarter cup of water; swish and expel four times per day. 
- CankerMelt disks contain 30 mg *Glycyrrhiza* extract. The disk is applied to the ulcer and allowed to dissolve over time; then a new disk is applied every 6 hours.

Homeopathy

- Mercurius solubilis is indicated if the RAUs are associated with foul breath and increased salivation. Use 6X or 6C potency four times per day until healing begins.
- Borax is indicated if the RAUs are brought on with citrus or acidic foods. The mouth usually feels dry even though some saliva may be present. Use 6X or 6C potency four times per day until healing begins.
- Arsenicum album is indicated in patients whose RAUs are brought on by stress and eased with hot drinks. Use 6X or 6C potency four times per day until healing begins.

Mind-Body Therapy

- Because stress is often a component of RAUs, stress reduction techniques, such as meditation and guided imagery, are usually

advisable to include in management (see [Chapter 94](#)).

Pharmaceuticals

- Topical therapy
 - Amlexanox (Aphthasol) 5% paste: 0.5 cm applied to sore four times daily 
 - Triamcinolone acetonide 0.1% in carboxymethyl cellulose paste (Kenalog in Orabase): 0.5 cm applied to the sore three to four times daily 
 - Viscous lidocaine (Xylocaine 2% solution): 15 mL swished every 3 hours as needed for pain 
 - Chlorhexidine gluconate 0.12% oral solution (Peridex or Periogard oral rinse): 15 mL rinsed and expelled twice daily 
 - Tetracycline 500 mg per 5 mL to make 60 mL, fluocinolone acetonide solution (Synalar) 30 mL, and diphenhydramine syrup (Benadryl) 60 mL, mixed together to make 150 mL; 10 mL swished and expelled four times daily 
- Systemic Therapy
 - Colchicine: 0.6 mg twice daily, increased to three times daily as tolerated in terms of gastrointestinal side effects 
 - Prednisone: 40 to 60 mg per day for 5 days 
 - Thalidomide: 200 mg per day; used only for most severe cases 

Cautery

- Premedicate with 2% viscous lidocaine and paint the ulcer once with silver nitrate stick until it turns white.
- This technique helps reduce pain but not ulcer duration.

CHAPTER 76

Seborrheic Dermatitis

Alan M. Dattner, MD

Pathophysiology

Seborrheic dermatitis (SD) involves a predisposition toward a specific inflammatory desquamative reaction pattern in typically oily areas rich in *Malassezia*. An overabundance of or an inappropriate immune reaction to the common skin and follicular microflora species known as *Malassezia* (formerly *Pityrosporum*) has been both demonstrated and disputed in the literature.¹ Since the identification of seven major strains of *Malassezia* in 1996, studies have begun to demonstrate which species are most predominant in SD in different populations. *Malassezia globosa* and *Malassezia restricta* predominate, according to some reports,^{2,3} and various other strains have been reported to be associated with SD as well. Evidence both for and against an association with increased or altered sebum production has been presented, but increased sebum production leading to greater growth of *Malassezia* seems to be a contributor.

Seborrhea is aggravated by Parkinson's disease and by drugs that induce parkinsonism; clinical improvement is obtained with levodopa treatment of Parkinson's disease. Aggravation by emotional stress and changes associated with cases of partial denervation suggest a neurohumoral influence as well. Some drugs have been implicated in inducing SD. Infantile SD, or Leiner disease, has been reported to respond to biotin and essential fatty acids (EFAs). Recent reports have shown a biotinidase deficiency in such infants.⁴

The observation of an increase in both frequency and severity of SD among patients with acquired immunodeficiency syndrome (AIDS) has renewed interest in this otherwise benign disorder. These findings suggest that immune alterations may play some role in SD. *Malassezia* metabolites including free fatty acids released from triglycerides of

sebaceous origin are also thought to induce the inflammation seen in SD.⁵

Malassezia is a genus of fungi found to cause seborrhea and skin depigmentation commonly associated with tinea versicolor. It requires fat to grow and thus is common in sebaceous glands.

Because *Malassezia* species are present in most people, one should ask why SD develops in some people and not others. Besides the specific species, sebum production, and particular circumstances just mentioned, reactions initiated by both the keratinocytes and the immune system may account for this difference. Some of the response in SD may be related to direct interactions between *Malassezia* organisms and keratinocytes that generate cytokines such as interleukin-8 (IL-8).⁶ Activation of innate immunity through Toll-like receptors (TLRs) also seems to play a role. Keratinocytes infected with *Malassezia furfur* upregulate TLR-2, as shown by RNA analysis.⁷

Another possible explanation of the mechanism of SD may come from the observation that symptomatic *Candida* vulvovaginitis does not develop unless an aggressive response by polymorphonuclear leukocytes occurs.⁸ A similar excessive neutrophilic hypersensitivity may play a role in SD because a neutrophilic infiltrate is a characteristic histopathological finding in SD.

My own interpretation of the pathophysiology is that the trigger involves cytokines and TLRs, as described previously, as well as a specific hyperactive cross-reactive immune response to some antigenic component of *Malassezia* that contributes greatly to the inflammation. The cross-reactive stimulation is a hyperactive response to the *Malassezia* organisms resulting from primary stimulation of the lymphocytes by *Candida* and other gut fungal microflora products. Patients with scalp psoriasis and seborrhea have been shown to have elevations of *Candida* organisms in the feces and on the tongue, a finding suggesting higher gut levels.^{9,10,11} Elevations of *Candida* in the stool and *Candida* phospholipase A, as well as the improvement of seborrhea with oral nystatin (which tends to remain in the gut), further argue for a role for *Candida* cross-stimulation in SD.¹² This phenomenon of primary stimulation and secondary response has been demonstrated in vitro¹³ and in the clinical setting.¹⁴

I believe that the immune response to the organism is biphasic, leading to both a tolerance to some components (epitopes) of yeast and a

hyperactive response to others. Cross-reactivity among *Malassezia*, *Candida*, and other yeasts relative to immunoglobulins has been well demonstrated.^{15,16} Such a biphasic response would explain the mixed results in the literature showing both hyporeactivity and hyperreactivity to *Malassezia* antigens in patients with SD. The first component allows some overgrowth of *Malassezia* and related organisms (i.e., yeasts in gut and on skin). The hyperactive response precipitates a cascade of immune-mediated activity leading to the erythema and desquamation characteristic of the disease. Resident microflora (especially *Candida*) and ingested antigens from related microflora (e.g., yeasts and molds and their byproducts) provide the cross-reactive stimulus leading to both the tolerance and the hyperreactivity. Consideration of this etiological hypothesis changes the way one treats chronic SD, described later.

The proinflammatory response disposition comes in part from a metabolic shift toward the production of proinflammatory prostanoids, caused by the common dietary oils rich in arachidonic acid.¹⁷ Antiinflammatory precursors, such as the omega-3 EFAs eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are insufficient. A study of psoriasis, a related skin disease, demonstrated a higher ratio of arachidonic acid to omega-3 EFAs in patients receiving fish oils than in a control group. Supplementing with fish oil reduced arachidonic acid and malondialdehyde (another inflammatory molecule that is a marker of oxidative stress) and was associated with clinical improvement.¹⁸ Arachidonic acid is a precursor to the proinflammatory leukotriene B₄ (LTB₄), which has been well documented to play a role in the pathogenesis of the psoriatic lesion.

The mixed nature of those findings may result in part from a lack of control of other critical factors influencing both lipid metabolism (e.g., oxidant status of the patient and relative intake of proinflammatory lipid precursors) and biochemical influences on the delta-5 and delta-6 desaturases, which play a key role in the metabolic pathway toward proinflammatory or antiinflammatory prostanoids. An additional key factor is that carbohydrate excess leads to excess insulin release. The excess insulin both inhibits the delta-6 desaturase and causes long-term release of proinflammatory cytokines,¹⁹ thus favoring the inflammatory disease process despite the antiinflammatory effects of ingested EFAs. Most published studies do not address this important variable, which is best managed by encouraging a diet low in simple carbohydrates. In my experience, such a diet leads to positive results in a significant proportion of patients with SD as well as in patients with other inflammatory

disorders of the skin (see [Chapter 88](#)).

Integrative Therapy

Changing to antiinflammatory oils, controlling yeast on the skin and in the bowel, and calming the nervous system are mainstays in controlling seborrheic dermatitis.

Nutrition

Omega-3 Essential Fatty Acids

Omega-3 unsaturated fatty acids should be substituted for other dietary fats. Saturated, heat-altered, and partially hydrogenated fats should be eliminated from the diet because they lead to production of proinflammatory prostaglandin E2 (PGE2) prostanoids. In addition, they block the delta-6 desaturase that catalyzes the formation of antiinflammatory leukotriene precursors. Extra fats contribute to the unfavorable ratio of proinflammatory lipids in the cell membrane and to weight gain because of their caloric content. Other indicators of a need for omega-3 oils are dry skin in winter, dryness around the nailfold area, a lack of dietary intake of such oils, depression, and a high ratio of arachidonic acid to omega-3 EFAs in the plasma or red blood cell membrane. EPA appears to be the primary antiinflammatory component of omega-3 unsaturated fatty acids.

An excellent source of omega-3 unsaturated EFAs is EFA-enriched fish oil capsules or liquid. Krill oil, cod liver oil, and other cold-water fish oils are also good sources. Eating four to five portions weekly of oily cold-water fish is also recommended. Flaxseed oil, which contains alpha-linolenic acid, is also a potential source, but it must undergo chain elongation involving an extra step requiring the delta-6 desaturase, and some people cannot use this oil effectively. Canola oil and walnut oil are lesser sources of omega-3 unsaturated EFAs.

Oils can be either taken as supplements or worked into the diet as foods. For example, flaxseed oil can be used in making smoothies or salad dressing. These oils should not be heated because the unsaturated bonds that make them useful are unstable on heating. Because of their unsaturated nature, they should be accompanied by vitamin E in the

diet. Similarly, other factors contributing to high oxidative stress in the individual patient should be corrected, or counterbalanced with additional antioxidants, to maximize the effectiveness of these oils. Omega-3 fish oil can induce glucose intolerance in diabetic patients. To counter this effect and to reduce the proinflammatory mediators from carbohydrate-stimulated insulin elevation, a proper balance of carbohydrate intake with protein intake and exercise should be achieved.

Dosage

The dosage is based on the severity of presentation, a history of inadequate dietary intake of omega-3 EFAs, and a low red blood cell membrane ratio of EPA to arachidonate. Whereas daily intake of five capsules (approximately one teaspoon) of flaxseed oil or EPA-DHA fish oils may be helpful, some patients may need as much as 15 mL (three teaspoons) per day for a short time, mixed into a shake to make it palatable. Vitamin E, 400 units/day, should be taken to protect these unsaturated oils from oxidation. At least 1000 mg of EPA should be present in the product used. Flaxseed oil may not be effective if the individual is unable to chain elongate the 18-carbon alpha linolenic acid.

Precautions

Fish oils have been known to prolong bleeding time through the anticoagulant effect of PGE3 for which they are precursors. Use of large doses in pregnant women has also been associated with elevated birth weight of their infants.

Yeast Elimination

For patients who require additional measures to control their seborrhea, a yeast and mold elimination diet should be instituted. The basis of this diet is the elimination of bread, cheese, wine and beer, excessive carbohydrates (especially sugar and simple starches), and other foods containing or produced by yeast or fungus. This diet has been touted as highly effective in the popular literature, and the success of different variations is probably related both to yeast reduction and to relief of different food allergies in patients with yeast sensitivities. Probiotics such

as *Lactobacillus acidophilus* and *Bifidobacterium bifidus* should be taken before or during meals to help repopulate the normal flora of the gut. Patients who cannot give up bread should be counseled to eat true sourdough bread, the leavening agent for which is derived from limited cultures of different yeasts captured from the air.

Supplements

Vitamins

Oils, which can be used as either foods or supplements, have already been discussed. Vitamin E, at 400 units/day, should be added as an antioxidant to protect the oils. Adequate levels of magnesium, zinc, vitamin C, and vitamin B6 should be maintained by supplementation if intake of any of these nutrients is insufficient in the diet, to enhance the function of the delta-6 desaturase. Vitamin B6 cream, 50 mg/g, compounded in a water-based cream by a compounding pharmacy, has been used for treatment of SD of the scalp.^{20,21}

Biotin is especially useful in infantile SD,²² and it may have a role in the treatment of adult seborrhea as well. Besides contributing to the generation of antiinflammatory prostanoids through activation of the delta-6 desaturase (as do other vitamins mentioned here), biotin is reputed to retard the formation of the mycelial form of *Candida*. Other B vitamins shown to be helpful in seborrhea are vitamin B6, folate,²³ and vitamin B12.²⁴

Dosage

One or two tablets per day of a high-potency multivitamin with mineral (even for those with a three- to six-tablet per day recommendation on the bottle label) can be used for vitamin B supplementation in most patients. If clinical improvement is not seen, extra biotin up to 7.5 mg/day and vitamin B6 or pyridoxal 5-phosphate, 20–50 mg/day can be added; zinc picolinate, 25–50 mg/day, and vitamin C, 500 mg one to three times per day, are also useful.

Probiotics

To address the yeast overgrowth, adding probiotic bacteria such as *Lactobacillus acidophilus* and *Bifidobacterium*, or the yeast *Saccharomyces boulardii* to the diet is nearly as important as proper diet in restoring normal gut flora and reducing the yeast population. Caprylic acid can be added to inhibit attachment of the yeast to the intestinal wall.

Dosage

GI Flora (Allergy Research Group, Alameda, California) is an economical, effective source of multiple probiotic strains; the dose is one or two capsules with meals. Ultra Flora Balance or the higher-potency Ultra Flora IB, one capsule per day (Metagenics, San Clemente, Calif), are other useful sources. Doses for caprylic acid are begun at one capsule three times per day before meals and are gradually increased to two capsules per meal, if necessary, or augmented by other anti-yeast supplements.

If the patient has known overgrowth of yeast in the gastrointestinal tract, consider Caprystatin (Ecological Formulas, Concord, California), which contains caprylic acid, a short-chain fatty acid that inhibits *Candida* growth and prevents attachment of yeast to the intestinal wall. Start with one capsule three times per day before meals, and increase the dose as necessary. Some patients, especially those who have associated fatigue or hypersensitivities, may have a die-off reaction and have some symptoms worsen before they improve. Follow these patients closely to ensure that they are not reacting to something in the treatment regimen. Resume the program at a slower rate if symptoms occur.

Precautions

The addition of a source of fiber is important to ensure that bowel movements are occurring at least one or more times per day during yeast reduction therapy, so that allergenic moieties are not absorbed from the dying organisms. Fiber also promotes healthy mucosa along the gastrointestinal tract in which bacteria live.

Probiotics should not be given to a patient with a compromised immune system because of the slight risk of infection.

Many companies that produce probiotics claim to offer the absolute best species, combinations, or strains of bacteria. Clinicians are advised to start with an affordable *Lactobacillus acidophilus* or *Bifidobacterium bifidus* preparation and then add others to their personal pharmacopoeia as evaluation of a specific product is found to be convincing and its effects are confirmed to be beneficial. Different patients do better with different probiotic bacteria. *Bifidobacterium bifidus* is thought to be more beneficial initially.

Topical Nicotinamide (Vitamin B3)

Topical nicotinamide cream 4% was found to cause a 75% reduction in SD scores as compared with placebo cream giving a 35% reduction. It was also found to work as well as 1% clindamycin for moderate inflammatory acne.²⁵

Dosage

Apply 4% cream twice per day after washing.²⁶

Precautions

Can cause drying of the skin and/or peeling and itching.

Botanicals

For topical treatment, any application that reduces yeast on the skin may be helpful. Various essential oils may be useful for their incorporation in scalp sebaceous lipids and antimicrobial action against *Malassezia*. Tea tree oil, honey, and cinnamic acid have been shown to reduce *Malassezia* and SD.²⁷ Tea tree oil and cinnamic acid, as well as other essential oils, however, can cause contact dermatitis, especially in inflamed skin, and honey is messy to use on the scalp. *Monarda fistulosa*, a distinctive-smelling herb from the mint family, has also been reported to yield an essential oil that is effective against seborrhea.²⁸

Many different antifungal herbs and combination products with probiotics are available on the market today, and a comprehensive evaluation of these products is beyond the scope of this chapter. A few

are mentioned here, but most that are effective in significantly reducing the yeast population in the gut will work. The use of fiber products such as psyllium and of other vegetable fiber is essential to maintain rapid passage of treated organisms through the bowel.

Grapefruit seed extract and *Artemisia annua* can also be added to reduce the yeast population. Some newer herbal preparations constituted for this purpose are available. Pau d'arco tea is another product with reported antiyeast activity. Application of aloe has been shown to be useful in seborrhea.²⁹

Dosages

Tea tree oil may be used in adults on an occasional basis, applied sparingly to the areas of intense scaling after wetting the scalp. Because it is a potent allergen, I do not recommend it for regular, ongoing use. Aloe vera (*Aloe barbadensis*) gel may be applied directly from the cut leaf of the plant. Avocado may contain oils and sugars³⁰ that are helpful in controlling SD.

Mind-Body Therapy

SD is more prevalent in patients with depression.³¹ Perhaps the improvement seen in the summer is the result either of reduced depression or of the effects of increased sunlight on melatonin release.³² Addressing depression or seasonal affective disorder with light therapy, visits to a sunnier climate, psychotherapy, Bach Flower Remedies, supplements, or medications may be considered in a patient with SD in whom the disease severity varies with his or her affective state.

Pharmaceuticals

Shampoos

The two mainstays of topical treatment of SD are tar shampoos and antiyeast shampoos. Antiyeast shampoos consist, in order of potency, of zinc pyrithione, selenium sulfide 1% (over-the-counter shampoos), selenium sulfide 2.5% (prescription), and ketoconazole shampoos (available over the counter in some countries). Tar shampoos have antiinflammatory and antiyeast activity.

Dosage

A more recent treatment for fungal infections is ciclopirox 1% shampoo (Loprox), which is also approved for use in SD. Side effects include pruritus (itching), burning, erythema (redness), seborrhea, and rash. This product comes in a gel and a shampoo. Use the shampoo twice a week for 4 weeks or apply the gel twice daily for 4 weeks.

Tar shampoo (Tegrin, T/Gel) is used three times per week initially and then once per week.

Keratolytic Treatments

Oils are applied to the scalp to loosen scale. Olive oil is particularly useful in this regard, especially in infants with thin hair. Wetting the scalp and applying a warm oil turban for an hour, with 6% salicylic acid mixed into the olive oil, may remove more adherent scale. Patients must remove the oil with dishwashing liquid detergent before they apply a therapeutic shampoo.

Other salicylic acid preparations may also be used for the same purpose when thick, adherent scale is difficult to remove. Urea preparations may be used for the same purpose. These preparations also need time to act and generally require shampoo for removal. After thick scale is removed, a therapeutic agent can be applied to penetrate the scalp more deeply. Keratolytics such as salicylic acid have antifungal properties as well.

Dosage

Consider the following treatment to help reduce scaling. Olive oil is compounded with 6% salicylic acid; the oil is applied to a wet scalp under a warm towel turban for 1 hour, and then scales are removed with a soft brush.

Topical Corticosteroids

Topical corticosteroids are another mainstay of conventional treatment of SD. Even 1% hydrocortisone cream brings temporary improvement in SD of the face and nasolabial folds in a previously untreated patient.

Liquids, gels, and even a foam vehicle are available, with a more potent

fluorinated corticosteroid used to avoid the hair and reach the scalp.

Dosage

Patients should apply 1% to 2.5% hydrocortisone cream sparingly once or twice daily for 1–2 weeks. Hydrocortisone cream, Triamcinolone solution or betamethasone valerate foam (Luxiq) once or twice per day can be used to relieve pruritus and inflammation for brief periods of time.

Precautions

Frequent or repeated application of corticosteroids results in tachyphylaxis (a progressively diminished response), requiring more potent steroids to obtain the same response. In addition, some patients behave as though they are addicted to the topical steroids. The problem becomes worse, and the corticosteroid is needed increasingly more often in higher strengths to control the redness and scaling. Repeated use on the face, especially of stronger corticosteroids, and even the use of hydrocortisone on the thin tissues of the eyelids, can result in atrophy of the skin with permanent show-through of the underlying capillaries or the development of problematic steroid acne.

Other Creams

Ketoconazole (Nizoral) cream applied sparingly twice daily is extremely helpful for management of SD of the face and hairline. It inhibits the *Malassezia*, gives dramatic clinical improvement, and does not cause the atrophy resulting from prolonged corticosteroid use. Other antifungal creams, including ciclopirox (Loprox) and nystatin cream, are also useful.

Dosage

Ketoconazole cream 2% is applied twice daily to affected areas, sparingly.

Lithium Succinate

Lithium succinate 8% ointment has been reported to be helpful in SD. An antiyeast effect has been confirmed in vitro,³³ as well as in patients.³⁴ The ointment is applied twice daily. The relationship between lithium as a drug for depression, which has been implicated as a cause of seborrhea, and direct application of lithium as a treatment for seborrhea is interesting to contemplate. A common mediator pathway for both disorders may exist.

Oral Antifungals

Oral antifungals should be used only when seborrhea is serious enough to warrant the risk of taking the drug or when the underlying condition of overgrowth has not responded to diet and herbal treatment alone.

Nystatin

Oral nystatin is useful to reduce the *Candida* population in the gut. It has the benefit of being poorly absorbed and therefore remaining in the gut. It works by causing defective yeast cell wall formation, resulting in release of intracellular contents, which has in turn been blamed for the aggravation of symptoms constituting a Herxheimer-type reaction (flulike feeling from the die-off effect of yeast) in some patients after a large dose.

Ketoconazole and Fluconazole

Ketoconazole (Nizoral) is well absorbed, exerts an antiyeast effect in the gut and skin, and is excreted in high concentrations in the sweat. Other oral antifungal agents, such as fluconazole (Diflucan), have also been used for severe cases of seborrhea. An antiyeast regimen should be instituted gradually, starting with diet, *Lactobacillus acidophilus*, and supplements and botanicals before oral pharmaceuticals are used. The first reason is to avoid rapid kill-off of a large number of organisms, which may result in a die-off effect, or Herxheimer-type reaction. The second reason is to reduce the intestinal yeast population less drastically. If the gut ecology is altered to favor a more gradual reduction in yeast population, a rebound growth of yeast resistant to the most powerful agents available is less likely to occur. Although these agents may be effective in the short term, I question whether it is responsible practice to use these agents without initially or simultaneously altering the ecological conditions that favor yeast overgrowth.

Dosage

The dose of nystatin for Candida is increased slowly from 500,000 units once daily to 1–2 million units three times daily; this dose is then maintained until the patient's condition is improved. Lesser dosages may be needed if seborrhea is the only manifestation of this issue. Dosing should begin with one capsule (500,000 units) per day of the powder, with addition of an extra capsule every 2 or 3 days until a total dose of four capsules three times daily (6 million units/day total) is achieved. Doses for the pure powder should begin with 1/8 teaspoon/day increased to 1/2–1 teaspoon/day (3–6 million units/day total, depending on response and severity) in the same gradual manner. This dose should be continued for 1 month or tapered for 1–2 weeks after symptoms clear.

The FDA has warned against using ketoconazole for skin and nail infections, and fluconazole is regarded similarly. Such off-label use is mentioned but not recommended, and should only even be considered when dietary measures have been instituted and all other methods have failed, and the risk of severe side effects or death is less than the risk of not trying the drugs. For fluconazole (Diflucan), the dose is 100–200 mg/day for 10–14 days. (Many drug interactions and cautions are cited in the package insert.) Seborrhea is not a listed indication and should only be used in cases with severe underlying yeast issues.

The dose of ketoconazole (Nizoral) is 100–200 mg/day. Ketoconazole should be used only if other indications exist and liver enzyme values are monitored. In general, this drug should be avoided, or the liver can be protected with silymarin (milk thistle). Seborrhea is not a listed indication and should only be used in cases with severe underlying yeast issues.

Precautions

Adverse effects include elevation in liver enzymes, hepatic failure (uncommon with oral ketoconazole and less likely with fluconazole), a Herxheimer-type die-off phenomenon (especially with nystatin), and overgrowth of resistant organisms.

Before an oral antifungal is considered, intestinal yeast growth should be reduced with dietary measures. This will help prevent the

growth of resistant strains of yeast and lead to improved response from the oral antifungal.

Therapies to Consider

Homeopathy

A homeopathic dilution of tobacco was reported to clear SD in a patient with tobacco sensitivity. I mention this not to recommend this specific remedy but rather to emphasize the potential benefits of choosing an appropriate homeopathic or other remedy that addresses prominent underlying imbalances in the patient. Other homeopathics, including natrum muriaticum, arsenicum album, and bryonia, may be considered, but homeopathics should be prescribed according to other characteristics of the patient besides local presentation.

Food Allergy

As in patients with atopic dermatitis, addressing food allergies by removing the offending foods from the diet may benefit some patients with recalcitrant SD (see [Chapter 86](#)).

Energy-Based Treatments

When addressing a variety of apparent causal factors is not sufficient, the clinician must address ways in which the seborrhea may be an expression of some deeper autonomic or psychological pattern. Psychotherapy may be useful if it is powerful and targeted. Classical homeopathy addressing mental and emotional symptoms may touch this level. Newer forms of treatment that use acupuncture meridian activation or tapping to release patterns of sensitivity in the autonomic nervous system, including Lang desensitization and neuromuscular therapy (NMT), may be considered by the practitioner skilled in these techniques.

Prevention Prescription

- Use a Mediterranean-type diet based on olive oil and fresh vegetables.
- Supplement with omega-3 essential fatty acids from fish oil, northern fish, and flaxseed.
- Reduce the intake of bread, cheese, wine, beer, and yeast.

- Reduce the intake of sugar, refined carbohydrates, and heated oils.
- Shampoo the scalp at least twice a week, with an antidandruff shampoo when necessary.

Therapeutic Review

The following is an outline of therapeutic options for the treatment of seborrheic dermatitis. Determining which factors lead to the disease presentation in a given patient may improve the chances of success of a given therapy. For more severe or resistant cases, a progressive, sequential approach with multiple therapeutic avenues is recommended, with either intensification of treatments or addition of systemic pharmacological agents, as indicated by the clinical response.

Antidandruff Shampoos

- Zinc pyrithione, selenium sulfide (Selsun), tar, or ketoconazole (Nizoral) shampoo is used for 5 minutes two or three times/week.
- If the patient has used one type with no clinical improvement, another can be tried. 

Antiyeast Creams

- Ketoconazole cream 2% (Nizoral) or another pharmacological or herbal substitute works well on the face and nonscalp areas. 

Supplements

- Eicosapentaenoic acid and docosahexaenoic acid (fish oils) can be added at 1–2 g/day and titrated to clinical improvement. 
- Other sources of omega-3 essential fatty acids—oily cold-water fish, such as salmon and sardines, three to five servings per week and flaxseed oil, one teaspoon/day—can be used.
- Vitamin E 400 units/day should be given with the aforementioned oils to prevent oxidation. 
- Vitamin B complex, vitamin B6 500 mg, and biotin up to 8 mg/day may be beneficial in patients with resistant cases. 
- Caprylic acid is taken at 100–200 mg two to three times per day to

reduce the attachment of yeast to the intestinal wall.

- Topical nicotinamide (B3), 4% cream twice per day. 

Nutrition

- A diet low in yeast and simple carbohydrates, especially one that eliminates bread, cheese, wine, beer, fermented foods, and starches, is helpful in patients with persistent cases.
- Some improvement may result from removal of other food allergens.

- Adding probiotic bacteria such as *Lactobacillus acidophilus*, one capsule per meal, or live-culture yogurt may also help. 

Botanicals

- The antiyeast botanicals grapefruit seed extract and *Artemisia annua* may be used at two to six capsules/day. 
- Undecenoic acid, derived from the castor bean, is another antiyeast product (Formula SF 722 [Thorne Research, Sandpoint, Idaho]), used at two to six capsules/day. 

Pharmaceuticals

- Nystatin is used in slowly increasing doses from 0.5–6 million units/day. 
- Hydrocortisone cream, triamcinolone solution or betamethasone valerate foam (Luxiq) once or twice per day can be used short-term to relieve pruritus and inflammation.

CHAPTER 77

Acne Vulgaris and Acne Rosacea

Hana Grobel, MD, and Sarah A. Murphy, MD

Acne Vulgaris

Pathophysiology of Acne Vulgaris

Acne vulgaris is a common skin condition that affects around 85% of adolescents around the world and can be moderate to severe in 20% of the world's population.¹ It commonly continues into adulthood, affecting 64% of those in their 20s and 43% of those in their 30s. There is a strong genetic component, with 80% of those affected having first degree relatives with similar conditions.²

Acne is a condition of the pilosebaceous unit of the skin, which includes the oil glands and hair follicles ([Fig. 77.1](#)). Following are the four main factors that contribute to acne formation and are the basis of most treatments³:

1. Keratinization of the pilosebaceous unit: The skin consists of pores that contain hair follicles that carry sebum and keratin from dead skin cells to the surface. When sebum and keratin are blocked due to increased proliferation and decreased desquamation of keratinocytes, a microcomedo forms (and later turns into closed or open comedones). This might be influenced by inflammatory cells. The follicle can then rupture and also trigger the inflammatory response.⁴
2. Increased sebum production: During puberty, sebum production increases, in part due to the effects of androgen on the skin. Androgen is not only produced by adrenal glands and gonads but also within the sebaceous glands of the skin. One study investigating men with androgen insensitivity found that they do not develop sebum or acne.⁵ This lipid-rich environment of the pilosebaceous unit makes it easier for *Propionibacterium acnes* (*P. acnes*) to multiply and thus might explain the

rise of acne formation during the adolescent period.

3. Colonization of sebaceous unit with *P. acnes*: *P. acnes* are anaerobic, gram positive bacteria that are part of the normal skin flora, yet there might be different pathogenic forms of the bacteria that can induce the inflammatory response. The anaerobic nature of the sebaceous follicles creates an environment where these bacteria can thrive and influence the inflammatory response.

4. Inflammatory response: The exact mechanism is unknown, but it is believed that the presence of *P. acnes* triggers the inflammatory cascade, including Toll-like receptors, cytokines, lymphocytes, and interleukins, which cause an inflammatory response in the skin, forming papules, pustules, and nodules.

Integrative Therapy

Hygiene

There has been some speculation that washing the face reduces the development of acne vulgaris. However, a systematic review done in 2005 showed that there is no great evidence that washing the face often helps prevent acne, and it might even harm the skin if done too often.^{1,8} Scrubbing the face can remove healthy oils from the skin surface and might trigger an increase in oil production.¹ One study reported less inflammatory lesions in people who used acidic gentle synthetic detergent cleansers (which have a pH of 5.5–7, closer to that of normal skin pH) rather than most alkaline soaps (with a pH of 9–10).⁹ The recommendation is to wash the face twice a day with a gentle nonsoap cleanser.

Emotional Stress

Many people who suffer from acne vulgaris and rosacea report stress to be a common trigger and worse than other exacerbating factors. In the United States (US), a small study of Stanford university students that measured acne severity during nonexam and exam times found the severity significantly increased during exam periods, particularly when those students reported an increase in their stress levels (even after controlling for diet and sleep changes during exams).¹⁴

The pathophysiology of stress contributing to dermatological issues includes the increase in serum cortisol level in people with acne who

experience emotional stress.^{13,16-18} Another contributing factor is corticotropin-releasing hormone (CRH), a neuropeptide involved in the stress response, specifically the hypothalamic-pituitary-axis. A study by Zouboulis investigated the role of CRH and discussed its influence on lipid synthesis in human sebaceous glands, thus possibly linking the relationship between stress and acne.¹⁹

Finding techniques that can help alleviate stress may therefore decrease the severity of acne vulgaris and rosacea. One study taught biofeedback-assisted relaxation and cognitive imagery to those with acne vulgaris in 12 sessions over 6 weeks and found a significant reduction in acne severity compared to controls.²¹

Diet

For the past several decades, diet and its relationship to acne was largely refuted by the dermatological community. More recent evidence demonstrates diet does influence acne. The most robust link to increased acne includes diets high in dairy and those with a high glycemic load.

PATHOGENESIS OF ACNE

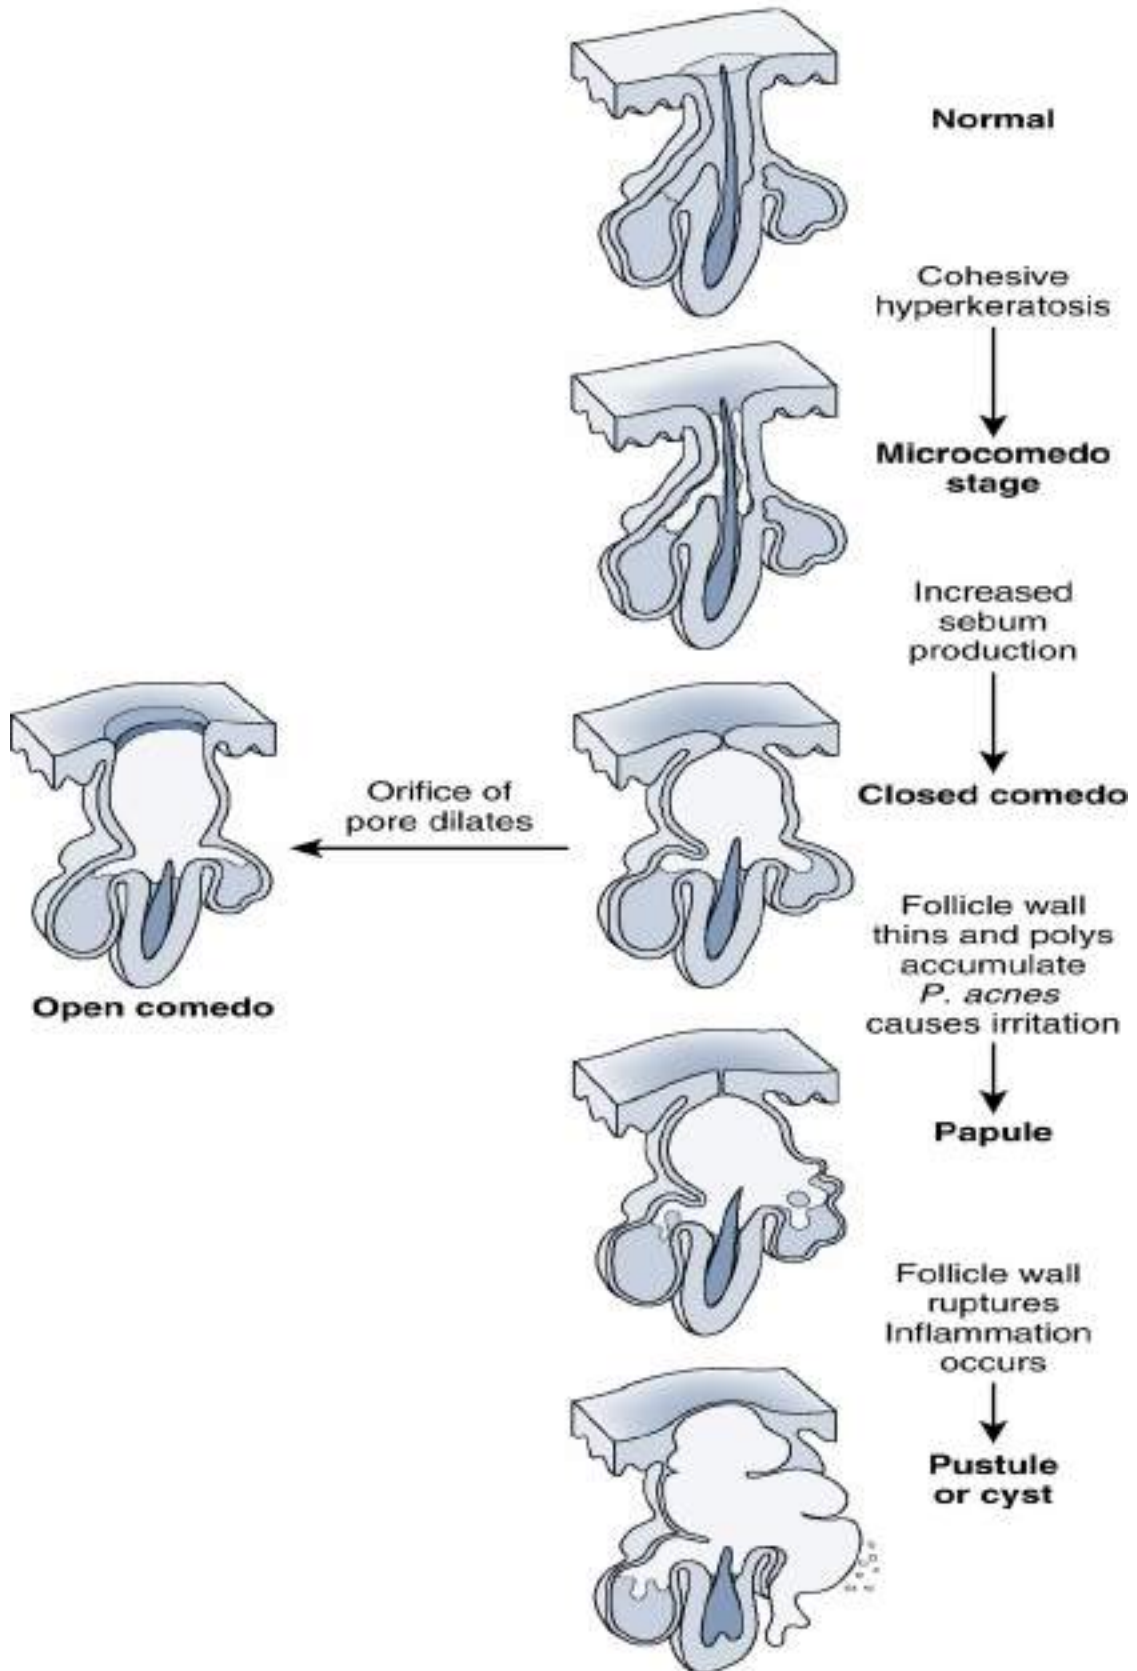

FIG. 77.1 The pathogenesis of acne vulgaris. (From Habif TP. Acne, rosacea, and related disorders. In: Habif TP, ed. *Clinical dermatology* . 5th ed. Philadelphia: Saunders; 2009.)

Dairy

There is compelling evidence that diets high in milk and other dairy products can contribute to increased acne.²⁷ The link between dairy and acne started with a 1949 survey of 1900 subjects with acne. It was found that milk was the food most often implicated in acne flares.²⁸ More recently, findings from a retrospective, recall-based study in more than 47,000 adult nurses²⁹ and a prospective self-assessment study in 6000 teenage girls³⁰ suggest an association between acne and intake of milk, particularly skim milk and other dairy products. Another prospective study of more than 4200 teenage boys suggested an association with skim milk only.³¹ It is hypothesized that milk is hormonally and biochemically active and that these factors might be more bioavailable or present in higher quantities in skim milk.³¹ It has also been shown that some dairy products, including milk, have a much higher effect on insulin than expected given their low glycemic index,³² which may account for some of its effects in a way similar to high-glycemic diets (see the following text).

In those with acne, encourage a plant-based diet that is low in dairy, rich in omega-3 fatty acids, and has a low glycemic load.

Low-Glycemic Load Diet

Glycemic load takes into account both the quantity of carbohydrates ingested as well as its effect on insulin (see [Chapter 87](#)) A well-done randomized controlled trial of 47 male patients showed decreased acne with a low-glycemic load diet (LGLD).³³ It is hypothesized that diets with a high glycemic load increase acne by multiple causes due to increased insulin and insulin like growth factor-1 (IGF-1).³⁵ Insulin and IGF-1 both increase the synthesis and bioavailability of androgens by inhibiting the synthesis of sex hormone-binding globulin in the liver.³⁵ Sebum production also increases with increased insulin and IGF-1.³⁶

Supplements

Omega-3 Fatty Acids

Omega-3 fatty acids are a group of polyunsaturated fatty acids that have been shown to decrease inflammation in multiple studies.³⁸ The omega-3s, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are found in high quantities in fatty fish. The omega-3 alpha-linolenic acids (ALAs) are from mostly plant sources. One recent, small study showed supplementation with 3 g of fish oil daily (930 mg EPA) for 12 weeks decreased acne severity in those with moderate to severe acne at baseline.³⁹

The other main polyunsaturated fatty acids are the omega-6s. There is an elevated omega-6 to omega-3 ratio in the Western diet versus more traditional diets, and such ratios are proinflammatory.⁴¹⁻⁴³ A major dietary omega- fatty acid is arachidonic acid, which is a precursor to the inflammatory signaling molecule leukotriene B4 (LTB4). The importance of decreasing LTB4 action was demonstrated in a study of a novel LTB4 blocker that showed a 70% reduction in inflammatory acne lesions over 3 months.⁴⁴ Increased omega-3 intake may decrease the production of LTB4 and other inflammatory signaling molecules.⁴⁵ Omega-3 fatty acids have also been shown to decrease IGF-1 levels in healthy men.⁴⁶ Therefore, a trial of supplementation with or a diet high in omega-3 fatty acids is recommended for the treatment of acne vulgaris (see [Chapter 88](#)).

Dosage

Suggested supplementation is with 1–3 g of the EPA plus DHA component of omega-3 fatty acids.

Precautions

Fatty fish and fish oil, common sources of omega-3s, can get contaminated with toxins. Purchase supplements that have undergone analysis by independent laboratories. For information on safe fish consumption, see the Monterey Bay Aquarium's Seafood Watch website: <http://www.seafoodwatch.org>.

High doses of omega-3s may inhibit blood coagulation and increase the risk of bleeding. They are considered safe and commonly used in children, pregnancy, and lactation.⁴⁸

Zinc

Zinc is an essential micronutrient that acts as a cofactor for hundreds of enzymatic reactions in the body and plays an important role in regulating gene expression.⁴⁹ It is involved in maintaining the health of many body systems, including immune function, skin health, and smell/taste sensation. Zinc deficiency is rare in developed countries, but conditions that pose the greatest risk include malabsorption syndromes (short bowel syndrome, celiac disease, history of gastric bypass), irritable bowel syndrome, alcoholism, and malnutrition.⁴⁹ Dietary zinc can be found in highest levels in red meat, poultry, beans, nuts, and whole grains.⁵⁰ In vitro studies using zinc have shown success in inhibiting growth of clindamycin-resistant strains of *P. acnes* as well as decreasing erythromycin-resistant strain development.^{52,53} Zinc supplementation has also been found to reduce the number of inflammatory acne pustules.⁵⁴

Dosage

Oral zinc gluconate: older than 13 years: 30 mg per day; 9–13 years old: 20 mg per day.^{49,61}

Precautions

Side effects of oral zinc supplementation can include metallic taste and gastrointestinal (GI) symptoms such as nausea, vomiting, bloating, and diarrhea.^{49,62} High doses for long periods of time (>40 mg elemental zinc per day and possibly higher) have been shown to cause sideroblastic anemia and copper deficiency. If taking zinc long term at high doses, we recommend supplementing with 2-mg copper.^{63,64}

Likely safe in pregnancy and lactation at aforementioned doses.^{60,61}

Brewer's Yeast (*Saccharomyces cerevisiae*)

Brewer's yeast is an active yeast used to make beer and is a commonly used nutritional supplement as it is a source of protein, B vitamins, chromium, and selenium.⁶⁵ One randomized controlled trial investigated the brewer's yeast strain Hansen CBS (*Saccharomyces boulardii*) and showed improvement in acne symptoms with oral supplement over a 5-month duration.⁶⁷

Dosage

Recommended dosage is 6 g of freeze dried daily (can take in divided doses: 3 g bid or 2 g tid)

Precautions

It is usually well tolerated. Side effects are GI in nature, including bloating and flatulence.⁶⁵ Migraine headaches have been reported in some users. Do not administer if patient is on a monoamine oxidase inhibitor (MAOI) as the high levels of tyramine in the brewer's yeast can lead to hypertension with concomitant MAOI use.⁶⁸ Caution in Crohn's disease as Brewer's yeast possibly relates to inflammation in Crohn's disease.⁶⁹

Vitamin A

Vitamin A is a fat-soluble vitamin that can be found as preformed retinoids or as provitamin carotenoids (i.e., beta carotene). Retinoids come from animal sources such as liver, kidney, eggs, and dairy. Carotenoids are found in plants such as dark or yellow vegetables, carrots, and tree nuts.⁷⁰ The studies on acne have used high doses of preformed vitamin A, which carries a risk of hypervitaminosis as preformed vitamin A is efficiently stored by the liver.⁷¹ There was historical interest in treating acne with vitamin A supplementation starting with articles in the 1940s and 1950s^{72,73} that demonstrated some success with treatment at high doses (100,000–300,000 IU/day). Since that time, there have been some studies showing positive⁷⁴⁻⁷⁶ and some negative⁷⁷⁻⁷⁹ results at these high doses.

Dosage

The tolerable upper intake of vitamin A is 10,000 IU/day for adults.⁷⁰ Doses used in the treatment of acne were much higher than this, but we do not recommend use at these doses.

Precautions

Symptoms of excess vitamin A without hypervitaminosis A was noted in a 4-month trial using vitamin A 300,000–500,000 IU/day.⁸⁰ However,

given the short treatment duration, it is likely hypervitaminosis A could develop using these doses for longer courses. Symptoms of excess vitamin A include nausea, vomiting, headache, and dry skin. Symptoms of hypervitaminosis A include hepatotoxicity, teratogenicity, reduced bone mineral density, alopecia, and xerosis.⁸¹

Botanicals

Tea Tree Oil (*Melaleuca alternifolia*)

Tea tree oil made from the leaves of the native Australian tree *Melaleuca alternifolia* has been shown to improve acne through its antimicrobial and antiinflammatory properties. It is the most well-studied botanical that has shown to be the most effective for acne vulgaris. Some studies found that topical application of at least 5% tea tree oil used for 4–8 weeks improved mild to moderate acne vulgaris as well as or better than 5% benzoyl peroxide, 2% topical erythromycin, or placebo. Although results took longer for those who used tea tree oil, the adverse side effects were fewer.⁸²⁻⁸⁵

Dosage

Recommended dosage is 5%–15% topical tea tree oil applied one to two times daily.

Precautions

There are few side effects, although some report minor pruritus, burning, stinging, itch, redness, and dryness (similar to all topical antiacne agents).

Green Tea

Green tea, made from unfermented leaves of *Camellia sinensis*, contains a high content of antioxidants called polyphenols (catechins) that help neutralize free radicals. The main polyphenol that has been studied is epigallocatechin-3-gallate (EGCG) and has antiinflammatory, anticancer, and antiandrogen properties that help decrease sebum production, inflammation, and bacterial growth (particularly *P. acnes*) in the skin.⁸⁶ Two randomized trials and one other study showed a significant

reduction in acne when using topical green tea lotion for treatment of mild to moderate acne vulgaris.⁸⁷⁻⁸⁹

Although the sample sizes were small, green tea appears to be promising in the treatment of acne vulgaris and one of the only agents, besides retinoids, that help decrease sebum production.

Dosage

- Recommended dosage is green tea lotion 2%–3% applied topically twice a day.
- Recommended daily intake of green tea is two to three cups a day (240–320 mg polyphenols).

Precautions

Green tea contains caffeine and can cause caffeine-related side effects.

Use with caution for those taking blood thinning medications because green tea has anticlotting properties. Green tea can increase the effect of some antibiotics and thus the risk of side effects.

Turmeric (*Curcuma longa*)

Turmeric is a rhizome (root) that comes from the plant of the ginger family (Zingiberaceae) native to India and is used as a spice in cooking. Curcumin is a component of turmeric that has been most studied for its antiinflammatory effects. One study showed decreased *Propionibacterium* activity in vitro by curcumin-containing, lipid-based vehicles (specifically lauric acid that can be found in coconut oil).⁹⁰ Although human studies are lacking specifically for the use of turmeric on acne, it might be a possible remedy for those with inflammatory lesions.

Dosage

Used as a topical mixture of turmeric powder with milk or coconut oil and placed on inflammatory lesions daily.

Ingested dose of turmeric is 500 mg two to four times a day.

Precautions

Topical turmeric can dye clothes and stain the skin. Side effects when ingested orally are rare but include GI problems (nausea, vomiting, diarrhea, and dyspepsia).

Pharmaceuticals: Topical Preparations

There are a variety of topical therapies for mild to moderate acne vulgaris that are useful for the different patterns of acne (inflammatory versus noninflammatory) and work on different mechanisms. They can be used alone or in combination. If side effects occur, mainly skin irritation, the therapy can be started at a lower dose and gradually increased or the formulation can be changed from alcoholic solutions (that are more drying) to washes or gels to creams or lotions.¹ It takes about 2–3 months of consistent treatment before significant improvement, and therefore patients should be given realistic expectations regarding therapy. Treatment of truncal acne might require oral medications due to the difficulty of reaching a larger area with topical therapy.

Benzoyl Peroxide

Benzoyl peroxide is one of the safest and most effective treatments for inflammatory lesions and is usually used in mild to moderate acne as a first-line therapy. It works as an antimicrobial, against *P. acnes*, although it does not cause bacterial resistance. Some studies have shown that it works better than topical tretinoin for inflammatory acne.^{93,94} Most studies have shown that lower doses work just as well as higher doses and cause less irritation, so there is no need to go higher than 5%.^{95,96} It has also been shown to improve the effect of antibiotics and decrease the amount of antibiotic resistance, and thus it is recommended to use benzoyl peroxide in combination with topical or oral antibiotics.⁹⁷⁻¹⁰⁰

Dosage

Recommended dosage is 2.5%–5% gel, lotion, or cream. Topical application one to two times a day

Precautions

Can cause skin irritation, including drying and peeling of skin, pruritis, burning, and redness. It can bleach hair and clothes.

Of note, benzoyl peroxide can inactivate tretinoin and make it less stable and thus should not be used at the same time. It is better to use benzoyl peroxide in the morning and tretinoin at night. There are newer formulations of tretinoin (micronized tretinoin gel, tretinoin gel microsphere) and other types of topical retinoids (adapalene) that are not affected by benzoyl peroxide and thus can be used in combination.¹⁰¹⁻¹⁰³

Topical Retinoids

Topical retinoids (tretinoin/ isotretinoin/ adapalene) are vitamin A derivatives that break down keratinocytes and reduce sebum excretion, follicular occlusion, and comedones.¹⁰⁴ They work best for all types of acne (inflammatory and noninflammatory) and can be used to decrease postinflammatory hyperpigmentation.¹⁰⁵ There are two types of topical retinoids available in the United States: tretinoin and adapalene. A meta-analysis of five randomized controlled trials found both to be equally effective, but adapalene was better tolerated.¹⁰⁶ Adapalene also might cause less photosensitivity.¹⁰³ Although tretinoin should not be applied in conjunction with benzoyl peroxide (because tretinoin becomes less stable), benzoyl peroxide can be used at the same time as adapalene (and tretinoin gel microsphere and micronized tretinoin gel).¹⁰¹⁻¹⁰³

Dosage

- Tretinoin: creams (0.025%, 0.0375%, 0.05%, and 0.1%), gels (0.01% and 0.025%), microsphere gels (0.04%, 0.08%, and 0.1%), and micronized 0.05% gel (contains fish proteins).
- Adapalene: creams 0.1%, gels (0.15% and 0.3%), and 0.1% lotion.
- Apply a thin layer (pea-sized amount) to the entire affected areas once daily, usually at bedtime.

Precautions

Can cause skin irritation including redness, dryness, burning, and soreness. Starting with the lowest dose and applying every third day and slowly increasing the frequency and dose can decrease skin irritation. Might make skin sensitive to ultraviolet light and thus better used at night time before bed; advise patients to wear sunscreen. All retinoids should not be used in pregnancy, and women of childbearing age must use contraception.

Topical Antibiotics

Topical antibiotics are useful against inflammatory acne vulgaris most likely through their action on *P. acnes*. They are not as useful for noninflammatory lesions. The most common topical antibiotics include clindamycin and erythromycin.¹ A newer topical antibiotic used in the treatment of acne vulgaris is dapsone. Two randomized studies showed that dapsone significantly improved inflammatory lesions better than placebo.^{107,108}

Due to increasing bacterial resistance, topical antibiotics are not used as monotherapy. Instead, they are used in combination with benzoyl peroxide or topical tretinoin to help reduce bacterial resistance.⁹⁷⁻¹⁰⁰

Due to increasing bacterial resistance, topical and oral antibiotics should not be used alone as monotherapy. Instead, they should be used in combination with benzoyl peroxide or topical tretinoin as both have been shown to improve the effect of antibiotics and decrease the amount of antibiotic resistance.⁹⁷⁻¹⁰⁰

Dosage

Applied twice a day:

- Clindamycin: 1% gel, lotion, solution, foam
- Erythromycin: 2% gel, solution
- Dapsone 5% gel

Precautions

Can cause skin irritation including erythema, burning, peeling, and pruritis. Bacterial resistance for erythromycin is increasing, making it

less effective.¹⁰⁸ Although hemolytic anemia is seen in those taking oral dapsones with glucose-6 phosphate dehydrogenase (G6PD) deficiency, those taking topical dapsones have not been affected. Thus it is not necessary at this time to test for G6PD deficiency before starting therapy.^{109,110} Dapsone can also cause temporary yellow discoloration of the skin when applied at the same time as benzoyl peroxide and thus should be applied at separate times of the day.¹¹¹

Salicylic Acid

Salicylic acid is a milder and safer treatment for mild to moderate acne vulgaris, with fewer side effects. It works as an exfoliant and mostly acts against comedonal acne by slowing follicular shedding of cells thus preventing clogging.^{1,112} One randomized control trial compared salicylic acid to tretinoin (both in combination with clindamycin) for 12 weeks to assess whether or not salicylic acid is as effective as tretinoin and found both to be equally effective, although tretinoin worked more quickly.¹¹³

Dosage

Recommended dosage is 0.5%–2% creams, gels, solutions, cleansers, soap, and foam. Apply one to three times a day.

Precautions

Can cause skin irritation including burning, stinging, and reddening.

Azelaic Acid

Azelaic acid is produced by a yeast (*Malassezia fur fur*, also known as *Pityrosporum ovale*) that is part of normal skin flora. It can help in both acne vulgaris and acne rosacea as an antimicrobial, antiinflammatory, and comedolytic. It can also be used for postinflammatory hyperpigmentation. One study that compared results of European clinical trials showed azelaic acid 20% cream is as effective as tretinoin 0.05%, benzoyl peroxide 5%, and topical erythromycin 2%.¹¹⁴ It is similar to benzoyl peroxide, but there is less evidence of its usefulness.¹¹⁵

Dosage

Recommended dosage is 20% cream for acne vulgaris and 15% gel for acne rosacea, both applied one to two times a day.

Precautions

Can cause hypopigmentation and some skin irritation but is usually well tolerated.

Pharmaceuticals: Systemic Preparations

Oral Antibiotics

Oral antibiotics are used in moderate to severe inflammatory acne or milder cases of truncal acne where topical application is difficult to reach. Antibiotics work against *P. acnes*, but resistance is increasing, and thus newer recommendations include limiting the use to less than 6 months if possible and using topical benzoyl peroxide or tretinoids in conjunction with antibiotics.¹¹⁶ One study found an increased incidence in *P. acnes* resistance from 20% in 1978 to 62% in 1996.¹¹⁷ A trial of 6–8 weeks with the same antibiotic is recommended before switching to a different class. If the antibiotic is discontinued, but was helpful and needs to be restarted, it is better to use the same antibiotic.¹¹⁶

Doxycycline: Most frequently used antibiotic due to less resistance and better tolerability. Can be used in smaller doses (20 mg bid) as an antiinflammatory rather than antibiotic.¹¹⁸

Dosage

- Doxycycline: 50–100 mg bid or 20 mg bid as an antiinflammatory rather than an antimicrobial
- Erythromycin: 500 mg bid
- Azithromycin: Optimum dosing not defined
- Tetracycline: 500 mg bid, take on empty stomach
- Minocycline: 50–100 mg bid
- TMP/SMX: 160/800 mg one to two times a day

Precautions

Can cause GI upset or vaginal candidiasis. Can increase occurrence of upper respiratory infections due to bacterial resistance.¹²⁰ Tetracycline, doxycycline, and minocycline are prohibited for use in children under 9 years of age or in pregnant/breastfeeding women due to the possibility of tooth discoloration and decreased bone growth. Photosensitivity might occur with doxycycline. Minocycline can cause skin discoloration and lupus-like syndrome. Azithromycin can worsen QT prolongation and should not be given in those with prolonged-QT syndrome.

Hormonal Treatment

Hormonal therapy can be used in postmenarchal women and works primarily to decrease the amount of androgens that are known to increase sebum production. Androgens can stimulate the production of acne and estrogens can inhibit the production. Combined oral contraceptives (estrogens and progesterones) are recommended. Estrogens decrease the production of androgen and increase sex hormone-binding globulin (which then decreases serum free androgen levels).¹²¹ Progesterone-only contraceptives may actually exacerbate acne and thus are not recommended for use in acne treatment. Another potential treatment is spironolactone, which blocks the androgen receptors.

Dosage

Any combined oral contraceptive pill (OCP) can be used for the treatment of acne, but three have been more studied than other OCPs¹²¹:

- All OCPs taken as one tablet daily:
 - Ethinyl estradiol 20/30/35 mcg/norethindrone 1 mg (Estrostep)
 - Ethinyl estradiol 35 mcg/norgestimate 180/215/250 mcg (Ortho Tri-Cyclen)
 - Ethinyl estradiol 20 mcg/drospirenone 3 mg (Yaz)
- Spironolactone 50–200 mg daily

Precautions

Combined OCPs can cause nausea, weight gain, and breast tenderness.

Combined oral contraceptives are contraindicated in women older than 35 years who smoke due to increased risk of cardiovascular disease and in women with breast cancer, migraine with aura, uncontrolled hypertension, liver cirrhosis or viral hepatitis, history or current stroke, up to 3 weeks postpartum, complicated heart valvular disease, and current or history of deep vein thrombosis.

Spirolactone is contraindicated in pregnancy and can cause GI symptoms, hyperkalemia, orthostatic hypotension, dizziness, and/or headaches.

Oral Isotretinoin

Oral isotretinoin is a vitamin A derivative used for severe nodular acne that is unresponsive to all other therapies. Oral isotretinoin works on all aspects of acne as an antiinflammatory, antimicrobial, comedolytic, and antiscarring agent by reducing the size of the sebaceous gland, thus decreasing the secretion of sebum and reducing the amount of *P. acnes*, which require sebum to survive. It also helps keratinocytes to differentiate.¹²²

Dosage

Recommended dosage is 0.5 mg/kg per day for the first month, increased to 1 mg/kg per day for a total dose of 120–150 mg/kg for 20 weeks or more.¹²³

Precautions

Category X in pregnancy—cannot be used in pregnancy, and all childbearing women should be on contraceptive therapy. Causes teratogenicity, including craniofacial, central nervous system, cardiac, and thymic malformations.¹²⁴ All childbearing women must be part of the iPLEDGE program, requiring two forms of birth control prior to the start of treatment and monthly pregnancy tests.

Many have debated the relationship between oral isotretinoin and mood disorders and have suggested an association with depression and suicide attempt. However, it is difficult to assess whether or not the medication actually causes increased mood disorders.¹²⁵

Can also cause cheilitis, photosensitivity, dry skin and mucous

membranes, and/or pruritus. Other side effects include myalgias, hypertriglyceridemia, and idiopathic intracranial hypertension.

Rosacea

Introduction/Epidemiology

Rosacea is a chronic inflammatory skin disorder with varying clinical features including transient or persistent facial erythema, telangiectasias, inflammatory papules and pustules, thickened skin, and ocular changes.^{6,7} These features are typically symmetrical on the face, with rare neck, upper trunk, and scalp involvement.¹³⁷ Rosacea has a prevalence rate of <1% to 20%, depending on the population studied,¹³⁸ with higher rates in women and those of Celtic or Northern European descent.⁷ It typically presents in the third to fourth decade of life, with the highest frequency among those more than 50 years old.¹³⁹

Classification of Rosacea

There are four subtypes and one variant of rosacea. Patients can have features of multiple subtypes at the same time.^{6,7} See [Table 77.1](#) for a summary of how each is treated.

I. Erythematous-telangiectasia—Transient flushing and persistent central facial erythema. Erythema of ears, neck, peripheral face, and upper chest can also occur. Telangiectasias are also commonly seen.

II. Papulopustular—Facial erythema plus transient papules and/or pustules in the central face. Unlike acne vulgaris there are no comedones (unless acne vulgaris occurs with rosacea). Burning or stinging can also occur.

III. Phymatous—Thickened, enlarged and irregular skin in areas with sebaceous glands, most commonly on the nose (rhinophyma), but can occur on the ears, cheeks, forehead, and chin ([Fig. 77.2](#)).

IV. Ocular—Eye and eyelid involvement, including foreign body sensation, burning, stinging, dryness, itching, watery or bloodshot eyes, blurry vision, telangiectasias in conjunctiva and lid margin, lid and periocular edema. Furthermore, often observed chronic blepharitis, conjunctivitis, irregular eyelid margins, light sensitivity, chalazion, and styes. Subtype: Granulomatous—Firm, indurated papules and nodules.

FIG. 77.2 Rhinophyma in phymatous rosacea. (From Habif TP. Acne, rosacea, and related disorders. In: Habif TP, ed. *Clinical dermatology* . 5th ed. Philadelphia: Saunders; 2009.)

Pathophysiology of Rosacea

The exact etiology of rosacea is unclear, but it is thought that a combination of environmental triggers on rosacea-prone skin causes the disease.^{6,141,136} Subtypes of rosacea, their characteristics and suggested therapies, can be found in [Table 77.2](#).

Neurovascular Dysregulation

Receptors involved in sensation, vasodilation and inflammatory signaling that are activated by known rosacea triggers (e.g., temperature, spice, heat) are upregulated and found in higher numbers in the skin of patients with rosacea.⁶

TABLE 77.2

Subtypes of Rosacea With Associated Characteristics and Suggested Therapies

Subtype	Characteristics	Interventions ^a
I. Erythematotelangiectatic	Flushing and persistent central facial erythema +/- telangiectasia	Flushing trigger avoidance Erythema: topical bromelain or azelaic acid Maintenance treatment with topical metronidazole or azelaic acid or anti-inflammatory doxycycline (40 mg) Telangiectasia and persistent erythema: devices—pulsed dye laser or intense pulsed light therapy
II. Papulopustular	Persistent central facial erythema with transient, central facial papules and/or pustules	First line: topical metronidazole or azelaic acid or topical retinoids and/or anti-inflammatory doxycycline (40 mg) Second line: topical metronidazole or azelaic acid + antimicrobial dose antibiotic (clindamycin, azithromycin) or low dose minocycline
III. Phymatous	Thickened skin, irregular surface nodules and enlargement, may occur on nose, chin, forehead, cheeks or ears	Oral isotretinoin (all cases when stopped +/- pulsed dye laser or intense pulsed light therapy) Advanced surgical interventions
IV. Ocular	Foreign body sensation in the eye, burning or stinging, dryness, itching, photosensitivity, blurred vision, telangiectasia of the sclera or other parts of the eye, periorbital edema, chronic blepharitis or conjunctivitis, chalazion or styes	Lid hygiene, warm compresses, artificial tears +/- cyclosporine ophthalmics Oral antibiotics: First line—anti-inflammatory doxycycline (40 mg) Second line—antimicrobial tetracycline, azithromycin

^a All types affecting the skin should include gentle skin care and daily sun protection. Consider use of products containing antioxidant, antiinflammatory, and UV protective botanical.

Interventions for rosacea. *Cochrane Database Syst Rev*. 2015(4): CD003262.

Disordered Innate Immunity

The innate immune system responds to environmental triggers such as microbes, ultraviolet light, and trauma.¹⁴¹ A triggering event usually leads to a controlled immune response. In rosacea there are disrupted cytokine and antimicrobial peptide (AMP) pathways.^{6,141} Triggers for

activation of innate immunity in rosacea include UV radiation and microbes. The microbes implicated include those on the skin or in the gastrointestinal tract; see the following text for details.

UV Radiation

UVA light has been shown to cause collagen denaturation,¹⁴⁴ UVB light contributes to hypervascularity via various growth factors,¹⁴⁵ and both increase reactive oxygen species (ROS) in the skin. Those with rosacea have been found to have higher levels of ROS in their skin,¹⁴⁶ which has both vasodilating¹⁴⁷ and proinflammatory¹⁴¹ effects. Many of the medicines for rosacea act to inhibit ROS formation or have antioxidant effects; see treatment section for details.¹⁴¹

Microbes

Skin Microbes

Implicated skin microbes include *Demodex* mites^{148,149} or the Gram-negative bacteria associated with them, *Bacillus oleronius*,¹⁵⁰ as well as strains of the colonizing skin bacterium *Staphylococcus epidermidis*.^{148,149}

Small Intestinal Bacterial Overgrowth

Small intestinal bacterial overgrowth (SIBO) is a condition where mostly gram-negative aerobic and anaerobic colonic bacteria colonize the small intestine, an area that usually has few bacteria. These bacteria ferment carbohydrates into gas, thought to cause some of the symptoms of SIBO—bloating, diarrhea, flatulence, and abdominal pain that can eventually lead to malabsorption syndromes. One study demonstrated a higher prevalence of SIBO in patients with rosacea (46% vs 5% in controls, $n = 113$) as well as improvement in rosacea when treating SIBO with Rifaximin.¹⁶⁴ Another study did not show higher prevalence of SIBO in rosacea (10% vs 7.8% controls, $n = 90$) but was underpowered to see a difference in rosacea symptoms when SIBO was treated.¹⁵⁷

Integrative Therapy

Environmental/Hygiene

Rosacea can be worsened or triggered by factors that initiate flushing, including exercise, emotion, menopause, spicy foods, hot liquids, and alcohol.^{137,166} In the external environment, sun, heat, wind, and cold can also exacerbate rosacea.^{137,167} The first step in care of rosacea is to avoid or limiting exposure to triggers. Proper skin care is also important given the disrupted epidermal barrier. Skin care should include washing with a gentle nonsoap cleanser with a neutral pH one to two times per day, moisturizing, avoiding products such as cosmetics that irritate the skin, and daily use of sunscreen.¹⁶⁷ Examples of gentle nonsoap cleansers include Cetaphil, Dove, Aveeno, and CeraVe.

Diet

Common dietary triggers of rosacea include spicy foods, hot liquids, and alcohol. An elimination diet may be helpful in identifying an individual's specific triggers. Other than avoiding known triggering foods, there are no studies to date that diet effects progression of rosacea. However, based on the role inflammation plays in the pathophysiology of rosacea, a trial of the antiinflammatory diet may be beneficial (see [Chapter 88](#) for details). Diet may also play a role if SIBO is diagnosed. Part of the SIBO treatment protocol usually includes eliminating specific fermentable carbohydrates.

Botanicals

There are few well-studied botanicals used in the treatment of rosacea. However, some botanicals have evidence for exerting dermatological antiinflammatory or antioxidant effects, absorbing UV light, or acting as barrier protection.^{168,169} Since these mechanisms are implicated in the pathophysiology of rosacea and many patients prefer to use botanicals, topical products containing the following ingredients may be helpful:

Colloidal Oatmeal

Oats (*Avena sativa*) are often topically used in treatment of atopic dermatitis and were approved by the Food and Drug Administration (FDA) in 2003 as a skin protectant.¹⁷⁰ Well established effects include barrier protection, antiinflammatory, antioxidant, and absorption of UV light.^{168,169}

Dosage

Varies. Products containing colloidal oatmeal include cleansers, soaps, shampoos, and moisturizers.

Precautions

Oat-based products have an excellent safety profile and can be used in children, pregnancy, and in lactation.

Licorice Extract

Extracts from licorice plants *Glycyrrhiza glabra* and *Glycyrrhiza inflata* have antioxidant, antimicrobial, and antiinflammatory properties.^{[168](#),[169](#),[171](#)}

Dosage

Licorice gel 2%, two to three times daily.

Precautions

Topical skin irritation, burning, and redness can occur.

Feverfew

Feverfew (*Tanacetum parthenium*) is a flowering herb traditionally used orally to treat fever, migraine headaches, arthritis, and other conditions.^{[173](#)} Feverfew has antiinflammatory, antioxidant, antibacterial, and antifungal properties.^{[168](#),[169](#),[173](#),[174](#)} Topical use should only contain the purified extract form (feverfew PFE). Feverfew PFE does not contain parthenolide, a component that can cause allergic contact dermatitis.^{[174](#),[175](#)}

Dosage

Varies, topical use. Important to obtain products labeled “purified feverfew extract” or “parthenolide free.”

Precautions

As with most topical products, local skin irritation can occur. There may be cross-allergenicity to those with allergies in the

Asteraceae/Compositae family (ragweed, chamomile, daisy, etc.) though parthenolide is one of the main causes of compositae allergy and is removed in the PFE/parthenolide free formulations.^{173,175}

Green Tea

Green tea has antiinflammatory and antioxidant activity; it decreases UV-induced erythema and photodamage and may be beneficial in rosacea.^{168,169,176} See details under botanical acne vulgaris treatments.

Pharmaceuticals: Topical Treatments

Topical Metronidazole

Metronidazole is a topical antibiotic used for papulopustular rosacea. It comes in cream, gel, and lotion forms. In addition to its antimicrobial action, metronidazole also has antioxidant and antiinflammatory effects.¹⁷⁷ Improvements tend to appear after 3–6 weeks^{141,178} with maximum effect after 8–9 weeks of treatment. Metronidazole often has to be used long term for maintenance therapy due to recurrence when stopped.

Dosage

Metronidazole 0.75% cream, gel or lotion once to twice* daily

OR

Metronidazole 0.1% cream or gel daily

Precautions

With topical metronidazole, the most common adverse effects include itching, skin irritation, and dry skin.

* Once daily use may be as effective as twice daily use.¹⁷⁹

Sodium Sulfacetamide

Sodium sulfacetamide has been used for years for the erythema and inflammatory lesions of rosacea.^{141,182} It acts as an antimicrobial and the

sulfur acts as a mild keratolytic.¹⁸³ Sodium sulfacetamide 10% plus sulfur 5% is the most common formulation and comes in lotion, cream, foam, cleanser, and cleansing pad forms.

Dosage

Sulfacetamide 10% or sulfur 5%, applied twice a day. Topically applied forms may be more effective than cleansers.

Precautions

Application site reactions such as dryness, erythema, and pruritus are the most commonly reported adverse events.^{141,184} Sulfacetamide should not be used by individuals who have a sensitivity to sulfur or sulfa.

Topical Ivermectin

Topical ivermectin was recently approved by the FDA for papulopustular rosacea. Oral ivermectin has been used in demodicidosis and for treatment of blepharitis.¹⁸⁵ It has both antiinflammatory and antiparasitic properties and decreases the *Demodex* mite load.

Dosage

Ivermectin, 1% cream (Soolantra), apply once daily. Improvement can be seen after 4 weeks but can take up to 12 weeks.¹⁸⁶

Precautions

The most common adverse events include local irritation and burning.

Alpha Adrenergic Agonists

Alpha adrenergic agonists, including brimonidine and oxymetazoline, are newer treatments that target the background erythema of rosacea.¹⁸⁸⁻¹⁹⁰ They act on muscles surrounding blood vessels in the dermal skin and cause vasoconstriction. Results can be seen within 30 minutes.¹⁹¹ They do not affect inflammation or telangiectasias, so they should be used in combination with antiinflammatory medications if they occur together.

Dosage

- Brimonidine gel 0.33% (Mirvaso)—Apply daily. Can work up to 12 hours after application.
- Oxymetazoline 0.05%—The active ingredient in some decongestant nasal sprays (such as Afrin). Apply daily or twice daily.

Precautions

The most common adverse events include local irritation, burning, flushing, pruritis, and allergic contact dermatitis.¹⁸⁹⁻¹⁹¹ There have been reports of rebound erythema. Theoretically the alpha-blocking action can have systemic effects, but a review of studies found no meaningful changes in intraocular pressure, blood pressure, or heart rate in any of the topical treatments.¹⁴¹

Pharmaceuticals: Systemic Treatments

Antibiotics

Antibiotics commonly used in treatment of acne vulgaris have also been used to treat acne rosacea, see earlier in the chapter for details. The most commonly used antibiotics for rosacea include tetracyclines (doxycycline, tetracycline, minocycline), macrolides (azithromycin, clarithromycin) and metronidazole, though other oral antibiotics have been used as well. In addition to antimicrobial effects, the tetracyclines have antiinflammatory activity. In fact, doxycycline at antiinflammatory doses of less than 50 mg per day (vs. antimicrobial at 50–200 mg per day) works just as well with fewer side effects.¹⁹² Macrolides (azithromycin preferred over clarithromycin)¹⁹³ or metronidazole can be considered for allergy or other contraindication to tetracyclines.

Dosage

Antiinflammatory dosage:

- Doxycycline 20 mg twice per day (\$40–80 / month retail)
OR
- Doxycycline 40 mg modified release (30 mg immediate and 10 mg delayed)

Antimicrobial dosage:

- Doxycycline 50–100 mg twice per day
- Tetracycline 250–500 mg twice per day
- Minocycline 50–100 mg twice per day

Precautions

Adverse effects of all antibiotics can include nausea/GI upset, allergic reaction, and vaginal yeast infection. Tetracyclines also cause photosensitivity. Take mineral supplements (iron, calcium, magnesium, etc.) and antacids at least 2 hours after taking tetracyclines to prevent decreased absorption of the medication. Should not be taken in pregnancy or by children younger than 9 years due to staining of teeth and reduced bone growth.

A specific precaution for azithromycin includes QT prolongation. Caution in those with known long QT or if taking other medications that also increase the QT interval (common medications include antiemetics, a complete list can be found at www.QTdrugs.org).

Isotretinoin

For refractory or phymatous rosacea consider off label use of oral isotretinoin. Unlike with acne vulgaris, there will be recurrence when the medication is stopped. One study found oral isotretinoin to be slightly more effective than doxycycline 50–100 mg.¹⁹⁴ However, given its side effect profile, this is not a first line medication.

See isotretinoin under acne vulgaris systemic treatments for details on mechanisms of action.

Dosage

Low dose isotretinoin, 0.3 mg/kg per day was found to be effective in rosacea and should be continued for a minimum of 3–6 months.^{141,195}

Precautions

Patients and physicians need to register at iPLEDGE.org given the teratogenicity of this medication. There are also significant mucocutaneous side effects (cheilitis, dry skin, photosensitivity). Other adverse effects can include myalgias and lipid abnormalities. Concern

for use of oral isotretinoin and associations with irritable bowel disease and suicidality have been raised but have not been definitively proven.

Laser and Light Therapy, Surgery

Laser and light based therapies are most effective at targeting telangiectasias in rosacea, though they have also been used in the treatment of background erythema.¹²⁶ A large review found pulsed dye laser about equivalent to intense pulse light therapy for treating telangiectasia in rosacea.¹²⁷ Rhinophymatous rosacea may require tissue debulking treatments. These include ablative laser and surgical interventions such as scalpel excision, dermabrasion, cryosurgery, and electrocautery.^{126,128}

Prevention Prescription for Acne Vulgaris

- Maintain healthy skin care: May wash twice a day with a gentle, synthetic detergent cleanser, but avoid excessive washing or scrubbing because this might reduce healthy oils in the skin.
- Decrease stress levels to protect the skin from developing acne vulgaris.
- Eat a low-glycemic diet and a diet high in omega-3 fatty acids. Maintain a healthy weight. Eliminate or limit the intake of milk and other dairy products.

Therapeutic Review for Acne Vulgaris

Mind-Body Medicine

- Practice stress-reducing techniques such as meditation, guided imagery, hypnosis, or biofeedback to help decrease stress and related acne lesions. 

Nutrition

- Maintain a low glycemic diet. 
- Limit the amount of dairy products. 

Supplements

- Omega-3 fatty acids: oral supplementation with 1–3 g of the EPA plus DHA components. 
- Zinc gluconate 30 mg/day orally (or 20 mg/day for those aged 9–13 years). 
- Brewer's yeast 6 g of freeze-dried, daily by mouth (can take in divided doses: 3 g bid or 2 g tid). 
- Vitamin A: up to 10,000 IU/day, orally. 

Botanicals

- Tea tree oil applied topically one to two times daily. 
- Green tea lotion 2%–3% applied topically twice a day (recommended daily intake of green tea two to three cups a day, 240–320 mg polyphenols). 
- Turmeric powder mixed with milk or coconut oil and placed topically on inflammatory lesions daily. (Ingested doses of turmeric: 500 mg two to four times a day). 

Pharmaceutical Therapy

- Benzoyl peroxide 2.5%–5% gel, lotion, cream, applied topically one to two times a day. 
- Topical retinoids: Apply a thin layer (pea-sized amount) to the entire affected areas once daily, usually at bedtime. 
- Topical antibiotics (erythromycin, clindamycin, dapson) applied twice a day, in combination with benzoyl peroxide or topical retinoids to decrease antimicrobial resistance. 
- Salicylic acid 0.5%–2% creams, gels, solutions, cleansers, soap, foam. Apply topically one to three times a day. 
- Azelaic acid 20% cream, applied topically one to two times a day. 
- Oral antibiotics (doxycycline, erythromycin, azithromycin, tetracycline, minocycline, and TMP/SMX) one to two times a day 

- Combined oral contraceptive pills once a day 
- Spironolactone 50–200 mg daily 
- Oral isotretinoin 0.5 mg/kg per day for the first month, and increased to 1 mg/kg per day for a total dose of 120–150 mg/kg for 20 weeks or more. 

Prevention Prescription for Acne Rosacea

- Skin care should include washing with a gentle nonsoap cleanser with a neutral pH one to two times per day, moisturizing, avoiding products that irritate the skin, and daily use of sunscreen.
- Avoid exposure to environmental triggers such as sun, wind, heat, and cold.
- Avoid dietary triggers such as alcohol and hot, spicy food, and drink. Consider an elimination diet to identify dietary triggers. Consider a trial of an antiinflammatory diet.

Therapeutic Review for Acne Rosacea

- Gentle skin care 
- Sun protection 
- Avoid environmental triggers 

Nutrition

- Avoid dietary triggers that flare rosacea 

Botanicals

- Colloidal oatmeal: dose in topical products varies 
- Licorice gel: 2% applied topically once or twice daily 
- Feverfew: dose in topical products varies, use products labeled “purified feverfew extract” or “parthenolide free” 

Pharmaceutical Preparations

- Metronidazole: 0.75% or 1% cream, gel or lotion, applied topically once daily 
- Azelaic acid: 15% gel and 20% cream, applied topically once to twice daily 
- Sulfacetamide 10% sulfur 5%: applied topically twice a day 
- Ivermectin: 1% cream (Soolantra), apply topically once daily 
- For erythema: Brimonidine: 0.33% gel, apply daily OR oxymetazoline: 0.05% liquid, apply topically daily or twice daily 
- Oral antibiotics at antiinflammatory (doxycycline) or antimicrobial doses (doxycycline, tetracycline, minocycline, azithromycin) 
- Isotretinoin: 0.3 mg/kg per day, taken orally once or in two divided doses daily. 

Surgical Therapy

- Laser and light therapy for telangectasia and erythema 
- Various surgical techniques for phymatous rosacea

Genetics

Rosacea commonly runs in families with a higher incidence in those of Celtic or Northern European descent indicating a genetic component.⁷

Abnormal Barrier Function

Skin in rosacea patients has increased water loss and decreased epidermal hydration.^{6,142,143}

The mite *Demodex folliculorum* is often found in sebaceous glands of healthy skin. Infestation rates are higher,¹⁵¹ and the mites can be found at a higher density on skin among people with rosacea.¹⁵² The mites can carry a Gram-negative bacteria, *Bacillus oleronius*, which has been implicated in activating both inflammatory¹⁵⁰ and proliferative¹⁵³ response in those with rosacea. *Staphylococcus epidermidis* is another possible candidate for stimulating the innate immune system as it has been cultured from rosacea pustules¹⁴⁸ and found to have more virulent properties on skin of people with rosacea compared to control subjects.¹⁴⁹

Gastrointestinal Microbes

Helicobacter pylori and bacteria overgrowth in the small intestine.

H. pylori

H. pylori is a Gram-negative bacteria that can infect the upper GI tract. There have been mixed results with regards to a link between *H. pylori* and rosacea, although more recent evidence supports such a link. Several studies have shown higher prevalence of *H. pylori* infection in patients with rosacea and treatment of the infection significantly improved rosacea symptoms.¹⁵⁴⁻¹⁵⁷ Other studies have not shown a higher prevalence of *H. pylori*¹⁵⁸⁻¹⁶⁰ or improvement upon treating *H. pylori*,^{161,162} though they have been criticized for using a less sensitive serology to assess *H. pylori* presence (serum versus stool Ag or urea breath test).¹⁵⁷ Patients with both rosacea and *H. pylori* have been noted to have higher prevalence of a more virulent strain of the bacteria.¹⁶³

Based on the available information, it is reasonable to test patients with gastrointestinal symptoms for *H. pylori* (using stool antigen test or urea breath test) and possibly SIBO (using hydrogen breath test), and if positive, treat accordingly. SIBO is a condition where the root cause should also be addressed in addition to antibiotic treatment to prevent recurrence.¹⁶⁵ It should be noted there is a relatively low specificity and sensitivity on breath tests for SIBO (vs. jejunal aspirate, which is not practical for routine testing).

Topical Azelaic Acid

For details see earlier in this chapter. Azelaic acid has antiinflammatory and antioxidant properties. It is FDA approved for the treatment of papulopustular rosacea but may also improve erythema. Azelaic acid can be effective after 3–6 weeks of use but maximum effect may take until 12 weeks.¹⁴¹ Like metronidazole, azelaic acid can be used for maintenance therapy.

Dosage

Azelaic acid, 15% gel and 20% cream once to twice daily. One study found once daily treatment had similar outcomes to twice daily.¹⁸⁰

Precautions

The most frequent adverse effects of azelaic acid tend to be transient and include mild to moderate burning, itching, and stinging.¹⁸¹

Therapies to Consider

There are two positive studies using the following botanicals in treatment of rosacea. However, the studied gel and cream are not easily obtainable. They are included here given their promising results.

Quassia Amara

Also known as bitterwood, a small tree from Jamaica.¹⁹⁶ Traditionally used as a digestive, to treat fever, and against hair parasites such as lice or fleas, *Quassia* has antiparasitic and antiinflammatory effects.¹⁹⁶ A small study of 30 patients showed improvement with 4% topical gel, used for 6 weeks.¹⁹⁷

Chysanthellum Indicum

A flowering plant from West Africa. Shown to have effects on vasculature.¹⁹⁸ Study ($n = 246$) with cream containing 1% *Chysanthellum indicum* showed a significant decrease in overall erythema in rosacea.¹⁹⁹ It is difficult to obtain.

CHAPTER 78

Breast Cancer

Lucille R. Marchand, MD, BSN, and James A. Stewart, MD, FACP

Breast cancer involves an interplay of genes with environmental factors (such as food choices, exercise, lifestyle, alcohol consumption, weight control, and postmenopausal estrogen/progestin exposure) and environmental toxins (such as radiation, electrical lighting at night, and pesticides). It is further complicated by genetic vulnerability to environmental factors.^{1,2} Integrative medicine emphasizes personal empowerment to make lifestyle choices that can help prevent cancer from occurring and slow its growth once it has occurred or prevent recurrence. Many factors may not be in our control, but many lifestyle choices are. These same healthy choices also limit the development of other chronic illnesses, such as heart disease, diabetes, obesity, and hyperlipidemia.¹

Breast cancer is currently the most common cancer among women in the United States. In 2015, it was estimated that 29% (231,840 new cases of breast cancer versus 810,170 of total new cases of all cancers) of women diagnosed with cancer had breast cancer. Overall lifetime risk is that one in eight women will be diagnosed with breast cancer, but risk increases with age. In women less than 50 years of age, the risk is 1 in 53 women; age 50–59 years, 1 in 44; age 60–69 years, 1 in 29; and older than 70 years, 1 in 15 women. It is the second most common cancer that causes death in women—15% mortality rate of all cancers estimated for 2015 (highest mortality rates in women are from lung cancer—26%).³ Five-year survival rates are high in women with early-stage cancers: stage 0, 100%; stages 1 and 2, 98.6% for local invasion and 84.4% for regional invasion; stage 3, 57%; and in women with metastatic breast cancer, 24.3%.⁴ The average age of diagnosis is 61 years, and 72% of breast cancer survivors are 60 years or older; 10% are less than 50 years.⁴ One percent of breast cancers occur in men.⁵

Pathophysiology

Breast cancer is generally a hormone-driven cancer; higher lifetime risk is associated with higher estrogen exposure. Seventy percent of breast cancers express receptors for progesterone or estrogen.⁶ Exogenous estrogen use, such as with hormone replacement therapy (HRT), pesticides that have an estrogenic effect in our bodies, and hormones from animal and dairy sources, are most concerning. Obesity is an intrinsic factor that increases risk as well, possibly from the increase in estrogen that comes from aromatization in fat tissue. Soy foods (rather than supplements), which are weak plant estrogens, may have a protective effect. Some genetic mutations have a higher likelihood of cancer development, such as *BRCA1* and *BRCA2* mutations, which are associated with a 60%–80% lifetime risk for breast cancer. These genetic markers are related to mutations that inactivate cancer suppressor genes.^{7,8}

Risk Factors

Factors that increase the risk of breast cancer include alcohol consumption of more than one serving per day, taking estrogen-containing products such as HRT and birth control pills, increased estrogen lifetime exposure including early menarche and late menopause, low intake of fruits and vegetables, obesity, exposure to radiation, and sedentary lifestyle (see [E-Table 78.1](#), available online at [ExpertConsult.com](#)). Aging is a risk factor in that 80% of women with a breast cancer diagnosis are older than 50 years. Family history of breast cancer and certain mutations, such as *BRCA1*, *BRCA2*, and *p53*, increase the risk for breast cancer. Deleterious *BRCA* gene mutations increase the lifetime risk for development of breast cancer from 40% to 85%. Women with a mother, sister, or daughter with breast cancer are twice as likely to develop cancer as is a woman with no family history of breast cancer in female relatives. Both paternal and maternal relatives are important in determining breast cancer risk.⁵

Risk-reducing surgery in patients with *BRCA1* and *BRCA2* mutations can attenuate risk of breast and ovarian cancer. Risk-reducing mastectomy significantly reduced the risk for development of breast cancer in mutation carriers compared with matched controls by 90%.¹⁰ Salpingoophorectomy reduced the incidence of breast cancer, ovarian

cancer, all-cause mortality, and breast and ovarian cancer–specific mortality.¹¹ In one study assessing 725 *BRCA1* and *BRCA2* carriers, 218 had been diagnosed with breast cancer within a 10-year period. This study assessed level of exercise with development of cancer and found an inverse relationship of greater intensity of exercise with decreased risk for development of cancer in these carriers, but the significance was at the $p = .053$ level.¹²

E-Table 78.1**Breast Cancer Risk Factors**

Factor	Magnitude of Risk
Well-Confirmed Factors That Increase Breast Cancer Risk	
Increasing age	++
Geographic region (Western world)	++
Family history of breast cancer	++
Mutations in <i>BRCA1</i> and <i>BRCA2</i> genes	++
Ionizing radiation exposure in childhood	++
History of benign breast disease	++
Late menopause (>54 years)	++
Early age at menarche (<12 years)	++
Nulliparity or older age at first birth	++
High mammographic breast density	++
High insulin-like growth factor 1 (IGF-1) levels	++
Hormone replacement therapy	+
Recent oral contraceptive use	+
Obesity in postmenopausal women	+
Tall stature	+
Alcohol consumption (more than one drink/day)	+
Probable Factors That Increase Breast Cancer Risk	
High saturated fat diet	+
High socioeconomic status	+
Well-Confirmed Factors That Decrease Breast Cancer Risk	
Geographic location (Asia and Africa)	--
Early age of first full-term pregnancy	--
Higher parity	--
Breastfeeding (longer duration)	--
Obesity in premenopausal women	-
Fruits and vegetables consumption	-
Physical activity	-
Pharmaceutical chemopreventive agents	-
Nonsteroidal antiinflammatory drugs	-

++, moderate to high increase in risk; +, low to moderate increase in risk; -, low to moderate decrease in risk; --, moderate to high decrease in risk

Risk factors are also reviewed in Costanza ME, Chen WY. Epidemiology and risk factors for breast cancer. *UpToDate*. www.uptodate.com; Updated 5.10.10.

Modified from Dumitrescu RG, Cotarla I. Understanding breast cancer risk—where do we stand in 2005? *J Cell Mol Med*. 2005;9:208-221.

In women at higher risk for developing breast cancer, chemoprevention may be an option. In 2013, new guidelines for chemoprevention were issued by the United States Preventive Services Task Force (USPSTF) and the American Society of Clinical Oncology (ASCO). Tamoxifen is recommended in premenopausal women and raloxifene in postmenopausal women. Informed decision-making includes discussion of benefits versus risks and needs to be individualized to each patient. Risk assessment tools and risk/benefit indices are available to clinicians and can be found in the [Key Web Resources](#) mentioned in the following text.⁹

A study in Sri Lanka identified prolonged breast-feeding (24 months in a lifetime) in significantly reducing risk of breast cancer. The mechanism may be reduction in lifetime estrogen exposure.¹³ Another study in Tunisia showed a similar protective effect of prolonged breast-feeding.¹⁴

Obesity is a significant risk factor for breast cancer occurrence, recurrence, and mortality. Limiting the intake of high-density foods, such as fat and sugars, and increasing plant-based lower density foods, such as fruits, vegetables, and whole grains, can help maintain healthy weight in combination with regular exercise for energy expenditure and glycemic control.^{15,16} Limiting portion size is an important weight control strategy.

Fat from adipose tissue is a major source of estrone (E_1) which is the main stimulatory hormone after menopause. Weight loss can significantly reduce this hormones influence on breast cancer.

Night-shift work and subsequent disruption of the natural circadian rhythm can put women at increased risk for breast cancer. Melatonin levels are suppressed with these disruptions, and low melatonin levels raise estradiol levels and increase risk of breast cancer.¹⁷⁻²⁰ Modern electrical lighting, which is rich in blue wavelengths, suppresses melatonin more than red or yellow light wavelengths, such as

candlelight or firelight. Fluorescent light, television or computer light, and bedside lamps can strongly suppress melatonin in the evening, and suppression has a more carcinogenic effect than just disruption of sleep or poor sleep in a dark room. People who are blind have the lowest incidence of cancer since their melatonin is less likely suppressed. Melatonin disruption rather than sleep–wake cycle contributes more strongly to cancer growth. By sleeping in the dark, cancer can be prevented and growth suppressed after diagnosis.²¹

2-Hydroxyestrone/16-Hydroxyestrone Ratio

In estrogen receptor–positive (ER⁺) tumors, estrogen metabolism can contribute to risk. Both strong and weak estrogen metabolites are produced from oxidative processes in the body. 2-Hydroxyestrones are weakly estrogenic and may be protective (similar perhaps in action to weak plant estrogens such as soy foods), and 16-hydroxyestrones are more strongly estrogenic. The 16-hydroxyestrones can stimulate estrogen receptors in vulnerable tissue, leading to ER⁺ tumors, and can disrupt DNA, which produces oncogenes and tumor suppressor genes (Fig. 78.1).^{22–24} Dietary measures (decreased alcohol intake, increased oleic acid such as in olive oil), physical activity, phytoestrogens such as flaxseed meal, and cruciferous vegetables can help favor weaker estrogen metabolites.^{23,25,26}

Exercise, weight loss, cruciferous vegetables, and lignan-rich flaxseed can improve the 2-hydroxyestrone/16-hydroxyestrone ratio, reducing the stimulatory effect on breast tissue.

In women receiving postmenopausal HRT, breast cancer risk for hormone receptor–positive cancers and HER2-positive tumors increases. In women taking estrogen and progestin replacement for more than 15 years, the risk of breast cancer increased by 83% compared with estrogen-only HRT, which increased risk by 19%. Risks associated with HRT were found only in women with body mass index (BMI) less than 29.9 kg/m², but not in women with a BMI more than 30.²⁷

Screening

Integrative Therapies

Lifestyle

The European Prospective Investigation into Cancer and Nutrition found that four lifestyle measures were critical in reducing risk of cancer as well as chronic illnesses, such as heart disease and diabetes. These measures included not smoking; BMI less than 30; 3.5 hours a week of exercise or more; and eating a healthy diet of fruit, vegetables, and whole grains, with little meat consumption. Having all four lifestyle factors reduced the risk of cancer by 36%.³³ For patients to make informed decisions about nutritional changes, consultation with a person trained in integrative nutrition must be made available.³⁴

Not smoking, having a BMI less than 30, 3.5 hours of exercise or more a week, and a healthy plant-based diet can reduce the risk of cancer by 36%.

The American Cancer Society introduced guidelines for nutrition and exercise for the prevention of cancer and for cancer survivors undergoing cancer treatment based on the recommendations of an expert panel of scientists and clinicians who reviewed all current research on these topics in 2006 with an update in 2012 (refer to resource section). In summary, the guidelines recommend a higher intake of fiber in the form of fruits and vegetables as well as whole grains, maintaining a healthy weight, and regular exercise.³⁵ In one study of breast cancer survivors, a low-fat diet had no effect on mortality, but a high-fat dairy diet contributed to increased cancer and noncancer mortality.³⁶

For breast cancer, screening mammography, with annual testing starting at the age of 40 years, has been the standard practice for decades.²⁸⁻³² Recent analysis of the overall benefit, cost, and toxicity of routine mammographic screening raises concern about the actual benefit, which is small.²⁸ There is also concern about expense and toxicity of treatment with overdiagnosis, that is, being diagnosed with a finding that would never have caused harm.²⁹ Mammogram guidelines have been very controversial.

One current recommendation promotes a more limited use of mammographic screening with routine screening of average-risk women starting at age 50 and stopping at 75 and in this group, screening every 2

years rather than yearly.³⁰ There is considerable controversy with reduction of screening age range and frequency.²⁸⁻³² Women have been taught for decades that yearly mammograms are optimal for screening, and to change recommendations is difficult, particularly if a better screening test is not offered. In addition, there is a large mammography based industry, and such recommendations severely alter that structure.

Other recommendations are even more restrictive with a review process in Switzerland recommending the phasing out of all mammography.³¹ Ideally, there would a better test for finding very early breast cancer coupled with effective preventive treatment strategies that did not involve the high false-positive rate and overall low yield of mammography.

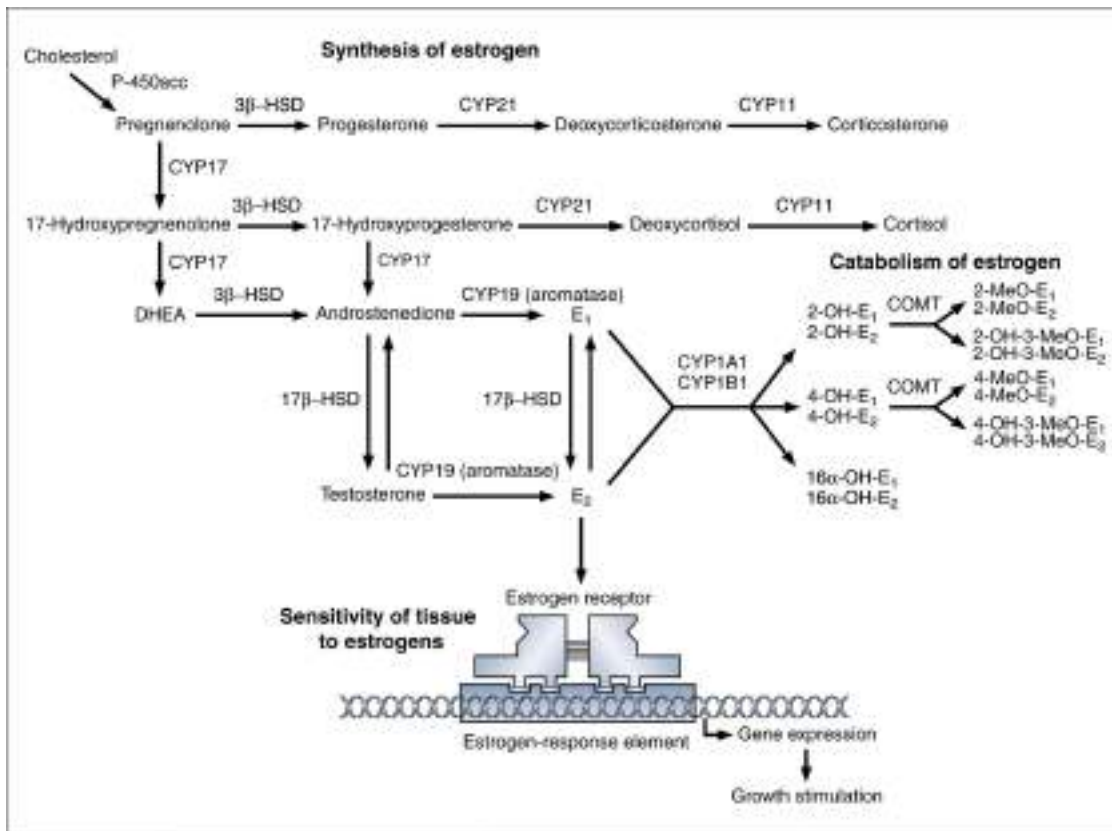

FIG. 78.1 Pathways of estrogen synthesis and catabolism. 2-MeO-E₁, 2-methoxyestrone; 2-MeO-E₂, 2-methoxyestradiol; 2-OH-3-MeO-E₁, 2-hydroxyestrone 3-methyl ether; 2-OH-3-MeO-E₂, 2-hydroxyestradiol 3-methyl ether; 2-OH-E₁, 2-hydroxyestrone; 2-OH-E₂, 2-hydroxyestradiol; 3β-

HSD, 3 β -hydroxysteroid dehydrogenase; *4-OH-3-MEO-E₁*, 4-hydroxyestrone 3-methyl ether; *4-OH-3-MeO-E₂*, 4-hydroxyestradiol 3-methyl ether; *4-OH-E₁*, 4-hydroxyestrone; *4-OH-E₂*, 4-hydroxyestradiol; *16 α -OH-E₁*, 16 α -hydroxyestrone; *16 α -OH-E₂*, 16 α -hydroxyestradiol; *17 β -HSD*, 17 β -hydroxysteroid dehydrogenase; *COMT*, catechol O-methyltransferase; *CYP11*, 11 β -hydroxylase; *CYP1A1*, cytochrome P-450 1A1; *CYP1B1*, cytochrome P-450 1B1; *CYP17*, 17 β -dehydroxylase; *CYP19*, P-450 aromatase; *CYP21*, 21-hydroxylase; *DHEA*, dehydroepiandrosterone; *E₁*, estrone; *E₂*, estradiol; *P-450*, cytochrome P-450; *scc*, side-chain cleavage enzyme. (From Clemons M, Goss P. Estrogen and the risk of breast cancer. *N Engl J Med*. 2001;344:276-285.)

Exercise

Exercise has a role in cancer prevention through weight control, increased muscle strength, and improved immunity and mood control. During and after cancer treatment, exercise can benefit mood, strength, weight control, energy levels, immunity, overall health and well-being, survival, prevention of recurrence, and quality of life (QOL). It allows patients to go through their cancer treatments with increased strength, less fatigue and muscle weakness, better balance, and fewer falls.³⁷ It can also have beneficial effects on pain, lymphedema, and improved self-image. One study that investigated breast cancer survivors versus controls showed that breast cancer survivors are less likely than non-breast cancer controls to adhere to physical activity recommendations.³⁹ Unfortunately, what was not assessed was what their health care providers were recommending for exercise and whether they advised continuing exercise during and after treatment. In a population-based study of breast cancer patients, consistent and long-term, higher activity (more than 3 hours / week) exercisers had lower risk of cancer mortality than did women with low activity levels.⁴¹ In another study of breast cancer survivors, women who had 2–3 hours of walking per week after diagnosis reduced their mortality risk by 45% compared with sedentary women. Women who decreased their activity after diagnosis increased their mortality risk four-fold.⁴² In one study, a simple walking intervention reduced pain and maintained cardiorespiratory fitness in patients with breast cancer undergoing radiation therapy and chemotherapy.⁴³ Physical activity improved mood in yet another study of

breast cancer patients which persisted for 60 months postintervention.⁴⁴

In one study, women with breast cancer participated in a tailor-made exercise group. This program increased self-esteem and wellbeing by allowing these women to self-identify more as healthy normal women rather than cancer patients.⁴⁵ Pain was significantly reduced in another longitudinal study of breast cancer survivors who exercised regularly and maintained their body weight.⁴⁶ Postmastectomy breast cancer survivors studied in a home-based 8-week exercise program experienced reduction of lymphedema and increased QOL⁴⁷ (see [Chapter 91](#)).

Nutrition

Mediterranean Diet

Diets high in fruits and vegetables, fish, fresh foods, and olive oil and low in animal fat (the Mediterranean diet) reduce the risk of breast cancer and many other cancers.⁴⁹ In one large French study of 2381 women with invasive postmenopausal breast cancer, a Western/alcohol-dominant diet was associated with higher risk of breast cancer incidence compared with a healthy Mediterranean diet. The Western diet included meat products, French fries, alcohol, pizza, high-fat foods, and processed foods. The Mediterranean diet included fruits and vegetables, fish, olive and sunflower oils, and nonprocessed fresh foods. This difference was especially significant in women with estrogen-positive, progesterone-negative (ER⁺/PR⁻) tumors.⁴⁹

Fiber

Intake of high-fiber foods, as shown by results of the National Institutes of Health–AARP Diet and Health Study, can reduce the risk of breast cancer, especially that of ER⁻/PR⁻ tumors.⁵⁰ In the Malmö Diet and Cancer cohort, intake of high-fiber bread reduced the risk of breast cancer.⁵¹ High-fiber foods are preferable to fiber supplements because of the beneficial nutrients intrinsic to food sources such as fruits, vegetables, beans, nuts and seeds, whole grains, and legumes.¹⁵

Alcohol

Emerging evidence exists for the role of alcohol increasing risk in breast cancer.⁵² In primary prevention, alcohol intake and lower folate levels are associated with an increased risk for breast cancer.³⁵ In one study of

secondary prevention, low to moderate alcohol intake was not associated with increased risk of recurrence or increased mortality.⁵³ Alcohol (more than one alcoholic drink per day in women) increases circulation of androgens and estrogens, and use of alcohol is associated with lower levels of important nutrients such as folate and B vitamins, with a protective effect noted in women with increased folate intake who drink alcohol.⁷ In the Women's Health Initiative study, women who consumed more than seven alcoholic drinks per week doubled their risk of hormone receptor-positive invasive lobular carcinoma. This effect was not seen in ER⁻ tumors or women with ductal breast cancer. Alcohol may have a differing effect on breast cancer risk, depending on the subtype of the breast cancer.⁵⁴ Deandrea et al.⁵⁵ found increased risk for alcohol and ER⁺ tumors.

Sugar

High sugar intake increases calories in the diet (sometimes excluding more nutritious food), contributes to weight gain, and increases insulin levels, which can have other deleterious metabolic effects that contribute to cancer cell growth.^{15,56} High sugar intake in the form of products with high fructose corn syrup, sugar, honey, and molasses is not recommended.¹⁵

Polyunsaturated Fatty Acids

Polyunsaturated fatty acids include omega-3 and omega-6 fatty acids. In large quantities and especially if hydrogenated for extended shelf life, omega-6 fatty acids such as sunflower, safflower, soy, sesame, and corn oils can be proinflammatory in the body. Omega-3 fatty acids (eicosapentaenoic acid [EPA] and docosahexaenoic acid [DHA]) are antiinflammatory and are present in fish oil, flaxseed oil, and the oil in walnuts. Omega-3 fatty acids are present in fatty fish (such as salmon, sardines, and mackerel), walnuts, green leafy vegetables, and flaxseed meal. The VITamins And Lifestyle (VITAL) study demonstrated that fish oil reduced the risk of ductal, but not lobular, breast cancers.⁵⁷ In a case-controlled study of patients with breast cancer and case controls with no malignant disease, fish omega-3 intake was found to reduce the risk of breast cancer in premenopausal and postmenopausal women, with the greatest reduction in postmenopausal women.⁵⁸ Cottet et al.⁴⁹ demonstrated in a large cohort study of postmenopausal women that there was a lower risk of invasive breast cancer with a Mediterranean

diet (high in fish, fruits, and vegetables) but a higher risk on a Western/ alcohol-type diet (high in saturated meat fat and processed foods).

Dosage

Approximately 1000 mg of combined DHA and EPA daily in less than 3 g of total high-potency fish oil is recommended. Lignan rich flaxseed oil can be substituted on a vegan diet. If any fishy aftertaste occurs, remember not to take with hot food or drinks and to take before eating; if these measures do not work, freeze fish oil capsules before ingestion.

Precautions

If any bleeding occurs, stop fish oil immediately because its action on decreasing adhesiveness of platelets in clotting can increase bleeding. Stop one week before surgery or any invasive procedure. Fish oil is contraindicated with platelet counts of less than 20,000. A more conservative approach is to discontinue fish oil if the platelet count is less than 50,000. Use with caution if the patient is taking any other anticoagulants.

Monounsaturated Fatty Acids

Oleic acid (omega-9 fatty acid) is found in olive oil, avocados, hazelnuts, and cashew nuts. It can help with suppression of HER2 tumor cell growth and can help enhance the action of trastuzumab.⁵⁹ Eating these nuts and using olive oil in cooking and as a salad dressing are recommended.

Green Tea

Green tea is a polyphenol that is a natural aromatase inhibitor.⁶⁰ Green tea consumption of more than three cups per day may reduce the risk of breast cancer recurrence but no consistent effect could be found on cancer incidence.⁶⁰ In a Chinese population, green tea and dietary mushrooms decreased the risk for development of breast cancer.⁶¹

Dosage

Three cups a day is the recommended intake.

Soy

In the recent past, a scarcity of research on soy made this food controversial with estrogen-sensitive tumors because soy is a phytoestrogen and theoretically could stimulate estrogen receptors. Studies in mice using the isoflavone genistein in isolation raised concerns about soy. In mice, genistein stimulated ER⁺ tumors; but in clinical studies of soy consumption, opposite effects are found.⁶² Because they are weak estrogens, however, they might also block receptors from being stimulated by stronger exogenous and intrinsic sources of estrogen. The Shanghai Breast Cancer Survival Study, which included 5042 breast cancer survivors, showed that soy food intake is inversely associated with breast cancer mortality and recurrence. The benefits existed for ER⁺ and ER⁻ tumors and for both users and nonusers of tamoxifen.⁶³ In another study of soy food intake, high soy intake reduced the risk of breast cancer recurrence in patients with ER⁺/PR⁺ tumors receiving the aromatase inhibitor anastrozole.⁶⁴ In another study of soy intake and breast cancer risk, an inverse association was found for high intake to lower risk of breast cancer.⁶⁵ In Korean women, soy intake was associated with lower breast cancer risk in postmenopausal women, and the inverse association was marked in women with ER⁺/PR⁺ tumors.⁶⁶

In two studies of breast cancer patients, soy food intake reduced mortality and breast cancer recurrence.^{67,68} In another study about soy food consumption of greater than 10 mg of isoflavones in U.S. and Chinese breast cancer survivors, mortality was not significantly reduced, but breast cancer recurrence was reduced.⁶⁹

Avoid soy isoflavones in supplements, given concerns in mice; but soy foods do not appear to be contraindicated and indeed seem to be valuable in reducing risk of breast cancer, recurrence, and mortality.

Dosage

One to three servings a day, in a balanced diet with other foods, are recommended unless an individual has sensitivity to soy.

Other phytoestrogens, plant lignans, can help reduce risk of breast cancer, especially in postmenopausal women.⁷⁰

Flax

Flax, usually consumed as flaxseed meal or oil, is a rich source of phytoestrogens containing alpha-linoleic acid. It has protective effects by decreasing inflammation in the body as an omega-3 fatty acid, inhibits aromatase activity, binds weakly to estrogen receptors, and increases the weaker 2-hydroxyestrones. It reduces the risk of breast cancer and decreases breast cancer cell growth.^{22,23,71}

Dosing

One to two tablespoons a day of the meal can be added to food. Flaxseed meal and oil can become rancid easily and should be kept in an airtight container, refrigerated, and used promptly.

Edible (Medicinal) Mushrooms

Medicinal mushrooms that have an antiinflammatory and immune-enhancing effect include maitake (*Grifola frondosa*), shiitake (*Lentinus edodes*), reishi (*Ganoderma lucidum*), and turkey tail (*Trametes versicolor*).⁷³ Mushrooms also have a number of other properties, including antifungal, antibacterial, antiviral, and tumor attenuating. Each mushroom has different characteristics. Maitake mushrooms in particular have high antitumor and antiinflammatory activity.⁷⁴ In one phase I/II trial of maitake extract, a statistically significant association was found with positive immune response. There was no dose-limiting toxicity.⁷⁵ In a review of *T. versicolor* research in Japan and China, Standish et al.⁷⁶ discussed data suggesting that this mushroom improves disease-free intervals and overall survival in breast cancer patients by immune modulation. More research is warranted.

Dosing

Mushrooms can be eaten in the diet or taken as a dried supplement.

Whey Protein

Whey protein, which is a byproduct of cheese making, is of the highest protein quality and high in glutamine, which helps prevent mouth sores (stomatitis) in patients receiving chemotherapy. It may be useful in preventing the peripheral neuropathy of certain chemotherapy agents, such as taxanes (Taxol). Glutamine is abundant in whey, and this is the preferred manner of ingesting this nutrient.

Dosage

Whey protein powder, 20–30 g twice daily in smoothies, will provide adequate glutamine to prevent these complications of chemotherapy. If whey is not tolerated because of allergy or sensitivity, glutamine can be taken as a supplement, 3–5 g one to three times daily.²²

Brassica (Cruciferous) Vegetables

Cruciferous vegetables include kale, broccoli, cauliflower, Brussels sprouts, and cabbage. Indole-3-carbinol is an important constituent of these vegetables that helps decrease cancer cell proliferation, increase apoptosis, and alter the ratio of weak to strong estrogens (2-hydroxyestrone / 16-hydroxyestrone) favorably. Breast cancer risk can be reduced by 20%–40% with one or two servings of cruciferous vegetables daily.^{26,78-80} Indole-3-carbinol can interfere with tamoxifen and is safer to eat in vegetable form than in supplement form.³

Dosage

One or two servings per day is the recommended intake. In supplement form, 400 mg/day of indole-3 carbinol (I3C) is recommended.^{23,81,82}

One head of cabbage contains approximately 1200 mg of indole-3-carbinol. Eating of one-third of a head of cabbage daily would equal the common supplemental dose of 400 mg daily and offer the other synergistic properties of the whole plant.

Supplements

Botanicals and supplements can be useful in promoting health; some have an anticancer effect or immunity-enhancing effect, and some are useful in attenuating the side effects of conventional cancer therapies. It is important to consider the interactions of some botanicals and supplements with chemotherapy and radiation therapy that might decrease the effectiveness of these modalities and in some cases increase toxicity. Antioxidants taken in high-dose supplement form can theoretically interfere with radiation therapy and chemotherapy by neutralizing free radical formation key to the effectiveness of these agents. Controversy remains, but most practitioners agree that foods high in antioxidants are safe, given the variety of antioxidants naturally occurring in many foods that act synergistically, are better absorbed, and do not reduce the effectiveness of radiation therapy and chemotherapy because they are in concentrations lower than in supplement forms.

Multivitamins

Vitamin D

Vitamin D deficiency is common, especially in patients chronically or acutely ill and in northern climates (above 35–40 degrees north or south of the equator). Those individuals with darker skin, who are obese, who have little unprotected sun exposure, who are older than 65 years, and who are taking particular medications such as glucocorticoids or anticonvulsants are also at risk for deficiency. It can express itself as diffuse body aches and can contribute to osteopenia and osteoporosis. It can also be manifested as low-back pain, proximal muscle weakness, and bone pain, especially over the sternum or tibia.^{86,87} Vitamin D is also important for immunity and has an anticancer effect. Vitamin D is ingested as vitamin D₂ (ergocalciferol) or vitamin D₃ (cholecalciferol), which is converted in the liver to 25-hydroxyvitamin D (calcidiol), the circulating form of vitamin D. Vitamin D₃ is also formed in the skin when 7-dehydrocholesterol, the skin precursor, is exposed to ultraviolet B light. Calcidiol is converted in the kidney to 1,25-dihydroxyvitamin D (calcitriol), the active metabolite. Calcitriol significantly inhibits cancer cell growth, especially in breast, colon, prostate, and ovarian tissue.⁸⁶ In testing for vitamin D deficiency, the 25-hydroxyvitamin D level is most helpful.

Strong evidence exists that vitamin D and calcium intake can help

reduce the risk of breast cancer.⁸⁸ In a meta-analysis of 36 studies, a 45% lowered risk was found in women whose 25-hydroxyvitamin D levels were in the highest quartile versus the lowest quartile. Decreased cancer risk was also observed in those with the highest quartile of calcium intake.⁸⁹ Blackmore et al.⁹⁰ found reduced risk of ER⁺/PR⁺ breast cancer in women with the highest intake of vitamin D. Nonsignificant positive trends were also seen in women with ER⁺/PR⁻ and ER⁻/PR⁻ tumors. Dark-skinned individuals such as African Americans convert less vitamin D in their skin and are more likely to be vitamin D deficient without supplementation. This increases cancer risk, which may help explain why this population group is more at risk for cancer with higher mortality.⁹¹

Aromatase inhibitors can contribute to myalgias, arthralgias, and loss of bone mass. In combination with other therapies that cause significant side effects and may further prevent meaningful sun exposure, vitamin D deficiency can contribute to these adverse effects of conventional therapy.

Vitamin D–fortified foods contain vitamin D in small and inconsistent amounts. Reliable and potent food sources of vitamin D are oily fish, including salmon, mackerel, and sardines.^{92,93} Supplements are usually needed to obtain adequate amounts of vitamin D. In general, a 25-hydroxyvitamin D level of less than 20 ng/mL (50 nmol/L) is deficiency range, and 20–30 ng/mL (50–75 nmol/L) is in the insufficiency range. Treatment of vitamin D deficiency includes oral vitamin D₂ (ergocalciferol) at 50,000 units per week for 8 weeks. After vitamin D levels are normalized, current recommendations are conservative for vitamin D₃ 800–1000 units daily.⁹⁵ Vitamin D is relatively contraindicated in patients with hypercalcemia, which can occur in metastatic breast cancer with bone involvement.⁹⁵ In an epidemiological projection of optimal serum 25-hydroxyvitamin D levels, Garland et al.⁹⁶ estimated prevention of 58,000 cases of breast cancer per year with year-round levels of 40–60 ng/mL (100–150 nmol/L). Abbas et al.⁹² found that vitamin D lowered the risk of premenopausal breast cancer. Other studies in Norway and England have found that patients with cancers diagnosed in summer or fall, when vitamin D levels are highest, had longer survival and a milder clinical course than did patients diagnosed in the winter or spring, when vitamin D levels are lowest.⁹³

Dosage

The recommended dose of vitamin D₃ is 1000–2000 units daily.^{95,97,98} Serum levels of 25-hydroxyvitamin D can be used to determine optimal dosing of vitamin D, which can vary from person to person and by time of year, latitude, and degree of sun exposure.

Precautions

Signs of vitamin D toxicity include nausea and vomiting, pancreatitis, nephrocalcinosis or vascular calcinosis, metallic taste, and headache.⁹⁵

One important resource for evaluating which supplements can improve the effectiveness of chemotherapy agents and which interfere with their activity is *The Definitive Guide to Cancer: An Integrative Approach to Prevention, Treatment, and Healing* by Lise Alschuler and Karolyn Gazella.⁵

Some supplements are potentially harmful in certain populations or of no benefit. Antioxidants such as beta-carotene and vitamin E are of no benefit in large doses, and beta-carotene can have a harmful effect in patients who smoke or have asbestos exposures. In these subpopulations, increased lung cancer risk has been found.⁸³ In one phase III trial of vitamin E in a low dose (400 mg/day), which is generally the dose in a multivitamin, vitamin E significantly lowered the neurotoxicity occurring with cisplatin.⁸⁴

In one study of postmenopausal women with invasive breast cancer, daily use of a multivitamin with minerals was associated with a 30% lower breast cancer mortality to nonusers. Users of multivitamins might have many characteristics that have a more powerful effect on this reduced mortality such as exercise and food choices. More research is needed in this area.⁸⁵

Melatonin

Melatonin has antioxidant, immune-enhancing, cytotoxic, and estrogen-regulating properties. It is also useful in the treatment of insomnia. Melatonin comes in an immediate preparation for individuals having difficulty in falling asleep and a sustained-release preparation for those having difficulty staying asleep.^{99,100} Avoiding melatonin suppression may be more effective than supplementation.¹

Dosage

Doses range from 1–20 mg before bed; a starting dose is 3 mg before bed. Titration occurs to effect, without causing a hangover the next day.

Precautions

Melatonin is contraindicated in bipolar illness, and it can worsen depression in some vulnerable individuals. Monitoring for optimal effect with minimal side effects is recommended. Caution must be exercised in use with other sedative medication.

Botanicals

Botanicals can be helpful in the treatment of cancer but must be used carefully during chemotherapy because many botanicals can interfere with the metabolism of the chemotherapy agent by increasing or decreasing its metabolism in the body. For example, certain botanicals can interfere with the metabolism of taxanes, platinum-based drugs, cyclophosphamide, doxorubicin, etoposide, and irinotecan.⁵ In general, botanicals do not interfere with radiation therapy. Botanicals such as St. John's wort can interact with a number of other drugs the patient may be taking through the cytochrome P-450 metabolic pathway.

Spiritual and Emotional Care

Patients who have social support, empowerment, and meaning often have more positive lifestyle behaviors and coping strategies. Those patients with lack of meaning and purpose often have more symptoms from treatment and more difficulty in coping, leading to more negative choices.¹⁰¹ Small-group psychological interventions for breast cancer patients led by a psychologist and concentrating on stress management and strategies to optimize conventional treatment and to improve mood helped decrease recurrence and mortality.¹⁰² Mindfulness intervention and supportive expressive therapy allowed telomere length to stabilize, rather than shorten, in the control group in a study of woman with breast cancer. Telomere length was not associated with mood or stress.¹⁰³

Emerging evidence on life review and internet-based social networking shows improvement in QOL measures; it is another intervention that is simple yet powerful in cultivating meaning through

the challenges of cancer.^{104,105} Spiritual and emotional assessment and recommendations for interventions such as support groups, journaling, life review, and psychotherapy with oncology health professionals are reviewed in other chapters (see [Chapters 82](#) and [114](#)).

Conventional Treatment

Of all cancers, breast cancer is one of the most thoroughly studied in terms of clinical trials. From the 1970s on there have been hundreds of randomized controlled trials evaluating surgical, radiation, and medical approaches to treatment. Large trials, often with many hundreds of patients, have incrementally improved treatment with more effective and less toxic strategies.^{106,107} A large body of literature documents the evolution of treatment for apparently localized breast cancer, a category that has increased as screening for early breast cancer has become more common.

The move away from mastectomy to breast preservation with lumpectomy and breast irradiation was a major change. An important discovery was that postoperative use of medicine with drugs including cytotoxic chemotherapy and antiestrogen agents such as tamoxifen could favorably influence the natural history of the cancer with greater survival. This occurred by control of apparent microscopic distant disease not detected in the pretreatment period by physical exam, blood tests, or imaging. Much work has been done to better understand the biology of each cancer and with gene expression pattern analysis it has been learned that there are multiple subcategories of breast cancer, each with different behaviors of metastasis and response to treatment.^{108,109} Lessons learned in the late 20th century included:

- For appropriate candidates, breast preservation with lumpectomy and radiation to the remaining breast tissue yields survival equivalent to mastectomy.¹¹⁰
- Cytotoxic chemotherapy, particularly in premenopausal women, can effectively improve overall outcome in patients with breast cancer that is likely to recur. The amount of benefit, and hence the benefit to toxicity ratio, depends on the risk of recurrence. Greater risk for recurrence is associated with greater absolute benefit from chemotherapy.¹⁰⁶
- Tamoxifen and other estrogen blocking or reduction agents can improve outcome in women with breast cancers that measure positive for estrogen and/or progesterone receptors (hormone receptor, or HR-

- positive cancers)¹⁰⁷
- Anatomic features of the cancer such as the extent of axillary nodal involvement, tumor size, and the histological grade help predict the natural history of the cancer and thus guide the need for postoperative medical therapy.

Surgical Approach

Only a small minority (5%) of patients in the United States diagnosed with breast cancer have identifiable overt distant metastatic disease at the time of diagnosis. Thus, nearly all women will be considered for local therapy (surgery and perhaps radiation) as well as systemic therapy (medicines such as with chemotherapy, antiestrogen therapy, and more recently possible antibody therapy) to optimize recurrence risk reduction.

Lumpectomy is well established as a surgical strategy that when done with postoperative breast irradiation offers excellent long-term control in the breast and survival that is comparable to mastectomy. In the past decade, the major surgical advance has been incorporation of *sentinel node biopsy*, which has replaced axillary dissection for most women.¹¹¹ With lymphatic mapping using the sentinel node procedure, a blue dye and or a radionuclide, which can be tracked by a detection device, is injected into the breast. A small incision in the axilla is done to identify the stained or radioactively “hot” node. This is the *sentinel node* (the initial landing site for cancer cells moving to axillary nodes), which can be tested for the histological presence of cancer cells. If none are seen, the patient is deemed to be “node negative” and no further node surgery is needed. Ongoing studies are being done to determine the value of node dissection in patients with positive sentinel nodes. The overall amount of axillary surgery has been reduced significantly with the introduction of the sentinel node procedure.

Breast *conservation* or breast *preservation* are terms that describe removal of the tumor only (lumpectomy) and not the entire breast as with mastectomy. The majority of women diagnosed with invasive breast cancer are candidates for lumpectomy and sentinel node procedure, and this approach became the preferred standard in the early 1990s.¹¹² Despite the reduction in toxicity with breast preservation and a survival equivalent to mastectomy, some women choose mastectomy or even bilateral mastectomy. A trend for this began in the late 1990s and is perhaps a reflection of fear of recurrence or new breast cancer.¹¹³ Some of

this concern is fueled by the fact that though breast cancer treatments are more effective than ever, many women still die of metastatic breast cancer, and once the disease is metastatic, we cannot offer cure as a realistic goal.

Radiation

Whole-breast radiation to the affected breast is standard after lumpectomy. Despite the lumpectomy being done with clear tissue margins, there is still a significant recurrence rate near the region of the excision. Radiation markedly reduces but does not eliminate risk for recurrence. Traditional schedules have included treatment with external beam radiation for 5–6 weeks, but recent studies in Canada and England suggest that shorter treatment duration, hypofractionated RT, is likely equivalent for disease control as well as short- and long-term toxicity for most patients.¹¹⁴ It is likely that in the United States shorter course external beam radiation will become the standard, at least for patients with negative nodes. Randomized trials have determined that for elderly women with stage I, HR-positive cancer undergoing lumpectomy radiation is of little value and can often be omitted.

Chemotherapy of Localized Breast Cancer

From the 1970s until recently treatment decisions about adjuvant therapy have been based primarily on anatomic features of the cancer with node positivity and tumor size being the most important predictors of recurrence. Now decision making incorporates protein products and tumor gene patterns and other features that help predict the behavior of the cancer. For example, it was shown in the 1980s that changing the hormonal environment with the antiestrogen tamoxifen could reduce recurrences by half in women with node-negative, hormone receptor-positive tumors.¹¹⁵ Other studies included node-positive women, and the standard approach of using estrogen blocking or estrogen reduction therapy with or without chemotherapy for women of all ages was established.

Once cytotoxic chemotherapy was shown to change the natural history of node-negative tumors as well, the use of chemotherapy for lower-risk tumors expanded. The result was that much chemotherapy was used for patients who did not need it. Tumor tissue from patients treated in these studies led to development of molecular testing that could allocate node-

negative, hormone receptor–positive tumors into higher versus lower recurrence-risk categories. The method also identified tumors that were more or less likely to benefit from chemotherapy. Genomic profiling, e.g., OncotypeDX, have become standard and provide guidance regarding which cancers will not need cytotoxic chemotherapy for optimal care. It is expected that in the future, molecular phenotyping will play a larger role in directing adjuvant therapy for node-positive tumors as well.¹¹⁶

Certain categories of breast cancer require different treatments. Fifteen to twenty percent of cancers have overexpression of the epidermal growth factor protein her-2 or amplification of the *HER2* gene. Testing for this is now standard. Without optimal adjuvant treatment, these tumors have a high risk for recurrence. Significant improvement in outcome occurs with the use of trastuzumab, a monoclonal antibody directed at *HER2*, in addition to chemotherapy. This combination treatment has dramatically improved the prognosis for this subtype of breast cancer. Another category, *triple negative* cancer, does not have hormone receptors (estrogen or progesterone receptor) nor overexpression of *HER2*. At present, only cytotoxic chemotherapy is available as adjuvant treatment. These tumors have a worse prognosis.

Chemotherapy of Metastatic Disease

The goal of adjuvant treatment is to prevent disease metastatic to distant organs. Common sites for metastases include bone, liver, lung, skin, and brain. Current goals of treatment for metastatic breast cancer are disease control, not cure, and prevention or treatment of symptoms. For disease that is HR-positive, medical treatment involves sequential use of hormonal strategies such as tamoxifen, aromatase inhibitors for postmenopausal women, ovarian suppression for premenopausal women, and fulvestrant, an estrogen receptor downregulator. Some patients over time respond to several of these agents and control of HR-positive cancer can be achieved for years. At some point, all patients will develop disease that is refractory to hormonal treatment. For disease that is HR negative at the outset or that has progressed despite hormonal therapy, chemotherapy, usually with sequential single agents, is done. For all patients with *HER2*–“positive” disease, a *HER2*-directed agent is used with chemotherapy. It is important to have confidence in the laboratory doing the *HER2* assay. Missing a *HER2*-positive cancer is a major mistake.

It is important to remember that management of metastatic breast

cancer can result in good function and a high QOL for many years. In general, there is need for long-term planning with expectations that the patient will receive numerous types of treatment over time, with each sequential treatment ideally offering a good deal of time with disease control. A good working partnership between the physician/nurse team and the patient/family is required. One of the more difficult decisions in patients with metastatic breast cancer is when to stop anticancer therapy. Because there can be periods of success with multiple treatments, there may be a tendency to lose sight of when to stop. Usually performance status and patient preference help determine when symptom management, and not chemotherapy, is the best path. If the patient's performance status is poor (e.g., Eastern Cooperative Oncology Group score 3 or worse, wheelchair-bound, etc.), chemotherapy is generally not well tolerated and not useful.

Summary

Treatment of breast cancer continues to evolve with less surgical morbidity, more effective systemic agents, and better understanding of breast cancer biology all being recent advances. Lessons learned in the early 21st century:

- For some patients with lumpectomy, shorter course radiation (3 weeks) is equivalent to longer treatment periods.
- Genomic profiling tests can identify breast cancers with a relatively good prognosis using adjuvant endocrine therapy only, so that patients can avoid cytotoxic chemotherapy.
- Sentinel node procedures allow the elimination of traditional axillary dissection for the majority of patients.

Integrative Management of Side Effects From Breast Cancer Treatment

E-Table 78.2

Recommended Reading in Integrative Oncology^a

Author	Title	Publisher	Summary	Notes
David Servan-Schreiber, MD, PhD	<i>Don't Cancer: A New Way of Life</i>	New York: Viking, 2007	The author's narrative of cancer is interwoven with research on nutrition, exercise, and mind-body interventions to reduce risk and recurrence of cancer.	Supplements are not emphasized.
Lisa Alschuler, ND, and Katelyn Garcia	<i>The Definitive Guide to Cancer: An Integrative Approach to Prevention, Treatment, and Healing</i> [eBook]	Berkeley, CA: Celestial Arts, 2010	This book is a guide to health practitioners on interactions of botanicals and supplements with cancer treatments. General information on integrative oncology is provided for a number of cancers.	
Anna Selman, PhD	<i>Cancer Fitness: Exercise Programs for Patients and Survivors</i>	New York: Simon and Schuster, 2004	Practical research and exercise programs for cancer survivors are presented. Important uses of low exercise help reduce effects of cancer and treatment are described.	Strength training and aerobic exercise are included. The author's cancer experience informs the book.
Keith Block, MD	<i>Life Over Cancer: The Block Cancer Program for Integrative Cancer Treatment</i>	New York: Bantam Books, 2009	Dr. Block describes his integrative oncology program, including content and treatment of cancer combined with nutrition, nutraceuticals, movement, and other therapies to optimize outcomes and well-being in treatment and recovery from cancer.	Dr. Block's integrative oncology program is individualized to the patient's particular profile.
Donald Abrams, MD, and Andrew Weil, MD	<i>Integrative Oncology</i>	New York: Oxford University Press, 2009	This edited book describes how conventional and therapies are combined with alternative therapies and healthy lifestyle for optimal cancer care.	Many experts contributed to this edited book.
Steven Pratt, MD, and Kirby Mathews	<i>SuperFood! HealthyStyle: Proven Strategies for Lifelong Health</i>	New York: HarperCollins, 2006	This is an excellent, practical guide on what to eat and how to choose a healthy lifestyle.	The book is geared to general public and not specifically to patients with cancer.
Kris Carr	<i>Crave: Sexy Cancer Tips</i>	Guilford, CT: Merri Publishing Group, 2007	A refreshing look is taken at the cancer journey and survivorship with use of integrative approaches.	The author does not have breast cancer but speaks to younger individuals in cancer survivorship.
Jennifer Barnhill	<i>Enhancing Cancer Care: Complementary Therapy and Support</i>	New York: Oxford University Press, 2007	This is an edited book on complementary therapies in cancer care.	
Harold Remick, MD	<i>Kitchen Table Wisdom: Stories That Heal</i>	New York: Riverhead Books, 1996	Inspiring stories on the topic of healing and what that means are told.	
Miriam Nelson, PhD, and Sarah Wernick, PhD	<i>Strong Women Stay Young</i>	New York: Bantam, 1997	A gentle strength training program that will maintain muscle mass and bone integrity and improve muscle-to-fat ratio is presented.	Steps, gentle exercises for any age group can easily be modified for the limitations of a particular person. The program is helpful to maintain balance.
Michael Murray, ND, Joseph Pizzosco, ND, and Lani Ficozzos, MA, LMT	<i>The Encyclopedia of Healing Foods</i>	New York: Arta Books, 2005	Everything you might want to know about foods is described. History, how to choose and prepare them, nutritional constituents.	This useful and practical guide describes how to use each food.

^a All readings are appropriate for public and professional audiences.

TABLE 78.1
Integrative Medicine and Breast Cancer Treatment Symptoms

Symptom	Treatment	Evidence vs. Harm Rating
Fatigue	Exercise	
	Acupuncture	
Postmenopausal symptoms of hot flashes	Medications such as selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, and gabapentin	
	Acupuncture	
	Exercise	
Nausea and vomiting due to chemotherapy	Acupuncture	
	Ginger	
	Cannabis	
Anxiety, stress, and depression	Acupuncture	
	Mindfulness-based stress reduction	
	Art therapy	
	Exercise	

	Yoga

Prevention Prescription

- Eat primarily a plant-based diet rich in cruciferous vegetables (broccoli, cauliflower, Brussels sprouts, cabbage, and kale). Eat one or two servings of cruciferous vegetables daily.
- Follow an antiinflammatory and Mediterranean diet. This diet avoids saturated fat in dairy and meats; it has no trans-fats and includes increased amounts of omega-3 fatty acids (ocean fish, walnuts, soybeans, greens, flaxseed meal). See [Chapter 88](#).
- Avoid processed foods.
- Organic foods that are not contaminated with pesticides and herbicides. Many organic meats, poultry, and produce can be purchased from local farms or farmers' markets.
- Fatty fish such as herring, mackerel, tuna, salmon, and sardines have high levels of omega-3 fatty acids. Minimize your eating of albacore tuna, shark, swordfish, king mackerel, and tile fish because they can have higher levels of contamination with mercury. You may want to

take omega-3 supplements that are detoxified. Fish, however, is an excellent protein source. Eat fish often (three times per week or less) or take fish oil supplements daily. (If you eat fish high in omega-3 content, do not take your fish oil supplements that day.)

- Do not skip meals. If breakfast is a problem, try protein-fortified smoothies in the morning. Whey protein powder is best, and if you are lactose intolerant, buy whey protein powder without lactose.
- Drink lots of water, filtered if possible. Bring it with you everywhere (reuse water bottles). Flavor it with lime or lemon (or cucumber, orange, or any other natural flavor you like).
- Drink green tea, two or three cups a day.
- Moderate alcohol intake if you drink alcohol (no more than one serving per day for women). Do not drink it at all if it makes you feel not well.
- Mushrooms contribute to a healthy diet, especially adding medicinal mushrooms (i.e., maitake, shiitake, reishi, turkey tail) as food or supplement.
- Eat one to three servings of soy food daily. Avoid soy (isoflavone) supplements.
- Eat one or two tablespoons of flaxseed meal daily.
- Consider taking a multivitamin with minerals daily.
- Vitamin D can be obtained from adequate sun exposure or a supplement. For most people, 2000 units/day will maintain adequate levels. I recommend determination of a 25-hydroxyvitamin D level in winter to assess for adequate intake.
- Maintain healthy weight with a BMI of less than 30 and ideally 25 (not overweight).
- Avoid smoking and passive tobacco exposure.
- Exercise for 30–60 minutes at least 5 days a week (more than 3 hours per week is recommended). Combine aerobic activity such as walking with a resistance or strength training program two or three times a week. Nordic walking sticks can increase the overall conditioning of walking while improving posture, balance, and core strengthening. Yoga, tai chi, and qi gong are meditative movement with the benefit of relaxation and exercise. Do exercise that is enjoyable to you.
- Optimize sleep at night. Melatonin can be added if sleeping

difficulties are occurring, starting at 3 mg before bed. Sleep in a darkened room at regular hours to improve sleep quality. Do not sleep with a television on in the bedroom.

- Maintain spiritual practices that give meaning and relaxation to your life.
- Maintain a strong support network with family and friends.
- Consider testing for a 2-hydroxyestrone / 16-hydroxyestrone ratio, and consider interventions to improve the ratio in favor of weak estrogens.
- Minimize use of estrogen replacement medication. For menopausal symptoms, consider nonhormonal measures first.
- Attend to self-care every day. Make healthy lifestyle choices a part of your routine.

Therapeutic Review

Nutrition

- The Mediterranean diet can lower the risk of breast cancer and other chronic health conditions, such as heart disease, diabetes, and obesity. This diet is high in omega-3 and omega-9 fatty acids; add five to nine servings of fruit and vegetables per day. 
- Cruciferous vegetables are beneficial in a healthy diet to decrease cancer risk. 
- In general, antioxidants are preferably obtained in food rather than in supplements. 
- Three cups of green tea per day can decrease breast cancer risk. 
- Soy foods in moderation are safe and protective for breast cancer. One to three servings of soy foods daily are recommended. Avoid isolated isoflavone supplements. 
- Flaxseed meal can lower breast cancer risk. 
- Avoid excessive alcohol intake. Drink no more than one alcoholic beverage daily. 

- Weight control and gradual weight loss if the patient is obese or very overweight can reduce risk of breast cancer. Weight loss can be achieved with regular exercise, portion control, and eating more fruits and vegetables and fewer calorie-dense foods. 
- Vitamin D in supplement form when adequate sun exposure is not available is important for bone health, anticancer effect, immunity, and muscle health. Higher levels of vitamin D are associated with decreased risk of breast cancer. Monitor levels of 25-hydroxyvitamin D in the winter to ensure adequate intake of vitamin D₃. 
- Medicinal mushrooms have many potential beneficial effects during cancer treatment and can be part of a healthy diet. 

Medication

- Avoid prolonged HRT of both estrogen and progesterone. 
- Nonhormonal therapies for postmenopausal symptoms of hot flashes can be effective. These include regular exercise, medications, and acupuncture. 
- Tamoxifen is commonly used for ER⁺ tumors for 5 years after treatment to prevent recurrence. The dose is 20 mg daily. 
- Aromatase inhibitors (anastrozole, exemestane, letrozole) are used in postmenopausal treatment of breast cancer to prevent recurrence. 

Exercise

- Exercising more than 3 hours per week can decrease cancer risk. 

Lifestyle

- Sleep is important in decreasing cancer risk. Melatonin is implicated in this mechanism of reduced cancer cell proliferation when melatonin levels are high. Suppression of intrinsic melatonin is to be avoided sleeping in a dark room and avoiding exposure to blue wavelength light in the evening after dusk and during the night. Supplemental melatonin can help improve circadian rhythms and quality of sleep. The dose is 1-3 mg at bedtime. Up to 20 mg has been

used. 

- Psychological interventions can be helpful in cancer care. Those most helpful are psychoeducation and psychotherapy conducted by a psychotherapist individually. 
- Mindfulness-based stress reduction programs can enhance well-being and coping and decrease anxiety during and after treatment. 
- See [Table 77.1](#).

Integrative Management of Side Effects From Breast Cancer Treatment

Block^{118,119} has described chronomodulation of chemotherapy to help reduce toxicities of chemotherapy. Chronomodulation involves not only the optimal timing of chemotherapy but also strengthening of circadian rhythms. Interventions to strengthen these rhythms include lifestyle modifications (diet, exercise) and mind-body therapies, all of which increase melatonin levels in the brain at night, producing a more restful and restorative and healing sleep. Inflammatory and stress hormones that disrupt the circadian rhythm can be addressed with herbs, diet, supplements, and mind-body therapies (meditation and meditative movement), which optimize the internal biochemical milieu.

Cannabinoids

Cannabinoids are used in symptom management of nausea and vomiting, anorexia, and pain, including neuropathic pain (see [Chapter 82](#) for description of use in symptom management). Cannabinoids may also have a role as anticancer agents.¹²⁰

Fatigue

Exercise throughout treatment for cancer and beyond is essential to help prevent fatigue and weakness from muscle mass loss. Rest, if it is not

balanced with gentle exercise, can increase fatigue rather than alleviate it. In one study, low rather than high-intensity exercise reduced fatigue, depression, and improved quality of life (QOL).¹²¹ Initial weight loss with cancer treatment is often associated with muscle mass loss. In general, cancer treatment causes weight gain, and this can be alleviated with regular exercise within an individual's limitations.^{37,122}

An 8-week acupuncture course in one study reduced fatigue and other symptoms that can contribute to fatigue, such as depression, anxiety, and pain.¹²³ In a small study, Takahashi¹²⁴ found that acupuncture could help relieve fatigue, dyspnea, and constipation in terminal cancer patients. In a systematic review, acupuncture was found to reduce overall as well as emotional and physical fatigue.¹²⁵

Vasomotor Instability

In a systematic review of nonhormonal interventions for hot flashes in women with a history of breast cancer, relaxation was the only nonpharmaceutical intervention that reduced hot flashes significantly. Black cohosh and other botanicals were not evaluated. Only one study on acupuncture and a few other complementary and alternative medicine therapies were included; the interventions of vitamin E, acupuncture, and magnetic devices did not show evidence of benefit. Clonidine, selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, and gabapentin showed mild to modest benefits in reducing the number and intensity of hot flashes.¹²⁶ Evening primrose oil is a botanical occasionally used in treatment of menopausal symptoms such as hot flashes that can occur with cancer treatment. There is insufficient evidence to recommend it for this indication.¹²⁷

Twelve weeks of acupuncture versus venlafaxine was found to be equivalent in effectiveness to control hot flashes in hormone receptor-positive breast cancer patients in a randomized controlled trial. Both groups experienced decrease in hot flashes and improvement in depressed mood and QOL. The drug group had numerous side effects, whereas the acupuncture group experienced improved libido, energy, thinking, and well-being.¹²⁸ Acupuncture reduced hot flashes and night sweats in a study of breast cancer patients receiving tamoxifen. Emotional and physical well-being were also improved without significant side effects.¹²⁹ In another randomized controlled trial, 10 weeks of acupuncture versus sham acupuncture significantly decreased day and night hot flashes in breast cancer patients receiving tamoxifen.¹³⁰

A large, recent, systematic review of acupuncture showed 46% decrease in hot flashes with acupuncture treatments, and in another study a 52% reduction existed with acupuncture compared with 26% reduction with sham acupuncture.¹²⁵ In one large study, phytoestrogen botanicals and black cohosh, used to treat vasomotor symptoms, were found to lower risk of invasive breast cancer in postmenopausal women.¹³¹ In a large study, black cohosh was not effective in decreasing hot flashes, but another smaller study did show a positive effect.⁷³ Of note, black cohosh is not estrogenic.¹³² Black cohosh may cause liver toxicity and needs to be used with caution. It is not recommended during chemotherapy, and evidence for its benefits is inconclusive.

Atrophic Vaginitis

See [Chapter 59](#) for recommendations on nonhormonal lubricants.

Osteopenia and Osteoporosis

Strength training and weight-bearing exercise are known to help prevent bone loss in postmenopausal women. Yoga is a form of meditative exercise that can also help maintain bone mineral density. Other strategies to help maintain bone health are vitamin D and calcium. One clinical trial of weight training in postmenopausal breast cancer survivors showed that a 24-month weight training program with adherence greater than 50% improved bone mineral density. Both groups took bisphosphonates, vitamin D, and calcium but were randomized to the program or no exercise.¹³³

Nausea and Vomiting

Moxibustion, which stimulates acupuncture points with heat generated from burning herbal preparations, was evaluated in several clinical trials; some evidence showed that this therapy could significantly reduce nausea and vomiting in patients undergoing chemotherapy.¹³⁴ The National Institutes of Health endorsed acupuncture for chemotherapy-associated nausea.¹³⁵ The Society of Integrative Oncology, on review of the evidence, also strongly endorsed acupuncture for this indication.³⁴ Acupressure of acupuncture point 6 at the wrist, sometimes stimulated with specialized wristbands, can help alleviate chemotherapy-related nausea^{34,136,137} (see [Chapter 111](#)).

Lee et al.¹³⁸ found that nausea intensity was less in breast cancer patients receiving adjuvant chemotherapy or radiation therapy who engaged in moderate exercise as opposed to no exercise.

Ginger (*Zingiber officinale*)

Ginger can help alleviate nausea. It has been found efficacious for nausea associated with chemotherapy but not for postoperative nausea. Its mechanism of action is unknown, but ginger appears to have a prokinetic effect.¹³⁹

Dosage

Take 500–1000 mg of ginger root extract every 4–6 hours as needed, or eat 1 tsp or 5 g of crystallized ginger every 2–3 hours as needed.

Precautions

Ginger candy or tea is less potent than the root and may yield anti-nausea effects that do not interfere with certain chemotherapy agents.⁵

Side effects are rare. Excessive doses can cause heartburn.

Anxiety, Stress, and Depression

One 8-week acupuncture course significantly improved anxiety and depression in patients with advanced cancer. It also helped improve psychological distress and life satisfaction.¹²³

An 8-week mindfulness-based stress reduction (MBSR) program improved depression and medical symptoms, mindfulness, coping with illness and stress, and sense of coherence after completion of the primary cancer treatment.¹⁴⁰ In another study on MBSR in cancer patients, similar results were found.¹⁴¹ In a study of MBSR by Kieviet-Stijnen et al.,¹⁴² positive effects on mood and vitality strengthened 1 year after completion of the program. A study of an 8-week program using imagery found positive results on anxiety, stress, and depression.¹⁴³ Meditation in another study helped with improve fatigue, anxiety, QOL, and emotional health.¹⁴⁴

Art therapy can be helpful in improving general QOL measures,

including physical and psychological functioning, in breast cancer patients undergoing radiation therapy.¹⁴⁵ A RTC of a heritage therapy intervention which used museum objects for discussion and handling, increased well-being in female oncology patients.¹⁴⁶

Anxiety can be managed effectively with exercise. Yoga in particular can help with anxiety, depression, mood, and QOL with its meditative and restorative movement.^{147,148}

Massage can help relieve anxiety and stress during chemotherapy.¹⁴⁹ The Society of Integrative Oncology also strongly endorsed massage for anxiety during cancer treatment.³⁴ Art therapy, dance, journaling, and aromatherapy all have positive effects on anxiety, depression, and QOL.⁷³

Support groups can be helpful with improvements in mood, less anxiety and depression, better coping, and decrease in pain, but the survival benefits reported by Spiegel et al.¹⁵⁰ in 1989 have not been duplicated in subsequent studies.¹⁵¹⁻¹⁵⁴ In a review of psychosocial interventions, Zimmerman et al.¹⁵⁵ found that psychoeducation had the strongest effect size for breast cancer patients. Other psychological interventions led by a psychologist were conducted individually. In a meta-analysis of 116 mind-body therapies, guided imagery, biofeedback, cognitive-behavioral therapy, meditation, relaxation, and hypnosis were effective in improving mood states, coping, anxiety, and depression.¹⁵⁶ In a recent RCT of a positive psychology group intervention of 14 weekly sessions, 175 women with breast cancer sustained improvements in self-esteem, resilience, optimism, well-being, happiness and positive affect. The control group later participated in the intervention, and the results were replicated in this innovative study design.¹⁵⁷

Insomnia and Other Sleep Disturbances

Good sleep hygiene can help induce sleep at night when production of melatonin is optimal. Minimizing sleep during the day, exercising regularly, sleeping in a quiet dark room, and going to sleep at a similar time each night promote sleep. Relaxation, meditation, and yoga can have positive effects on melatonin and sleep states.¹⁵⁸ In one multicenter, RCT, the Yoga for Cancer Survivors program improved sleep disruption, improved sleep quality, and reduced use of sleep medication.¹⁵⁹

Cognitive-behavioral therapy has also shown positive effects on sleep.¹⁶⁰

In one RCT of Mindfulness Based Stress Reduction (MBSR) versus cognitive behavioral therapy (CBT), CBT was superior to MBSR in improving sleep quality and relieving insomnia.¹⁰³

Regular exercise can help reinforce normal circadian rhythm and maximum endogenous melatonin production by increasing wakefulness during the day and sleep at night.³⁶ Melatonin in supplemental form can also be helpful.

Breast cancer survivors tend to have 10% more sleep disturbances even long term compared with age-matched women without breast cancer. These sleep disturbances in both groups are associated with hot flashes, depression, more distress, and worse physical conditioning.¹⁶¹ Breast cancer survivors tended to do less physical activity and had more hot flashes than did women without breast cancer¹⁶² (see [Chapter 9](#)).

Pain and Peripheral Neuropathy

Pain and other uncomfortable neurological sensations can occur in posttreatment breast cancer survivors. In 1543 patients studied, Gartner et al.¹⁶³ found that 47% of women reported pain, and 13% of this group had severe pain. Pain was associated with young age (younger than 40 years) and adjuvant radiation therapy; axillary lymph node dissection was associated with increased likelihood of pain compared with sentinel lymph node dissection; and pain complaints from other parts of the body were associated with increased risk of pain in the surgical area. Pain was not associated with chemotherapy. Women undergoing mastectomy versus breast-conserving surgery did not significantly differ in frequency of reporting pain, but pain was generally more severe in patients reporting pain after mastectomy. Thus type of surgical technique and radiation therapy do affect chronic pain incidence during and after treatment of breast cancer.

Acupuncture can help with pain relief. One study showed improved pain scores and psychological functioning with an 8-week course of acupuncture.¹²³ The Society for Integrative Oncology, on review of the literature, strongly endorsed acupuncture for this indication.³⁴ A recent systematic review of acupuncture for pain and the symptoms of peripheral neuropathy showed improvement with acupuncture over sham acupuncture, with decreased severity of pain and improvement in pain control, as well as reductions in tingling and numbness.¹²⁵ Massage can also be helpful in relieving pain.³⁴

Exercise (a walking intervention) during radiation therapy and chemotherapy can attenuate the negative side effects on physical functioning, increase cardiorespiratory fitness, and reduce pain in breast cancer patients, especially in those who are younger.⁴³

Cannabinoids can help with neuropathic pain associated with the neuropathy that can be caused by some chemotherapeutic agents, such as taxanes and platinum-derived drugs.¹²⁰

Lymphedema and Musculoskeletal Issues

Exercise involving the upper extremities and physical therapy are now recognized to improve and not worsen lymphedema. It occurs in 20% of women with axillary lymph node dissection and 6% with sentinel node dissection.⁴ In a review of exercise programs in the recovery of breast cancer patients, early exercise with the upper extremities improved shoulder function and range of motion but did not increase lymphedema. Early exercise interventions were superior to delayed exercise interventions.¹⁶⁴ In a randomized controlled trial of progressive weightlifting twice weekly in patients with breast cancer, this program did not exacerbate lymphedema but instead reduced lymphedema and its symptoms and increased strength.¹⁶⁵ In a systematic review of 11 RCTs, resistance training did not significantly reduce lymphedema, but did increase muscle strength and improved body mass index and QOL. There were no ill effects to weight training for lymphedema, and moreover, it was found to be safe.¹⁶⁶ Moderate exercise can help relieve limited range of motion of the shoulder, pain, and fatigue during radiation therapy in breast cancer patients.¹⁶⁷

Aromatase inhibitors can cause arthralgias and joint stiffness. In a randomized controlled trial of acupuncture, these symptoms were significantly relieved.¹⁶⁸ Acupuncture also increased shoulder range of motion and decreased lymphedema and its symptoms of heaviness and tightening in a small study by Alem and Gurgel.¹⁶⁹ In a systematic review, acupuncture reduced lymphedema by 1 cm in arm circumference.¹²⁵ Massage can help with pain and edema control. Massage is recommended only with a trained health professional in this area of treatment. Deep massage into vulnerable tissue is not recommended.³⁴

Dermatitis From Radiation Therapy

Calendula cream applied multiple times daily to the skin being irradiated can reduce the severity of dermatitis from therapy.¹⁷⁰ Aloe vera lotion applied prophylactically to the skin reduced radiation-induced dermatitis.¹⁷¹

“Chemobrain” or Postcancer Treatment Cognitive Changes

Cognitive changes which commonly occur during and after breast cancer treatment may be caused by a number of factors, and it is unclear whether chemotherapy is the main cause.¹⁷² In one small RCT study of breast cancer patients averaging 6 years after treatment, cognitive training that included 48 training sessions over 12 weeks with a computerized, home-based intervention improved cognitive function especially the executive functions of thinking and problem-solving.¹⁷³ Another study of cognitive behavioral therapy for cancer-related fatigue showed improvement in perceived cognitive dysfunction.¹⁷⁴

CHAPTER 79

Lung Cancer

Kaushal B. Nanavati, MD, FAAFP, ABIHM, and Eric Reed, BA

Introduction

Lung cancer is the leading cause of cancer-related deaths in the United States, accounting for 26% of cancer-related deaths in women and 28% in men.¹ Lung cancer continues to be the second most common newly diagnosed cancer in both men and women in the United States, accounting for about 13% of all cancer diagnoses. In men, the incidence has been declining since the mid-1980s, but in women, the incidence has only been declining since the mid-2000s.¹ The average age of presentation is 60 years. The lifetime probability of developing lung cancer is 1:13 for men and 1:16 for women. The 5-year survival rate is poor but has improved from 16.4% in 1975 to 21.4% in 2010.²

The lifetime probability of developing lung cancer is 1:13 for men and 1:16 for women.

Pathophysiology

The classical bifurcation of lung cancer is non-small cell lung cancer (NSCLC), the more common type, and small cell lung cancer (SCLC). SCLC is typically less amenable to surgical resection, whereas NSCLC can more often be treated with surgery. NSCLC can be divided into three major histological subtypes: squamous cell carcinoma, adenocarcinoma, and large cell lung cancer. It is also possible for lung cancers that have mixed features to be identified as mixed small cell/large cell cancers.

Signs and Symptoms

Symptoms do not usually occur until the cancer is advanced and can include persistent cough, hemoptysis, chest pain, voice changes such as hoarseness, worsening shortness of breath, recurrent pneumonia, or bronchitis.¹

Risk Factors

Smoking and Tobacco Use

Cigarette smoking is by far the most important risk factor for lung cancer, wherein risk increases with both the quantity and duration of smoking.¹ Approximately 90% of lung cancers are the result of tobacco use, and the risk of a smoker developing lung cancer is 25 times greater than that of a nonsmoker. Smoking is strongly linked with SCLC and squamous cell carcinoma, and adenocarcinoma is the most common type in patients who have never smoked.³

Smoking is strongly linked with SCLC and squamous cell carcinoma. Adenocarcinoma is the most common type in patients who have never smoked.

Environmental Carcinogens

Environmental risk factors that have been implicated in lung cancer include exposure to radon (the second most common cause), secondhand smoke, asbestos, metals (chromium, cadmium), tar exposure, arsenic, certain organic chemicals such as bis(chloromethyl) ether, silica, radiation exposure, air pollution, and diesel exhaust. Certain occupations may increase exposure to lung carcinogens, including rubber manufacturing, paving, roofing, painting, and chimney sweeping. In addition to asbestos exposure, cigarette smoke greatly increases the chances of an asbestos-related lung cancer.¹

Genetics and Biomarkers

Lung cancer is a complex and heterogeneous disease, not only at the biochemical level (genes, proteins, metabolites) but also at the tissue, organism, and population levels.⁴ There are many early detection

biomarkers for lung cancer, including both tissue- and biofluid-based biomarkers such as airway epithelium, sputum, blood, and exhaled breath. Mutations in p53 have been seen in chronic smokers before there is evidence of neoplasia, making it a potentially useful predictor of lung cancer. Due to the heterogeneity of lung cancer, detection by one single biomarker remains difficult. Panels of biomarkers can be used, but these frequently have overlap with other diseases, especially other cancers and inflammatory conditions.⁵

Mutations in p53 have been seen in chronic smokers before there is evidence of neoplasia, making it a potentially useful predictor of lung cancer.

Screening and Detection

Spiral Computed Tomography

Compared with standard chest X-ray (CXR), screening with spiral computed tomography (CT) has been shown to reduce lung cancer–related deaths by 16–20% among adults with a 30 pack-year history who were current smokers or who had quit within the past 15 years.¹ Current American Cancer Society guidelines suggest discussing utilization of low-dose helical CT (LDCT) in current or former smokers aged 55–74 years in good health with at least a 30 pack-year history of smoking. A “pack-year” is the packs of cigarettes smoked a day (1 pack = 20 cigarettes) multiplied by the number of years smoked. “Clinicians with access to high-volume, high-quality lung cancer screening and treatment centers should initiate a discussion about lung cancer screening with apparently healthy patients ages 55–74 who have at least a 30 pack-year smoking history and who currently smoke or have quit within the past 15 years. A process of informed and shared decision making with a clinician related to the potential benefits, limitations, and harms associated with screening for lung cancer with LDCT should occur before any decision is made to initiate lung cancer screening. Smoking cessation counseling remains a high priority for clinical attention in discussions with current smokers, who should be informed of their continuing risk for lung cancer. Screening should not be viewed as an alternative to smoking cessation.”⁶

Low-dose helical CT (LDCT) ([Fig. 79.1](#)) is recommended annually starting at age 55 until age 79 in those with a 30 pack-year smoking history. This recommendation continues if a nodule measuring ≤ 4 mm is found. For nodules that measure 4–6 mm, repeat LDCT in 6 months. If the nodule grows to 6–8 mm or greater, radiology may recommend positron emission tomography (PET)/CT or bronchoscopy based on nodule characteristics.

Chest Radiography

CXR is no longer recommended as a screening technique for lung cancer and is less useful than newer technologies such as LDCT. According to the large Prostate, Lung, Colorectal, and Ovarian cancer screening trial published in 2011, annual screening with chest radiography did not reduce lung cancer mortality when compared with a “usual care” group who did not receive an annual chest radiograph.⁷

Sputum Cytology

This technique is more likely to be helpful in the detection of cancers that start in the major airways, such as squamous cell lung cancers.⁸ According to four prospective randomized controlled studies of lung cancer screening using a combination of CXR and sputum cytology, there was no significant reduction in lung cancer mortality associated with an invitation to undergo sputum cytology screening.⁶

FIG. 79.1 A nodule detected in the right lower lobe with low-dose helical computed tomography (CT) in screening for lung cancer. From Tzung B, Julien PJ. Lung cancer screening. In: Lewis MI, McKenna RJ Jr, et al., eds. *Medical management of the thoracic surgery patient*. Philadelphia: Saunders Elsevier; 2010:197–200.)

Positron Emission Tomography

Not all patients with lung cancer will require a PET scan; however, it can be a useful tool for determining cancer staging.⁹ It can be effective for determining the level of tissue activity and is more effective than CT in distinguishing between benign and malignant lesions.¹⁰ Glucose uptake alone is nonspecific because it can be increased with inflammatory conditions.

Laser Bronchoscopy

Conventional white–light bronchoscopy (WLB) alone identifies the lesion in only 29% of cases.¹¹

Integrative Therapy

Mind–Body Modalities

Patients with lung and other poor-outlook cancers are particularly vulnerable to heavily promoted claims for unproven or disproven “alternatives.” Inquiring about patients’ uses of these therapies should be routine because these practices may be harmful and can delay or impair treatment. Physician-guided mind–body modalities and massage therapy can reduce anxiety, mood disturbance, and chronic pain. Acupuncture can assist in the control of pain and other side effects and help reduce quantities of pain medication required.¹²

Yoga

Some controlled trials suggest yoga is beneficial for chemotherapy-induced nausea, anticipatory nausea, pain, invigoration, acceptance, fatigue, and appetite loss, and can decrease salivary cortisol levels. Investigators also report a positive dose-response relationship.¹³

Massage

Massage therapy, an effective adjunct to cancer supportive care, can reduce anxiety, depression, and pain. The evidence that supports its effect on anxiety is stronger than that on depression. However, there is a lack of systematic reviews regarding consistent massage methodology and quality for most of the clinical trials.¹³

Exercise-Based Pulmonary Rehabilitation

Overall, the studies published to date suggest that short-term (6–8 weeks), low-intensity, multidisciplinary, exercise-based rehabilitation is potentially feasible and safe for select patients with inoperable NSCLC. The preliminary data further suggest that low-intensity, multidisciplinary, exercise-based rehabilitation is associated with modest improvements in exercise tolerance and functional capacity endpoints in select patients who are able to tolerate and achieve reasonable adherence.

Published studies have important methodological limitations, and further carefully designed studies in select populations are warranted¹³ (see [Chapter 92](#)).

Acupuncture

Acupuncture is a relatively safe and minimally invasive modality that may be useful for treating symptoms of lung cancer and side effects of anticancer treatment. A small case series showed some improvement in both an analog pain scale and well-being score for patients with lung cancer.¹⁴ Overall, there is a lack of data on whether acupuncture could be useful in the treatment of chemotherapy-induced peripheral neuropathy.¹³

Nutrition

Nausea and vomiting are common side effects of chemotherapy treatments. There are numerous methods for treating chemotherapy-related nausea, including corticosteroids, dopamine antagonists, serotonin antagonists, benzodiazepines, aprepitant, and cannabinoids. Ginger can also be recommended for both its anti-nausea and anticancer benefits.¹⁵ Generally, a diet rich in nonstarchy vegetables and fruits and low in red meat is recommended. B-complex vitamins, tea, and cruciferous vegetable can also be recommended. For patients with weight loss, nutritional supplements may be recommended along with a diet rich in protein while still limiting red meat consumption. In patients with sarcopenia, supplementation with n-3 fatty acids may be beneficial.¹³ Oral supplementation of eicosapentaenoic acid (EPA) in patients with NSCLC significantly improves energy, protein intake, and body composition, while decreasing fatigue, neuropathy, and loss of appetite, according to a recent randomized trial.¹⁶

In general, a diet rich in nonstarchy vegetables and fruits and low in red meat is recommended.

Curcumin

Curcumin, also called diferuloylmethane, is a hydrophobic polyphenol that is the main curcuminoid of turmeric. “The mechanisms implicated in the inhibition of tumor genesis by curcumin are diverse and appear to

involve a combination of antiinflammatory, antioxidant, immunomodulatory, proapoptotic, and anti-angiogenic properties via pleiotropic effects on genes and cell-signaling pathways at multiple levels.”¹⁷ Gene inhibition of cyclooxygenase (COX)-2 is thought to be the main antiinflammatory activity of curcumin. Curcumin tends to be well tolerated; however, its systemic bioavailability after oral dosing is poor, which may limit its effectiveness outside the gastrointestinal tract. Piperine, a major component of black pepper, has been shown to increase the bioavailability of curcumin.¹⁸

Piperine, a major component of black pepper, has been shown to increase the bioavailability of curcumin.

Smoking Cessation

Smoking cessation continues to be the most important factor in reducing the risk for lung cancer. People who discontinue smoking, even well into middle age, avoid most of their subsequent risk for lung cancer, and discontinuing smoking before middle age avoids more than 90% of the risk attributable to tobacco.¹⁹

Traditional Treatments

Traditional treatments include surgery, radiofrequency ablation (RFA), radiation therapy, chemotherapies, targeted therapies, and immunotherapy. Palliative therapies may also be used to help with symptoms.

Surgery

Surgery to remove lung cancer may be an option for early stage NSCLC. More advanced lung cancer, especially with metastasis, may not be helped by surgery. If surgery can be done early, it provides the best chance to cure NSCLC. The risk for serious consequences is high.⁸ Types of lung surgery include pneumonectomy, lobectomy, and segmentectomy (wedge resection).

Radiofrequency Ablation

RFA may be useful for some small NSCLC tumors that are near the outer

edge of the lungs, especially in people who cannot tolerate surgery. In RFA, a thin probe is inserted through the skin and into the tumor. The probe is used to heat the tumor to destroy the cancer cells. This is typically done as an outpatient procedure. Major complications are uncommon but can include a partial collapse of the lung or bleeding into the lung.⁸

Radiofrequency ablation (RFA) may be useful for some small NSCLC tumors that are near the outer edge of the lungs, especially in people who cannot tolerate surgery.

Chemotherapy

Patients with SCLC are frequently treated with chemotherapy. If the disease is in a limited stage, radiation therapy and rarely surgery may be used for SCLC.²⁰ The side effects of treatment with chemotherapy for SCLC include hair loss, mouth sores, loss of appetite, nausea, vomiting, diarrhea, constipation, immunodeficiency, easy bruising, and fatigue.²⁰

Radiation Therapy

The two major types of radiation therapy include external beam radiation therapy (EBRT) and brachytherapy, a type of internal radiation therapy. The use of EBRT is less common than in the past because there are newer treatments that allow for greater accuracy.⁸ When radiation is given with chemotherapy, the side effects are often worse.

Therapies to Consider

Further research is ongoing at various stages with herbal and natural preparations with astragalus, ginseng, pomegranate, rosemary, sage, parsley, oregano, and various combinations of Chinese herbs, although definitively conclusive evidence is not yet apparent.^{21,23}

Techniques such as mindfulness-based stress reduction, group visit models for education and clinical evaluation, green space exposure, and engagement are being evaluated and studied further to assess their potential impact on health-related quality of life.

Prevention Prescription

- Assess patient readiness for smoking cessation and assist them toward quitting smoking.
- Guide patients to avoid smoke-filled areas and secondhand smoke exposure.
- Educate patients on environmental and occupational hazards and provide resources that guide people on appropriate safety measures and precautions to minimize exposure.
- A diet rich in nonstarchy vegetables and fruits and low in red meat is recommended. Processed meats should be avoided.
- Regular physical exercise is recommended. Encourage people to get 150 minutes of moderately intense exercise weekly and 2 days of strength training.

Therapeutic Review

This review is based on the American College of Chest Physician's evidence-based clinical guidelines for complementary therapies and integrative medicine in lung cancer.²²

Nutrition

- In people who might develop lung cancer, a diet rich in nonstarchy vegetables and fruits is suggested to reduce the risk for lung cancer. 
- In people who might develop lung cancer, limiting the consumption of a large amount of red and processed meat is suggested; lower meat consumption may reduce the risk for lung cancer. 
- In patients undergoing treatment of lung cancer who have experienced weight loss, the addition of high-calorie and protein supplements (1.5 kcal/mL) as a nutritional adjunct is suggested to achieve weight stabilization. 
- In patients with lung cancer who have sarcopenia, oral nutritional supplementation with n-3 fatty acids is suggested in order to improve nutritional status. 

Mind-Body

- Mind–body modalities are suggested as part of a multidisciplinary approach to reduce anxiety, mood disturbance, sleep disturbance, and improve quality of life (QOL). 
- Mind–body modalities are suggested as part of a multidisciplinary approach to reduce acute or chronic pain. 
- Mind–body modalities are suggested as part of a multidisciplinary approach to reduce anticipatory chemotherapy-induced nausea and vomiting. 

Acupuncture

- In patients with cancer-related pain and peripheral neuropathy, acupuncture is suggested as an adjunct treatment in patients with inadequate control of symptoms. 
- In patients having nausea and vomiting from either chemotherapy or radiation therapy, acupuncture or a related technique is suggested as an adjunct treatment option. 

Massage

- In lung cancer patients whose anxiety or pain is not adequately controlled by usual care, the addition of massage therapy performed by trained professionals is suggested as part of a multimodality cancer supportive care program. 

Yoga

- Yoga, a movement-based mind–body modality, is suggested as part of a multidisciplinary approach to reduce fatigue and sleep disturbance while improving mood and QOL. 

Pulmonary Rehabilitation Exercises

- In postsurgical lung cancer patients with compromised lung function, supervised exercise-based pulmonary rehabilitation is suggested to improve cardiorespiratory fitness and functional capacity. 

- In advanced (inoperable) lung cancer patients receiving palliative anticancer therapy and with compromised lung function, supervised exercise-based pulmonary rehabilitation is suggested to improve cardiorespiratory fitness and functional capacity.

CHAPTER 80

Prostate Cancer

Richard T. Lee, MD

Background

Prostate cancer accounts for nearly one-quarter of all newly diagnosed cancers in men and is the most common cancer found in them. It is also currently the second leading cause of cancer-related death among men in the United States.¹ Although approximately one in seven men will be diagnosed with prostate cancer, only a small percentage will die because of it.² Among men newly diagnosed with prostate cancer, more than 90% will live for 5 years and even past 10 years.³ This demonstrates that for the majority of patients with prostate cancer, the disease may prove to be indolent, and they may eventually die of other causes.

The single most important risk factor is age as 95% of all cases occur in men aged 50 years and older.⁴ Other risk factors include an African ancestry and family history ([Box 80.1](#)). Individuals with a strong family history such as two or more close relatives diagnosed under the age of 55 may want to consider further evaluation with a genetic counselor. Additionally, certain genetic syndromes, such as Lynch syndrome and *BRCA1/2* mutations, have also been linked with increased risk and may be associated with 5%–10% of all cases. Other factors that may change the biology of prostate cancer but not incidence include obesity, a diet high in meat or dairy, and smoking.⁵

BOX 80.1 Risk Factors for Prostate Cancer

Age

Family history

African American race

Obesity

Prostate Cancer Screening

The main function of the prostate is to produce seminal fluid. Symptoms of localized prostate cancer are similar to those of benign prostatic hyperplasia (BPH)—aka benign enlarged prostate. Men may experience increased urination, including at night, difficulty emptying the bladder, and difficulty starting urination.

Prostate cancer screening remains a controversial topic in the medical community as studies have conflicting data on the survival benefit of screening with a prostate-specific antigen (PSA). The United States Preventive Task Force recommends against routine screening with the PSA test, while the American Cancer Society (ACS) and American Urological Association (AUA) currently recommend the PSA for informed men who wish to be tested and have a life expectancy of at least 10 years. Specifically, the ACS recommends starting the screening at the age of 50 years for the general male population, 45 years for men with increased risk factors, and 40 years for men with a risk for hereditary prostate cancer (several first-degree relatives diagnosed before the age of 65 years). Although the PSA can detect prostate cancer at an early stage, the concern is that it will detect insignificant cancers that will not have an impact on overall survival and may adversely affect quality of life. The counter argument is that the portion of PSA-detected prostate cancers are clinically significant and, if left untreated, will lead to prostate cancer-specific death.⁶

Two large randomized controlled trials were conducted to test the impact of prostate cancer screening on prostate cancer-related mortality. The trials reached different conclusions. At 7 and 10 years, the Prostate, Lung, Colorectal, and Ovarian (PLCO) cancer screening trial failed to show a reduction in prostate cancer-related mortality in men who underwent prostate screening compared with the control arm.⁷ Conversely, the European Randomized Study for Prostate Cancer (ERSPC) showed 20% fewer deaths in the screening arm than in the control arm after a mean of 8.8 years.⁸ However, to prevent one prostate cancer-related death, 1410 men (or 1068 men who actually participated in screening) would have to be screened (NNS) and an additional 48 men would have to be treated (NNT). A further decrease in prostate cancer-specific mortality was seen among men who had been on the trial for 12 years (36% lower mortality; NNS = 500). The incidence of T3 and T4

tumors was 22% lower, and the incidence of M1 lesions was 41% lower in the screening arm of the ERSPC trial than in the control arm. Fundamental differences between the two studies may account for the divergent conclusions.

The ERSPC trial studied 162,000 men from seven European countries, whereas the PLCO trial studied 76,693 men from a single country. The majority of men (85%) with indications for biopsy in the ERSPC trial accepted a prostate biopsy. In contrast, only 30% of men in the screening arm in the PLCO study with an abnormal PSA level had a prostate biopsy. Moreover, in the PLCO trial, 52% of the men in the control arm underwent PSA screening during the study, which may explain why the incidence of and death rate due to prostate cancer were not significantly different between the screening and control arms.

Some data exist to further help identify patients with increased risk for prostate cancer by incorporating percentage-free PSA and PSA velocity.⁶ Percentage-free PSA measures the ratio between total PSA (bound and unbound) and unbound or “free” PSA. This test is most useful for PSA values between 4 and 10 ng/mL. The lower the percentage, the higher the risk of prostate cancer.⁹ For example, in men aged 50–64 years, if the percentage-free fraction is more than 25%, there is only a 5% risk of prostate cancer; however, if it is less than 10%, the risk of prostate cancer jumps to 56%. Unlike the total PSA value, the percentage-free PSA is affected by manipulation of the prostate gland. Therefore, the clinician should not order a percentage-free PSA test on the same day as rectal examination or within 24 hours of intercourse. PSA velocity (PSAV) is determined by measuring three PSA values at least 6 months apart. A PSAV of more than 0.75 ng/mL per year in men with PSA values between 4 and 10 ng/mL is associated with an increased risk of prostate cancer.⁶ PSAV is also relevant for men with PSA values less than 4 ng/mL in which a PSAV of more than 0.4 ng/mL per year may be associated with adverse pathological features and a two-fold increase in significant prostate cancer.¹⁰ The use of free PSA and PSAV is not considered a standard evaluation for screening of prostate cancer.

Overall, all men should have a discussion with their medical team about the controversy regarding screening that is performed using PSA detailing the risks and benefits. Patients with symptoms and/or a strong family history should consider having this discussion before age 50.

Unlike the total PSA value, the percentage-free PSA is affected by

manipulation of the prostate gland. Therefore the clinician should not order a percentage-free PSA test on the same day as rectal examination or within 24 hours of intercourse.

Prostate Cancer Diagnosis and Staging

The finding of elevated PSA levels (>4 ng/mL) can be due to noncancerous reasons, such as prostatitis, BPH, and urinary tract infection. A digital rectal exam should also be performed if prostate cancer is suspected and will not affect the general PSA test. An elevated PSA more than 20 ng/mL significantly increases the likelihood of prostate cancer. Regardless of the PSA, the diagnosis of prostate cancer requires a tissue biopsy similar to most other cancers. Normally, a sample of 8–12 needle biopsies will be performed in order to sample different regions of the prostate gland.

The pathologists will examine the biopsy, and if prostate cancer is present, a Gleason scoring system is used to grade the aggressiveness of the histology seen ([Table 80.1](#)). The lowest score is 1 and the highest 5, with the pathologist providing two numbers—the most predominant grade seen and the highest grade in the entire sample. For example, a low-grade prostate cancer may be reported as 3+3 in 1 out of 10 cores, while a high-grade sample may have a score of 4+5 in 10 out of 10 cores. For precancerous lesions, the term high-grade prostatic intraepithelial neoplasia (HGPIN) is used, and these may require follow-up biopsies.

Further evaluation studies may be indicated depending on the risk of further spread to other tissues. Individuals with a high PSA (10–20 ng/mL) and a T1–2 or Gleason > 8 or T3–4 should undergo bone scan to search for bone metastases and/or a computed tomography (CT)/magnetic resonance imaging (MRI) to search for lymph node involvement. Patients with symptoms consistent with metastases, such as bony pain, should also be considered for further imaging to complete staging evaluation. For patients with a more limited prognosis (<5 years) due to other comorbidities, a discussion should be conducted about whether to pursue further diagnostic tests, especially if these will not result in pursuit of treatment. Once the workup has been completed, staging can be accurately determined. This is critical as the staging will help determine the most appropriate therapy ([Table 80.2](#)).

TABLE 80.1

T Categories (Clinical)

There are four categories for describing the local extent of a prostate tumor, ranging from T1 to T4. Most of these have subcategories as well.	
T1	Your doctor cannot feel the tumor or see it with imaging such as transrectal ultrasound.
• T1a	Cancer is found (accidentally (by accident) during a transurethral resection of the prostate (TURP) that was done for benign prostatic hyperplasia (BPH). Cancer is in no more than 5% of the tissue removed.
• T1b	Cancer is found during a TURP but is in more than 5% of the tissue removed.
• T1c	Cancer is found by needle biopsy that was done because of an increased PSA.
T2	Your doctor can feel the cancer with a digital rectal exam (DRE) or see it with imaging such as transrectal ultrasound, but it still appears to be confined to the prostate gland.
• T2a	The cancer is in one-half or less of only one side (left or right) of your prostate.
• T2b	The cancer is in more than half of only one side (left or right) of your prostate.
• T2c	The cancer is in both sides of your prostate.
T3	The cancer has grown outside your prostate and may have grown into the seminal vesicles.
• T3a	The cancer extends outside the prostate but not to the seminal vesicles.
• T3b	The cancer has spread to the seminal vesicles.
T4	The cancer has grown into tissues next to your prostate (other than the seminal vesicles), such as the urethral sphincter (muscle that helps control urination), rectum, bladder, and/or the wall of the pelvis.

N Categories

N categories describe whether the cancer has spread to nearby (regional) lymph nodes.

NX	Nearby lymph nodes were not assessed.
N0	The cancer has not spread to any nearby lymph nodes.
N1	The cancer has spread to one or more nearby lymph nodes.

M Categories	
M categories describe whether the cancer has spread to distant parts of the body. The most common sites of prostate cancer spread are to the bones and to distant lymph nodes, although it can also spread to other organs such as the lungs and liver.	
M0	The cancer has not spread past nearby lymph nodes.
M1	The cancer has spread beyond the nearby lymph nodes.
• M1a	The cancer has spread to distant (outside of the pelvis) lymph nodes.
• M1b	The cancer has spread to the bones.
• M1c	The cancer has spread to other organs such as lungs, liver, or brain (with or without spread to the bones).

TABLE 80.2 Stage Grouping

Once the T, N, and M categories have been determined, this information is combined, along with the Gleason score and prostate-specific antigen (PSA) level, in a process called <i>stage grouping</i> . If the Gleason score or PSA level are not available, the stage can be based on the T, N, and M categories. The overall stage is expressed in Roman numerals from I (the least advanced) to IV (the most advanced). This is done to help determine treatment options and the outlook for survival or cure (prognosis).	
Stage I One of the following applies	T1, N0, M0, Gleason score 6 or less, PSA less than 10 The doctor cannot feel the tumor or see it with an imaging test such as transrectal ultrasound (it was either found during a transurethral resection or diagnosed by needle biopsy done for a high PSA) (T1). The cancer is still within the prostate and has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The Gleason score is 6 or less, and the PSA level is less than 10.
	T2a, N0, M0, Gleason score 6 or less, PSA less than 30 The tumor can be felt by digital rectal exam or seen with imaging such as transrectal ultrasound and is in one-half or less a fourth one side (left or right) of the prostate (T2a). The cancer is still within the prostate and has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The Gleason score is 6 or less, and the PSA level is less than 10.
Stage IIA One of the following applies	T1, N0, M0, Gleason score 6-7, PSA less than 20 The doctor cannot feel the tumor or see it with imaging such as transrectal ultrasound (it was either found during a transurethral resection or was diagnosed by needle biopsy done for a high PSA level) (T1). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor has a Gleason score of 7. The PSA level is less than 20.
	T1, N0, M0, Gleason score 6 or less, PSA at least 10 but less than 20 The cancer cannot feel the tumor or see it with imaging such as transrectal ultrasound (it was either found during a transurethral resection or was diagnosed by needle biopsy done for a high PSA) (T1). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor has a Gleason score of 6 or less. The PSA level is at least 10 but less than 20.
	T2a or T2b, N0, M0, Gleason score of 7 or less, PSA less than 20 The tumor can be felt by digital rectal exam or seen with imaging such as transrectal ultrasound and is in only one side (left or right) of the prostate (T2a or T2b). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). It has a Gleason score of 7 or less. The PSA level is less than 20.
Stage IIB One of the following applies	T2c, N0, M0, any Gleason score, any PSA The tumor can be felt by digital rectal exam or seen with imaging such as transrectal ultrasound and is in both sides of the prostate (T2c). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor can have any Gleason score, and the PSA can be of any value.
	T1 or T2, N0, M0, any Gleason score, PSA of 20 or more The cancer has not yet spread outside the prostate. It may (or may not) be felt by digital rectal exam or seen with imaging such as transrectal ultrasound (T1 or T2). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor can have any Gleason score. The PSA level is at least 20.
	T1 or T2, N0, M0, Gleason score of 8 or higher, any PSA The cancer has not yet spread outside the prostate. It may (or may not) be felt by digital rectal exam or seen with imaging such as transrectal ultrasound (T1 or T2). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The Gleason score is 8 or higher. The PSA can be of any value.
Stage III	T3, N0, M0, any Gleason score, any PSA The cancer has grown outside the prostate and may have spread to the seminal vesicles (T3), but it has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor can have any Gleason score, and the PSA can be of any value.
Stage IV One of the following applies	T4, N0, M0, any Gleason score, any PSA The cancer has grown into tissues next to the prostate (other than the seminal vesicles), such as the urethral sphincter (muscle that helps control urination), rectum, bladder, and/or the wall of the pelvis (T4). The cancer has not spread to nearby lymph nodes (N0) or elsewhere in the body (M0). The tumor can have any Gleason score, and the PSA can be of any value.
	Any T, N1, M0, any Gleason score, any PSA The tumor may or may not be growing into tissues near the prostate (any T). The cancer has spread to nearby lymph nodes (N1) but has not spread elsewhere in the body (M0). The tumor can have any Gleason score, and the PSA can be of any value.
	Any T, any N, M1, any Gleason score, any PSA The cancer may or may not be growing into tissues near the prostate (any T) and may or may not have spread to nearby lymph nodes (any N). It has spread to other more distant sites in the body (M1). The tumor can have any Gleason score, and the PSA can be of any value.

Integrative Therapy

An integrative approach to prostate cancer aims to enhance care for the patient by implementation of a comprehensive, evidence-based treatment plan that will lead to optimal outcomes both in regards to the treatment of the cancer as well as the health and wellbeing of the patient. At the core remain conventional treatment approaches that continue to lead to improvement in cure and/or disease control for the patient, depending on the stage. Treatment planning should also include consideration of comorbidities and life expectancy. Patients with stage I prostate cancer are often monitored as they may not require surgery, especially if they have other active comorbidities and/or limited life expectancy of less than 10 years. Intermediate stage prostate cancers (stage II–III) are highly curable, and treatment should be discussed unless the patient has a limited life expectancy. Patients with advanced prostate cancers (stage IV) should be offered treatment as the disease is likely to impact survival and quality of life.

Conventional Treatments

Observation

Observation and active surveillance is a reasonable approach for patients with early-stage, low-grade prostate cancer as indicated by a T1 or T2a lesion with a Gleason ≤ 6 and a PSA < 10 ng/mL. This is especially true for patients that have a life expectancy of < 10 years due to other comorbidities. These patients are often reevaluated every 6–12 months unless other symptoms arise. Such patients should be encouraged to incorporate other aspects of an integrative approach focusing on optimizing their health and well-being, which may have an impact on disease trajectory.

Definitive Treatment—Surgery and Radiation

Patients with early to intermediate stage prostate cancer (stage I–III) have a very good chance for cure, with overall 5-year survival rates more than 95%. These patients should undergo evaluation for definitive curative therapy with surgery or radiation. Both options have essentially equivalent outcomes in terms of disease control, although they each have their own side-effect profile. Surgery involves a radical prostatectomy (RP) and pelvic lymph node dissection (PLND) that will remove the prostate and local lymph nodes. Patients need to undergo presurgical evaluation to determine if they are good surgical candidates. Radiation therapy is available in two forms—external beam radiotherapy (EBRT) and brachytherapy. The latter involves the placement of radioactive seeds into the prostate. Each of these therapies has its own side-effect profile and involves different short- and long-term risks, with erectile dysfunction, incontinence, gastrointestinal side effects due to EBRT, skin changes, and hematuria being some of the most common. Additionally, some patients may have difficulty undergoing 4–6 weeks of EBRT, while RP + PLND and brachytherapy may only require a shorter treatment period. Most patients should undergo evaluation by both a surgeon and radiation oncologist to help make an informed decision about what option would be best for that individual.

Hormonal Therapy

A varietal of hormonal therapies are used to help reduce the risk of recurrence and control metastatic disease as prostate cancer is very sensitive to changes in testosterone levels. The most common initial

therapy is called androgen deprivation therapy (ADT) and typically involves luteinizing hormone–releasing hormone (LHRH) for which there are several agonist/antagonists. These essentially will cause the circulating level of testosterone to go <50 ng/dL (normal: 250–1000 ng/dL) and for almost all patients, lead to disease control. Patients with high-risk, intermediate-stage prostate cancer may be provided LHRH therapy for 4–6 months after EBRT. For patients with metastatic disease (stage IV), LHRH is considered the standard first-line therapy.

Abiraterone is another hormonal therapy that blocks testosterone production by inhibiting the CYP17 enzyme and is commonly used when resistance to an LHRH therapy develops, which is referred to as castrate-resistant prostate cancer (CRPC). Antiandrogens, such as bicalutamide, are often combined with LHRH therapy when CRPC develops. Enzalutamide is a newer agent that is an antiandrogen and blocks signaling of the androgen receptor. Other hormonal therapies include corticosteroids, ketoconazole, and estrogen.

The low levels of testosterone induced by hormonal therapy may cause a variety of side effects, including hot flashes, impotence, decreased libido, osteoporosis, anemia, loss of muscle mass, weight gain, fatigue, and mood changes. Many patients will be on hormonal therapy for months to years and thus are at risk for developing metabolic changes such as obesity, insulin resistance, and elevated triglycerides. Patients may want to consider integrative therapies to help mitigate many of these side effects, and these are discussed later in this chapter.

Chemotherapy

In the past, chemotherapy was usually reserved until after resistance to hormonal therapies, although based on new data, chemotherapy is now often considered much earlier in patients with aggressive metastatic disease.¹¹ More commonly used chemotherapies include docetaxel, cabazitaxel, and mitoxantrone with prednisone. These are intravenously administered on an every 3-week schedule. As with other chemotherapies, these may lead to fatigue, nausea, vomiting, low blood counts, and hair thinning. A trial of 4–6 cycles is usually provided, followed by restaging studies to determine response to treatment.

Immunotherapy

Sipuleucel-T is a cancer vaccine specific for prostate cancer and has been shown to prolong survival for approximately 4 months. This therapy

involves collection of blood from patients, to obtain their white cells, and then shipping it to the laboratory for processing. Several weeks later after the activation of white cells, the patients receive three infusions of their own activated white cells, each 2 weeks apart. Patients may experience side effects similar to those experienced after transfusion, including chills, fevers, and fatigue.

Lifestyle Therapy

A pilot study of men with prostate cancer examining the effects of an intensive integrative program of diet, exercise, and mind-body approaches was able to find biological changes that would impact the progression of prostate cancer.¹²⁻¹⁴

Smoking

Among other carcinogens, tobacco contains cadmium, a heavy metal that may increase prostate cancer risk.¹⁵ Although data for smoking and an increased risk of prostate cancer are conflicting, smoking increases the risk of lung, bladder, and other epithelial cancers, and it may induce a more aggressive form of prostate cancer. According to a meta-analysis of 24 prospective cohort studies, the heaviest smokers had a 24%–30% greater risk of death from prostate cancer compared with nonsmokers.¹⁶

The message is clear: do not smoke.

Physical Fitness and Obesity

A growing body of research indicates that prostate cancer biology may respond to specific integrative therapies, such as exercise. Additionally, some of the side effects experienced by prostate cancer patients can be treated using nonpharmacological integrative therapies. At a minimum, patients with prostate cancer should focus on guidelines published by the ACS and American Institute for Cancer Research (AICR) to help reduce side effects and improve quality of life.^{5,17} A provocative pilot study in 10 men demonstrated that a plant-based diet in the context of mindfulness-based stress reduction delayed PSA doubling time from 6.5 to 17.7 months.¹⁸ Regardless of the food source, excessive calorie intake promotes obesity, which increases premature mortality and overall cancer-related death rates, including prostate cancer.^{19,20} This was also shown in a study looking at the role of weight and risk of death after diagnosis showing obese men with prostate cancer had a 34% increase in

the risk of death.²¹

Nutrition

The role of nutrition is growing, and several cancers are known to be impacted, both positively and negatively, by certain types of foods. Additionally, specific foods are currently being researched as potential therapies for prostate cancer; however, the research remains preliminary. Thus incorporation of these food groups is recommended rather than pursuing specific processed supplements. In general, the ACS and AICR guidelines focus on several key components of a healthy diet, and these should be followed by every prostate cancer survivor.

Limiting Red Meat

Limit consumption of red meats (such as beef, pork, and lamb) and avoid processed meats. Men in the highest quartile for red meat consumption have a significantly higher risk of being diagnosed with prostate cancer and a 30% increased chance for development of advanced disease. Processing of meat and barbecuing and grilling of meat is also associated with an increased risk of total and advanced prostate cancer.²²

Limit Consumption of Energy-Dense Foods

Although no known link exists between sugary drinks like sodas and prostate cancer, increased intake of these energy-dense foods may lead to obesity. Thus the AICR recommends reduction of these types of foods to prevent obesity, which is a risk factor for several cancers.

Eat a Variety of Vegetables, Fruits, Whole Grains, and Legumes

Higher vegetable intake, especially cruciferous vegetables, is associated with decreased prostate cancer risk.^{23,24} More recent studies show that a classic Western style diet is associated with 2.5× higher risk of prostate cancer-specific death, and similarly, those following a diet high in fruits and vegetables have a 36% lower risk of death.²⁵ Encourage at least five servings of fruits and vegetables daily.

Soy Protein

Soy protein isoflavones, most notably genistein, inhibit prostate cancer

cell growth in vitro and in vivo by promoting apoptosis; by blocking beta-estrogen receptor activity in the prostate; by inhibiting angiogenesis and endothelial cell proliferation; and by blocking 5- α -reductase, aromatase, and tyrosine-specific protein kinase activity.²⁶⁻²⁸ Even though the age-adjusted incidence of latent prostate cancer in native Japanese and American men is roughly the same, clinical prostate cancer is 10 times higher in American men. Researchers attribute some of this discrepancy to dietary differences. A typical American diet is high in saturated animal fat but low in fruits, vegetables, fish, and soy protein, whereas a typical Japanese diet is the reverse. Japanese men consume substantially more soy protein and fish but less saturated fat from dairy and red meat than American men.²⁷ According to one report, Japanese men have isoflavone concentrations 30 times higher in the urine and more than 100 times higher in the blood than Western men.²⁹ A 16-year-long prospective health study showed that men who consumed several glasses of soy milk daily lowered their risk of prostate cancer by 70%.³⁰ For men with prostate cancer, higher doses of daily soy consumption may provide additional protection. Researchers found that men taking 100 mg of soy isoflavones twice daily slowed the growth of an aggressive form of prostate cancer called androgen-insensitive prostate cancer by 35% and slowed overall cancer growth by 84%.^{31,32} Other studies have found promising, although limited, results in patients with prostate cancer.³³⁻³⁵

Replacing cow's milk with soy milk can be an effective strategy to reduce the risk of prostate cancer.

Soy protein is available in a variety of food items including tofu, tempeh, soy milk, soy cheese, textured soy foods, and soy flour. Soy protein yields up to 3 mg of isoflavones per gram and provides five times as much protein as wheat and 25 times as much protein as beef. Patients with prostate cancer should consider incorporating soy into their diet as it may have beneficial effects for prevention and disease control.

Lycopene

Lycopene is a cancer-fighting antioxidant vitamin that gives tomatoes, strawberries, and watermelon their rosy color. Although not all studies have found that lycopene confers a protective effect against prostate cancer,³⁶ data from a variety of case-control and large prospective studies

focusing on dietary assessment show a beneficial effect, especially against advanced prostate cancer.³⁷⁻³⁹ According to one report, men who consumed tomato products four times weekly reduced their prostate cancer risk by 20% and those who ate 10 or more helpings weekly reduced their risk by 45%.⁴⁰ Studies have also been conducted in men with prostate cancer, with some indicating an ability to impact progression.⁴¹⁻⁴³

Lycopene is found within the cells of tomato and should be cooked to help release lycopene and increase bioavailability. Other sources of lycopene include papaya, watermelon, pink guava, and pink grapefruit. Men with prostate cancer should consider incorporating foods with lycopene.

Pomegranate

Pomegranate juice contains polyphenolic compounds, especially ellagic acid, which exert antiproliferative and antimetastatic effects on prostate cancer cells. According to a phase II study of 46 men with recurrent prostate cancer after surgery or radiation therapy, consumption of 8 oz of pomegranate juice daily significantly slowed PSA doubling time from 15.6 months to 54.7 months.⁴⁴ Pomegranate extract also inhibits prostate cancer cell growth.²⁶ Additional follow-up studies have shown mixed results with the randomized placebo-controlled study showing no difference between groups.⁴⁵⁻⁴⁷

Men with prostate cancer may want to consider incorporating either the fruit or the juice into their diet. Those with diabetes will need to be cautious due to the sugar content.

Green Tea (*Camellia sinensis*)

Green tea contains a variety of antioxidants called catechins that have antitumor activity against prostate cancer cells. In vitro and in vivo studies have shown that green tea can inhibit prostate cancer cell growth by inducing apoptosis, activating tumor suppressor genes, and mitigating the activity of stimulatory messenger molecules. According to preliminary data, the beneficial effect of green tea may be dose related, and it may be more effective against early-stage prostate cancer as opposed to end-stage disease.²⁶ Sixty men with high-grade prostate intraepithelial neoplasia who took 200 mg three times a day of mixed green tea catechins had an 80% reduction in progression to prostate cancer as compared to the placebo group.^{48,49} However, two phase II

clinical trials in men with prostate cancer did not find any clinical benefit.^{50,51}

Green tea has been found to cause liver toxicity when taken in large, concentrated doses.⁵² Additionally, there has been shown to be medication interactions with bortezomib, a chemotherapy for multiple myeloma.⁵³ Patients with liver disease or multiple myeloma should be cautious about ingesting green tea. Otherwise, drinking green tea in moderation (two to three cups daily) may have benefit for those with HGPIN and for prevention.

Flaxseed

Flaxseed contains a variety of compounds, and lignans and α -linoleic acids are actively being evaluated for potential benefits. Lignans are thought to have antioxidant properties and may alter testosterone levels.⁵⁴ A small phase II study examining dietary flaxseed in prostate cancer patients found significant decreases in proliferation rates among men randomized to flaxseed.⁵⁵ More studies are needed to understand this potential outcome. Incorporation of natural flaxseed into the diet is reasonable to consider.

Alcohol

Alcohol yields 9 calories per gram, the same as fat. Therefore, excessive alcohol consumption increases energy intake and promotes obesity. Nevertheless, only a few studies have found a direct association between alcohol consumption and prostate cancer risk. According to one study, excessive drinking of alcohol—more than 96 oz of alcohol weekly (about 10 drinks)—tripled the risk for development of prostate cancer.⁵⁶ On the other hand, moderate consumption of red wine may confer protection against prostate cancer. Red wine is a rich source of resveratrol, a polyphenol that induces apoptosis and modulates androgen receptor function in prostate cancer cell lines.⁵⁷ Researchers reported that men who consumed 4 oz of red wine four times weekly experienced a 50% reduction in prostate cancer and a 60% reduction in the diagnosis of Gleason 8 disease.⁵⁸

If consumed at all, limit alcoholic drinks to two for men and one for women a day.

Limit Salt

Several studies have found that total salt consumption, especially that

linked to preserved foods, increases the risk for cancer, specifically gastric cancer.⁵⁹ Although no strong link exists with prostate cancer, salt intake should be monitored.

Limit consumption of salty foods and foods processed with salt (sodium).

Physical Activity

Although data are inconclusive, physical activity may reduce prostate cancer risk by lowering body fat concentration and by improving use of insulin-like growth factor 1 (IGF-1).¹⁵ IGF-1 has mitogenic and antiapoptotic effects on normal and malignant prostate cells. In one study, men with the highest quartile of IGF-1 levels had a 4.3-fold greater risk for prostate cancer than those in the lowest quartile.⁶⁰ Exercise can also lessen the risk for development of aggressive or advanced prostate cancer. Data from the Health Professionals Follow-Up Study show that men older than 65 years who exercise vigorously at least 3 hours per week in activities such as running, biking, and swimming have a 70% lower risk of being diagnosed with high-grade, advanced, or metastatic prostate cancer.⁶¹ Similarly, a British study of 45,887 men aged 45–79 years showed that men with the highest lifetime physical activity had a 16% overall lower incidence of prostate cancer as well as lower risk of advanced prostate cancer compared with men with the lowest activity. Each 30-minute increment of activity reduced the risk of prostate cancer by 7%.⁶² For men with prostate cancer, data is also growing regarding the benefits including survival. Kenfield et al. published a study following 2705 nonmetastatic prostate cancer patients and found those exercising vigorously ≥ 3 hours had 61% decreased risk of prostate cancer-specific death.⁶³ Additionally, this same cohort demonstrated improvements in quality of life through increased activity.⁶⁴ The ACS and AICR guidelines should be followed.

Men should incorporate moderate-intensity exercise (e.g., walking, jogging, and swimming) for a total time of 150 minutes per week.

Data from the Health Professionals Follow-Up Study show that men older than 65 years who exercise vigorously at least 3 hours per week in activities such as running, biking, and swimming have a 70% lower risk of being diagnosed with high-grade, advanced, or metastatic prostate cancer.⁶¹

Mind-Body Medicine

Psychosocial interventions can improve the quality of life for cancer patients including simple interventions such as meditation, yoga, and support groups. In a study of men undergoing RP, those randomized to a stress management intervention showed improved emotional and physical symptoms, and a correlative study found that subjects maintained immune function better than those in the control group.^{65,66}

Men with prostate cancer should consider utilizing a regular relaxation technique.

Acupuncture

Acupuncture involves the placement of solid, sterile, stainless steel needles into various points on the body to help manage different symptoms. Clinical studies have found acupuncture may help treat nausea caused by chemotherapy drugs and surgical anesthesia and help treat both postoperative and chronic pain in cancer patients.⁶⁷ A growing number of clinical trials, both controlled and uncontrolled, suggests that acupuncture is beneficial for hot flashes experienced by men on ADT.⁶⁸

Supplements

Vitamin E (Mixed Tocopherols) and Selenium

Secondary endpoints from several key epidemiological and prospective cohort studies suggested that vitamin E and selenium supplementation could decrease prostate cancer incidence and mortality, especially among smokers.^{69,70} Accordingly, the Southwest Oncology Group in collaboration with others sponsored a phase III randomized, placebo-controlled trial of 35,553 men to determine whether taking selenium (200 mcg/day from L-selenomethionine) and vitamin E (400 units/day of all-*rac*-tocopheryl acetate), either alone or in combination, to determine if these supplements provided a protective benefit against prostate cancer—the Selenium and Vitamin E Cancer Prevention Trial (SELECT).⁷¹ The study was terminated prematurely after 4 years because of concern about a small but significant increased incidence of prostate cancer in the vitamin E-alone arm and a small but insignificant increase in prostate cancer in the combined vitamin E and selenium arm and the selenium-alone arm. Compared with placebo, the hazard ratios for prostate cancer were 1.13 in the vitamin E-alone cohort, 1.05 in the selenium and vitamin

E cohort, and 1.04 in the selenium-alone cohort. There was also a nonsignificant increase in the risk for development of diabetes (relative risk [RR], 1.07) in the selenium-alone arm.

On the basis of these data, supplementation with vitamin E and selenium for the prevention of prostate cancer is not recommended.

Vitamin D

Vitamin D is a steroid hormone that can be acquired from the diet and dietary supplements, or it can be synthesized in the skin from 7-dehydrocholesterol in response to ultraviolet radiation. Ultraviolet irradiation of ergosterol from yeast yields vitamin D₂. Ultraviolet irradiation of 7-dehydrocholesterol from lanolin yields vitamin D₃. Although there is no consensus on the optimal blood level of vitamin D, deficiency is defined as a 25-hydroxyvitamin D level of less than 30 ng/mL. According to several studies, 40%–100% of men and women still living in the community are deficient in vitamin D.^{72,73} Both prospective and retrospective epidemiological studies have shown that vitamin D deficiency is associated with an increased risk for development of prostate cancer.^{72,74} Vitamin D is involved in the regulation of more than 200 genes, including genes that are responsible for cellular proliferation, differentiation, apoptosis, and angiogenesis. Vitamin D decreases cellular proliferation of normal and cancer cells and promotes their terminal differentiation. It also inhibits prostate cancer invasion and metastasis.^{26,72} Vitamin D intoxication is extremely rare, but it can occur with excessive consumption of vitamin D. Oral supplementation with vitamin D should be monitored with periodical laboratory testing for 25-OH vitamin D levels.

Consider checking vitamin D 25-OH level and supplement the diet with sufficient vitamin D₃ to maintain a vitamin D level of at least 30 ng/mL for bone health. Further supplementation may be required if the level remains low. A rough rule of thumb is to add 1000 IU of D₃ to raise serum levels by 8–10 ng/mL.

Multivitamins

Researchers examined a cohort of 1,063,023 adult Americans between the years of 1982 and 1989 and compared the mortality of vitamin nonusers with that of users of multivitamins alone; vitamin A, C, or E alone; and vitamin A, C, or E in combination. Surprisingly, the risk of dying of prostate cancer significantly increased with more than 5 years of

multivitamin use (RR, 1.31). Furthermore, male smokers who used vitamins A, E, or C alone or in combination with multivitamins had a greater risk of fatal cancer (RR, 1.44 and RR, 1.58) than that of vitamin nonusers.⁷⁵ Data from the National Institutes of Health–American Associations of Retired Persons (AARP) Diet and Health Study showed that men who consumed multivitamins more than seven times per week had a significantly increased risk of advanced or fatal prostate cancer (RR, 1.32 and RR, 1.98).⁷⁶ Neither the ACS nor the AICR guidelines recommend any supplements at this time for cancer prevention.

Therefore multivitamin consumption is not recommended for the prevention or treatment of prostate cancer. Aim to receive all vitamins and minerals through food.

Hormone-Altering Medications and Supplements

Injudicious use of dehydroepiandrosterone (DHEA), androstenedione, and human growth hormone may increase the risk for development of prostate cancer or promote the growth of existing prostate cancer by increasing IGF-1 levels.^{77,78} Although testosterone has not been proven to cause prostate cancer, testosterone is a potent promoter of benign and malignant prostate cell growth. Chondroitin is used as a marker for prostate cancer as there are higher levels in men with it. There is also limited data showing concern that it may promote metastasis and/or recurrence of prostate cancer.⁷⁹

Therefore, men should avoid taking these supplements or androgen replacement therapy unless it is medically indicated, especially men at increased risk for prostate cancer.

Omega-3 Fatty Acids

Although the relationship is complex and data are conflicting, animal data have shown that excess dietary omega-6 polyunsaturated acids generally stimulate tumor growth, whereas omega-3 polyunsaturated fatty acids, especially from fish, and monounsaturated omega-9 fatty acids from olive oil have the opposite effect.⁸⁰⁻⁸² More recent epidemiological studies indicate conflicting data on whether or not n-3 fatty acids are beneficial or harmful.⁸³ Until further research clarifies this relationship, patients should avoid taking concentrated supplements of omega-3 fatty acids.

Pomi-T

A recent study randomized 199 men with localized prostate cancer to a supplement containing pomegranate, green tea, broccoli, and turmeric and demonstrated changes in PSA rise favoring the Pomi-T arm. Further research is needed to determine if this supplement will prove to be beneficial for prostate cancer patients.^{83a}

Pharmaceuticals for Prevention

5 α -Reductase Inhibitors—Finasteride and Dutasteride

Studies have examined the ability of 5 α -reductase inhibitors (finasteride and dutasteride) to prevent prostate cancer. In contrast to finasteride, dutasteride inhibits both type 1 and type 2, 5 α -reductase enzymes. Type 1, 5 α -reductase enzyme predominates in prostate cancer, whereas type 2 enzyme predominates in normal and hyperplastic prostate tissue. The Prostate Cancer Prevention Trial (PCPT) randomized 18,882 men to a 7-year course of placebo or 5 mg of the 5 α -reductase type 2 enzyme inhibitor finasteride daily.⁸⁴ The results showed a 24.4% prevalence rate of prostate cancer in the placebo arm (1147/4692) versus an 18.4% prevalence in the finasteride arm (803/4368). Although there were a higher number of high-grade tumors in the finasteride group, researchers attribute this difference to an artifact of trial design. The Reduction by Dutasteride of Prostate Cancer Events (REDUCE) trial was a randomized, double-blind, placebo-controlled phase III trial of 8000 men from 42 different countries between the ages of 50 and 75 years with a PSA level of 2.5–10 ng/mL with normal findings on prestudy prostate biopsy. The REDUCE trial data showed that dutasteride reduced the risk of prostate cancer during 4 years by 23% compared with placebo.⁸⁵

Nonsteroidal Antiinflammatory Drugs

Aspirin reduces inflammation by inhibiting cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2) enzymes. According to a systematic review of the literature and meta-analysis, long-term consumption of aspirin (5 years or more) was inversely associated with the risk for development of prostate cancer. The risk reduction was more pronounced for advanced prostate cancer (odds ratio [OR] = 0.7) than for total prostate cancer (OR = 0.9).⁸⁶ A cohort study of 70,144 men reported similar findings; regular use of nonsteroidal antiinflammatory drugs (NSAIDs) decreased the risk of prostate cancer by 18% and the risk of advanced prostate cancer by 33%.⁸⁷ Taking one 81-mg baby aspirin daily

may be sufficient to reduce prostate cancer risk.

Suppression of COX-2 activity with COX-2–selective inhibitors may also reduce prostate cancer risk.⁸⁸⁻⁹⁰ Although rofecoxib was withdrawn because of adverse cardiovascular side effects, high doses of the COX-2 inhibitor celecoxib markedly slowed PSA doubling times in men whose PSA level started to rise after local curative therapy without causing any serious adverse cardiovascular effects.⁹¹

These medications are still undergoing evaluation and currently not approved for prostate cancer prevention. These should not be taken without further discussion with the patient and entire medical team to review the risks and benefits. Patients with an elevated risk for prostate cancer (e.g., strong family history) may want to discuss the risks or benefits of these medications. Patients taking anticoagulation or antiplatelet medication and those with a history of heart, renal, or gastrointestinal disease should check with their health care provider before taking aspirin or NSAIDs. The side effects from finasteride and dutasteride include decreased libido and gynecomastia.

Prevention Prescription

- For men at normal risk, discuss the pros and cons of PSA screening at 50 years and provide information on prostate cancer prevention.
- For men at high risk, a careful discussion at 40 years regarding routine screening should include the opposing recommendations from the ACS and United States Preventative Task Force.
- Encourage exercise for 30 minutes or longer at least five times weekly.
- Encourage intake of five to nine servings of fruits and vegetables daily.
- Encourage normal body weight with a goal BMI of 18.5–25.
- Avoid hormone-altering medications such as DHEA, androstenedione, human growth hormone, and testosterone, unless medically indicated.
- Limit meat consumption.
- Limit alcohol intake.
- Emphasize that patients should avoid tobacco products.
- Incorporate soy into the diet.
- Moderate natural dietary intake of soy, green tea, flax seed, lycopene, and pomegranate.

- Incorporate relaxation techniques regularly.

Therapeutic Review

Men with a diagnosis of prostate should focus on a comprehensive approach to their care, incorporating standard treatments along with optimizing their health and minimizing side effects from treatment

Nutrition

- Follow the ACS and AICR guidelines on nutrition. Focus on increasing fruits and vegetables (minimum five servings per day), limiting red meat, alcohol, and energy-dense foods like sugary drinks. Consider incorporating foods like soy, flaxseed, drinking green tea (two to three cups per day), lycopene from cooked tomatoes, and pomegranates. Refer receptive patients to a qualified dietitian. 

Exercise

- Exercise for 30 minutes or longer five times weekly. 
- Consider referral to a physical trainer or physical therapist, especially for patients with physical impairments or risks such as bone metastases.

Supplements

- Check vitamin D levels, and if <30 ng/mL, consider supplementation with vitamin D₃, especially important for patients with bone metastases. 
- Avoid any kind of hormonal supplements like DHEA, human growth hormone, androstenedione, chondroitin sulfate, and supplemental androgens.

Mind-Body

- Discuss mindfulness-based stress reduction techniques, especially for men with high risk, and refer receptive patients to a qualified professional. 

Acupuncture

- Consider using acupuncture to help with symptoms of pain, nausea, or hot flashes. 

Tobacco

- If currently using any form of tobacco, assess for willingness to quit and consider referral to a tobacco treatment program.

CHAPTER 81

Colorectal Cancer

Sriyani Sridhar, MD

Natural History

Most colorectal cancers begin as a noncancerous polyp, which can be detected during a routine screening colonoscopy. From the time the first abnormal cells start to grow into polyps, it takes 10 to 15 years for them to develop into colorectal cancer. Adenomatous polyps have a higher rate of turning into cancer, while hyperplastic and inflammatory polyps are typically not precancerous.² Dysplasia is a type of precancerous condition that is usually seen in people with long-standing ulcerative colitis or Crohn's disease as these conditions cause chronic inflammation of the colon. If cancer forms in a polyp or dysplastic area, it can invade the wall of the colon or rectum locally and progress via lymphatic or hematogenous spread. Patients with oligometastatic disease, where only one or two lesions are present in an organ such as the lung or liver, can still experience long-term disease-free survival after treatment.

Incidence and Prevalence

The lifetime risk for developing colorectal cancer is about 1 in 20 (5%), and it is 60% more common in developed countries. This risk is slightly lower in women than in men, but it is the third leading cause of cancer and second leading cause of cancer-related deaths in the United States.¹ Survival rates have been improving, which is thought to be from more consistent screenings, improvement of treatment regimens, and the adoption of healthier eating habits.

Screening

Regular screening can detect colorectal cancer early when it is most likely to be curable. In many people, screening can also prevent colorectal cancer altogether because polyps can be found and removed before they have the chance to turn into cancer. Colorectal cancer screening tools include the guaiac-based fecal occult blood test (gFOBT) and fecal immunochemical test (FIT), both of which are used to detect blood in the stool; a stool DNA test to check for polyps and cancer; and sigmoidoscopy, colonoscopy, and computed tomography (CT) colonography, which directly visualize the polyp or cancer. The frequencies of screening are as follows: gFOBT/FIT annually, stool DNA test every 3 years, sigmoidoscopy every 5 years with gFOBT/FIT every 3 years, or colonoscopy every 10 years. One in three adults aged 50–75 years has not been screened for colorectal cancer as recommended by the U.S. Preventive Services Task Force. Symptoms of colorectal cancer are nonspecific and include blood in the stool, persistent abdominal pain, and unexpected weight loss but may often only present late into the disease. It is imperative that clinicians encourage patients to pursue routine colorectal cancer screening.

The number needed to screen (NNS) to detect one case of colon cancer is 154 for colonoscopy, 166 for stool DNA panel, and 208 for fecal immunochemical testing.³

Risk Factors

Regular screening and removal of polyps with colonoscopy reduces the risk of developing colorectal cancer by up to 90%. People with a first-degree relative who has had colorectal cancer have two to three times the risk for developing the disease compared with those with no family history. About 20% of all colorectal cancer patients have a close relative who was diagnosed with the disease. About 5% of individuals with colorectal cancer have a genetic syndrome that causes the disease. These individuals should have increased screening frequency based on their risk⁴ ([Table 81.1](#)).

Primary and Secondary Prevention

The modifiable risk factors listed in the following require recommendations to lower risk. However, initiation and maintenance of comprehensive diet and lifestyle changes may not be easy to follow. Clinicians can use motivational interviewing tools to guide people on how to follow sustainable health practices. Up to 70% of colorectal cancers can be prevented by diet and lifestyle changes¹¹ ([Table 81.2](#)).

Integrative Therapy

Nutrition

Part of the reason for the difference in colorectal cancer incidence in other countries compared with that in the United States is the difference in diet. People in other countries, especially Asia, tend to have diets higher in fiber, fish, and vegetables and lower in red meat and processed foods.

TABLE 81.1

Risk Factors

Increase in risk:

- Age older than 50 years
- African-American race
- Personal or family history of adenomatous polyps or colon cancer
- Inflammatory bowel disease (Crohn's or ulcerative colitis)
- Genetic syndromes: familial adenomatous polyposis or hereditary nonpolyposis colon cancer, and others
- Type 2 diabetes
- Obesity⁵⁻⁷
- Smoking and high alcohol use
- Red and processed meats⁸⁻¹⁰

TABLE 81.2

Modifiable Lifestyle Factors That Decrease Risk

- High-fiber diet¹²⁻¹³ consisting of fruits, vegetables (especially cruciferous),¹⁴ and omega-3 fats¹⁵
- Moderate exercise 150 minutes per week or vigorous exercise 75 minutes per week^{16,17}
- Maintenance of a healthy body weight (body mass index [BMI] less than 25)¹⁸
- Limiting alcohol use no more than the recommended maximum daily allowance
- Avoiding tobacco use
- Maintaining good glycemic control by avoiding hyperinsulinemia

Fiber

A large meta-analysis of prospective studies found that increased fiber in the diet contributes to a lower incidence of colon cancer, with dietary fiber, cereal fiber, and whole grains showing the greatest reductions. A linear inverse relationship indicated that every 10 grams of fiber intake resulted in a 10% risk reduction for colon cancer.¹² Another analysis found no association between fiber intake and rectal cancer incidence.¹⁹ It is recommended that one consume at least 30 grams of dietary fiber a day.

Omega-3 Fatty Acids

Omega-3 fatty acids are found in cold-water oily fish. Their activity against colorectal cancer involves modulation of cyclooxygenase (COX)-2 activity, alteration of cell surface receptor function, an increase in oxidative stress, and the creation of antiinflammatory lipid mediators.²⁰ Epidemiological studies have shown varied results with regard to the influence of omega-3 fatty acids on colorectal cancer risk. A meta-analysis found up to a 22% nonsignificant reduction in colon cancer risk between the highest and lowest fish consumption groups when the difference was seven fish meals per month.²¹ A subsequent meta-analysis found that the colorectal cancer risk reduction from omega-3 fatty acids

was only significant in men, with the reduction reaching borderline significance with marine omega-3 intake.²² Because of the amount of mercury in fish, no more than two to three servings of cold-water fish are recommended per week. Fish high in omega-3 fatty acids are wild salmon, mackerel, sardines, anchovies, black cod, and albacore tuna. The omega-3 fatty acid content of 100 grams of salmon and sardines is between 1 and 2 grams. One may also consider taking 1000 mg of omega-3 fatty acids daily in supplement form.

Soy

Soy foods, which consist of soybeans (edamame), tofu, tempeh, miso, and soy milk, are a common part of the Asian diet. A 2010 meta-analysis did not find a connection between soy consumption and a reduction in risk for colorectal cancer. However, when separating the sexes, soy consumption was associated with a 21% risk reduction in females, but not in males.²³

Red and Processed Meat

Two large meta-analyses have found that greater consumption of red meat was linked to an increased risk for colorectal cancer, with processed meats contributing to a greater risk.^{9,10} There was a 36% increased risk for colorectal cancer for every 100 g/day intake of red meat and a 28% increased risk for every 50 g/day intake of processed meat.⁹ Heterocyclic amines and polycyclic aromatic hydrocarbons, which form during frying and barbecuing of meats, are carcinogenic. The heme iron content of meats may contribute to colorectal neoplasia by inducing oxidative DNA damage and by increasing endogenous formation of N-nitroso compounds that are also carcinogens. Red meat intake is associated with a risk for large adenomas.¹⁰ Processed meats include most lunchmeats found at deli counters, anything with a casing or in sausage form, and anything smoked or cured, like bacon. Choosing other sources of protein or baking, boiling, and slow cooking unprocessed meats instead are advisable.

Processed meat is treated with sodium nitrate to preserve the pink color, which combines with the amino acid amine in the meat to form nitrosamine, which is oncogenic to the colon.

Garlic

Garlic (*Allium sativum*) is characterized by a high content of organosulfur compounds and flavonoids, and can be consumed raw or cooked. The allyl sulfur constituents in garlic, which comprise 1% of its dry weight, are responsible for its health benefits. Its anticancer properties include blockage of cell growth, proliferation, and angiogenesis; apoptosis induction; and inhibition of COX-2 expression. Several studies show that a high consumption of garlic decreases the risk for colorectal cancer by 30%, with a greater protective effect on the distal colon.^{24,25}

Glycemic Control

Impaired glycemic control is the result of a diet high in simple carbohydrates (fructose and sucrose), which leads to diabetes and hypertriglyceridemia. A 2012 meta-analysis did not support an independent association between diets high in carbohydrates, glycemic index, or glycemic load and colorectal cancer risk.²⁶ Another review found that glycemic index, but not glycemic load, was associated with an increased risk for colon cancer.²⁷ It is advisable to avoid simple carbohydrates and refined sugars because of their associations with many other chronic diseases that can result in heart attack and stroke (see [Chapter 87](#)).

Mediterranean Diet

The principal aspects of this diet include proportionally high consumption of olive oil, legumes, unrefined cereals, fruits, and vegetables; moderate-to-high consumption of fish; moderate consumption of dairy products (mostly as cheese and yogurt); moderate wine consumption; and low consumption of meat. A European study found that adherence to the Mediterranean diet was associated with an 8%–11% risk reduction in colorectal cancer. This association was stronger in women and was not affected by alcohol intake²⁸ (see [Chapter 88](#)).

Obesity

Obesity is defined as a body mass index (BMI) of 30 or greater and is a risk factor for many solid tumors and chronic diseases. Abdominal obesity, measured by hip and waist circumference, is closely associated with adverse metabolic profiles such as insulin resistance, dyslipidemia, and systemic inflammation, which contribute to cardiovascular disease,

diabetes, and certain types of cancer. Studies show that both general and central obesity were associated with an increased risk for colon cancer, with a stronger association in men.^{4,7} Childhood obesity and weight change in adulthood may also be associated with colorectal cancer risk. Patients are advised to maintain BMI between 19 and 25.

Dietary Supplements

Calcium

Two meta-analyses indicated that supplemental calcium was effective for preventing colorectal adenoma recurrence in populations with a history of adenomas but not in populations without any risk.^{29,30} Food sources of calcium include dairy, white beans, bone-in sardines, kale, black eyed peas, dried figs, seaweed, tofu, and soy milk.

Dosage

The dosage is 1200 mg calcium citrate daily.

Vitamin D

Vitamin D may decrease cancer risk by improving differentiation and apoptosis and decreasing proliferation, invasiveness, metastatic potential, and angiogenesis. There is an inverse association between circulating 25-hydroxyvitamin D (25(OH)D) levels and colorectal cancer, with a stronger association for rectal cancer.³¹⁻³³ A 50% lower risk for colorectal cancer was associated with a serum 25(OH)D level greater than or equal to 33 ng/mL compared with less than or equal to 12 ng/mL.³⁴

Dosage

Target 25(OH)D level is between 50 and 80 ng/mL. Every 1000 IU of vitamin D₃ will increase the level by 8–10 ng/mL.

Folate

Folic acid is a type of vitamin B. It is the synthetic form of folate that is found in supplements and added to fortified foods. Two meta-analyses

found that a higher intake of total folate in the diet and supplements were associated with a reduced risk for colorectal cancer,^{35,36} whereas another found no association with colorectal cancer occurrence.³⁷ Two meta-analyses actually found an increased risk for colorectal cancer incidence and recurrence in those supplemented with folate.^{38,39} Instead of taking a folic acid supplement, it is advised to obtain folate through the diet. Food sources of folate include lentils, most beans, asparagus, spinach, avocados, broccoli, and oranges.

Vitamin B₆

In the United States, the prevalence of inadequate vitamin B₆ intake among adults older than 50 years is about 20% for men and 40% for women. A meta-analysis found that vitamin B₆ intake and blood pyridoxal 5'-phosphate levels were inversely associated with the risk for colorectal cancer, with a 20% decreased risk when comparing high versus low intake.⁴⁰ Overall, the risk for colorectal cancer decreased by 49% for every 100-pmol/mL increase in the blood pyridoxal 5'-phosphate level. Food sources of vitamin B₆ include garlic, tuna, cauliflower, mustard greens, bananas, celery, cabbage, cremini mushrooms, asparagus, broccoli, kale, collard greens, Brussels sprouts, cod, and chard.

Dosage

The dosage is 50 mg daily or in a multivitamin.

Precautions

Vitamin B₆ can cause neuropathy with supplementation at high doses, generally above 150 mg. Do not exceed 50 mg with supplementation.

Curcumin

Curcumin is a compound extracted from turmeric (*Curcuma longa*), a yellow Indian spice. The bioavailability of curcumin consumed orally increases when it is taken with black pepper (piperine) and a meal containing a healthy fat (i.e., coconut oil, avocado, olive oil, etc.). A small open-label trial showed a 60% reduction in colorectal adenoma number and 50% reduction in size in individuals with familial adenomatous polyposis (FAP) who took 1440 mg of curcumin with quercetin daily for

6 months.⁴¹ Another open-label trial found a 40% reduction in aberrant crypt foci in smokers who took 4 grams as opposed to 2 grams of curcumin daily for 30 days prior to colonoscopy.⁴² Curcumin can cause blood thinning, so use it with caution in individuals with a low platelet count, anemia, or using medications or herbs that thin the blood. It may cause gastrointestinal discomfort, so titrate the dose up slowly.

Dosage

The dosage is 1.5–4 g/day for antiinflammatory benefits. More research is needed with regard to colorectal cancer prevention.

Coriolus (Trametes) versicolor

Over 400 in vitro and animal studies of *Coriolus versicolor* mushroom extract have demonstrated that it stimulates the immune system, inhibits the growth of cancer cells, and acts as a strong antioxidant. Polysaccharide-K (Krestin; PSK) and polysaccharide peptide (PSP) are bioactive extracts of *C. versicolor*. In Japan, PSK is an anticancer drug currently used as a cancer treatment along with surgery, chemotherapy, and radiation therapy. It is used as an adjunctive treatment for esophageal, lung, stomach, breast, and colon cancer. A study found that stage II and III colorectal cancer patients who received conventional therapy along with 3 grams of PSK per day had a greater percentage of 5-year disease-free survival and a decreased relative risk for regional metastases.⁴³ A meta-analysis of three trials involving 1094 subjects with colorectal cancer confirmed that those who took PSK showed a significant improvement in overall survival and disease-free survival.⁴⁴

Dosage

No definite dosing schedule has been established.

Physical Activity

One review found that physical activity reduced the incidence of colon cancer but not rectal cancer. There was a 30%–50% risk reduction in people with the highest level of physical activity, with a stronger

reduction in left-sided cancers.⁴⁵ Another review discusses that increased physical activity after the diagnosis of stage I–III or advanced colon cancer reduced cancer-related mortality. Additionally, there was a reduction in colon cancer recurrence or death in people with the highest level of physical activity 6 months after chemotherapy. This was independent of other lifestyle factors, and walking at a normal or brisk pace for 30 minutes or more daily is effective.⁴⁶ Patients who have received chemotherapy that can affect heart function should take extra precautions and talk to their doctor before starting a vigorous exercise program.

Smoking

In November 2009, the International Agency for Research on Cancer reported that there is sufficient evidence to conclude that tobacco smoking causes colorectal cancer. The association appears to be stronger for rectal cancer than for colon cancer.⁴⁷ The latency period between tobacco exposure and colorectal cancer diagnosis is about 30–40 years.

Alcohol

Colorectal cancer has been linked to even moderate alcohol use. Individuals who have a lifetime average of two to four alcoholic drinks per day have a 23% higher risk for colorectal cancer than those who consume less than one drink per day.⁴⁸

Medications

Aspirin and Nonsteroidal Antiinflammatory Drugs

The chemopreventive effect of aspirin and NSAIDs has been attributed to their inhibition of COX enzymes. COX-2 is abnormally expressed in many cancer cell lines and implicated in the processes of carcinogenesis, tumor growth, apoptosis, and angiogenesis. Studies indicate that regular aspirin use of 75 mg or more for greater than 5 years leads to a 20%–30% reduction in colon cancer incidence.⁴⁹ Meta-analyses confirm that daily aspirin use of 81–325 mg reduced the occurrence of tubular adenomas in those with a history of them.^{50,51} However, NSAID use prior to diagnosis

does not affect survival in colon cancer patients.⁵² An international consensus determined that more studies on aspirin and cancer prevention are needed to define the lowest effective dose, the age at which to initiate therapy, the optimum treatment duration, and the subpopulations for which the benefits of chemoprevention outweigh the risks for adverse side effects.⁵³ The American Cancer Society does not currently recommend the use of these drugs for colorectal cancer prevention because of the potential side effect of gastrointestinal bleeding.

Postmenopausal Hormone Replacement

There is substantial evidence that women who use postmenopausal hormones have lower rates of colorectal cancer than those who do not.⁵³ Decreased risk is especially evident in women with long-term hormone use, though the risk returns to that of nonusers within 3 years of cessation.^{54,55} However, use of postmenopausal hormones increases the risks for breast and other cancers, as well as cardiovascular disease, so it is not recommended for the prevention of colorectal cancer.

Treatment

The mainstay of treatment for colorectal cancer is surgery to remove the tumor. When a section of the colon is removed, the ends can often be reconnected. If not, a temporary (rarely permanent) colostomy may be required in the interim. Chemotherapy and radiation are required if the tumor has invaded beyond the muscle wall of the bowel. Surgery can result in fatigue, changes in bowel consistency, sexual side effects, and pain, which improves with healing. Radiation treatment may cause local skin irritation, nausea, diarrhea, rectal or bladder irritation, tenesmus, fatigue, and sexual problems. Chemotherapy frequently causes gastrointestinal side effects, fatigue, hair loss, low blood counts, and neuropathy, many of which can reverse with time after completion of treatment. Maintenance of physical activity, healthy nutrition, and stress reduction are recommended throughout the entire cancer process.

Supplements for Treatment Support

The conventional treatments for colorectal cancer can cause many side

effects, only some of which can be treated with medications. Other side effects take time to resolve after the treatment is complete, but some do not resolve at all. [Table 81.3](#) summarizes the numerous evidence-based integrative therapies and supplementation available to prevent and treat the side effects of conventional treatments and symptoms of cancer.

TABLE 81.3
Complementary Therapies for Colorectal Cancer Treatment⁵⁷⁻⁹¹

Nausea	Acupuncture, peppermint, ginger, astragalus, relaxation techniques, yoga, energy work, music therapy, massage
Fatigue	Energy conservation, aerobic exercise, MBSR, CBT, energy work, acupuncture, relaxation techniques, massage, yoga, L-carnitine
Pain	Music therapy, acupuncture, massage, CBT, relaxation techniques, meditation, energy work
Depression, Anxiety	Counseling, therapy, support groups, meditation, MBSR, music therapy, massage, yoga, energy work, relaxation techniques, hypnosis
Insomnia	CBT, meditation, MBSR, yoga, relaxation techniques
Neuropathy	Acupuncture, L-glutamine, acetyl-L-carnitine
Diarrhea	L-glutamine, probiotics

CBT, cognitive behavioral therapy; MBSR, mindfulness-based stress reduction.

Energy work: reiki, healing touch, therapeutic touch.

Relaxation techniques: hypnosis, progressive muscle relaxation, guided imagery.

Survivorship and Tertiary Prevention

Because of the technological advancement in the early detection and treatment of colorectal cancer, the number of deaths has been decreasing. Millions of people are currently in remission after treatment. The 5-year survival rate for localized colorectal cancer is 90%. Tertiary prevention should focus on the same modifiable risk factors included in primary prevention, especially dietary modifications that can be overseen by a clinician and supported by the family. Compliance with follow-up screening procedures should be emphasized, as a personal history of colorectal cancer increases an individual's risk for the development of new colorectal cancers.

Prevention Prescription

Screening and early detection should focus on identifying high-risk populations, including those with a genetic condition or a family history of colorectal cancer. Those with a normal risk should undergo

screening colonoscopy at the age of 50 years. Primary, secondary, and tertiary prevention of colorectal cancer should include the following:

- A whole-food plant-based diet with five to nine servings of fruits and vegetables daily that is low in processed foods, sugar, and red meat
- Moderate physical activity of 30 or more minutes per day (e.g., brisk walking)
- Maintenance of a BMI between 19 and 25
- Minimal alcohol consumption
- Avoid tobacco use
- Supplementation with omega-3 fats, vitamin D₃, and calcium citrate as appropriate
- Mind-body tools for stress management practiced for 10–15 minutes daily

Consistent reevaluation of this comprehensive approach is necessary for adherence, patient satisfaction, and efficacy and to determine if new tools in each category are indicated.

Therapeutic Review

Primary Prevention

- Risk reduction in populations with higher risk 

Screening and Early Detection

- Identify high-risk populations for increased surveillance and early intervention. 
- Follow the American Cancer Society (ACS) recommendation for screening average-risk populations with colonoscopy starting at the age of 50 years. 

Nutrition

- A plant-based, high-fiber diet obtained from fruits and vegetables with minimal red meat and sugar 
- The diet may include omega-3 fats, unprocessed, preferably

fermented soy foods, garlic, and natural sources of calcium.  B₁

- Maintain a BMI between 19 and 25.  B₁

Exercise

- Moderate physical activity of 30 or more minutes per day (e.g., brisk walking)  B₁

Mind–Body

- Mind–body stress reduction to support treatment  C₁

Supplements

- Calcium citrate 1200 mg daily for prevention of colorectal adenoma recurrence  A₁
- A vitamin D₃ level maintained between 50 and 80 ng/mL, with daily baseline supplementation of 1000 IU/day once that level is achieved, may decrease cancer risk.  B₁
- Folate obtained from food sources reduces colorectal cancer risk, whereas supplementation with folic acid increases the incidence.  A₁
- Vitamin B₆ 50 mg daily reduces cancer risk.  A₂
- Curcumin 1.5–4 g/day for antiinflammatory benefits  C₂
- *Coriolus* PSK improves overall and disease-free survival in individuals with colorectal cancer.  A₂

Treatment Support

- Acupuncture and acupressure given prior to, during, or after treatment relieve chemotherapy-induced nausea.  A₁
- Ginger root 1 gram daily starting on the first day of chemotherapy and continued for 5 days OR 500 mg every 4 hours starting on the day of chemotherapy and continuing as long as needed relieve chemotherapy-induced nausea.  A₂
- Mind–body techniques including meditation, clinical hypnosis, guided imagery, and yoga improve tolerance of, adherence to, and

quality of life during treatment. 

- L-glutamine 10 grams three times a day during the first 7 days of chemotherapy, or 5–10 grams two to three times a day during chemotherapy to reduce neuropathy. 
- Acetyl-L-carnitine 1 gram three times a day to reduce fatigue and neuropathy.

CHAPTER 82

Palliative and End-of-Life Care

Lucille R. Marchand, MD, BSN

Integrative palliative care (IPC) encompasses whole-person, relationship-centered care using conventional and complementary and alternative modalities (CAM) with an emphasis on health and healing.¹ When delivered at the end of a person's life, palliative care (PC) is usually referred to as hospice care ([Fig. 82.1](#)). PC includes evidence-based care directed at the relief of symptoms of advanced serious illness and side effects of treatment as well as communication directed to establishing ever-evolving goals of care based on patient (and family and/or surrogate) preferences. It is appropriate at any stage of the disease trajectory but especially helpful earlier in the course of serious illness so that patients have PC services available throughout the disease trajectory. It occurs together with life-prolonging measures, and with the relief of symptoms and improvement in quality of life (QOL), it may actually prolong life.² Goals of care in hospice care and PC include optimization of well-being and QOL, relief of distressing symptoms, empowered decision making, support of caregivers, and effective life closure for peaceful and meaningful dying and death. Bereavement services for family and friends of the person dying are an essential element of care. Grief and loss often begin with the diagnosis of serious diseases. PC incorporates the use of a multi- and interdisciplinary team of health professionals working together to best meet the needs of the patient and family. The team can include the patient's primary and specialty care clinicians and the hospice care and PC clinicians, which may include physicians, nurse practitioners, physician assistants, nurses, certified nurses' aides, chaplains, bereavement counselors, social workers, housekeepers, dietitians, volunteers, occupational and physical therapists, and other integrative practitioners who work in health care settings, including PC outpatient and inpatient programs and hospice, are affiliated with the hospice, or caring for the patient and family in the

community.³ IPC calls on us to be creative and innovative in the care of seriously ill patients, expanding options to enhance healing, maintain hope, and improve well-being in a unique way for each person.

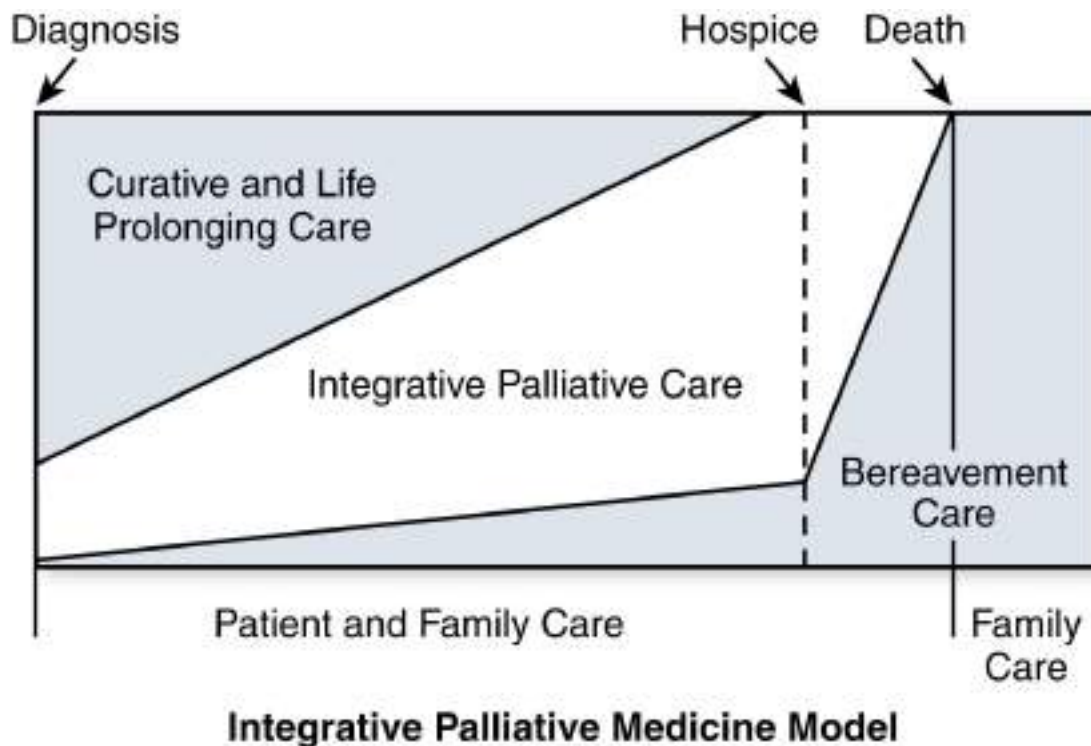

FIG. 82.1 Model of Integrative Palliative Medicine.

In a survey of complementary therapy services provided by hospices, 60% of responding organizations offered such therapies. The most common services were massage therapy (83%), music therapy (50%), therapeutic touch (49%), pet therapy (48%), guided imagery (45%), reiki (36%), aromatherapy (30%), harp music (23%), reflexology (20%), art therapy (20%), hypnotherapy (4%), yoga (3%), acupuncture (1%), and humor therapy (1%). Constraints to providing CAM services were lack of funding, lack of staff time, lack of qualified CAM therapists, inadequate knowledge about these services, and patient and staff resistance to CAM therapies. Even in hospices that offered these services, less than 25% of the patients received them.⁴ In a 2008 survey of 27 Nevada and Montana hospices using the survey instrument developed by Demmer, it was found that 70.4% of hospices offered CAM services, but less than 25% of hospice patients received them. The most-used CAM therapies included

massage and music therapy; 61.1% of hospices had a salaried CAM provider and 88.3% had CAM volunteers. None of the hospices had an assessment tool to determine the patients who might benefit from the CAM services. Barriers to use were the same as those cited for constraints to providing CAM services.⁵ Preliminary research outcome data on the program have been favorable.⁶ Demmer and Sauer⁷ found that patients who received CAM therapies were more satisfied with their hospice services. Sirios⁸ compared consumers seeking consultation with CAM practitioners in 1997 and 2005. During that period, consumer motivation changed from the use of CAM due to negative attitudes toward conventional medicine to the use of CAM modalities for their positive effects and a whole-person, empowered approach to health care. In a Canadian hospital PC unit, integration of CAM therapies decreased the severity of pain, restlessness, discomfort, low mood, and anxiety. It also added to a sense of peace.⁹

For patients dying with uncontrolled symptoms, such as pain, the symptoms are often more frightening than death itself. Patients desire pain and symptom control; the ability to prepare for their dying and to have their choices honored; life completion; mental clarity; being touched; being at peace with their God; having clinicians one can trust, who listen, and with whom one is comfortable talking about dying; and being in the presence of loved ones without being a burden.¹⁰ Ira Byock¹¹ describes the essential elements of meaningful living as the expression of forgiveness, appreciation, and love. The phrases "Please forgive me," "I forgive you," "Thank you," and "I love you" embody these elements; they can improve relationships at any time in life, particularly at life's closure.¹¹

Pathophysiology

General criteria in patients with advanced chronic illness who are dying are as follows: unintentional weight loss of more than 10% body weight, serum albumin value lower than 2.5 g/dL, spending more than 50% of time in bed (Karnofsky score), inability to perform most activities of daily living, progression of disease, and uncontrolled symptoms despite aggressive treatment of the underlying illness.¹² Physicians tend to be overly optimistic about prognosis, an error that leads to delayed hospice referrals, less time for the patient and family to prepare for death, delay or absence of end-of-life care discussions with informed decision making,

lack of preparatory bereavement services, and inappropriate life-prolonging interventions. An important question for clinicians to ask themselves is: “Would I be surprised if this patient died in the next 6 months?” If the answer is no, the patient has reached the end of life; communication about treatment preferences becomes more important and referral to hospice appropriate.¹³

Communication lies at the heart of integrative PC. “Hoping for the best” needs to be balanced with “preparing for the worst.”¹⁴ Conversations must be sensitive in eliciting how much a patient wants to know.¹⁵ Goals of care are explored in a patient-centered way, which then serve as guides for further decision making. Armed with knowledge about patient preferences for care, clinicians can avoid unwarranted treatment. Hope is then in keeping with what the patient wants to accomplish in his or her remaining life. Goals and hope will change as the process unfolds. Hope can be viewed as an inner power that moves a person forward in life. Questions that can be helpful in palliative medicine conversations with patients to uncover what will move them forward and inspire hope include the following: “What is your understanding of your situation? How can I be most helpful to you? What worries you most now and for the future? What is important or meaningful to you right now?” When the clinician listens to the answers intently without interruption and with presence, empowerment and a sense of hopefulness can arise in the patient. It allows the patient to heal and to live well in the face of serious illness and end of life. Hope becomes a fluid process of living fully rather than fixed on a particular outcome.¹⁶

Hope can also help alleviate clinical symptoms and improve well-being.¹⁷ Communicating “bad” or challenging news constitutes an essential skill that is well described by Buckman.¹⁸ It requires deep listening, empathy, presence, and emotional awareness on the part of the clinician (see [Chapter 3](#)).

Hope does not lie in a way out, but in a way through.

Robert Frost

Common Issues in Palliative Care

Common symptoms managed in PC are pain; nausea, vomiting, and constipation; dyspnea; depression and anxiety; and delirium. Lancker

et al., in a systematic review and meta-analysis of symptoms in older patients with cancer receiving PC, found that more than 50% of patients suffered from pain, incontinence, asthenia, anxiety, constipation, fatigue, and excretory symptoms.¹⁹ Unrelieved physical, emotional, or spiritual discomfort must be treated as a PC emergency, and careful assessment and intensive palliative resources must be applied to prevent unnecessary suffering.²⁰ Uncontrolled symptoms can lead to the patient's desire for a hastened death.²¹ On occasion, physical and psychological symptoms cannot be controlled with conventional and CAM therapies, and palliative sedation must be used to control symptoms such as intractable and intense pain, seizures, and existential psychological suffering. The intention of this therapy is to treat intractable suffering, not to hasten death. Careful guidelines have been developed for its use.²²⁻²⁶

Discussing conventional symptom management in detail is beyond the scope of this chapter. Many valuable PC resources are available for this information.^{3,27-30}

Pain Management

Opioids are important in pain management as serious illness, such as cancer, progresses. Pain, however, is a complex phenomenon involving physical, emotional, social, and spiritual aspects that must be addressed for "total pain" management as described by Cicely Saunders, the founder of the modern hospice movement.^{31,32} The World Health Organization (WHO) ladder of pain management recommends various levels of pain treatment, depending on pain severity.²⁷ Physical pain is often a combination of nociceptive and neuropathic pain, and opioids alone are usually not effective in treating the neuropathic component of pain without adjunctive medications, such as antidepressants and anticonvulsant medication.³²

Methadone is a unique opioid that can effectively treat both components but must be dosed carefully, given its large volume of distribution, and its kinetics differ from those of other opioids. The switch from another opioid to methadone must be done carefully, and it usually requires consultation with a pain or palliative medicine consultant.³³⁻³⁵ No ceiling dose exists for opioids, but careful titration of the dose to relieve pain is recommended (see [Key Web Resources](#): Fast Facts). Opioid-induced hyperalgesia, noted clinically in some cases of rapid increased titration of opioids, is a condition reported in the

literature, but one paper argues that there is little evidence to support this concern.³⁶ Pain that is unrelieved by opioids can be treated with agents such as ketamine and parenteral lidocaine, nerve blocks, and, in some cases, palliative sedation.^{32,37-40}

CAM therapies can be especially helpful in addressing all components of pain. Depression, anxiety, and spiritual distress can all increase the perception of pain intensity, and addressing these components of pain can reduce the need for pain medication.^{41,42} A multicontinental WHO study in primary care revealed that persistent pain is associated with greater psychological illness.⁴³ Lin et al.,⁴⁴ in a large randomized controlled trial (RCT), found that amelioration of depressive symptoms decreased pain and improved both functional status and QOL.⁴⁴ Because most antidepressants, including St. John's wort, take 2–6 weeks to exert effect, treatment at the end of life depends on the length of life expected. Psychostimulants, such as methylphenidate, may have immediate effects in alleviating depression.⁴⁵ Other modalities, such as psychotherapy, energetic medicine, and mind-body, may also have a beneficial effect.

Many integrative modalities for the pain management of chronic conditions are covered in other chapters in this volume and can be applied in PC. Relatively few studies have focused solely on CAM treatments of pain at the end of life.

Never order opioids without also scheduling a stool softener and/or laxative, such as senna, to prevent constipation that can lead to bowel obstruction (unless the patient is having diarrhea not due to partial large bowel obstruction). A common stool softener is docusate sodium. A laxative is usually needed in conjunction with a stool softener to have a bowel movement every day or every other day as a usual goal.

Botanicals for Pain

Cannabis (Medical Marijuana)

Cannabis can help alleviate pain. Dronabinol (delta-9-tetrahydrocannabinol or delta-9-THC)—a schedule III substance—and nabilone—a schedule II substance—are the oral synthetic forms of cannabis and were licensed and approved in 1986 for chemotherapy-induced nausea and vomiting and the wasting syndrome associated with human immunodeficiency virus (HIV) disease.⁴⁸ The medicinal use of

cannabis dates back to thousands of years.⁴⁹ Other uses of cannabis include its use in treating cancer-related pain, HIV-associated neuropathy, and neuropathic pain. It is a schedule I substance. The cannabis plant has more than 100 different cannabinoids, with delta-9-THC being the most psychoactive component. Cannabidiol (CBD) also has powerful therapeutic effects, but without psychoactive side effects, and can help modulate central nervous system effects of THC. Oral forms of cannabis have low and variable bioavailability, whereas the inhaled form is rapidly absorbed and metabolized for rapid onset and shorter duration of action. It can interact with cytochrome P450 enzymes in the liver, potentially affecting other drugs metabolized via this system. It also has a good safety profile.⁴⁹

Cannabinoid receptors are located in the central and peripheral nervous system (CB1) and the immune system (CB2).⁵⁰ Abrams and Guzman summarize the research on the effectiveness of cannabis to relieve neuropathic pain and reduce the dose needed of opioids to relieve cancer pain. Cannabis relieves pain at 10- to 20-mg doses; higher doses have more side effects such as sedation. Abrams and Guzman suggest that cannabis has a potential prominent role in PC as a single agent that can address anorexia, pain, nausea, insomnia, depression, pain, and anxiety.⁴⁹

In 23 states and the District of Columbia, natural cannabis in inhaled or oral form is available as medical marijuana.⁴⁹ If legal and available in your state, it can be titrated for effective dosing starting with very small doses as needed. Facilities that are under federal law regulations may not be able to use it.

Dosage

Dronabinol is not effective in relieving pain syndromes.⁴⁸

Oral dosing produces milder effects, given its variable bioavailability, and it is available as a tea.

Given variable absorption of oral cannabis, the inhalation route remains the most reliable titration to effect with minimal side effects. Vaporization of cannabis is an alternative to smoking it. The Office of Medicinal Cannabis recommends the inhalation route via vaporization to avoid damage to lungs.⁵¹ In a review of 165 studies on medical marijuana use, less than 7 mg of THC is considered as low dose, 7–18

mg as medium dose, and greater than 18 mg as high dose. Tolerance often occurs in a few days through downregulation of cannabis receptors.⁵²

Side Effects

Side effects include dizziness, dry mouth, sedation, fatigue, headache, hypotension, irritability, and poor memory or concentration. More serious side effects include paranoia, psychosis, and disorientation.⁴⁸

Precautions

Psychoactive side effects are observed in patients with mental illness, dementia, or delirium.

Nausea, Vomiting, and Constipation

Whenever nausea, vomiting, and constipation symptoms appear, it is important to establish the cause for the antiemetic to be targeted to the responsible mechanism. Common causes are dysmotility, obstruction, side effects of medication such as opioids, metastases in the brain, and vestibular apparatus irritation (sometimes caused by dehydration).

Constipation is a common cause of nausea and vomiting. Corticosteroids (such as prednisone and dexamethasone) can reduce nausea and vomiting caused by cerebral edema that occurs due to brain metastases.

Laxatives, stool softeners, and enemas can prevent and relieve constipation and bowel obstruction due to severe constipation. The goal is to achieve a bowel movement once daily and at least every other day^{56,57} (see [Chapter 46](#)). Bulking agents should be avoided in patients consuming insufficient fluids or those on fluid restriction.

Metoclopramide can relieve nausea due to dysmotility but can have extrapyramidal side effects, especially in older persons (should be avoided in patients with Parkinson's disease). For dysmotility, promethazine is a potent anticholinergic drug that should not be used for nausea in this situation because it will cause further slowing of gut motility.⁵⁸

Antiemetics represent a variety of drugs with antihistamine, antidopaminergic, antiserotonergic (5-hydroxytryptamine type 3 [5-HT₃] receptor antagonists), and anticholinergic effects. They are not interchangeable. Promethazine is an antihistamine with potent anticholinergic and very weak antidopaminergic effects, making it a poor

choice for treating the nausea due to opioids. For opioid-induced nausea, metoclopramide can improve motility. Long-acting opioids can prevent drug level peaks that can cause nausea. 5-HT₃ antagonists such as ondansetron are expensive second-line agents that are preferred for treating nausea due to chemotherapy or when other agents have failed or are contraindicated, such as metoclopramide in Parkinson's disease.⁵⁸ There is evidence that acupuncture as well as other mind-body and energetic therapies can also help relieve nausea. In cases of bowel obstruction, exercise extreme caution with any prokinetic or anticholinergic drugs or laxatives.

Botanicals for Nausea

Ginger (*Zingiber officinale*)

Ginger can help alleviate nausea. It has been found to be efficacious in nausea of pregnancy, motion sickness, and nausea associated with chemotherapy but not for postoperative nausea.^{59,60} Its mechanism of action is unknown, but ginger appears to have a prokinetic effect.⁵⁹

Dosage

Take 500–1000 mg of ginger root extract every 4–6 hours as needed, or eat 1 tsp or 5 g of crystallized ginger every 2–3 hours as needed.

Precautions

Side effects are rare. Excessive doses can cause heartburn.

Cannabis

Cannabis can help alleviate nausea and improve appetite. In a study of HIV-positive patients, it significantly improved nausea and appetite.⁶¹

In 1986, it was approved for use in chemotherapy-associated nausea and vomiting.⁴⁹

Dosage, Precautions, and Side Effects

See the section on [cannabis](#).

Dyspnea

“Total dyspnea,” like the concept of “total pain,” encompasses the physical, emotional, social, and spiritual aspects of breathlessness and the suffering it causes.⁶² Opioids and oxygen are important palliative treatments of dyspnea. Opioids, such as low-dose oral morphine at 2–4 mg every 3 hours as needed, relieve the sensation of breathlessness and can improve the patient’s functional capacity. Diuretics can help relieve dyspnea from fluid overload. Benzodiazepines lack evidence of beneficial effect on breathlessness but can help relieve anxiety that can make breathlessness worse.⁶² Optimal treatment of the underlying condition is essential, but standard conventional interventions may no longer reverse or improve the condition in end-stage disease. Oxygen administered to nonhypoxemic patients has no benefit over inhaled air.⁶³ Nonpharmacological strategies to help relieve dyspnea include the use of fans for a well-ventilated environment and cool ambient temperature. CAM therapies include mind-body and energetic modalities. Anxiety-reduction training, activity pacing and energy conservation, and use of handheld fans can improve breathlessness.⁶²

Scopolamine, glycopyrrolate, atropine, and hyoscyamine are used for drying oral secretions and decreasing the “death rattle.”^{64,65} Dying is usually marked by progressive dehydration that keeps a patient comfortable by eliminating excessive secretions. Thirst is relieved with small sips of fluids and by keeping the mouth moist with frequent swabbing. Artificial feeding through a gastric tube and artificial intravenous fluids can cause respiratory congestion, pain, nausea, and vomiting. Families and health care professionals who equate caring with feeding can be encouraged to provide caring by other means, such as touch (e.g., hand massage), life review, listening, and expressing love and appreciation to the dying person.^{66,67}

Dyspnea is often accompanied by anxiety and is effectively treated using anxiolytics. If carefully titrated, opioids and anxiolytics do not hasten death or cause respiratory depression but make the patient comfortable. Care must be taken in the opioid-naive patient, and initial dosing is low.^{64,66}

In a Cochrane review of nonpharmacological interventions that are most effective in relieving malignant and nonmalignant dyspnea, there was strong evidence for the positive role of neuroelectrical muscle stimulation and chest wall vibration, moderate evidence for breathing training and walking aids, weak evidence for the role of acupuncture,

and no evidence for the benefit of music therapy. There was insufficient evidence for other modalities, such as relaxation breathing and psychological interventions. Most of the reviewed studies included patients with chronic obstructive pulmonary disease.⁶⁸

Anxiety and Depression

Anxiety and Depression

Anxiety is common in serious illness. Anxiolytics provide relief of short-term anxiety, whereas selective serotonin reuptake inhibitors (SSRIs) can effectively treat long-term anxiety and depression. Because SSRIs can take 2–6 weeks for effect, a patient’s life expectancy must be considered. Depression can be treated using psychostimulants such as methylphenidate when an immediate antidepressant effect is needed. Psychostimulants can also increase energy and appetite in dying patients and counter the sedating effects of opioids.⁴¹

Anxiety and depression can be caused not only by uncomfortable physical symptoms but also by underlying psychological illness, spiritual concerns, or emotional needs.⁶⁹ The patient can be evaluated for these causes using current assessment tools. Anxiety must also be differentiated from agitation and restlessness of delirium and the agitation from progressive dementia, which are not optimally treated with anxiolytics.⁷⁰ Weissman⁷¹ advises careful assessment of patients to prevent “automatic” treatment of any physical, emotional, psychological, or spiritual distress with anxiolytics. Depression must also be differentiated from grief, but the two often occur simultaneously in a dying patient. A number of mind-body and energetic therapies can ease anxiety and depression.

Botanicals for Anxiety and Depression

St. John’s Wort (*Hypericum perforatum*)

St. John’s wort can be used for treating depression. Effects can take 2–6 weeks. A meta-analysis of 23 randomized controlled trials (RCTs) of St. John’s wort demonstrated efficacy comparable to that of standard antidepressants and significant superiority to placebo for treating mild-to-moderate depression.⁷² Two large RCTs to test this effect, however,

did not demonstrate the efficacy of this botanical plant for major depression.^{73,74}

Dosage

St. John's wort, 300 mg, is given three times a day, followed by maintenance treatment at twice-daily dosing. Use standardized products containing 2%–5% hyperforin or 0.3% hypericin.

Side Effects

Side effects include gastrointestinal distress, dry mouth, constipation, and fatigue.

Precautions

St. John's wort interacts with many medicines that are also metabolized by the cytochrome P-450 system, including warfarin. It should not be taken with another SSRI. Because supplements and their quality control are not regulated by the U.S. Food and Drug Administration, the amount received by the patient may vary. Pharmaceutical SSRIs may provide more consistent and effective therapeutic results.

Cannabis

Cannabis can help alleviate depression and anxiety. In a study of HIV-positive patients, cannabis improved depression and anxiety significantly.⁶¹

Dosage, Precautions, and Side Effects

See the section on [cannabis](#).

Delirium

The patient's inability to focus, fluctuating level of consciousness, poor memory, agitation, hallucinations, hyperactivity and restlessness or hypoactivity and somnolence, tangential thinking, insomnia, anxiety, and significant distress characterize delirium. Delirium is often

unrecognized and undertreated, especially hypoactive delirium. Even without agitation, delirium can cause great suffering for the patient and family.⁷⁵ There are many delirium subtypes.⁷⁶ Careful assessment of a delirious patient is essential, and there are many scales that effectively screen for delirium.⁷⁶ Delirium should not be reflexively treated using anxiolytics, which can potentially make it worse.⁷¹ Benzodiazepines, however, are the first-line treatment of the delirium associated with alcohol withdrawal or seizures.⁷⁷ Medications commonly cause delirium, especially those with anticholinergic side effects, such as tricyclic antidepressants and antihistamines. Opioids can also cause delirium, and decreasing the dose or substituting another opioid with fewer active metabolites—especially in decreased renal clearance—, such as hydromorphone, can help. Steroids can cause delirium as well as hepatic encephalopathy, hypoxia, and hypoglycemia as potential causes. Haloperidol continues to be the first-line medication for initial treatment of acute delirium.

The treatment goal, however, is to treat the underlying cause.⁷⁸⁻⁸¹ If delirium cannot be readily reversed, atypical antipsychotics, such as risperidone, olanzapine, and aripiprazole, can be used in scheduled and prn dosing. In a study comparing the efficacy of these agents and haloperidol in treating delirium, all agents were equally effective but differed in side effects. Olanzapine increased sedation (which may be desirable in some patients at bedtime), and extrapyramidal side effects were associated with haloperidol. These agents must be used with great caution in the elderly.⁸² All can prolong the QT interval, but this is less of a concern as the patient nears end of life. Palliative sedation (reason for palliative expert consultation) is a possible treatment for refractory delirium with irreversible cause that is leading to severe suffering of the patient.^{76,83}

Near-death awareness encompasses a dying person's experience of the dying process. When a patient experiences the presence of a deceased relative, clinicians can interpret this event as delirium with hallucinations and can inappropriately medicate the person with an antipsychotic or anxiolytic agent. The patient, however, may not demonstrate other criteria for delirium. Patients can feel annoyed, frustrated, and isolated in their profound end-of-life experiences. This is a time for clinicians to listen. Patients will attempt to describe these experiences or request something to ensure a peaceful death. They may indicate when they will die. They may use symbolic language to describe their experiences, which can be difficult to interpret. By being curious and appreciative of

the experience, clinicians can validate and support the patient, help family members understand the experience, and perhaps learn themselves about the dying process.⁸⁴⁻⁸⁶

Do not treat agitation reflexively using anxiolytics. Careful assessment is needed to determine the cause of agitation, especially in patients with decreased cognitive function such as dementia. Causes can include delirium, near-death awareness, spiritual distress, depression and anxiety, unrelieved pain, and other uncontrolled physical symptoms.

Spiritual Care

Serious illness and end of life bring questions about life's meaning and purpose. Spiritual and religious concerns often affect decision making.⁸⁷ In one study questioning ambulatory outpatients, 66% of respondents said that they would want their physician to ask about their spiritual beliefs if they became gravely ill, and 16% said they would not.⁸⁸ In a study of physicians, 81% of 1878 surveyed physicians believed that spiritual distress could worsen physical pain and 88% felt that addressing spiritual distress was just as important as relieving pain.⁸⁹ Careful spiritual assessment can help the patient who desires supportive spiritual resources to obtain them. Expressive therapies such as music, art, collage, movement, and writing can facilitate the exploration of spiritual issues.⁹⁰ Life review or reminiscence therapy can encourage the discovery of meaning. Chibnall and associates⁹¹ reported that higher levels of death distress in patients correlated with higher levels of physical and psychological symptoms, living alone, lower spiritual well-being, and less physician communication as perceived by the patient. In a study of patients with cancer, Meraviglia⁹² found that higher levels of finding meaning in life and greater use of prayer correlated with higher psychological well-being and less physical distress. Use of a spiritual assessment tool can facilitate communication about life's meaning, life closure, and treatment goals and help assess a patient's strengths. It can also be used as a therapeutic tool to increase self-efficacy and well-being.⁹³⁻⁹⁷ Puchalski's model for spiritual assessment with the acronym FICA includes questions related to faith and belief, importance of that faith and belief, spiritual or social community, and how to address those

beliefs in PC and end-of-life care ([Table 82.1](#)).⁹⁴ The clinician can learn how the patient copes with illness, what support systems are in place, and what beliefs the patient may have that could affect decision making.⁹⁸ Supporting the dignity of the patient and his or her “personness” is essential in effective spiritual care. Miller et al.⁹⁹ demonstrated better spiritual and psychological well-being in patients with life-threatening illnesses who were given supportive-affective group experiences with a spiritual inquiry tool.

TABLE 82.1
FICA: Taking a Spiritual History*

Faith and belief	Do you consider yourself spiritual or religious? <i>or</i> Do you have spiritual beliefs that help you cope with stress? If the patient responds no, the physician might ask: “What gives your life meaning?” Sometimes patients respond with answers such as family, career, or nature.
Importance	What importance does your faith or belief have in your life? Have your beliefs influenced how you take care of yourself in this illness? What role do your beliefs play in regaining your health?
Community	Are you part of a spiritual or religious community? Is this of support to you? How? Is there a group of people you really love or who are important to you? Communities such as churches, temples, mosques, or a group of like-minded friends can serve as strong support systems for some patients.
Address in care	How would you like me, your health care provider, to address these issues in your health care?

: The acronym FICA can help structure questions for health care professionals taking a spiritual history.

© Christina M. Puchalski, MD, 1996. Modified with permission from Puchalski CM, Romer AL. Taking a spiritual history allows clinicians to understand patients more fully. *J Palliat Med.* 2003;3:129–137.

Requests from the patient for prayer with the clinician need not compromise the clinician’s religious beliefs. A clinician may choose to be with the patient in silence as the patient prays.^{98,100} Often, the patient can identify a spiritual mentor, such as a priest, minister, or rabbi, who can guide him or her through the spiritual territory of their illness and dying process. If not, involving the PC or hospice chaplain can provide needed spiritual support. Spiritual support, however, can come from the entire PC and health care team, family, and friends¹⁰¹ (see [Chapter 114](#)).

Bereavement

The loss of the “healthy or nonseriously ill” self begins at the time of

diagnosis of illness. Delivery of “bad” or “important” news requires skill in managing the grief of the patient and family for this loss.¹⁸ Grief is the experience of loss, and bereavement is the process of journeying through grief. Mourning is the public expression of grieving. Grief or bereavement targets the restoration of wholeness and a gradual adjustment to a new reality. Each person journeys through the grief process uniquely, but certain tasks of grieving are universal; they are to gradually accept the reality of the loss, experience the pain of the loss, adjust to a new reality where the deceased is not, and reinvest energy into new relationships and realities.^{102,103}

In PC and hospice care, bereavement services are offered to the patient and family before the death (grief can occur for the patient and family before the death) and to the family up to 13 months after the patient’s death. Supportive interventions for grief of the patient and family help prevent depression in the patient and complicated grief in the family and significant others left behind by the death. Periyakoil and Hallenbeck¹⁰⁴ suggest psychosocial–spiritual interventions with the acronym RELIEVER: reflect with the patient on emotions, empathize, lead with questions to facilitate grieving, improvise interventions to the unique individual, educate about the grief process and what to expect, validate the experience, and recall the life story and accomplishments of the patient. All health care professionals and bereavement counselors can facilitate this process. As in spiritual exploration, the use of the humanities such as art, music, writing, and collage can help individuals express their grief and work through it one-on-one or in bereavement groups.

Encouragement of healthy grieving can prevent complicated grief, such as delayed grief, absent grief, distorted grief, and chronic grief. When complicated grief occurs, refer to a bereavement counselor, psychiatric consultant, or spiritual counselor. Grief can also be complicated by major depression, anxiety disorder, posttraumatic stress disorder, and, in children, adjustment disorder. Those at risk for complicated grief include mothers after the death of a child, widowers, family members who feel guilt or anger or “unfinished business” with the deceased; survivors of a sudden violent death of a loved one; children and teenagers who have lost a parent; persons with a history of psychiatric illness or substance abuse; and refugees. Patients presenting with somatic or psychiatric symptoms may be experiencing complicated grief, and this should be explored. In a patient interview, the clinician starts a therapeutic intervention by acknowledging the loss and then

supporting the patient in the grief process.¹⁰⁵ A study revealed that those who had strong spiritual beliefs were more resilient in the face of grief and had lower incidence of complicated grief.¹⁰⁶

Depression must be differentiated from grief in the dying patient because depression requires some different interventions for successful treatment. Depression is characterized by flat affect, anhedonia, hopelessness, worthlessness, guilt, and social withdrawal. One must remember that pain can also cause flat affect, anhedonia, and withdrawal. In grief, sadness fluctuates and responds to social support; some activities can be enjoyed, and sadness improves with time. Symptoms such as insomnia and loss of appetite cannot be used to differentiate depression and grief in the dying process. Patients can, at times, sense whether they are depressed or grieving, and asking them if they are feeling depressed can help differentiate between the two states.¹⁰⁷

Integrative Therapies

Nutrition

Appetite naturally decreases at the end of life, and progressive dehydration is the rule. Food and fluids optimally are flavorful and of an appropriate consistency to facilitate swallowing. Food is often equated with caring, but forcing the patient to eat and drink is to be avoided. Offering small quantities of food and foods desired by the patient is optimal. Avoid dietary restrictions unless certain foods cause uncomfortable symptoms. In conditions such as congestive heart failure and pneumonia, fluid overload is to be avoided. Cool foods are often better tolerated than warm or hot foods, unless the patient prefers the latter. Fruit-flavored juices, ices, or smoothies can relieve dry mouth and are usually well tolerated. Cancer and its therapies can change taste sensation, and foods that taste good to the patient should be maximized.^{108,109}

For patients earlier in the illness trajectory, especially in cancer, nutritious foods can help improve QOL, symptoms of the disease, or treatment and decrease progression of the disease. An authoritative, evidence-based guide to nutrition and exercise in cancer survivors is the American Cancer Society's guidelines.¹¹⁰ Use of cannabis can also help stimulate appetite.⁴⁹

Movement

A number of studies show that exercise in advanced cancer can help with improvement of fatigue, pain, functional capacity, mood, and QOL. Often, seriously ill patients are discouraged from movement due to concerns that movement will cause them more fatigue. Careful pacing of exercise or any movement modality is essential, and supervision is needed for more exacting exercise such as yoga or resistance training.^{2,110,111}

Supplements

Polypharmacy with nutritional supplements is to be avoided, just as polypharmacy with medications in PC and end-of-life (EOL) care can increase the burden on the patient without significant benefit. Only those nutritional supplements essential to the patient's well-being should be continued. In most cases of patients imminently dying, almost all nutritional supplements can be discontinued except for those giving specific symptom relief. Patients and families must be a part of this decision-making process because they may hold strong beliefs about what supplements are essential for their well-being. These supplements can be continued unless the patient is having difficulty swallowing them or if they are contributing to distressing symptoms or contraindicated (e.g., fish oil in a patient with the potential for bleeding or actively bleeding).

Mind-Body Therapies

Mind-body therapies are efficacious in chronic pain, anxiety, depression, and insomnia. In a telephone survey of 2055 Americans, 18.9% had used one mind-body therapy in the past year.¹¹²

Mindfulness-Based Stress Reduction

In a meta-analytic review of mindfulness-based stress reduction (MBSR), an 8-week program of teaching moment-to-moment awareness of mind-body interactions was significantly correlated with reductions in anxiety, chronic pain, stress, and depression often found in patients at the end of life.^{113,114} Practices that can be used in PC include walking, sitting, or lying meditation, depending on the condition of the patient; body scan meditation; gentle Hatha yoga; and breath awareness.¹¹⁵ MBSR has also

been combined with art therapy in patients with cancer, achieving higher quality-of-life measures than in controls as well as diminished psychological distress.¹¹⁶

MBSR can increase coping, calmness, and peace and in another study improved mood, QOL, and well-being.^{117,118} It can help improve mood including anxiety and depression.¹¹⁹

Life Review and Reminiscence Therapy

Life review and reminiscence therapy are techniques used in end-of-life care as therapeutic interventions. Reminiscing is often done in a group setting, focuses on happy memories, and aims to improve socialization and communication skills.¹²⁰ It is especially effective in patients with dementia.¹²¹ Life review, in contrast, is performed individually by a health professional who guides the patient in specific recollections to reframe, reexplore, and redefine life events and explore them for meaning. Using Milton Erickson's life-stage approach, life review is a critical developmental task enabling older persons and the dying to achieve ego integrity rather than despair.¹²² With the achievement of ego integrity, a person finds meaning in his or her life and dying experience and, it is hoped, fears death less.¹²³ Chochinov has developed a life review tool to guide patients in looking over their lives for meaning and purpose and to help them maintain their person-ness and dignity in the dying process. The dignity-conserving perspectives fostered by this style of life review include continuity of self, role preservation, maintenance of pride, hopefulness, autonomy and control, generativity and legacy, acceptance, resilience, and fighting spirit. Three personal approaches that enhance dignity are living in the moment, maintaining normalcy, and finding spiritual comfort.⁹⁷ More research is needed to document the effects of life review, although many working in PC acknowledged that this tool has significant effects in relieving the existential suffering of patients with advanced illness.^{124,125} Wise and Marchand found that in an RCT of life review, a sense of peace was enhanced.¹²⁶

Hypnosis and Guided Imagery

In small trials, hypnosis and guided imagery have been shown to reduce anxiety, pain, and stress and to promote relaxation. Hypnosis creates a state of "focused awareness and attention," which can facilitate improvement in coping, well-being, and acceptance of death.¹²⁰ Guided imagery can be facilitated with music to evoke deeper connection.^{115,127,128}

Hypnosis was found to be efficacious in attenuating nausea and vomiting associated with cancer chemotherapy as well as pain.¹²⁹ Hypnosis and guided imagery may be helpful in decreasing pain and increasing relaxation in patients at the end of life, although more research is needed in this area.^{130,131} Guided imagery can also be used before death to imagine a person's optimal dying process: who would be with the person, what environment he or she would be in, what he or she would like to hear or say, and so on. Once this process is defined through imagery, family / clinicians can do their best to recreate it (see [Chapters 95](#) and [97](#)).

Music Therapy

Simple music that is relaxing can be provided by anyone, but music therapy is provided by a certified music therapist. In active approaches to music therapy, the patient creates music with voice or instruments as a way of relating or expressing deep feelings. In receptive music therapy, the patient is receptively engaged in listening to music rather than creating it. Some forms of receptive music therapy involve the playing of music while a patient reminisces, paints, relaxes, meditates, or moves gently. Goals of therapy include relief of pain or other discomfort, relaxation, increased energy, better sleep, and relief of depressive symptoms. Music therapy has a clear theoretical framework for its effects. Although a number of studies have examined the use of music therapy for depression, the variety of modalities of music therapy makes it difficult to create a systematic review with strong recommendations.¹³²

Music can raise endorphin levels in the brain and lower adrenaline levels.^{133,134} The noise level in an intensive care unit (ICU) can exceed 60 dB, engendering anxiety and pain in patients being treated there. Music can help modulate this noisy environment when it is played through earphones, but music therapy need not be continuous, and optimal treatment periods are 25–90 minutes.¹³⁵⁻¹³⁷ Studies by Chlan¹³⁴ and Wong et al.¹³⁸ have shown that 30 minutes of music therapy for relaxation is more effective than uninterrupted rest of patients in an ICU undergoing mechanical ventilation, and Zimbardo and Gerrig¹³⁹ found that 30 minutes of classical music therapy in an ICU setting equaled the relaxation effects of 10 mg of diazepam. In a 2010 Cochrane review, because of the high risk of bias and a limited number of studies, insufficient evidence was found for beneficial effects of music in end-of-life care to improve QOL.¹⁴⁰ Music therapy can improve mood in

depression.¹⁴¹ This modality reduced the intensity of pain by up to 70% in one study and can decrease opioid requirements.⁵⁵

Music thanatology combines music therapy as medicine and spirituality. Its goals are to relieve suffering and pain and to promote a peaceful and conscious death. The therapy depends on the assessment of the musician and the needs of the patient and is therefore described as prescriptive music. A bedside vigil lasts 45–60 minutes, and caregivers are encouraged to be present. A portable harp produces a polyphonic sound that is described by Therese Schroeder-Sheker,¹⁴² founder of the Chalice of Repose Project in End of Life Care in Oregon and North Carolina, as dissolving, which is well suited to the various environments in which the vigils are held. The tempo of the music is synchronized to the heart and respiratory rate of the patient to produce entrainment to a more relaxed or sleep state.¹⁴³ In a study of harp therapy, 77% of patients and families found the therapy to be of great benefit, and 23% found it to be of some benefit. Anxiety was relieved in 84% of patients, fear in 70%, dyspnea in 71%, nausea in 92%, and pain in 63%.⁶

Massage

Massage encompasses many different styles, but in ill patients, gentler forms such as Swedish massage may be better tolerated. Massage is beneficial in treating depression and pain, and it can help alleviate anxiety and promote more restful sleep.¹⁴⁴⁻¹⁵³ In a study of 1290 patients with cancer, massage reduced moderate-to-severe symptoms of pain, fatigue, anxiety, and nausea by about 50%.¹⁵⁴ Another study also found this result.¹⁵⁵ A Cochrane review found evidence that massage, especially paired with stress-reduction techniques, improved QOL in patients with HIV/acquired immune deficiency syndrome.¹⁵⁶ Hand massage may be helpful for patients with dementia who are agitated. This modality can promote relaxation.¹⁵⁷ This modality is also combined with aromatherapy at times for a synergistic effect.

Aromatherapy

Aromatherapy is often used together with massage. One RCT showed that massage therapy with or without lavender oil helped promote sleep; massage therapy appeared to be the essential intervention.¹⁵⁸ Lavender oil aromatherapy alone was found to relieve anxiety in two small studies.^{159,160} Use of rosemary oil increased alertness and decreased anxiety.¹⁵⁹ In a small study of 20 terminally ill patients with cancer, a

regimen of lavender oil aromatherapy, followed by a foot soak with oil and warm water, followed by application of reflexology significantly relieved fatigue.¹⁶¹ In another small experimental study of 17 hospice patients, inhaled lavender aromatherapy helped relieve anxiety and pain.¹⁶² In a systematic review, aromatherapy massage showed benefit for psychological well-being and anxiety. Limited evidence exists for benefits in nausea, pain, and depression.¹⁶³ In one RCT using spearmint and peppermint oils in the treatment of nausea due to chemotherapy, these oils significantly reduced nausea and vomiting without adverse effects. The oils reduced the overall cost of treatment.¹⁶⁴ The species of plant used for the oil and the quality of the essential oil can have an impact on the therapeutic effect.¹⁶⁵ Many essential oil blends exist for specific indications, and the reader is encouraged to read a definitive text on this modality or to seek out the services of a certified aromatherapist.

Energy Medicine

Subtle energies involved in some complementary therapies work on a level of physics that is new to a purely mechanical, materialistic, and chemical view of life, and new discoveries have been slowly accepted in the understanding of biological systems. DNA has been found to have electronic as well as acoustical resonances, in which quantum fluctuations affect DNA expression. Music thanatology, described previously, may very well affect acoustical resonances at a DNA level as well as on a universal healing plane.¹⁶⁶ The emerging understanding that exists today makes the RCT perhaps too insensitive a research tool with which to study these energetic modalities, especially at the end of life, when a person's vibrational energies merge with the energies beyond the human form (see [Chapter 116](#)). In a review of biofield therapies for symptom management in PC, the authors found benefit for improving pain and QOL.¹⁶⁷

Healing or Therapeutic Touch and Reiki Therapy

In small, non-RCT studies, therapeutic touch has been found to reduce anxiety and pain and to improve relaxation. Therapeutic touch is the focused intention to heal on the part of the practitioner; it involves the transfer of energy from the environment through the practitioner to the patient.¹⁶⁸ In a large descriptive study, a hospital evaluated its inpatient therapeutic touch program. The investigators found that it decreased anxiety and pain and increased relaxation.¹⁶⁹ It is challenging to research

therapeutic touch with RCTs because it is difficult to have a control group, and the effects cannot be differentiated from a placebo response.¹⁷⁰ Four trials of therapeutic touch for wound healing were variable in effect.¹⁷¹ A Cochrane review on touch therapies found modest effects on decreasing pain, and positive results seemed to be in part related to the experience of the practitioner.¹⁷²

Reiki therapy balances the bioenergy fields on a deep vibrational level. Its therapeutic goals are to restore balance and resiliency and to promote nonspecific healing. A light touch is used on specific areas of the head and torso. If the patient has lesions, the practitioner's hands can hover a few inches above the patient. Reiki therapy may reduce anxiety and pain.¹⁷³ Miles and True¹⁷⁴ reviewed RCTs of Reiki therapy and found inconclusive results.

Acupuncture and Traditional Chinese Medicine

Traditional Chinese medicine has been practiced for thousands of years as a system of healing modalities, including herbs, acupuncture, and qi gong, designed to balance the life energy called *qi*. Acupuncture is an effective modality for breathlessness, nausea and vomiting, and pain.¹⁷⁵⁻¹⁷⁷ One RCT showed a significant decrease in neuropathic pain with acupuncture compared with sham acupuncture.¹⁷⁸ Acupuncture is effective for pain in a number of musculoskeletal pain syndromes, such as headache, chronic neck and back pain, and osteoarthritis. Adverse reactions are rare.¹⁷⁹⁻¹⁸³

Despite these positive studies for acupuncture use, a Cochrane review of acupuncture for cancer pain did not find sufficient evidence to support its use.¹⁸⁴ A systematic review of acupressure studies showed some efficacy for dyspnea, fatigue, and insomnia.¹⁸⁵

Therapies to Consider

Art therapy is useful in bereavement groups, especially with children and teens, and with individuals as a means of expressing feelings, communications about the death, and their resulting grief. Pet therapy is increasingly more popular in PC and EOL care. Anyone dying who has a relatively trained pet should be allowed to have the pet present if at all possible. The comfort provided may reduce anxiety.¹⁸⁶ Other modalities to consider in PC are homeopathy, chiropractic care, osteopathic manipulation, and humor therapy. See [Key Web Resources](#) for a list of

resources for patients and clinicians.

Prevention Prescription

- Prevention is focused on maximizing comfort, well-being, healing, and life closure rather than on prolonging the dying process.
- Carefully apply and titrate therapeutic interventions to minimize side effects and maximize well-being.
- Avoid skin breakdown with frequent turning and gentle massage.
- Prevent anxiety and spiritual discomfort with supportive and trusting therapeutic relationships, effective symptom management, empowered decision making by the patient, and bereavement and spiritual care.
- Address grief and loss with effective grief services before and after death.
- Advocate the use of advance directives, educate the patient and family on options in end-of-life care, elicit and honor patient treatment preferences, and deliver PC on the basis of the patient's treatment goals. Doing so will reduce unnecessary and unwanted interventions at the end of life.

Therapeutic Review

A number of therapeutic interventions can be used synergistically to maximize therapeutic effect, in some cases reducing the dose of medication needed for effect and minimizing side effects. In addition to controlling symptoms, many integrative modalities can improve well-being by enhancing psychological and spiritual health as well as by providing physical comfort. In end-of-life care, unnecessary therapies are discontinued and less-invasive modalities are increased in keeping with the needs and goals of the patient, the resources available, and the patient's response to them. Attentive listening, careful assessment, and keen observation are essential in guiding therapeutic choices.

Pain Management

Pharmaceuticals

- Treat pain as an emergency. Addiction at the end of life is generally a nonissue. Believe the patient's report of pain (suffering), but consider the concept of "whole pain." Treat pain carefully but aggressively. Use a lower starting dose in patients who are opioid naive and in older persons, but increase dosage rapidly and carefully for an adequate response. No ceiling dose exists for opioids.³²
- For unrelieved severe pain, increase the immediate-acting opioid dose by 50%–100% every 24 hours; for moderate pain, increase the dose by 25%–50%. The dose of short-acting opioids for breakthrough pain should be about 10% of the total 24-hour dose of sustained-release medication and should be given every 2–3 hours as needed. Consider increasing the bedtime dose by 50% or less to avoid administration during the night. Opioid-induced sedation caused by initiation of or increase in the dose of an opioid analgesic usually clears within a few days.^{32,187,188}
- Use scheduled dosing of an oral long-acting medication for chronic pain to prevent oversedation and nadirs of pain relief. Adjust dose, generally, every 1–2 days after a steady state is achieved. Increase the dose of immediate-acting opioids for uncontrolled pain. Administer through mouth whenever possible. Avoid intramuscular injections.³²
- The lowest dose of the fentanyl transdermal patch is 12 mcg/h, which is replaced generally every 3 days. The 25-mcg/h patch is equivalent to approximately 50 mg of oral morphine daily. The patch should be avoided in opioid-naive patients, for whom the starting dose may be too strong. Most patients can take oral medication, which also costs less. The transdermal patch takes 8–24 hours to achieve the analgesic effect and therefore should not be used alone to treat acute pain. Also, once the patch is removed, the analgesic effect continues for 17–24 hours. Dosage may be usually titrated every 2–3 days. Absorption increases with fever. Subcutaneous fat is needed as a reservoir for the drug. Avoid placing on bony areas.^{32,187}
- Decrease dose and intervals of analgesics in patients with reduced hepatic and renal clearance and in those who are dehydrated and oliguric.³²
- Extended-release tablets cannot be crushed or chewed. Extended-release granules can, however, be mixed with food or fluids or given via a gastric tube.³²

- Avoid use of meperidine because of its problematic metabolites when used for chronic pain.¹⁸⁷
- For severe chronic pain, start with extended-release morphine, 15-mg tablet twice daily, with immediate-acting morphine, 10 mg every 3 hours, as needed. Kadian, a long-acting morphine preparation, consists of a capsule containing sprinkles that can be given via a gastric tube or mixed with food.³²
- Hydromorphone does not have toxic metabolites and is preferred in patients with severe renal insufficiency. Morphine and oxycodone are excreted renally and should be used carefully or avoided in patients with severe renal insufficiency.³²
- In patients with liver impairment, morphine is preferred. Avoid acetaminophen and tricyclic antidepressants in patients with liver impairment.³²
- Methadone is useful in the treatment of nociceptive and neuropathic pain; it is inexpensive and can control pain that is not responsive to other opioids.³⁰ Initiation and titration of methadone therapy are unique, and appropriate resources must be carefully used; alternatively, the clinician can consult with a palliative medicine or pain consultant.^{33,35} Conversion to methadone from another opioid is also unique, and guidelines for optimal, safe conversions are available.^{32-35,37} 
- Always use a gentle laxative when treating a patient with opioids. Stool softeners alone are generally ineffective. They can be used together. Use laxatives liberally; senna at a starting dose of one to two tablets at bedtime works well. The goal is for the patient to have a bowel movement every day or every other day. A stool softener alone is often not effective, and use with a laxative is needed. 
- Neuropathic pain often requires the addition of adjuvant medications, such as anticonvulsants (e.g., gabapentin starting at 100 mg three times a day) or antidepressants (e.g., the tricyclic antidepressant nortriptyline starting at 10 mg/day or amitriptyline starting at 25 mg at bedtime), for adequate relief. Opioids alone, except methadone, are usually not adequate to treat neuropathic pain.³² Use caution in patients with renal or hepatic impairment.

Botanicals and Supplements

- For pain, especially neuropathic pain, cannabis inhaled is most effective. Medical marijuana is only available legally in specific states in the United States and countries worldwide. Check local laws and clinical resources. 

Other Modalities

- Consider acupuncture for neuropathic and nociceptive pain, often in conjunction with medication. 
- Massage can help relieve pain. 

Nausea and Vomiting

Lifestyle

- Target the mechanism of cause and either discontinue the offending medication or treat the underlying cause.

Pharmaceuticals

- Stimulation of chemoreceptor trigger zone (CTZ) in the fourth ventricle of the brain by medications including opioids, hypercalcemia, or uremia commonly causes nausea and vomiting. The CTZ has dopamine and serotonin (5-HT₃) receptors. Antidopaminergics such as prochlorperazine and haloperidol and 5-HT₃ antagonists such as ondansetron most effectively treat this cause of nausea and vomiting.⁵⁸
 - Prochlorperazine: start at 5 mg every 6 hours as needed orally or 25 mg twice daily as needed via rectal route
 - Haloperidol: start at 0.5 mg orally three times daily as needed; may also be given subcutaneously 
- Nausea caused by constipation is relieved with laxatives.⁵⁸ 
- Nausea caused by infection and inflammation responds well to anticholinergic and antihistamine antiemetics, such as promethazine 12.5–35 mg every 4–6 hours orally and intramuscularly, and 25 mg rectally every 6 hours as needed.⁵⁸ 
- Nausea caused by dysmotility of the gut, such as in the use of opioids,

is relieved best with prokinetic agents such as metoclopramide, starting at 5 mg orally, subcutaneously, or intravenously every 6–8 hours as needed. Anticholinergic drugs make this kind of nausea worse. Avoid this drug in patients with Parkinson’s disease and renal failure.⁵⁸ 

- Vestibular causes of nausea respond best to antihistamine, anticholinergic drugs such as promethazine, and scopolamine; one patch every 72 hours should be administered as needed.⁵⁸ 

Botanicals

- Ginger: 500–1000 mg of ginger root extract as needed (boiled to make a tea), or eat 1 tsp or 5 g of crystallized ginger as needed for nausea. 
- Cannabinoid: Inhalation most effective for nausea and to improve appetite. 

Dyspnea

Pharmaceuticals

- Oxygen therapy can help relieve dyspnea caused by low oxygen saturation.
- Morphine and other opioids can help relieve the sensation of breathlessness.⁶⁴ In elderly and opioid-naive patients, consider initially using very low doses of morphine solution in doses of 2–4 mg every 3 hours either as scheduled or as needed. Immediate-release morphine can also be given if the patient must exert himself or herself above baseline activities or if a more strenuous activity causes more dyspnea. The dose is given 30 minutes before the more strenuous activity. If short-acting morphine is needed regularly, consider using long-acting morphine. 
- In patients already receiving opioids for pain, the dose of opioid to control breathlessness may need to be 1.5–2.5 times the analgesic dose.³²
- Drying secretions with glycopyrrolate can help with the sensation of dyspnea at the end of life. Glycopyrrolate does not cross the blood–brain barrier and cause sedation and can be given orally or IV.

Avoidance of overhydration is also important. 

- Anxiolytics such as lorazepam (Ativan), 0.5–2 mg every 6–8 hours as needed, can help in anxiety associated with breathlessness. 

Energy Medicine

- Acupuncture can help relieve dyspnea. 

Delirium

- Assess for delirium carefully because the patient can be in a hyperactive / agitated or hypoactive / somnolent delirium state. Do not treat states of agitation reflexively using anxiolytics, which have a high potential to make delirium worse. Medications (especially with anticholinergic side effects), steroids, benzodiazepines, and opioids are often the culprit, and offending medications must be discontinued or changed, the dose decreased, or the route of administration changed. Treatment is aimed at the underlying cause. [71,78,79](#)
- Delirium must be differentiated from near-death awareness. [86](#)

Pharmaceuticals

- Haloperidol is the drug of choice for treatment of acute delirium; dosing starts at 0.5–2 mg orally two or three times a day or 0.5–2 mg intravenously or intramuscularly every 1–4 hours as needed. The dose can be titrated down by 25% daily once the optimal effect is stabilized. It is less sedating and has fewer side effects than other neuroleptics. Side effects are extrapyramidal, consisting of restlessness and tremor. [71,78](#) Use caution if the QTc interval is prolonged, except in patients at the end of life. 
- Benzodiazepines are indicated for delirium caused by seizures and alcohol or sedative withdrawal and in cases not responding to haloperidol. [77,78](#) 

Spiritual Care

- Indigenous cultural and spiritual practices are important in facilitating healing as well as peaceful, meaningful dying and death. Ritual and ceremony are important in supporting the patient and

relieving emotional and spiritual distress, which can have an ameliorating effect on physical symptoms. 

- Spiritual inquiry using a spiritual assessment tool, meditation, and prayer can improve spiritual and psychological well-being in the dying process and also relieve physical symptoms. 

Bereavement

- Grief work for the patient can help relieve existential distress, and grief work for the family, friends, and health care staff when needed can help diminish complicated grief after the death. 

Nutrition

- Reducing food and fluid intake is normal in the dying process, and patient discomfort can occur if food or fluids are forced or if given intravenously or via tube feedings. Substitute the nurturing aspects of feeding with touch and other ways to show love and care to the patient. Offer foods in small quantities that the patient enjoys and finds palatable. Swab the mouth frequently to prevent feeling of thirst. 

Mind-Body Therapies

- Mindfulness-based stress reduction can decrease anxiety, chronic pain, stress, and depression. 
- Music therapy encompasses many modalities. Harp therapy can decrease pain, existential and physical suffering, anxiety, and nausea and can improve sleep.
- Massage therapy also includes many different styles of treatment; it can ameliorate pain, fatigue, anxiety, depression, and nausea as well as promote better sleep. 
- Reminiscence therapy can improve cognition in patients with dementia. 
- Life review therapy improves depression, spiritual distress, and quality of life and alleviates pain. 

- Hypnosis and guided imagery can reduce anxiety, pain, and stress and promote relaxation. 

Energy Therapies

- Aromatherapy massage has been shown to be of benefit for psychological well-being and anxiety. Limited evidence exists for its benefits in nausea, pain, and depression. 
- Therapeutic touch may reduce anxiety and pain and promote relaxation. Other benefits are also possible, but this modality is challenging to research. 
- Acupuncture is an effective modality for nausea and vomiting and pain.

SECTION XV

Substance Abuse

OUTLINE

[Chapter 83. Alcoholism and Substance Abuse](#)

CHAPTER 83

Alcoholism and Substance Abuse

Donald Warne, MD, MPH

Alcohol use disorder (AUD) is a medical diagnosis characterized by problem drinking that becomes severe. In the United States, approximately 17 million adults aged 18 and older had an AUD in 2012 (7.2% of adults). Minors can also be diagnosed with an AUD, and approximately 855,000 adolescents aged 12–17 had an AUD in 2012. Diagnostic criteria for AUD are described in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM). According to the DSM-5, anyone meeting two or more of the 11 criteria within a 12-month timeframe is diagnosed with AUD. AUD severity (mild, moderate, or severe) is determined by the number of criteria met.¹

In addition to alcohol, there are numerous drugs of abuse, including opiates, marijuana, cocaine, methamphetamines, tobacco, and others.² See [Box 83.1](#) for a simple three-question screening tool for alcohol disorders (AUDIT-C).

Alcoholism and substance abuse have a negative impact on other chronic diseases managed in the primary care setting due to the direct effects of the substances abused and issues related to compliance and self-care.³ Acute injury and illness resulting from alcohol and substance abuse are analogous to exacerbations of chronic conditions and therefore constitute issues of extreme importance in the arena of primary care. Unfortunately, many physicians do not routinely address these issues,⁴ and few conventional allopathic interventions are easily accessible and efficacious. This chapter examines the treatment options available to the primary care physician and also provides a source of information for appropriate referrals. A multitude of both illicit and prescribed substances are abused; the focus of this chapter is primarily on alcohol, tobacco, opiates, cocaine, and marijuana.

Addiction to drugs and alcohol should be treated as a chronic illness not unlike diabetes mellitus or hypertension.⁵ Like these disorders,

addiction has behavioral components as well as underlying biochemical mechanisms. Within chronic addiction and recovery, there are also exacerbations of abuse as well as chronic multiorgan system complications.⁶ Successful treatment of all chronic diseases requires a good rapport between patients and providers and the use of a nonjudgmental approach.^{7,8} [Box 83.2](#) provides simple guidelines to assess the severity of alcohol risk.

Pathophysiology

Alcoholism and substance abuse have many dimensions, each with unique implications and standards of treatment. The processes of alcoholism and substance abuse may be divided into broad categories or stages: craving, active abuse, intoxication, withdrawal, detoxification, recovery, and relapse prevention.

A proposed mechanism of addiction for all substances of abuse involves the sudden release of dopamine in the “reward pathway” connecting the midbrain to the prefrontal cortex. This rush of dopamine is believed to cause a sense of euphoria and pleasure that is at the root of drug abuse. With extended drug use, there is a profound alteration in brain chemistry. This neurophysiological change in the central nervous system eventually causes a “switch” in the affected person from a state of drug abuse to one of addiction with uncontrollable cravings and dependence. The exact mechanisms of this process are as yet unknown.⁹

The process of addiction is, of course, not limited to brain chemistry. The effects of environmental, social, cultural, genetic, and behavioral factors are significant in the development of alcoholism and substance abuse.¹⁰ These factors assume varying levels of importance in the development of addiction for each person. Addiction is therefore most accurately viewed as a complex illness with varying degrees of environmental and biochemical features.¹¹

Integrative Therapy

Pharmaceuticals

In the last decade, several new and effective pharmacological options have become available to the primary care physician to treat alcoholism and substance abuse. Some of the most effective pharmaceutical agents

are available only through licensed intensive outpatient and inpatient programs specializing in the treatment of addictions. However, with the U.S. Food and Drug Administration (FDA) approval of new medications, including acamprosate (Campral) in 2004 and buprenorphine (Subutex) in 2002, primary care physicians have the opportunity to take a more active role in the treatment of addiction to alcohol and opiates.^{12,13} For physicians interested in using these medications for their patients with addictions, it is important to remember that these agents are most effective when they are used as part of a comprehensive management program that involves psychosocial support such as counseling and support groups. [Table 83.1](#) provides an overview of pharmaceutical treatments for alcohol and substance abuse. As noted, these treatments may be divided into the broad categories of detoxification/withdrawal and craving/relapse prevention.

Management of Alcohol Withdrawal and Recovery

The most common treatment of acute alcohol withdrawal is administration of diazepam or another benzodiazepine.^{14,15} A benefit of benzodiazepine treatment is relief from the anxiety and sleep disturbances experienced during the withdrawal phase. A disadvantage of benzodiazepine therapy is the potential for dependence if the drug is not prescribed appropriately.¹⁶ A benzodiazepine for detoxification should be prescribed only for a short time in a supervised setting. Phenobarbital or carbamazepine (Tegretol) is occasionally used in managing withdrawal seizures. There is evidence that opioid receptors play a role in the physiological response to alcohol. Naltrexone (ReVia), an opioid antagonist, has been shown to be effective in preventing alcoholic relapse.¹⁷ Disulfiram (Antabuse) inhibits aldehyde dehydrogenase and produces unpleasant effects, such as nausea, vomiting, and dizziness, when alcohol is consumed.

BOX 83.1 AUDIT-C Screening for Alcohol Use Disorders

Instructions: For each question, please check the answer that is correct for you.

1. How often do you have a drink containing alcohol?
Never (0)
Monthly or less (1)

- Two to four times a month (2)
- Two to three times per week (3)
- Four or more times a week (4)

2. How many drinks containing alcohol do you have on a typical day when you are drinking?

- 1 or 2 (0)
- 3 or 4 (1)
- 5 or 6 (2)
- 7 to 9 (3)
- 10 or more (4)

3. How often do you have six or more drinks on one occasion?

- Never (0)
- Less than monthly (1)
- Monthly (2)
- Two or three times a week (3)
- Four or more times a week (4)

Add the numerical value of each answer selected to get your total score.

TOTAL SCORE: _____

The maximum score is 12. A score of ≥ 4 identifies 86% of men who report drinking above recommended levels or who meet criteria for alcohol use disorders.

A score of > 2 identifies 84% of women who report hazardous drinking or alcohol use disorders.

From National Council for Community Behavioural Healthcare.

http://www.thenationalcouncil.org/galleries/business-practice%20files/tool_auditc.pdf;

Accessed July 5, 2011.

Acamprosate, an amino acid derivative that modulates activity of gamma-aminobutyric acid (GABA) neurotransmission in the brain, appears to be effective in reducing alcohol cravings.¹⁸ As opposed to limiting the “high” sensation of alcohol (as naltrexone does) or producing unpleasant side effects (as disulfiram does), acamprosate can assist in preventing alcohol relapse by reducing the anxiety and sleep disturbances associated with alcohol craving, although its exact mechanism of action is unknown.¹⁹ Pharmacological treatments for alcohol withdrawal generally work well and can potentially be used for outpatient withdrawal management if the primary physician is able to monitor the patient closely. Treatments for relapse prevention generally

are not efficacious in the absence of comprehensive follow-up care.²⁰

BOX 83.2 Alcohol Risk Terms: Abstinence, Moderate, and Risky or Hazardous

Abstinence

No alcohol use

Moderate

Men: no more than 2 standard drinks per drinking day

Women and older persons (older than 65 years): no more than 1 standard drink per drinking day

Risky or Hazardous

Men

More than 4 standard drinks per drinking day

More than 14 standard drinks per week

Women and older persons (older than 65 years)

More than 3 standard drinks per drinking day

More than 7 standard drinks per drinking week

TABLE 83.1

Pharmaceutical Agents Used for Treatment of Alcoholism and Substance Abuse

Substance of Abuse	Agents Used for Detoxification/Withdrawal	Agents Used for Craving/Relapse Prevention	Agents Used for Other Purposes
Alcohol	Benzodiazepines Phenobarbital	Naltrexone Acamprosate Topiramate	Disulfiram
Tobacco	Nicotine Bupropion	Nicotine Varenicline	Bupropion
Opiates	Methadone Clonidine Buprenorphine	Methadone L-Alpha-acetylmethadol	Naloxone
Cocaine	Selective serotonin reuptake inhibitors Monoamine oxidase inhibitors Amantadine	Tricyclic antidepressants	
Marijuana	N/A	N/A	

N/A, not applicable.

For patients who have not abstained from alcohol, topiramate

(Topamax) has been found to reduce heavy drinking and days of any drinking over a 12-week period. It is also cleared through the kidney and thus does not exacerbate toxicity to the liver. It is generally used for 6–12 months as part of a comprehensive treatment program.²¹ Research also suggests that topiramate at a mean dose of 200 mg/day may work better to maintain abstinence with reduced cravings than naltrexone at a mean dose of 50 mg/day.²²

Dosage

- Naltrexone 50 mg/day orally reduces the high sensation associated with alcohol.
- For the reduction of the craving of alcohol, acamprosate 333–666 mg three times a day or topiramate titrated from 25 to 300 mg weekly over 8 weeks ([Table 83.2](#)) is prescribed.
- Disulfiram 150–500 mg/day creates unpleasant side effects when it is used with alcohol.
- For help with tapering and withdrawal from alcohol, the dosage of benzodiazepine is titrated to achieve a calming effect. High doses may be needed initially. An example is clonazepam (Klonopin) 1 mg three times a day, with a gradual taper over 10–14 days.
- Match the pharmaceutical treatment to the individual's greatest need for successful abstinence.
 - For cravings: use acamprosate or topiramate.
 - For negative feedback and avoidance: use disulfiram.
 - To reduce the high associated with use: use naloxone or topiramate.
 - To reduce symptoms of withdrawal: use a benzodiazepine (diazepam or clonazepam) or clonidine.

Management of Nicotine Withdrawal: Smoking Cessation

Effective outpatient treatment regimens are available for smoking cessation. Tapered nicotine replacement therapy (NRT) is effective in the management of nicotine withdrawal and cravings.²³ Bupropion (Zyban) has been shown to be effective in managing symptoms of anxiety associated with nicotine withdrawal and craving and can be used in combination with NRT.²⁴ Varenicline (Chantix), a partial nicotine receptor agonist, has been found to help increase smoking cessation more

than placebo and as well as bupropion.²⁵ These medications can be used successfully in the outpatient primary care setting.²⁶

TABLE 83.2

Titration of Topiramate for Treatment of Alcohol Dependence

Week	Morning Dose (mg)	Afternoon Dose (mg)	Total Daily Dose (mg)
1	0	25	25
2	0	50	50
3	25	50	75
4	50	50	100
5	50	100	150
6	100	100	200
7	100	150	250
8	150	150	300

Dosage

Bupropion 150 mg is administered twice daily for 6 weeks, with a target quit date of 2 weeks after the start of therapy. Varenicline is started 1 week before smoking cessation: 0.5 mg orally for 3 days, 0.5 mg twice daily for 4 days, and then 1 mg twice daily for 11 weeks; the general course of therapy is 12 weeks.

Precautions

Varenicline has a black box warning for neuropsychiatric side effects including behavior change, hostility, agitation, depression, and suicidality. These can be exacerbated when it is used long term with nicotine. Adverse events associated with the use of bupropion in clinical trials most commonly included insomnia, headache, dry mouth,

nausea, and anxiety.

Management of Opiate Withdrawal and Recovery

Acute opiate withdrawal is commonly treated with methadone, an opioid receptor agonist that can block withdrawal symptoms without producing the euphoria caused by heroin and other opiates. Owing to this effect, methadone is also commonly used in long-term maintenance programs to reduce cravings and relapse. Clonidine has been shown to be effective in lessening opiate withdrawal symptoms and does not foster physiological dependence.²⁷ L-Alpha-acetylmethadol (LAAM) is derived from methadone and acts in a fashion similar to that noted for methadone.²⁸ The advantage of LAAM in maintenance therapy is that its effect lasts 72 hours, allowing dosing every other day or three times per week. Naloxone is an opiate antagonist used for treatment of acute opiate overdose.²⁹

Perhaps the most significant pharmaceutical development in the management of opioid addiction is the 2002 FDA approval of the use of buprenorphine (*brand name, Suboxone; combines buprenorphine with naloxone*) in the United States. An opiate receptor partial agonist, buprenorphine has shown benefit in managing opioid addiction and preventing relapse.³⁰ Opioid partial agonists bind to the opioid receptor, but only partially activate the receptor and generate significantly less euphoric sensation than opiate agonists like heroin do.³¹ Potential for abuse of buprenorphine is much lower than those of other opiates, and buprenorphine has been shown to be as effective as methadone in weaning clients off this class of drugs.³²

Buprenorphine requires specific training for prescribing, and referral to an appropriately qualified physician is required. More information is available at the U.S. Department of Health and Human Services Substance Abuse and Mental Health Services Administration (SAMHSA) website (<http://buprenorphine.samhsa.gov>).

Management of Cocaine Dependence

Cocaine withdrawal is typically associated with minimal symptoms as compared to other substances of abuse.³³ Several classes of pharmaceutical agents have been studied for their efficacy in treating cocaine dependence and relapse prevention, although none of these are approved by the FDA for this purpose. Extensive abuse of cocaine can cause depression by depleting baseline levels of dopamine.³⁴ Several

antidepressants have been studied for their roles in treating cocaine addiction, including tricyclic antidepressants, selective serotonin reuptake inhibitors, and monoamine oxidase inhibitors; however, results are mixed and inconclusive. Propranolol has been studied for its effectiveness in reducing cocaine withdrawal severity and is showing some promise in mitigating severe symptoms.³⁵ Amantadine, a dopamine agonist, has been studied for its role in cocaine dependence. In theory, dopamine agonist therapy should cause dopamine restoration and reduce the need for cocaine, but findings of studies have not been convincing.³⁶ In addition, the results of studies examining the role of buprenorphine in the management of cocaine addiction have been mixed.³⁷

Botanicals

Various herbs and combinations of herbs are reported to be effective in reducing cravings, but in general, no studies have proven their effectiveness.

Kudzu

Kudzu, a traditional Chinese herb, has been used as an “antiinebriation” treatment for hundreds of years, although its mechanism of action is not yet known.^{38,39}

A small study showed that in heavy drinkers of alcohol, kudzu did result in a reduction of the number of beers consumed after 7 days of treatment.⁴⁰ It has not been found to enhance sobriety in chronic alcoholics.⁴¹

Dosage

The recommended dose is 1.2 g twice daily.

Precautions

Kudzu is considered safe, with few side effects other than the potential for an allergic reaction to the plant.

Cytisine

In a study comparing cytisine to nicotine replacement, 40% quit on

cytisine compared to 31% on nicotine replacement. Cytisine is a plant-based alkaloid found in the seeds of the golden rain tree (*Cytisus laburnum*). It is a partial agonist of nicotine acetylcholine receptors. It works similar to the drug varenicline (Chantix) and has been available in Eastern Europe since the 1960s. The leaves of this plant were smoked by Russian soldiers during World War II when there was a shortage of tobacco. It was known as *false tobacco*.

Dosage

Cytisine 1.5 mg (*Tabex*) were used in this study. Patients were told to taper smoking over the first 4 days and quit on the 5th day. The following tapering dose of cytisine was used:

Days 1–3: 1 tablet every 2 hrs, up to 6 tablets a day.

Days 4–12: 1 tablet every 2.5 hrs, up to 5 tablets per day.

Days 13–16: 1 tablet every 3 hrs, up to 4 tablets a day.

Days 17–20: 1 tablet every 4–5 hrs, up to 3 tablets a day.

Days 21–25: 1 tablet every 6 hrs, up to 2 tablets per day.

Precautions

The plant *Cytisus laburnum* from which cytisine is derived is traditionally used as an emetic and purgative, so nausea and vomiting is the main side effect. Like varenicline, it can disrupt the sleep cycle and cause nightmares.

Herbal Antidepressants and Anxiolytics

Because people who struggle with alcoholism and substance abuse commonly have coexisting depression and anxiety,^{42,43} it is possible that herbal remedies used for these conditions may have a role in recovery and abstinence. Poorly managed anxiety may lead to higher alcohol intake.⁴⁴ Herbs that are effective in treating anxiety and insomnia, such as valerian and kava kava, might be helpful in managing anxiety associated with detoxification and cravings. These herbs have been shown to enhance the levels and action of GABA and therefore might also have a role in the control of alcohol cravings and prevention of relapse. Caution should be taken with the use of kava kava in alcoholic patients because it has been associated with liver toxicity.⁴⁵ St. John's wort has a mechanism

of action similar to that of the selective serotonin reuptake inhibitors and has been shown to be effective in treating depression.⁴⁶ Its role in managing depression associated with alcoholism and substance abuse is yet to be determined. The potential uses of herbal antidepressants in addiction recovery warrant further investigation.

Other Herbal Remedies

Lobelia is described as a respiratory stimulant and has been used in homeopathic preparations as an aid to stop smoking.⁴⁷ Milk thistle, which has been studied for its hepatoprotective effects, appears to be a promising treatment for alcoholic cirrhosis.⁴⁸

Acupuncture

Acupuncture is perhaps the most extensively studied and most promising integrative treatment of addictions. The practice of acupuncture is documented in Chinese literature as early as the Han dynasty in the second century BC in the *Huang Di Nei Jing (Yellow Emperor's Classic of Medicine)*. In acupuncture terms, the body is seen as having several energy channels, or meridians, that allow the free flow of *qi* (pronounced "chee"), or energy. In a healthy or balanced state, *qi* flows smoothly throughout the body and provides for homeostasis. With disease, injury, or a state of imbalance, the normal movement of *qi* is obstructed or impaired. Acupuncture treatments are designed to unblock obstructions of meridians and to promote the healthy flow of energy.⁴⁹

In 1973, Wen and Cheung⁵⁰ reported that opiate-addicted patients who were using electroacupuncture for treatment of postoperative pain described relief from symptoms of withdrawal. Omura brought the treatment protocol to Lincoln Hospital in New York in 1974, and Smith and Kahn⁵¹ developed a five-point auricular acupuncture treatment protocol for addictions that is currently being taught and advocated by the National Acupuncture Detoxification Association (NADA).

In acupuncture terms, substance abuse can be seen as an attempt by the patient to self-treat an imbalance in the flow of *qi*. The "drug of choice" provides temporary relief from energy imbalance, but unfortunately, it also commonly causes further underlying imbalance. As a result, the baseline imbalance slowly worsens, and the need for more drugs slowly increases. The acupuncture treatment therefore provides energy balancing without the need for alcohol or drugs, as well as

relaxation and relief from cravings.⁵²

Acupuncture treatments influence the flow of *qi* to achieve energy balancing, relaxation, and reduced cravings for alcohol, tobacco, and illicit drugs.

Another proposed mechanism of action is that the acupuncture needles stimulate peripheral nerves to cause release of endorphins in the brain, thereby resulting in relaxation and a sense of well-being; acupuncture thus can provide direct biochemical treatment for opiate and ethanol craving and withdrawal.⁵³ The NADA treatment protocol and certification course emphasize the multifaceted nature of this modality and describe treatment benefits in the biochemical, psychological, and social realms as well as in the traditional Chinese paradigm.

FIG. 83.1 Acupuncture points for the National Acupuncture Detoxification Association (NADA) treatment protocol. (Reprinted with permission from Joseph Helms, MD, and Medical Acupuncture Publishers, Berkeley, CA.)

The specific points used in the NADA protocol are shen men (spirit gate), sympathetic nervous system, kidney, liver, and lung ([Fig. 83.1](#)). These points have roles in balancing energy and calming as well as in regulating sympathetic nervous system function and specific organ function from the modern and traditional Chinese perspectives of physiology. The kidney, liver, and lung each have specific roles in the generation, regulation, and flow of *qi*. These organ-specific functions are described in acupuncture texts⁵⁴ and are beyond the scope of this chapter.

Auricular acupuncture has been studied in the treatment of addiction to various drugs, including alcohol, cocaine, opiates, and marijuana. In 1989, Bullock et al.⁵⁵ reported that auricular acupuncture was effective in

the treatment of relapsing alcoholics. In this study, 80 relapsing alcoholics who were enrolled in a treatment facility were randomly assigned to receive either the appropriate acupuncture treatment protocol (treatment group) or sham acupuncture points at sites close to the appropriate points (control group). The outcomes measured included completion of the treatment program and self-reported abstinence at 1, 3, and 6 months after the end of the program. Of the 40 subjects in the treatment group, 21 finished the program, whereas only 1 of 40 in the control group completed treatment ($p < .001$). Information about self-reported drinking episodes was collected from all available subjects, including those who did not complete treatment. Fewer treatment group subjects than control group subjects reported drinking episodes at 1-, 3-, and 6-month follow-up evaluations.

In 1998, Shwartz et al. compared residential detoxification programs that used acupuncture with programs that did not. In this retrospective study, 6907 patients completed nonacupuncture programs, and 1104 patients completed programs that used acupuncture as an adjunctive therapy. The study subjects were dependent on alcohol, cocaine, crack, heroin, marijuana, or a combination of these drugs. The primary outcome measured was readmission to a detoxification program in the 6 months after discharge. After controlling for baseline differences among the patients in the study, those who completed programs offering acupuncture were readmitted to detoxification less frequently than those from conventional programs ($p < .02$).⁵⁶ A randomized controlled trial of auricular acupuncture for cocaine dependence published in 2000 studied 82 patients who were randomly allocated to receive appropriate acupuncture treatment, sham acupuncture, or relaxation therapy. Thrice-weekly urine screening for cocaine was conducted during an 8-week period. The patients who received the appropriate acupuncture protocol were less likely to test positive for cocaine on urine screening than patients in the sham acupuncture control group ($p = .05$) or the relaxation control group ($p = .01$).⁵⁷

Auricular acupuncture has been shown by these studies to be a useful adjunct in treating alcoholism and substance abuse. Other investigations have found mixed results or little benefit from acupuncture in treating addiction.^{58,59} Further investigation in this area is warranted.

Mind-Body Therapies

As more is learned about the connection between thoughts and

physiology, the field of mind-body medicine continues to grow and to gain acceptance. Commonly used therapies classified as mind-body interventions are meditation, biofeedback, hypnosis, guided imagery, yoga, and prayer. Research in this field appears promising for mind-body medicine as an adjunctive intervention for alcoholism and substance abuse.

Meditation

Meditation can be divided into three broad categories: concentrative, mindfulness, and transcendental. Concentrative meditation focuses attention on breathing, imagery, or sounds; mindfulness meditation involves focused awareness on the passage of thoughts and images as they spontaneously appear. Transcendental meditation (TM) is a technique brought to the United States by Maharishi Mahesh Yogi in the 1960s. TM was developed from the ancient East Indian Vedic belief system and helps practitioners of this technique balance the physical, mental, emotional, and spiritual components of health.⁶⁰ Within this belief system, prolonged or excessive stress leads to holistic imbalance, which causes illness, including alcoholism and substance abuse. The sense of balancing offered by TM allows optimal function and decreases the need for drugs and alcohol.⁶¹ Several studies and review articles have shown TM to be effective in the treatment of alcoholism and substance abuse; however, most of these studies had flaws in their designs and methods without randomization, blinding, or appropriate control groups.⁶² A randomized controlled trial indicated improvement in the number of days of alcohol abstinence with the use of TM or biofeedback compared with electronic neurotherapy and the Alcoholics Anonymous program or counseling.⁶³ TM has been shown to significantly raise serotonin levels and to decrease cortisol levels in as little as 4 months of practice.⁶⁴ This is a possible mechanism for improving senses of balance and well-being and for reducing the effects of stress. In a group of polysubstance abusers, when goal management training was combined with mindfulness-based meditation, there was significant improvement in emotional risks associated with substance use.⁶⁵ A study published in 2010 showed effectiveness of Qigong meditation on improved addiction treatment outcomes, particularly among females⁶⁶ (see [Chapter 100](#)).

Mind-body therapies, including meditation, biofeedback, hypnosis, guided imagery, yoga, and prayer, use the power of the mind to

influence the body. Relaxation and reduced physiological responses to stress are helpful in the recovery process.

Biofeedback

Biofeedback is a technique that uses electronic monitors, including electroencephalography, electromyography, and electrocardiography, as well as cutaneous thermometers and pulse oximeters to teach the patient how to consciously control physiological functions such as respiratory rate, heart rate, skin temperature, and blood pressure. Conscious regulation of these functions is achieved through concentration, meditation, and the use of relaxation techniques. Biofeedback has been shown to be useful in managing stress-related disorders such as hypertension, irritable bowel syndrome, pain, and substance abuse.⁶⁷ Electromyographic biofeedback, which focuses on relieving muscle tension, has been shown to be an effective tool in treating alcoholism.⁶⁸ Unfortunately, there are only limited studies on the use of this intervention in treating addictions. The mechanism of action and efficacy of biofeedback in managing alcoholism and substance abuse have not yet been determined.

Hypnosis

The German physician Franz Anton Mesmer introduced modern hypnotherapy in the eighteenth century as mesmerism. The American Medical Association recognized hypnosis as a legitimate medical therapy in 1958, and it has been applied by various health care practitioners in the treatment of numerous disorders, including alcoholism and substance abuse. Hypnotherapy involves concentration, mental focusing exercises, relaxation techniques, guided imagery, and suggestion. Studies have shown that hypnosis improves memory and cognitive function⁶⁹ and can affect physiological function by reducing sympathetic nervous system activity, heart rate, blood pressure, and oxygen consumption.⁷⁰ Many techniques are used in hypnotherapy, making standardization difficult for research purposes; however, there are case reports of positive results of its use in substance abuse treatment and relapse prevention.⁷¹ Controlled trials have not shown long-term benefits in the management of addictions. Some techniques used in hypnosis may be useful as adjunctive modalities in comprehensive recovery programs. One study used self-hypnosis tapes in a residential treatment program for drug and alcohol abuse. Those who listened to the tapes three to five times a week

showed the highest levels of self-esteem and serenity and the least amount of anger or impulsivity compared with less frequent users⁷² (see [Chapter 95](#)).

Guided Imagery

Guided imagery uses the power of the mind to directly affect physiological function. Practitioners of this technique report improved insight into emotional and physical health. Imagery can modulate heart rate, blood pressure, oxygen consumption, and various other physiological measures. Deeper insight into emotions, behaviors, and thoughts can help patients deal with the anxiety and depression associated with the recovery process^{73,74} (see [Chapter 97](#)).

Yoga

A traditional East Indian healing system, yoga combines specific postures, breathing control, and meditation to reduce stress and to promote balance and a sense of well-being. Yoga, meaning “union,” attempts to help its practitioners address and equilibrate the physical, mental, and spiritual forces that coalesce in the process of disease or disharmony. Yoga has been shown to have a beneficial effect on stress-related conditions, including chronic pain, hypertension, and recovery from addiction.⁷⁵ There are, however, no randomized controlled trials specifically assessing the efficacy of yoga for management of addictions. The use of this technique has been shown to be beneficial as part of a comprehensive treatment program.⁷⁶

Spirituality

The role of spirituality in medicine and recovery has been steadily gaining acceptance from mainstream health care practitioners.⁷⁷ Numerous studies on the role of spirituality in the recovery from addiction have been conducted.⁷⁸ Defining spirituality and religion and identifying interventions that exist within these realms are difficult. Spirituality is a subjective concept that can be considered to represent a person’s connection with and relationship to a transcendent or higher power.⁷⁹ Religion can be defined in terms of a structured value and belief system with its own hierarchy, rituals, and practices.⁸⁰

Commonly described practices in spirituality are prayer and meditation. The field of mind-body medicine often includes prayer with

meditation as a synergistic tool to promote wellness and healing. Spirituality is addressed separately here because it transcends mind-body interventions and is not easily defined by objective markers. The role of spirituality—and, to some extent, religion—in the recovery process cannot be ignored. The regular practice of prayer and meditation is strongly correlated with recovery and abstinence from drugs of abuse.⁸¹ Active participation in spiritual practices such as prayer appears to be more important in the recovery process than being prayed for by others.⁸²

“Negative spirituality” may be at the root of addictions, and a “spiritual awakening” may be required before an individual can genuinely recover from addiction.⁸³ Regular church attendance has been associated with negative perceptions of addiction and lower rates of alcoholism, substance abuse,⁸⁴ and tobacco use.⁸⁵ The extent of family religious practice also has an effect on youth perspectives on substance abuse.⁸⁶ Obviously, spirituality cannot be prescribed in the primary care setting, but it is important for the clinician to be aware of the client’s spiritual beliefs and value systems when identifying appropriate recovery programs for referral (see [Chapter 114](#)).

Twelve-Step Programs

Alcoholics Anonymous (AA) has helped millions of people in their approach to recovery from alcoholism worldwide since it began in 1935. The AA program of recovery is spiritually based, with frequent meetings, mentoring, and social support. The basic spiritual framework is described in the Twelve Steps of AA, presented in [Box 83.3](#).

AA is rooted in spirituality, not religion. The AA preamble, commonly recited at the start of meetings, states that “AA is not allied with any sect, denomination, politics, organization, or institution.” The belief in a “higher power” is seen as a point of connection for all AA members, no matter what each calls this higher power. This generalized belief allows a group/mutual connection to a transcendent power that can help in the healing and recovery process without the need for all members to share a common belief system or religion.

Meetings generally begin with reading of the AA preamble and end with reading of the serenity prayer. Meetings may be open, which anyone may attend, or closed, which only alcoholics may attend. AA groups serve specific populations, such as racial or ethnic groups, gays, and lesbians, as well as specific professions, such as doctors, nurses, and

other health care providers. Approximately 100,000 AA groups in nearly 150 countries now serve millions of members.

Several concepts used in AA add to the success of the program, including sponsorship, anniversaries, and social support. A new member of AA is mentored by another member, a sponsor, who is usually of the same gender and has been active in AA for a minimum of 1 year. New members are encouraged to contact their sponsors when they are considering drinking or are having difficulties with sobriety. This system of social support and mentoring has been shown to be beneficial both to the new member and to the sponsor. Cross et al.⁸⁶ showed that 91% of sponsors had maintained their abstinence from alcohol after 10 years.

BOX 83.3 The Twelve Steps of Alcoholics Anonymous

Reprinted with permission of Alcoholics Anonymous World Service, Inc. Permission to reprint this material does not mean that AA has reviewed or approved the contents of this publication or that AA agrees with the views expressed herein.

We:

Admitted we were powerless over alcohol; that our lives had become unmanageable.

Came to believe that a Power greater than ourselves could restore us to sanity.

Made a decision to turn our will and our lives over to the care of God as we understood Him.

Made a searching and fearless moral inventory of ourselves.

Admitted to God, to ourselves and to another human being the exact nature of our wrongs.

Were entirely ready to have God remove all these defects of character.

Humbly asked Him to remove our shortcomings.

Made a list of all persons we had harmed, and became willing to make amends to them all.

Made direct amends to such people wherever possible, except when to do so would injure them or others.

Continued to take personal inventory and, when we were wrong, promptly admitted it.

Sought through prayer and meditation to improve our conscious contact with God as we understood Him, praying only for

knowledge of His will for us and the power to carry that out. Having had a spiritual experience (awakening) as the result of these steps, we tried to carry this message to alcoholics, and to practice these principles in all our affairs.

Anniversaries of sobriety are emphasized in the AA model. Special events or parties are scheduled to coincide with the individual's anniversary of sobriety. The arrangement encourages members to meet goals of prolonged abstinence and provides another avenue of social support. The social nature of these events also allows members to have fun and to make strong connections with others in the group without consuming alcohol. Primary care physicians should be aware of the AA groups in their geographic area and also should know their patients' sobriety anniversaries to be supportive and to acknowledge their accomplishments in the recovery process.

Several other 12-step programs use models similar to that of AA, including Narcotics Anonymous, Cocaine Anonymous, and Al-Anon. Family support groups like Al-Anon are available to family members and friends of alcoholics and substance abusers for the support of people close to the addicted person who are also deeply affected by substance abuse-related behaviors.

Traditional Native American Interventions

Native American Indians have the highest alcohol-related death rates and the highest prevalence of illicit drug use reported among any racial or ethnic group in the United States. According to Indian Health Service data, the total age-adjusted alcohol-related death rate among Native Americans is over six times greater than that of the U.S. all-races population.⁸⁷ SAMHSA reports that 10.6% of Native Americans are illicit drug users. Although alcoholism and substance abuse are common in many Native American communities, there are significant differences between tribes from different regions, and not all tribes are significantly affected by addiction.

Native American people have experienced an immense history of injustice in the past several hundred years. The theft of land, language, culture, and spirituality has created a sense of despair that continues today in many Native American communities. A detailed account of historical events is beyond the scope of this chapter, but it is important to recognize the relatively recent dramatic cultural changes that have

occurred. I was fortunate to grow up in a family with many traditional healers and spiritual leaders from the Lakota tribe, and I incorporate this traditional philosophy into my medical practice.

The effect on people of Native American heritage of the loss of their land and culture is recognized by many current traditional leaders. This sense of loss and mourning is at the root of the high rates of depression, alcoholism, substance abuse, and other chronic diseases experienced by Native Americans. As Ed McGaa, Eagle Man, states, "Native American Indians learned how to live with the earth on a deeply spiritual plane."⁸⁸ The loss of land resulted in a loss of spiritual tradition. According to *Wounded Warriors*, a book delineating the loss faced by many Native Americans, "We need to understand that the primary reason our people are so afflicted with addiction, poverty, abuse, and strife, is that our way of life was taken from us. Everything was taken. And nothing was replaced."⁸⁹ From a traditional perspective, not unlike that previously described for acupuncture and mind-body medicine, the use of alcohol and illicit drugs by some Native Americans fills the void created by the loss of spirituality.

FIG. 83.2 Traditional Lakota Indian medicine wheel.

The medicine wheel is a symbol that has been used by numerous tribes to represent wholeness and balance. To be healthy, each person must achieve a sense of balance among spiritual, mental, physical, and emotional forces (Fig. 83.2). This image provides a visual format for depicting the connection between spirituality and mental, physical, and emotional health. Another interpretation of the medicine wheel shows values, decisions, actions, and reactions as representing the spiritual, mental, physical, and emotional realms, respectively. From a spiritual perspective, in this interpretation, personal values (spiritual) are interpreted into decisions (mental). These decisions are then implemented into actions (physical), and the actions produce reactions (emotional). The emotions then provide feedback to the value system (spiritual). In this way, all decisions, actions, and emotions are rooted in the spiritual realm (Fig. 83.3). When the spiritual realm is weakened or broken, negative emotions such as depression, anger, and low self-esteem have no spiritual basis or value system in which to be processed. As a result, these negative emotions affect decision making and actions. For many Native American people, the sense of a “broken spirit” and emotional despair lead to high rates of alcoholism and substance abuse (Fig. 83.4).

Within this model, health care practitioners can see the importance of addressing the concept of spiritual healing and promoting balance in treating addictions. Clearly, simple allopathic pharmacological interventions are not enough to address addiction in this setting. Comprehensive programs that incorporate traditional cultural perspectives and philosophy with AA and other treatment methods are the most successful in treating substance abuse in Native Americans.

Healing ceremonies such as the sweat lodge and talking circle are commonly used in Native American treatment programs. The sweat lodge is a traditional gathering for prayer, meditation, and purification. The talking circle is analogous to a support group, in which individuals share thoughts, emotions, and prayers in a culturally relevant and sacred manner. Anecdotally, most of my patients who participate in these healing rituals in the treatment of any chronic condition, including alcoholism and substance abuse, find the traditional interventions to promote a sense of balance and wellness more effectively than anything offered by modern allopathic medicine.

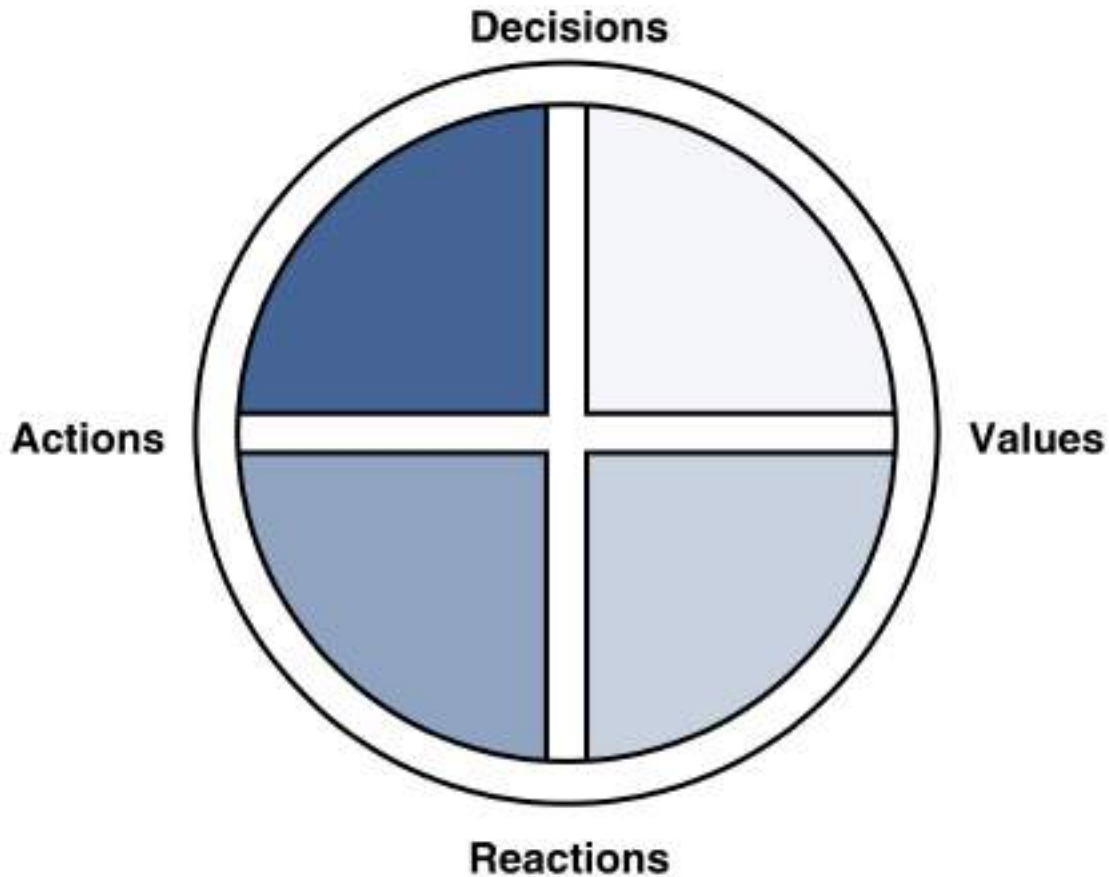

FIG. 83.3 Medicine wheel showing spiritual values in decision making.

Therapies to Consider

Nutrition

There may be a connection between nutritional deficiencies and addiction. Alcoholism is known to cause nutritional deficiencies, but it is not clear whether nutritional disorders lead to addiction. Some studies of nutritional supplements appear promising in maintaining sobriety, reducing depression, and minimizing cravings.^{90,91} Amino acid supplementation may be an effective adjunct in the treatment of alcohol and cocaine addiction.⁹²

FIG. 83.4 The “broken spirit” factor in alcoholism and substance abuse.

Homeopathy

Homeopathic remedies have been reported to be helpful in managing addictions, anxiety, and depression. The nature of homeopathy is such that the treatment regimen is formulated to address the patient’s specific

characteristics and complaints. Therefore, there is no specific “antiaddiction” homeopathic remedy. A skilled homeopath may be able to prescribe remedies for specific patients that can aid in the recovery process.

Prevention Prescription

- Encourage patients to make a connection with something that gives life deeper meaning and purpose.
- Treat depression and anxiety. Work with a spiritual care provider or other health care providers before symptoms result in self-medication with alcohol or other substances.
- Encourage patients to avoid the use of illicit drugs.
- Be aware of the patient’s alcohol intake. If he or she displays any of the following traits, begin an integrative approach for treatment of the addiction:
 - Craving: a strong urge to drink alcohol
 - Loss of control: being unable to stop drinking once the patient has started
 - Physical dependence: symptoms such as sweating, shaking, and anxiety after the patient stops drinking
 - Tolerance: the need for greater quantities of alcohol to feel intoxicated

Therapeutic Review

The following is a summary of options for treatment of alcoholism and substance abuse. If a patient presents with a history and symptoms consistent with alcohol or substance abuse withdrawal, immediate referral to a detoxification center is warranted.

Laboratory

Laboratory testing is not helpful in screening, but liver assessment can help in monitoring the toxic effects of heavy drinking and can be a tool in motivating behavior change.

- Alanine aminotransferase (ALT), gamma-glutamyltransferase (GGT), and carbohydrate-deficient transferrin (CDT): CDT is least affected

by nonalcoholic liver disease and thus is a specific indicator of heavy ethanol use. It can be elevated if four or five drinks have been consumed at one time in the previous 2 weeks.

- Consider a complete blood count and determination of levels of B₁₂, folate, electrolytes, magnesium, uric acid, lipase, and prealbumin in chronic alcohol users.

Pharmaceutical Agents

Alcohol

- Benzodiazepines are commonly used for detoxification and withdrawal symptoms:
 - Consider clonazepam 1 mg three times daily, with a gradual taper over 10–14 days. 
- To reduce the “high” sensation associated with alcohol:
 - Naltrexone (ReVia): 50 mg / day orally 
- To reduce the craving for alcohol:
 - Acamprosate (Campral): 333–666 mg three times a day 
 - Topiramate (Topamax): titrate 25–300 mg weekly over 8 weeks (see [Table 83.2](#)) 
- To create unpleasant side effects with use of alcohol:
 - Disulfiram (Antabuse): 250–500 mg / day 

Tobacco

- Tapered nicotine replacement: oral, patch, or inhaled over 3–4 weeks 
- Cytisine 1.5 mg tablets with a tapering dose over 25 days 
- Bupropion (Zyban): 150 mg twice a day × 6 weeks. The patient should set a quit date after taking the medication for 2 weeks. It is effective in managing symptoms of withdrawal and cravings. 
- Varenicline (Chantix) is started 7 days before the quit date: days 1–3, 0.5 mg daily; days 4–7, 0.5 mg twice daily; and the subsequent 11 weeks, 1 mg twice daily. It can be used for up to 24 weeks if needed to prevent relapse. 

Opiates

- Methadone 15–20 mg / day orally for opiate addiction is the most commonly used pharmaceutical agent for relapse prevention and management of cravings. 
- Buprenorphine (Subutex) is an opioid partial agonist that reduces cravings and helps prevent relapses. It also has a lower potential than methadone for dependence. Extra training is required to prescribe it.

Cocaine

- Antidepressant medications (selective serotonin reuptake inhibitors and tricyclic antidepressants) 
- Amantadine 100 mg orally twice daily has been used to decrease cravings and to prevent relapse, with varying success. 

Botanicals

- For anxiety, insomnia, and depression associated with substance abuse, consider the following:
 - Valerian: for anxiety, 300–450 mg three times daily or 400–900 mg 2 hours before sleep. It must be used for 2–3 weeks before an effect can be seen. 
 - Kava kava extract standardized to 70% kava-lactones: 100 mg three times a day for anxiety. Avoid in patients with liver disease because of the potential for hepatic toxicity. 
 - St. John's wort 300 mg three times daily or 450–600 mg twice daily is used for depression, but its role in alcohol and substance abuse recovery is yet to be determined. 
 - Kudzu is a traditional Chinese herb that has been used in alcohol recovery. The recommended dose is 1.2 g twice daily. 

Acupuncture

- Acupuncture is effective in producing relaxation and minimizing cravings for most substances of abuse.
- Treatment protocols typically involve five needles placed in each ear several times a week and are most effective as part of a

comprehensive treatment program.

- Not all treatment facilities offer acupuncture, and referring practitioners should be aware of the treatment options available in their geographic area. 

Mind-Body Therapies

Meditation, biofeedback, hypnosis, guided imagery, yoga, and prayer have been shown to be effective adjunctive therapies in treatment programs, but most of the studies conducted to assess them have not been well controlled. 

Spirituality

Numerous studies have shown a benefit in the recovery process in persons who have strong spiritual connections or actively participate in various religious practices. There is no correlation between a specific religion or belief system and recovery; the important factor appears to be the presence of a spiritual connection or practice. 

Twelve-Step Programs

- AA has proved to be successful in the alcoholism recovery process. The Twelve Steps are rooted in spirituality and social support.
- Other programs, such as Narcotics Anonymous, Cocaine Anonymous, and Al-Anon, use similar principles and focus on other substances of abuse and their effects on the abuser's family.
- Primary care physicians should be aware of the programs available in their geographic area. 

Culturally Specific Interventions

- Various cultural and ethnic groups have been affected by alcoholism and substance abuse to different degrees. In many cultures, including Native American cultures, culture-specific interventions and practices can aid in the recovery process. 
- Physicians should be aware of the patient's cultural background and belief system when making referrals to treatment facilities.

[Chapter 84. Cataracts](#)

[Chapter 85. Age-Related Macular Degeneration](#)

CHAPTER 84

Cataracts

Robert Abel Jr. MD

Pathophysiology

The lens is one of the body's most solid tissues, being approximately 36% solid. It is composed of mostly proteins (crystalline fibers and enzymes) and some carbohydrates and polyunsaturated fatty acids. The lens curvature and the alignment of the fibers are designed for the bending of light rays in the visual spectrum and the absorption of radiation above and below that spectrum. A cataract is any opacification of the normally clear crystalline lens of the eye. Oxidation of lens fibers, catalyzed by short, phototoxic ultraviolet (UV) wavelengths of light, destroys the sulfhydryl protein bonds. Breaking of these bonds leads to denaturation and clumping of the protein, with consequent loss of lens clarity.

The eye is a remote outpost that relies on good nutrition, liver function, circulation, and breathing. The lens in particular has no direct vascular or neurological innervations and therefore must rely on the circulation of the small amount of aqueous humor, flowing from the ciliary body out through the trabecular meshwork, for delivery of nutrition and removal of toxins.

The aqueous humor has very high levels of water-soluble compounds, such as ascorbic acid, glutathione, and its key amino acid, cysteine, the major diet-derived antioxidants that protect lens clarity.

However, the eye is not an isolated organ; it is connected to the brain and cardiovascular and digestive systems. It requires protection from bright illumination, which is provided by the lids, lashes, watery tear film, cornea, and iris. Cataract formation is often symptomatic of deeper abnormalities and systemic imbalances. In a common clinical scenario, the ophthalmologist tells the patient that he or she has a cataract, followed by reassurance of its nonacute nature, "Don't worry, I'll see you

in 6 months.” Six months later, the patient is told, “It’s time to operate!” Earlier interventions directed at the disturbances underlying cataract formation can halt or significantly retard this inevitable progression.

There has been evidence to suggest the role of diabetes in the development of cataracts. From a biochemical perspective, the sugar within the bloodstream diffuses into the aqueous humor and, in combination with light, performs photooxidation of the lens proteins.¹ Therefore, it is not unusual for diabetic patients to present with eye complaints related to cataract earlier than one would expect. In fact, Iranian researchers compared patients with type 2 diabetes and a control group to show that the diabetic patients demonstrated visually debilitating cataracts 5 years earlier than the control group.²

Cataracts are the leading cause of vision impairment in both developed and developing countries and are the major cause of blindness worldwide.

Vision provides up to 80% of our sensory input and is to be preserved at any cost. This chapter reviews the current evidence correlating antioxidant deficiency with the prevalence of cataract formation as well as the administration of specific antioxidants to reduce the incidence of lens opacification.

Screening

Changes in Vision

Subtle cataract development leads to unrecognized loss of color interpretation and fine detail, and to difficulty with contrast and distance vision. In younger patients, fluctuating vision is often related to refractive error, computer use, diminishing accommodation, and even medications. As reported by mature adults, the following visual symptoms may indicate early cataract formation and can serve as the basis for questioning the patient during a general medical history and physical examination:

- Blurred vision
- Difficulty with reading road signs and distance vision
- Trouble reading
- Loss of depth perception

- Difficulty following a golf ball
- Difficulty with night driving
- Glare, especially at night
- Double vision
- Reduced vision

Patients may not volunteer information about decreasing vision because they do not notice the gradual decrement, may fear losing a driver's license, or are anxious about having their eyes examined.

Primary Care Diagnosis

The small-pupil Welch Allyn ophthalmoscope enables primary care physicians to look at the fundus of the eye to detect diabetic and other changes. The device is focused by a simple rotary movement of the thumb. With this instrument, it is possible to assess lens transparency as well as observe the fundus.³ Patient complaints are the first symptom. Distance vision problems and glare far exceed near-vision disturbances in patients with cataracts; the reverse is true in patients with macular degeneration.

Ophthalmological Referral

The definitive diagnosis of cataract is made by ophthalmological referral and slit-lamp examination. Distance visual acuity, near vision, and depth perception as well as contrast sensitivity and peripheral vision can be evaluated. Glare testing may also approximate real-world conditions and may corroborate functional impairment.

Documentation of Progression

Because cataracts are slowly progressive and phacoemulsification removal with intraocular lens implantation is an elective procedure, most ophthalmologists choose to wait for patients to volunteer information about the level of inconvenience or significant loss of function. The mere appearance of early cataract changes alone rarely warrants surgical intervention. Additional difficulty is posed by lens grading because it requires multiple observers.

Every year in the United States, cataract surgery is performed in more than 3 million people, engendering more than \$2 billion in Medicare costs. Delay of cataracts for 10 years would lead to tremendous cost savings.

Epidemiology

Cataracts are by far the leading cause of blindness worldwide. In fact, cataracts are a major cause of reversible blindness in the United States and Western Europe. The frequency increases with age; modern dogma is that everyone will get cataracts, but the truth is that most will.⁴

Risk Factors

The incidence of cataract formation varies with a number of risk factors ([Box 84.1](#)). Cataract formation is not inevitable with age. It is not unusual to find men and women in their 80s and 90s with relatively clear lenses who have had healthy lifestyle habits. The following risk factors for cataract formation have been identified:

- Age
- Sunlight exposure

BOX 84.1 Major Stressors to the Eye and Lens

Ultraviolet and blue light (sunlight)

Inadequate nutrition

Lifestyle habits

Stress

Chronic disease

- Stress
- Medications
- Smoking
- Alcohol excess
- Obesity and high body mass index

- Chronic disease
- Malnutrition
- Diet high in saturated fat
- Heredity and genetics
- Trauma
- Congenital disorders
- Inborn errors of metabolism
- Dehydration
- Diabetes
- Vitamin deficiencies
- Low estrogen
- Glass blowing
- Lead exposure
- Long-term aspirin use
- African-American race

Integrative Therapy

Lifestyle Interventions

Ultraviolet Light–Blocking Sunglasses

Increased solar exposure and high altitudes have long been known to raise the frequency of cataracts in all decades of life. UV light, especially in the presence of oxygen, contributes strongly to the denaturation of lens protein, which results in cataract formation; this phenomenon was known to occur even before the deterioration of the ozone layer.

There currently are anecdotal veterinary reports of a higher incidence of cataract in rabbits in Patagonia and in dogs in Australia, both due to thinning of the ozone layer. Beachgoers and sunlamp users must be counseled to always wear adequate eye protection. Parents should encourage their children, including infants, to wear sunglasses and other forms of eye protection. Airline pilots have also been found to have a higher incidence of nuclear cataracts, as have astronauts, who may go into space only once in their lifetime. Part of this risk may be attributable to cosmic radiation and blue light as well as to UV light.

Nevertheless, appropriate protective lenses should also be used in occupations such as welding and ironwork, in which workers experience prolonged exposure to hazardous radiation, even above and below the visual spectrum (400–700 nm). Use of hats and visors has been the

recommendation of several long-term epidemiological and longitudinal studies. UVA (also called near-UV) light and UVB (far-UV) light constitute toxic radiation, and their long-term effects are cumulative. Near-UV light penetrates the cornea and is generally absorbed by the lens, whereas far-UV light is more damaging, but is usually absorbed by the cornea, although not entirely. For this reason, astronauts have been known to take large amounts of *N*-acetylcysteine (3000 mg/day), a glutathione booster, while on space missions.

Stress Management

Stress depresses immune function, alters sleep patterns, impairs gastrointestinal absorption, and reduces available antioxidants. Stress also stimulates the sympathetic nervous system, causing vasoconstriction, increasing muscle tension, and, over long periods, decreasing microcirculation through the ophthalmic artery and its tributaries. A direct correlation between stress and cataract formation remains to be proved in humans, but there is ample evidence that stress, smoking, nutritional deficiency, radiation, and corticosteroids increased cataract formation in animal models.

Pharmaceuticals

More than 300 common medications are known to be photosensitizing agents. Many antibiotics, diuretics, antihypertensives, botanicals (St. John's wort), psoralens, and other agents increase the sensitivity of lens protein to UV damage. Therefore, it is important to advise all people taking medicine to wear sunglasses and to ask their pharmacists about whether their medications are photosensitizers. Many medications also require hepatic excretion and may interfere with normal nutritional biochemistry in the liver. For instance, many cholesterol-lowering agents decrease the production of coenzyme Q10 and glutathione in the liver. Glutathione, a sulfur-containing tripeptide, is a major free radical scavenger in the human lens. A recent study has shown that statin use is associated with increased risk of cataract development.⁵

Corticosteroids

Corticosteroids by any route of administration (topical, oral, intranasal, inhaled, or intravenous) are known to raise the incidence of both cataracts and glaucoma in susceptible persons. This adverse effect is most common with topical corticosteroids used in treatment of ocular

inflammation and allergies. Therefore, it is advisable for patients who are prescribed ocular steroids for allergies not to have refills without appropriate ophthalmological supervision. There are other ways to treat ocular allergy, such as with topical antihistamines, mast cell stabilizers, and the administration of oral vitamin C (1000 mg/day) and the eucalyptus bioflavonoid preparation quercetin (1000 mg/day).

Often, the patient who sees many physicians develops a polypharmacy, which is perpetuated. Chinese and Ayurvedic healers tend to use a mixture of herbal remedies for a limited time; they then reevaluate the patient within 2 weeks and readjust the formula. This approach is a good one to incorporate into contemporary Western medicine.

Smoking

Smoking not only reduces available ascorbic acid and alpha-tocopherol but also has a direct toxic effect on the lens of the eye. The longitudinal Physicians' Health Study and Nurses' Health Study have shown a significant rise in cataract formation in smokers, with twice the incidence in the male physicians' study and two-third times more cataract surgeries in women who smoked.^{6,7} In many pack-a-day smokers, a yellow-brown cast to the nucleus develops during 20 years of smoking.

Alcohol

Excess intake of alcohol is known to raise the incidence of cataract formation, probably by causing loss of some of the B and fat-soluble vitamins as well as through the possible alteration of liver function.

Lack of Exercise

Exercise stimulates breathing and parasympathetic activity. This effect is especially desirable in persons with chronic glaucoma conditions and macular degeneration. A group of University of Oregon investigators⁸ found that 30–40 minutes of walking four times weekly lowered intraocular pressure and also reduced stress. Improved aqueous flow is important to the health of the crystalline lens of the eye as well.

Overweight

Obesity or an unfavorable waist-to-hip ratio has been associated with a higher incidence of cataract formation.⁹ Chinese researchers noted that

there was a higher rate of so-called age-related cataracts in individuals who were deemed overweight and obese by body mass index.¹⁰ This association is yet another reason why it is important to encourage maintenance of ideal body weight and moderation of calorie intake.

Management of General Medical Conditions

Patients with diabetes have three to five times the risk of cataract formation noted in the general population.¹¹ Effective management of diabetes is important for avoidance of both the highs and lows of serum glucose levels. An elevation in blood glucose concentration causes an influx of fluid into the lens of the eye, significantly changing the refractive error. This change in permeability ultimately enhances protein decomposition and cataract formation through the sorbitol pathway ([Fig. 84.1](#)). Quercetin, a preparation of naturally occurring eucalyptus bioflavonoids, inhibits the aldose reductase pathway. Several studies also indicate that hypothyroidism is more common in persons with cataracts. Hypertension and Cushing syndrome are also associated with cataract formation; this is the result of photosensitizing blood pressure medications in the former and elevated steroids in the latter condition.

Female Gender

Some studies have indicated a higher incidence of cataracts in women that cannot be accounted for solely by the slight preponderance of women in the general population older than 65 years. Replacement estrogen therapy is correlated with a protective effect; therefore, the use of natural or synthetic estrogens may be appropriate in patients without contraindications to them.

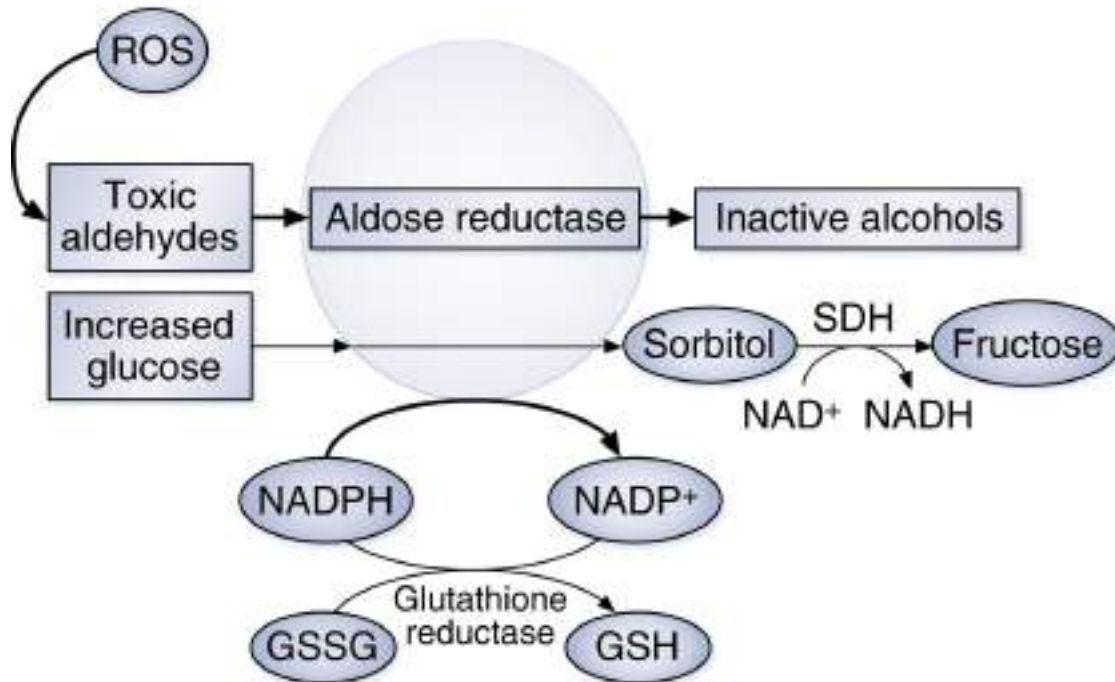

FIG. 84.1 The sorbitol pathway. *GSH*, reduced glutathione; *GSSG*, oxidized glutathione; *NAD⁺*, oxidized form of nicotinamide adenine dinucleotide (*NAD*); *NADH*, reduced form of *NAD*; *NADP⁺*, oxidized form of nicotinamide adenine dinucleotide phosphate (*NADP*); *NADPH*, reduced form of *NADP*; *ROS*, reactive oxygen species; *SDH*, sorbitol dehydrogenase. (From Brownlee M. Biochemistry and molecular cell biology of diabetic complications. *Nature*. 2001;414:813–820.)

Aging and Longevity

Because the incidence of cataract rises every decade after the age of 45 years, it is important to screen people older than 45 years for general health and driving ability. Several studies in the orthopedic literature have indicated that visual disability is one of the risk factors for hip fracture. The loss of depth perception makes people particularly vulnerable to falls because they assume that they can see well with one eye, yet may be likely to miscalculate steps and distances. Cataract development is seemingly related to overall health and other medical conditions. Several articles point to an inverse relationship between cataract development and lifespan. In fact, Age-Related Eye Disease Study (AREDS) participants with age-related macular degeneration and cataracts had a shorter life expectancy than those without both diseases.¹²

Lack of Sleep

Patients should be advised to get plenty of sleep. Darkness is a time when the eyes, especially the retinae, have a chance to rest, recover, and replenish. The lens and intraocular structures are bombarded by light, with the formation of free radicals, all day; sleep provides an opportunity for the liver and circulation to replenish the necessary antioxidants and minerals to the lens and other ocular tissues.

Nutrition

Fruits and Vegetables

Ascorbic acid, carotenoids, tocopherol, and glutathione are present in the lens epithelium and lens fibers. Proteolytic enzymes that act to remove damaged protein are also present in the lens and are spared by glutathione and other free radical scavengers. In general, the colored bioflavonoids and carotenoids are nature's protectors and should be part of a balanced diet. Multiple studies have identified green leafy vegetables as being preventive for cataract as well as age-related macular degeneration.¹³ The Australian Blue Mountains Eye Study, which involved 3654 persons, found that subjects consuming a diet high in protein, fiber, vitamin A, niacin, thiamine, and riboflavin had a lower incidence of nuclear cataracts. Persons whose diet had higher levels of polyunsaturated fatty acids had a significantly lower rate of cortical cataract formation.¹⁴ Low serum levels of alpha-tocopherol may not reflect the actual concentration within the lens; interestingly, this may be true for many other nutrients as well.¹⁵ Increased dietary fructose induces cataracts in diabetics and nondiabetics.¹⁶ Dietary total antioxidant capacity reduced the risk of age-related cataract.¹⁷

Vitamin C

Citrus fruits and many other fruits and vegetables contain high levels of ascorbic acid, which is a major antioxidant in the lens of the eye. The lens and aqueous humor concentrate ascorbic acid in amounts more than 10 times of those found in human plasma. Ascorbate is richer in the cortical fibers than in the older, nuclear fibers. As expected, patients with senile cataracts have a lower serum ascorbate level than that of controls.¹⁸ Higher blood levels of the vitamin seem to confer some protection

against cataract. Persons with higher than average vitamin C intake appear to have a lower risk of nuclear cataract, and those younger than 60 years have a lower risk of cortical opacities, with an intake range of 150–300 mg/day.¹⁹

Lutein-Containing Foods

Spinach, kale, collard greens, guava, and even corn and eggs contain lutein, which has been found to be protective against cataract formation. People who consume high levels of green leafy vegetables and whose serum lutein levels are in the highest quintile have a 20% reduced risk of cataract formation.^{20,21} In both the Physicians' Health Study and the Nurses' Health Study, cataract surgery was associated with lower intake of foods such as spinach, which are rich in lutein and zeaxanthin carotenoids rather than beta-carotene.

Avoidance of Saturated Animal Fat

By reducing saturated fats, the patient will find it easier to reach and to maintain an ideal body weight. The change from saturated fat and trans-fatty acids to polyunsaturated fatty acids is protective to the lens and is currently being evaluated in AREDS 2.²² As an added benefit, the change also helps the patient improve his or her serum lipid profile.

Hydration

The patient should be encouraged to drink plenty of water. The lens of the eye is a dehydrated tissue much like a fingernail, another avascular ectodermal structure. Drinking six to eight glasses of filtered water a day is an excellent way to increase aqueous humor circulation, which supports lens health. Tips for prevention of dry eyes are presented in [Box 84.2](#).

BOX 84.2 Tips for Prevention of Dry Eyes

- Adequate hydration can be promoted by drinking six to eight glasses of water daily.
- It is important to remember to blink, especially during work with computers and other tasks requiring visual concentration.

- The beneficial fats in the tear film can be reinforced with supplementation of docosahexaenoic acid (DHA) and fat-soluble nutrients such as vitamin A and lutein. DHA produces significant improvement in comfort within a week. Recommend 800 to 1000 mg/day (or 2 g/day of fish or krill oil).^{19a}
- Use of eye drops and ointments as moisturizers is recommended. For example, Tears Again (Cynacon/OCuSOFT, Inc., Rosenberg, TX), a liposomal vitamin A and E spray, can be applied externally on the lid and appears to penetrate the eye quickly, providing relief.
- Mechanical problems with the lower lids should be ruled out, especially in patients who may be sleeping with their eyes open. When observing the patient, the clinician should check to see whether the lower lid moves during routine blinking.
- A humidifier should be kept in the bedroom.
- Periodic evaluation of the patient's medication profile is recommended.

Sulfur-Containing Foods

Glutathione, a major antioxidant in the lens, is found in such foods as onions, garlic, avocados, cruciferous vegetables, asparagus, and watermelon. Glutathione and its boosters are thiol compounds, which scavenge free radicals. These glutathione boosters include L-cysteine, lipoic acid, and methylsulfonylmethane. Glutathione also spares proteolytic enzymes in the cortical lens fibers. In studies from the late 1960s, extracted mature cataracts were demonstrated to contain very low levels of glutathione and ascorbic acid; this finding was considered to represent a secondary aspect of cataract formation. In retrospect, this deficiency appears to be a preliminary event and one that can be managed nutritionally.

Algae-Eating Fish

Single-cell algae are at the bottom of the food chain. When the early hominids began eating fish, their brains developed further, approaching human dimensions. The traditional Japanese diet appears to protect against cataract formation because of the inclusion of cold-water fish and algae, both of which are rich in docosahexaenoic acid (DHA). (Examples

of such fish are tuna, mackerel, salmon, sardines, and cod.) Currently, fish such as salmon are being farm raised. Because farm-raised fish are fed grain instead of algae, they contain less DHA and provide less benefit to the eyes and body.

Supplements

For a more complete listing of supplements that promote eye health, see [Chapter 85](#).

Lutein and Zeaxanthin

Results of the Physicians' Health Study and Nurses' Health Study have indicated an approximately 20% protection against cataract formation among persons with serum lutein values in the highest quintile.^{20,21} Lutein and its isomer, zeaxanthin, are present in high levels in ocular tissues, including the lens. Their importance may lie in the fact that they absorb and reflect the phototoxic blue and UV wavelengths. The carotenoids present in the lens turn out to be lutein and zeaxanthin more than beta-carotene. A daily dose of 2.4 mg of lutein has been shown to double the serum level. Olmedilla et al.²³ showed that lutein had a slowing effect on cataract progression during their 2-year study. In fact, they concluded that visual function improved in patients who received lutein supplementation, suggesting that higher intakes of lutein may enhance vision in spite of cataractous lens changes. Christen et al.²⁴ found that supplementation with vitamins C and E, lutein, and zeaxanthin significantly lowered the risk of cataracts.

Dosage

Patients with early cataracts should take 10 mg/day of lutein for the first month, then 6 mg/day as part of their daily regimen.

Vitamin C

Numerous studies have shown that increased vitamin C consumption (60–600 mg/day) over many years protects against cataracts. In one study, the 5-year risk for the development of any cataract was 60% lower

among 3634 participants, aged 43–86 years, who had been taking a multivitamin that included vitamin C for 10 years than in participants who had not.²⁵ Another study showed a 45% protection rate against cataract surgery in women who had consumed vitamin C supplements for 10 years.²⁶ Jacques et al.²⁷ found that women with a mean vitamin C intake of 359 mg/day for 10 years had a 77% lower prevalence of earlier lens opacities.

Dosage

The investigators of the study on vitamin C supplementation recommend approximately 300 mg/day of vitamin C, although I recommend 1000 mg/day.

Precautions

Vitamin C supplementation can cause gastrointestinal disturbance, including cramping and diarrhea.

Vitamin A

Hankinson et al.²⁶ found a 39% lower incidence of cataract formation in more than 50,000 nurses who had an adequate intake of vitamin A during an 8-year period than in nurses in the study who did not. This association has been reported in other studies as well. However, this finding must be balanced with a study²⁸ that has described an association between hip fractures and vitamin A supplementation at more than 17,000 units/day in women. This association may be due to competition of vitamin A with vitamin D absorption in some way.

Dosage

Most good multivitamins contain 5000 units of vitamin A or beta-carotene. Additional supplementation is usually not warranted.

Multivitamins

Multivitamin intake has been observed to reduce the risk of cataracts by

approximately 20%–60%, depending on the content of ascorbic acid. Vitamin E (*d*-alpha-tocopherol) is also protective, as found by numerous studies. Robertson et al.²⁹ found that vitamin C (300–600 mg/day) and vitamin E (400 units/day) had a 50% protective effect.

The 10-year randomized AREDS was concluded early. It supported the use of a multivitamin with A, C, E, and zinc in macular degeneration, but did not find a reduction in cataract development. There is not enough scientific evidence to support the notion that a high dose of a single nutrient provides a greater benefit in reducing cataract risk than a daily multivitamin or a healthy diet.³⁰ One randomized clinical trial showed that one multivitamin preparation prevented the development of cataract but did not stop the progression once it was fully developed.³¹ Others found that ascorbate, lutein, and retinol inversely affected the rate of cataract development.³² Christens and associates found a significant reduction in the risk of cataract formation in middle age and older U.S. males followed for 10 years.³³

Dosage

Taking a multivitamin is a convenient way to obtain a daily amount of beta-carotene or vitamin A, trace minerals, lutein, and other essential nutrients in two to four capsules, depending on the brand.

Precautions

Recent medical reports have indicated an association between copper and an increased risk of memory loss and Alzheimer's disease. Many leading brands of eye vitamins that were created after the AREDS contain very high levels of copper and zinc. The highest recommended daily dose of zinc is 30 mg because higher doses can inhibit the absorption of important minerals including copper, calcium, magnesium, iodine, selenium, and boron. Over time, this loss of minerals can lead to deficiencies in other parts of the body.

Vitamin E

The Lens Opacities Case-Control Study confirmed that alpha-tocopherol is protective against lens opacity.³⁴ Another study from Linxian, China also found vitamin E to be protective against cataract formation in

persons older than 45 years.³⁵ Results of other studies suggest that vitamin E had no protective effect against cataract formation,³⁶ but the question remains whether natural (*d*-alpha) or synthetic (*dl*-alpha) vitamin E was administered in these studies.

B Vitamins

The B vitamins, especially riboflavin (3 mg), thiamine (10 mg), and niacin (40 mg), were found to be protective against cataracts in both the Blue Mountains Eye Study in Australia and another study from Linxian, China.^{14,35}

Docosahexaenoic Acid

DHA, the end product of omega-3 fatty acid metabolism, is known to protect cell membranes and thiol groups. An important constituent of the retina and brain, DHA has also been found in the lens of the eye. With its presence in all cell membranes and its six double bonds, replenishment of this compound is important. Reduction of DHA stores in women who have experienced pregnancy may be a reason for the gender discrepancy in cataract development. The DHA available in breast milk has been documented to reduce learning disabilities in children and to improve head size and growth in the first year of life. The Mediterranean diet has a 1:1 ratio of omega-3 to omega-6 fatty acids, whereas in the average American diet, the ratio ranges from 1:6 to 1:20.

Dosage

A supplemental regimen of 500–1000 mg/day of DHA is helpful for almost all adults. Amounts up to 6 g/day have not shown any toxicity in volunteers. This supplement, like all fat-soluble vitamins and supplements, should be taken with a meal for enhanced bioavailability.

Carnosine

N-Acetyl-*L*-carnosine eye drops are appearing everywhere on vitamin store shelves. Toh et al.³⁷ reviewed the modern treatment of cataracts and stated that the results of clinical trials with carnosine eye drops are

encouraging. Marc Babizhayev has found that carnosine eye drops can halt and occasionally reduce early-to-moderate cataracts. My clinical experience has demonstrated a moderate effect.³⁸ Carnosine is commonly found in antiaging products because of its inhibition of advanced glycosylation end products. Limited human data are available.

Botanicals

Numerous herbs are known to improve blood flow to the eye and to strengthen liver function. Bioflavonoids in certain berries have been proved to enhance capillary formation; however, their effect on night vision is inconclusive. Astragalus, milk thistle (silymarin), oleander, turmeric root, garlic bulb in oil, and wheat sprouts are botanicals that strengthen liver function.³⁹ Some supplements are used to improve and support liver function, such as *S*-adenosyl-L-methionine (SAME) and silymarin.

Turmeric

Curcumin, a constituent of turmeric (*Curcuma longa*), is a spice found in Indian curry dishes. This compound is an effective antioxidant known to induce the glutathione-linked detoxification pathways in rats. It significantly reduced the rate of cataract formation in laboratory rats, but human studies have not been performed in the West.⁴⁰

Cineraria

Cineraria maritima, or *Senecio cineraria* (silver ragwort), has been used for centuries as an eye drop preparation for the treatment of conjunctivitis and early cataract. Homeopathic preparations have also been employed, but they have not been subjected to controlled studies.

Bioflavonoids

The eucalyptus bioflavonoid preparation quercetin has been found in multiple laboratory studies to inhibit the formation of cataracts induced by steroids, diabetes, and radiation.

Surgery

Cataract surgery is the most common surgery performed in the United States today; more than 3 million procedures are performed annually. The subsequent laser treatment of an opacified capsule ranks among the 10 most common surgical procedures. With appropriate history and physical examinations and regular eye examination, early cataract formation can be detected long before functional visual loss develops.

Cataract surgery is performed under sterile conditions with local anesthesia. The procedure involves removal of the cataract by phacoemulsification and insertion of an implant within the lens capsule. The synthetic implant may be silicone, polymer, or acrylic. The complications of cataract surgery include infection, lens dislocation, retinal hemorrhage, and retinal detachment. With modern technology, however, this is one of the safest surgical procedures today. In fact, most patients who undergo cataract surgery in one eye can immediately notice the difference and are satisfied with the results.^{41,42}

Untreated poor vision contributes to the progression of dementia. Lerner reported that cognition improved after cataract surgery and Owsley found that the incidence of motor vehicle accidents decreased after cataract procedures.⁴³⁻⁴⁵

Prevention Prescription

- Eye examination is recommended every 1–2 years for people older than 50 years and for people at risk. Use of preventive measures is appropriate, even in patients with early cataracts.
- Advise use of sunglasses, with side shields as necessary, as well as hats or visors and sunblock in persons whose occupation or interests dictate spending time outdoors.
- Recommend a balanced diet with five or six servings of fruits and vegetables as well as grains, nuts, berries, and organic eggs for amino acids, with consumption of cold-water fish two or more times per week.
- Recommend lutein-rich foods, such as spinach, three times a week; these foods are especially important for ocular protection.
- Promote adequate hydration with intake of six glasses of filtered water daily, with reduction in intake of soft drinks and artificial

sweeteners.

- Recommend a daily multivitamin including taurine, zinc, lutein, an additional 1000–2000 mg of vitamin C, 400 units of vitamin E, and 5000 units of vitamin A palmitate.
- Be certain that there is no copper in your multivitamin because of the risk of memory loss at high levels, and avoid multivitamins with more than 30 mg of zinc.⁴⁶
- Advise the patient to maintain an appropriate body weight and to avoid animal fat in their diet.
- Encourage the healthful lifestyle habits of stretching, exercise, moderate alcohol intake, and a regular sleep pattern, with cessation of smoking.
- Advise the patient to maintain a positive attitude and optimism.
- Periodically review prescription and other medications for ophthalmological effects.
- Encourage regular physical examination and vision testing.

Therapeutic Review

Abundant evidence suggests that we can develop new strategies to maintain our health now, instead of waiting for cataracts to form.

Here is a summary of therapeutic and preventive options for cataracts. If a patient presents with severe symptoms, such as profound visual obstruction, it would be to his or her benefit for the clinician to immediately begin a more aggressive therapy, such as referral for elective surgery. For the patient who has mild-to-moderate symptoms, however, this ladder approach is appropriate.

Remove Exacerbating Factors

The patient should be encouraged to

- Stop taking steroid-containing and photosensitizing medications for prolonged durations.
- Stop smoking; have moderate alcohol intake; try to lose weight, if needed, through diet and exercise; and substitute good fats in place of bad fats in the diet.
- Wear sunglasses or transition lenses while outside and a hat or visor with at least a 3-inch brim.

Nutrition

- Encourage a low-fat, low-cholesterol diet. 
- Encourage foods rich in omega-3 fatty acids (wild salmon, nuts, flaxseed) or supplementation with DHA 500–1000 mg/day. 

Supplements

- Multivitamins: a daily multivitamin including taurine, zinc, lutein, an additional 1000–2000 mg of vitamin C, 400 units of vitamin E, and 5000 IU of vitamin A palmitate 
- DHA: 500–1000 mg/day 
- Lutein: 6 mg/day for 1 month, then 2 mg/day 

Botanicals

- Turmeric is a major antiinflammatory agent used throughout Asia; there are many data in the Chinese literature demonstrating its effectiveness in reducing the risk of cataracts. 

Surgical Therapy

If the patient's symptoms persist or worsen despite the preceding measures, referral for ophthalmic evaluation and treatment is warranted:

- Cataract extraction by phacoemulsification with intraocular lens insertion (one-step)

CHAPTER 85

Age-Related Macular Degeneration

Robert Abel Jr. MD

Nowhere has there been so much scientific documentation about nutritional prevention as in the case of macular degeneration. The irony lies in the fact that this information is often virtually ignored by the very specialists who manage patients with the disease.

Pathophysiology

Age-related macular degeneration (AMD) is the scourge of the “golden years.” People aged 65 years and older constitute the fastest-growing segment of the population in developed countries; the risk for AMD and its impact will only become greater in the future. There is a tremendous need to develop preventive strategies to counter AMD and to arrest early cases before the loss of useful vision.

Retinal photoreceptors are subjected to oxidative stress from the combined exposure to light and oxygen on a daily basis. The body’s ability to resupply the photoreceptors and underlying pigment epithelium with essential nutrients is the basis for maintenance of good vision throughout life. Diseases of the retina are the leading cause of blindness throughout the developed countries of the world. Among these diseases, macular degeneration is the most common, and its incidence is rising as the population ages. Population-based studies indicate that approximately 10% of people aged 65–74 years and 30% of those 75 years and older demonstrate early signs of the disease, and 7% already have late signs of the disease.¹

Free radicals are thought to attack the rod and cone cell membranes; the retinal pigment epithelium (RPE), a monolayer beneath the retina, fails to keep up with the removal of lipid debris, which accumulates as drusen (yellow spots of different sizes). The melanin pigment protects

the retina from radiation, but the amount of this pigment diminishes with age, smoking, and low serum lutein levels. When the RPE cells drop out, pigmentary defects can be noted by ophthalmoscopic examination and on retinal photography. Drusen and progressive RPE atrophy characterize the dry form of macular degeneration, which accounts for 90% of cases of AMD ([Figs. 85.1](#) and [85.2](#)).

The other 10% of cases are attributable to the exudative or vascular type of AMD. A hyaline membrane (i.e., Bruch's membrane) separates the choroidal blood supply from the RPE and overlying retina. Degeneration of Bruch's membrane, retinal anoxia, and impairment of choroidal circulation are believed to be factors that induce the vascular ingrowth characteristic of this form of the disease. These fragile new vessels grow rapidly and may bleed spontaneously.

Most ophthalmologists agree that oxidative stress combined with the failure to fortify the retinal photoreceptors is a major pathophysiological mechanism in this disease, which currently affects 20 million older Americans. Many of these physicians also consider vision loss from macular degeneration to be inevitable, believing that nothing can be done for the dry form and that perhaps only recent interventional therapies are useful for treatment of the wet form of macular degeneration if it is detected in time. Nowak et al.² demonstrated significantly higher concentrations of lipid peroxidation products in AMD patients. This finding adds credence to the considerable evidence that nutritional approaches play a major part in prevention and management of this age-related disease. Cumulative photooxidative stress, other systemic diseases, and nutritional deficiencies contribute to the onset and progression of AMD. With aging, the protective cell-derived enzymes—catalase, superoxide dismutase, and glutathione peroxidase—decrease, as does the ability to absorb the diet-derived antioxidants.

Screening

Owing to the swelling ranks of the elderly, the number of persons with macular degeneration is growing. Routine dilated-eye examinations are fundamental to early detection and management of AMD. The onset is often so gradual as to go unnoticed.

Use of an Amsler grid, a 4 × 4-inch checkerboard square with a central dot for fixation, is an excellent way to diagnose AMD and allows home monitoring of the condition. This approach to management is especially

useful in patients with the slowly progressive, dry form of the disease ([Fig. 85.3](#)).

Primary care physicians should know the AMD risk profiles to alert patients about preventive steps and the need for periodic eye examinations. Patients with multiple systemic diseases are at greatest risk. Early detection offers greater flexibility in the use of complementary therapies.

Referral to an ophthalmologist is indicated for dilated funduscopy examination and retinal imaging (photograph, laser tomography, and fluorescein angiography), which can clearly document the stages of AMD. On occasion, retinal specialists are needed for advanced management.

FIG. 85.1 Atrophic (dry) age-related macular degeneration. Geographic atrophy of the retinal pigment epithelium causes loss of central vision. (From Fillit H. *Brocklehurst's textbook of geriatric medicine and gerontology* . 7th ed. Philadelphia:

Saunders; 2010.)

FIG. 85.2 Exudative (wet) age-related macular degeneration. Leakage and scarring from a subretinal neovascular membrane destroy central retinal function. (From Fillit H. *Brocklehurst's textbook of geriatric medicine and gerontology*. 7th ed. Philadelphia: Saunders; 2010.)

Primary care physicians should help patients coordinate the various medicines used in the management of underlying and concurrent diseases. Periodic review of medications is important because polypharmacy may contribute to the risk for AMD.

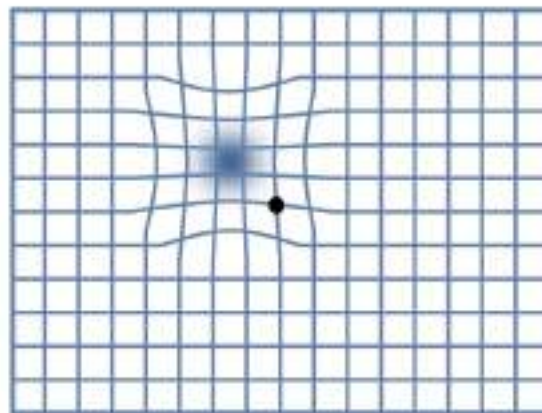

Risk Factors

The following risk factors for AMD have been identified:

- Age
- Sunlight exposure
- Previous cataract surgery
- Light-colored irises, fair complexion

Normal

Indication of AMD

FIG. 85.3 Amsler grid. This checkerboard-patterned square has parallel vertical and horizontal lines. The patient looks at the central dot with one eye covered and notes the pattern of the lines. If any line in any direction is missing or wavy, the patient marks it in with a pencil or makes a note. The Amsler grid can be used to determine whether there is a disorder of the optic nerve or macula; in particular, use of the grid is an excellent way to monitor macular degeneration to determine whether it is stable or progressing.

- Obesity
- Female gender, parity
- Postmenopausal status
- Inflammation
- Smoking
- Physical inactivity

- Elevated serum cholesterol values
- Hypertension
- Nocturnal hypotension
- Poor digestion, use of antacids
- Hypothyroidism, use of thyroid hormones
- Family history
- Low dietary intake of carotenoids, low serum carotenoid levels
- Low macular pigment density
- Low serum zinc levels
- High refractive errors

The National Health and Nutrition Examination Survey demonstrated that for 65- to 70-year-old respondents, the chance for development of AMD was nearly five times that for 45- to 54-year-old respondents.³

Sunlight

Reducing exposure to sunlight through the use of hats and sunglasses has been stressed in numerous studies.⁴ A University of Wisconsin study of 3684 persons between the ages of 43 and 84 years found a positive correlation between daily sun exposure and the development of AMD. Persons who spent more than 5 hours a day in the sun were twice as likely to have AMD as those with less than 2 hours a day of sun exposure.⁵

Gender

The incidence of AMD is at least three times greater in postmenopausal women than in men of similar age. Two studies have indicated that hormone replacement therapy (HRT) significantly reduces this risk, although a third study did not find any correlation. Apparently, women require more lutein than men do because it is preferentially deposited in fatty tissue rather than in the retina.⁶ Obstetricians and gynecologists should inform their patients about early prevention and participate in decisions about biocompatible HRT when appropriate.

Inflammation

Clemons et al.⁷ showed that early or moderate AMD advances with smoking, increasing body mass index, and, probably, with the use of antacid and antiinflammatory medications. Seddon et al.⁸ demonstrated

that C-reactive protein levels were higher in individuals with advanced AMD.

Smoking and Other Factors

Numerous investigators have determined that current smokers, especially those who smoke one pack a day or more, have a significantly higher risk for development of AMD than nonsmokers and persons who have given up smoking 10 years previously. The Nurses' Health Study revealed that women who smoked 25 or more cigarettes a day were more than twice as likely as nonsmokers to have AMD.⁹ The Physicians' Health Study also showed a greater than twofold incidence of AMD in men who smoked 20 or more cigarettes daily.¹⁰ One study indicated an association between smoking, low serum selenium levels, and the development of AMD. Smoking has been shown to contribute to reduced levels of circulating antioxidants as well as of the lutein pigment in the macular area.

The Age-Related Eye Disease Study (AREDS) found that smoking is associated with three of the five stages of macular degeneration.¹¹ This multicenter, randomized controlled trial also found that hypertension, obesity, hyperopic refractive error, white race, and an increased use of thyroid hormones and antacids were indicators for the most severe stages of the disease.

Integrative Therapy

Lifestyle Interventions

Sunglasses, Hats, and Visors

Everyone's need to wear sunglasses with light protection, hats, and visors should be emphasized as early as childhood. People with dilated pupils, outdoor workers, and people who frequent tanning beds may be at a higher risk for development of macular degeneration. Microscope light during cataract surgery is another source of phototoxicity. Sun exposure is a known causative factor in the progression of the hereditary disorder retinitis pigmentosa.

Stress Management

Hormonal imbalance and lack of sleep contribute to debilitation of retinal

health. Depression contributes to food habituation, overeating, and abnormal sleep patterns. Ocular health remains in a sensitive balance between oxidative stress and antioxidant support of cell membranes. Therefore, smoking and inadequate nutrition both tip the scale toward increased or imbalanced free radical activity.

Limiting Alcohol Intake

Excessive alcohol intake has been associated with cardiovascular and liver disorders. The Beaver Dam Eye Study documented an association between beer consumption and risk of RPE degeneration. Two further studies have indicated that one or two glasses of red wine daily may confer a 40%–50% reduction in risk for AMD. However, the Physicians' Health Study and Nurses' Health Study, conducted between 1980 and 1994, could not confirm any significant benefit. Red wine has a protective effect on cardiovascular health and may improve retinal and choroidal blood flow. Apparently, white wine, which lacks the high levels of grape skin bioflavonoids, does not confer as much ocular protection.

Recognition of Medication Effects

Numerous medications, including phenothiazines, hydroxychloroquine, and ethambutol, may negatively affect the RPE. Other agents may alter digestion or liver function. The liver not only filters out all of the nutrients and toxins from the gastrointestinal tract but also stores fat-soluble vitamins, activates the B vitamins, and manufactures glutathione. Chinese and Ayurvedic physicians have known for millennia that the liver is essential to good vision.

Antacid use has been positively correlated with the development of AMD. The lack of gastric acidity reduces the stimulus for secretion of pancreatic and biliary enzymes into the duodenum. Proton pump inhibition can cause vitamin B₁₂, iron, magnesium, and calcium deficiency.

Hydration

Drinking six or more glasses of filtered water a day hydrates the body, flushes the liver and kidneys, and decreases appetite. Patients should be counseled against excessive consumption of caffeinated soft drinks and

artificial sweeteners.

Exercise

Exercise plays a role in cardiovascular health and in stimulating the parasympathetic nervous system. Physical activity also plays a part in relaxation of the mind, decreasing intraocular pressure, and improving ocular blood flow.

Breathing

Deep breathing relaxes the mind, strengthens the diaphragm, and improves blood flow to the eye. Conscious attention to breathing is the foundation of meditation and stress reduction practices.

Whole Body Health

Management of concurrent medical conditions is essential. Regulating blood pressure, maintaining a normal serum cholesterol level, controlling diabetes, supporting necessary weight reduction, and managing cardiovascular health are important to the long-term maintenance of good vision. It is wise to remember that the eye is intimately connected to the rest of the body.

Estrogen

Women are more likely than men to have AMD. Several studies have demonstrated that postmenopausal women who are taking HRT exhibit a lower incidence of macular degeneration, especially the wet form of the disease.¹² However, one study was unable to determine any significant effect of estrogen replacement therapy. Nonetheless, clinicians have observed that more postmenopausal women have AMD than men do.

Sleep

Sleep is crucial to restoration of photoreceptor and ocular health. The eye requires darkness to restore photoreceptor integrity and to replenish nutrients consumed during the daylight hours, when ultraviolet wavelengths and bright light are constantly bombarding the eye.

Attitude

Adopting a positive attitude is the first step in lifestyle modification. The

placebo effect is another demonstration of the “power of positive thinking.” In one study, 68% of persons who took a multivitamin for 6 months showed an improvement in macular appearance on electroretinograms; however, 32% of the placebo group also showed improvement. Similarly, in an initial study of photodynamic therapy to control retinal bleeding, approximately 50% of subjects receiving the therapy demonstrated some benefit compared with 28% of the placebo group. The placebo effect, which occurred in approximately 30% of subjects and contributed to the cessation of retinal bleeding, is a demonstration of the power of positive thinking.

Nutrition

[Box 85.1](#) lists the foods recommended for the preservation of sight.

Fruits and Vegetables

Fruits and vegetables contain vitamins A, C, and E as well as beta-carotene and lutein. The yellow-orange vegetables, such as carrots and sweet potatoes, are important for daytime vision. Cho et al.¹³ found strong evidence of a protective role of fruit against the risk of neovascular AMD or age-related maculopathy.

BOX 85.1 Top 10 Foods for Sight Preservation

- Cold-water fish (sardines, cod, mackerel, and tuna): an excellent source of DHA, which provides structural support to cell membranes and is recommended for dry eyes, treatment of macular degeneration, and sight preservation (see [Chapter 86](#)).
- Spinach, kale, and green leafy vegetables: rich in carotenoids, especially lutein and zeaxanthin; lutein, a yellow pigment, protects the macula from sun damage and from blue light.
- Eggs: rich in cysteine, sulfur, lecithin, amino acids, and lutein; sulfur-containing compounds protect the lens of the eye from cataract formation.
- Garlic, onions, shallots, and capers: rich in sulfur, which is necessary for the production of glutathione, an important antioxidant for the lens of the eye and for the whole body.
- Soy: low in fat, rich in protein; has become a staple in vegetarian

diets; contains essential fatty acids, phytoestrogens, vitamin E, and natural antiinflammatory agents.

- Fruits and vegetables: contain vitamins A, C, and E, and beta-carotene; the yellow vegetables, such as carrots and squash, are important for daytime vision.
- Blueberries and grapes: contain anthocyanins, which improve night vision; a cupful of blueberries or huckleberry jam or a 100-mg bilberry supplement may improve dark adaptation within 30 minutes.
- Wine: known to exert a cardioprotective effect; has many important nutrients that protect vision, heart, and blood flow (as with any alcohol, moderation is always important).
- Nuts and berries: nature's most concentrated food sources; grains such as flaxseed are high in the beneficial omega-3 fatty acids, which help lower serum cholesterol and stabilize cell membranes.
- Extra-virgin olive oil: a monounsaturated oil and a healthy alternative to butter and margarine.

Lutein-Containing Foods

Spinach, collard greens, kale, guava, and many other green and yellow fruits and vegetables contain lutein and its isomer, zeaxanthin. These two carotenoids are concentrated in the macular pigment; their accumulation depends directly on dietary intake and serum level.

The complete name of the visually sensitive center of the retina is “macula lutea” because of its yellow color (Latin *luteus*, “yellow”). Lutein and zeaxanthin are responsible for the yellow color. The normal retina is capable of concentrating these carotenoids to a level that is several orders of magnitude greater than the serum level. Evidence suggests that the lutein in macular pigment is entirely of dietary origin and is highly protective against AMD.¹⁴

In one study, persons consuming lutein-rich foods five times a week were eight times less likely to have AMD than those consuming such foods once a month.¹⁵ In addition, persons with serum lutein values in the highest quintile had a 43% lower risk for AMD. Another study demonstrated that consumption of 4–8 oz / day of spinach for 4 months resulted in greater macular pigment density. The vitamin K content in spinach may interfere with blood-thinning agents such as warfarin sodium. Preliminary data have demonstrated improvement in the visual

function of patients with the dry form of AMD whose diet was modified to provide an abundance of dark green vegetables.¹⁶

There is 44 mg of lutein per cup of cooked kale, 26 mg per cup of cooked spinach, and 3 mg per cup of broccoli.

Avoidance of Saturated Fats

Patients should be advised to decrease their intake of saturated fats. Diets high in saturated fats contribute to the risk of developing AMD, whereas those high in unsaturated fats reduce the risk.¹⁷

Cold-Water Fish

Docosahexaenoic acid (DHA), found in cold-water, deep-dwelling fish, is an essential nutrient for good brain and retinal function. The flesh of algae-eating fish is high in DHA, which is important in building and protecting photoreceptor membranes. In one study, persons consuming cold-water fish more than once a week were half as likely to experience macular degeneration as those consuming fish less than once a month.¹⁸ The same study found a 2.7-fold greater incidence of AMD in persons consuming high levels of dietary cholesterol. Eating oily fish at least once weekly, compared with less than once weekly, halved the incidence of neovascular AMD.¹⁹

Wine in Moderation

Most researchers agree that consumption of moderate amounts of red wine reduces the risk of macular degeneration. In addition, many studies have reported that moderate wine consumption is associated with a lengthened life span.

Glutathione

An important study found that glutathione and related precursor amino acids are protective against damage to human RPE cells, which underlie the macula. Foods that contain the tripeptide glutathione are onions, garlic, avocados, asparagus, watermelon, and cruciferous vegetables.

Supplements

Multivitamins

Many studies have demonstrated the protective effect of antioxidants on retinal photoreceptors and the RPE. Some studies have demonstrated an association between vitamin or mineral deficiencies (e.g., zinc, tocopherol, carotenoids, and taurine) and a higher risk of AMD.

Ascorbate, as well as lipoic acid, help recycle tocopherol in retinal tissue. Patients with AMD, in general, were found in one study to have a lower intake of tocopherol, magnesium, zinc, pyridoxine, and folic acid. In an important Veterans Affairs study, patients with AMD who were taking an antioxidant capsule (containing 19 ingredients) twice daily maintained better vision than the placebo control group.²⁰ One review found positive evidence for vitamins A, C, and E as well as for beta-carotene, lutein, zeaxanthin, selenium, and zinc, with the best evidence for vitamins C and E, lutein, and zeaxanthin.²¹

The 10-year randomized-controlled AREDS was concluded 3 years early because of the significant difference in the vitamin groups versus placebo. It demonstrated that the combination of vitamins C and E, beta-carotene, and zinc significantly reduced the progression of macular degeneration.²² Ophthalmologists regard this as a landmark study acknowledging the effect of supplementation on macular degeneration. This proof of specific benefits of a balanced diet and broader nutrient supplementation has exciting implications.

The National Eye Institute is instituting AREDS II. It will reduce the amounts of zinc and beta-carotene in the study combination and add lutein and DHA.²³ In a 1-year Italian study, a combination of vitamin C, vitamin E, zinc, copper, lutein, and zeaxanthin improved established AMD.²⁴ The 6-month TOZAL study revealed similar results with a multivitamin including C, E, zinc, beta-carotene, and lutein and recommended prolonged administration.²⁵

Multivitamins, which contain high levels of zinc and copper, should be avoided for long-term use. More than 30 mg of zinc will compete with the absorption of calcium, magnesium, selenium, and all other two valance compounds. Copper is an oxidant and has been associated with an increased risk of Alzheimer's.²⁶

Lutein

Carotenoids are powerful antioxidants. Lutein and zeaxanthin have been precisely identified at high levels in the retina, particularly in the macular area. They have also been identified at significant concentrations

in the iris, choroid, and lens (where they are needed to quench singlet oxygen and to filter out blue light). Greater lutein consumption is directly associated with elevated serum values and an increased macular pigment density. Investigators studying 23 pairs of donor eyes found that the eyes with lower lutein and zeaxanthin levels were the ones with histopathological signs of AMD.²⁷ Another study evaluated lutein and zeaxanthin levels in 56 donor eyes affected by AMD and 56 donor eyes known to be without the disease. Donor eyes with the highest amounts of lutein and zeaxanthin were 82% less likely to exhibit the signs of macular degeneration.²⁸

Lutein and zeaxanthin are associated with improved retinal function in early AMD as well as increased neural processing.²⁹

As little as 2.4 mg/day of lutein can double the serum level. A dose of 6 mg/day resulted in a 43% lower prevalence of AMD.¹⁵ The Veterans Lutein Antioxidant Supplementation Trial (LAST) documented improvement in visual function with lutein alone or in combination with other nutrients.³¹ With the addition of DHA, lutein buildup in the macular pigment density is even more effective.³² AREDS II has replaced beta-carotene with lutein and DHA in their current formula. However, high levels of zinc and copper still remain.³³

Dosage

Healthy persons should select a multivitamin containing 6 mg of lutein, and patients already diagnosed with AMD should take 10 mg/day or more for several months to build up plasma and macular levels of this nutrient.

Beta-Carotene, Vitamin A, and Other Carotenoids

Investigators have confirmed, in both laboratory and clinical studies, that carotenoids such as vitamin A protect retinal cell membranes from light damage. Vitamin A is required to provide adequate levels of rhodopsin for optimal rod function. Severe vitamin A deficiency causes keratomalacia, xerophthalmia, and visual impairment. Administration of vitamin A has been helpful in patients suffering from retinitis pigmentosa. An early study documented an association between low vitamin A levels and macular degeneration and encouraged the inclusion of yellow fruits and vegetables in the diet.³ The value of beta-carotene in

the management of AMD remains inconclusive.^{34,35} Only one study has indicated a specific beneficial effect of the carotenoid lycopene on the macula.

Tocopherols

Tocopherols protect against lipid peroxidation in cell membranes. Multiple studies have shown a powerful protective effect of *d*-alpha-tocopherol against macular degeneration. Some of these studies indicate a similar protective effect of plasma ascorbic acid and beta-carotene as well. High serum levels of *d*-alpha-tocopherol have been associated with decreased prevalence of drusen and late macular degeneration. French researchers examining 2500 patients found that those with the highest serum levels of vitamin E had an 82% lower prevalence of AMD.³⁶ Gamma-tocopherol and tocotrienol may prove to be superior to *d*-alpha-tocopherol.

Vitamin C

Ascorbic acid reduces the loss of rhodopsin and photoreceptor cell nuclei that occurs on exposure to light. Vitamin C also rejuvenates vitamin E and cell membrane-related enzymes. In several of the major studies that showed a protective effect of multivitamins against AMD, the multivitamin included at least 60 mg of vitamin C. Ocular tissues, especially the lens, contain high levels of vitamin C and glutathione.

Alpha-Lipoic Acid

Alpha-lipoic acid is an important nerve stabilizer that reduces insulin resistance in diabetic patients. It may protect the remaining ganglion cells and nerve fibers in patients with glaucoma. In addition, alpha-lipoic acid helps regenerate the reduced form of ascorbic acid.

B Vitamins

Pyridoxine deficiency has been identified in two observational studies in AMD populations. Folate deficiency has been identified in one of the studies. The B vitamins, in general, are important for nerve conduction, and the methylators (B₄, B₆, and B₁₂) reduce homocysteine levels. Christen et al.³⁷ reported a reduction in AMD development in 5205 women observed for 7.3 years who were given a supplementation consisting of folate, pyridoxine, and cyanocobalamin. Niacin, a B vitamin used to treat

lipid abnormalities, has been shown to increase choroidal blood volume within 30 minutes of administration; however, the perfusion is at a slower rate. Thus, niacin has not been shown to increase total flow to the choroid.³⁸

Vitamin D

Vitamin D is the only vitamin that is also a hormone and influences hundreds of genes. Studies have shown that vitamin D deficiency affects the risk of macular degeneration, neurodegenerative disease, and musculoskeletal health.³⁹ Garland has also reported a relationship between low serum vitamin D levels and all causes of mortality.⁴⁰

Glutathione

Glutathione has been reported to be protective against damage to human RPE cells. Glutathione is manufactured in the liver after ingestion of the appropriate amino acids and sulfur-containing foods. This underappreciated water-soluble compound serves as an antioxidant and regenerator of vitamin E and carotenoids, as well as an intracellular enzyme. Because glutathione is hydrolyzed in the stomach, supplementation with glutathione boosters is recommended. The following have been found to increase glutathione: *N*-acetylcysteine, 600 mg twice a day; methylsulfonylmethane, 1000 mg once daily; *S*-adenosylmethionine (S_{AM}e), 200 mg twice daily; and alpha-lipoic acid, 250 mg twice daily.

Bioflavonoids

Studies have shown that quercetin, a preparation of eucalyptus and citrus bioflavonoids, facilitates vitamin E protection of bovine and rat retina from induced lipid peroxidation. It also exerts an antihistaminic effect that may be beneficial for patients with chronic allergies.

Amino Acids

Taurine, the only nonbound circulating amino acid, is a stabilizer of biological membranes that protects the rod's outer segments, supports cardiovascular function, and modulates nerve transmission. Isolated taurine deficiency has been documented to cause retinal degeneration, and taurine administration has been shown to stabilize retinal changes in several studies.⁴¹

Arginine is one of the most important regulators of ocular perfusion. Intravenous administration of arginine has been shown to increase retinal (and choroidal) blood flow in healthy volunteers. This discovery merits further investigation in the AMD population.⁴²

Minerals

Zinc and Copper

Zinc is found in high concentrations in the retina, RPE, and choroid. This trace mineral serves as a cofactor with many important retinal enzymes, including superoxide dismutase, catalase, carbonic anhydrase, retinol dehydrogenase, and protein phosphorylase; it also releases vitamin A from the liver. A 2-year study demonstrated that 100 mg/day of zinc sulfate significantly slowed the progression of AMD compared with the course of the disease in controls.⁴³ A good multivitamin for long-term use includes 15–30 mg of zinc and no copper. Both copper and zinc are needed to synthesize superoxide dismutase, and both act with other retinal enzymes to scavenge free radicals.

Magnesium

Magnesium has a significant role in nerve conduction and also dilates blood vessels. This mineral is important for maintenance of blood flow to the eye and brain in older persons with macular degeneration or diabetes, whenever blood pressure is decreased because they are lying down. The dose is 400–500 mg at bedtime.

Selenium

Selenium (maximum dose, 200 mcg/day) is a cofactor for vitamin E and glutathione enzymes. Low serum selenium levels and smoking have been associated with AMD.

Docosahexaenoic Acid

The primary source of DHA is algae and the cold-water, deep-dwelling fish that eat them. DHA not only supports retinal health in general but also improves hand-to-eye coordination, sharpens night-driving ability, and stabilizes cell membranes throughout the body. With its six unsaturated double bonds, it comprises 30%–50% of the “good” fat in the outer segments of the retinal photoreceptors. Because people are

undersupplied with DHA from infancy, it is important to incorporate DHA capsules in the diet. The suggested supplementation amount is 500–1000 mg/day. One study found that lutein supplementation at 12 mg/day increased macular pigment ocular density (MPOD) in the peripheral macula, whereas the addition of DHA (800 mg/day) increased peripheral and central MPOD.⁴⁴ This evidence strengthens the support for supplementing polyunsaturated fatty acids in the diet to raise their concentration in macular photoreceptors. Feher et al.⁴⁵ reported that the combination of omega-3 fatty acids, acetyl-L-carnitine, and coenzyme Q10 showed significant stabilization and improvement in vision in a 106-patient study. These three compounds, along with vitamin E, favorably affect mitochondrial lipid metabolism. A 12-year study confirmed the reduction in neovascular AMD with a high intake of omega-3 fatty acids.⁴⁶

Alpha-linolenic acid (present in flaxseed oil, among others) is the parent omega-3 fatty acid. It takes 20–30 of the 18-carbon alpha-linoleic acid molecules to make one 22-carbon DHA molecule, which is a building block for every cell membrane in the body.

Botanicals

Ginkgo

The ginkgo tree is the sole survivor of a family of trees that flourished before the Ice Age. *Ginkgo biloba*, which increases cerebral blood flow, has been demonstrated to improve retinal blood flow by 23%⁴⁷ and is prescribed regularly by certain glaucoma specialists. For vasodilation, I recommend either 15–60 drops of a ginkgo solution (24% ginkgolides) in water or a 30-mg tablet twice daily. Be sure to check the patient's other medications first for possible blood-thinning influences because ginkgo can exacerbate this effect.

Sage

Sage (*Salvia officinalis*) also improves circulation, but unlike ginkgo, which has an excitatory effect, it has a calming effect.⁴⁸ A controlled study from Hunan Medical College in China indicated that *Salvia miltiorrhiza*, as part of a four-herb formula, improved visual field in one-third of a glaucoma population receiving the formula for more than 19

months. Herbalists recommend 1 g orally twice daily. More studies are necessary, however.

Bilberry

Bilberry (*Vaccinium myrtillus*) has been shown to improve night vision; with the exception of one preliminary French study, however, it has not been proven to be effective in stabilizing AMD. Bilberry only improves the effectiveness of rhodopsin, which is necessary for night vision.

Milk Thistle

Silymarin, from the herb milk thistle (*Silybum marianum*), is a major supporter of liver function. The liver is the key organ for maintenance of eye health because the fat-soluble vitamins and glutathione are stored and the B vitamins are activated there. The usual dose of milk thistle is 150 mg two or three times a day. SAME in a dose of 200 mg twice daily is an alternative.

The eye is subjected to bright light throughout the day, and the important ingredients for molecular repair are stored in the liver. When the liver is overburdened, eyesight is compromised.

Chinese Herbs

Experienced herbalists report that tien chi root, dang gui root, triphala, lycium fruit, ginseng root, cooked and raw rehmannia, shilajatu, wild asparagus root, and elderberry have been used in ancient formulas to treat vascular disease inside the eye.⁴² None of these remedies have been used in controlled studies, although there is ample anecdotal evidence in the Chinese literature of success as measured by nonprogression of disease during 3 years.

Pharmaceuticals

Ranibizumab (Lucentis), bevacizumab (Avastin), and aflibercept (Eylea) are three vascular endothelial growth factor (VEGF) inhibitors that can remarkably reverse leakage into the retina in wet AMD. Ranibizumab has been approved by the U.S. Food and Drug Administration (FDA); bevacizumab, an intravenous therapy for colon cancer, is used off label.

Intraocular injections of steroids, pegaptanib sodium (Macugen, an intraocular anti-VEGF), and verteporfin (Visudyne, an intravenous dye that highlights leaky retinal vessels) are relegated to ancillary roles. Dosages are to be determined by the retinal specialist.

Other Therapy

The FDA may soon approve implantable silicone devices that will serve as replacements for damaged retina. Implantable devices and telescopic lenses are also in phase II FDA testing.

Low-vision experts have many optical devices to support people with failing vision.

Prevention Prescription

- Adoption of a positive attitude and awareness of risk factors and potential medication effects
- Use of sunglasses and other sun protection
- Increased consumption of green leafy vegetables
- Diet rich in polyunsaturated fatty acids and low in saturated fats
- Multivitamins with zinc, taurine, and lutein
- Use of supplements, with attention to overall good dietary nutrition
- Avoidance of long-term use of antacids or gastric acid suppression
- Regular exercise
- Performance of deep-breathing exercises on a regular basis
- Periodic eye examinations with use of the Amsler grid
- Use of low-vision aids for vision loss

Early intervention after recognition of macular degeneration is crucial. The performance of an Amsler grid examination is recommended in all patients (see [Fig. 83.3](#)). It is important to remember that the retina can be rebuilt.

Therapeutic Review

If a patient presents with severe symptoms, such as profound visual loss, it would be to his or her benefit for the clinician to immediately begin a more aggressive therapy. For the patient who has mild to

moderate symptoms, however, the following nutritional and lifestyle approach is appropriate.

Remove Exacerbating Factors

- Encourage smoking cessation, moderate alcohol intake, weight management, and exercise.

Nutrition

- Encourage foods rich in omega-3 fatty acids (wild salmon, nuts, or flaxseed). 
- Increase foods rich in carotenoids, such as lutein and zeaxanthin (dark green leafy vegetables). 

Supplements

- Multivitamins have been the focus of many epidemiological studies over the years. It is known that the combination of low-dose antioxidants is supportive of macular function; this fact became evident in the landmark AREDS. The multivitamin should include vitamin C, vitamin E, zinc, selenium, taurine, lutein, and zeaxanthin. 
- Incorporate lutein: 6–10 mg/day (6 mg for prevention, 10 mg for treatment). 
- DHA supplementation: 500 to 800 mg daily 
- Vitamin C, 1000 mg/day, has been shown useful in some observational studies to act as an antioxidant and therefore to protect the retinal pigment epithelium from oxidative stressors. 

Botanicals

- *Ginkgo biloba* has been shown to improve ocular blood flow by 23%; 30 mg twice daily. 
- Milk thistle is the primary source of the bioflavonoid silymarin, a major supporter of hepatocyte function, which in turn supports eye health; 150 mg two or three times a day. 

Chinese Herbs

- Although clinical data are lacking, there is an abundance of historical data on the benefits of the use of Chinese herbs for AMD. 

Pharmaceutical Injection

Antivascular endothelial growth factor (VEGF) therapy

- Intraocular injections of ranibizumab (Lucentis) and bevacizumab (Avastin) have become the best treatment of more advanced disease.

The Elimination Diet

Suhani Bora, MD, and J. Adam Rindfleisch, MPhil, MD

Detecting and eliminating specific antagonistic foods, and designing a nutritionally sound diet to ensure the optimum health of the food-sensitive person, is the ultimate aim in food sensitivity management. This process is often tedious and time consuming, and requires tremendous knowledge, skill, commitment, and dedication...However, when a person who has been chronically sick suddenly feels well for the first time in many years, as so often happens, the rewards for both practitioner and client more than justify the time and effort of the endeavor.

J. V. Joneja¹

For centuries, Indian Ayurvedic healing has emphasized the elimination of certain foods and the use of others.² In recent years, we have seen a rise in thinking of food as medicine.³ We have also seen an increase in the prevalence of food allergies⁴ and the number of diagnoses of celiac disease and eosinophilic esophagitis⁵ for which the mainstay of treatment is elimination of certain foods. Recent dietary trends parallel this with a rise in restrictive diets such as the paleo, gluten-free, and dairy-free diets. Globalization has increased our exposure to traditional, sometimes religiously based, diets that include restrictions such as vegetarianism and veganism. Celebrities and the media have made “detoxing” and “clean eating” mainstream.⁶ Pesticide contamination, use of growth hormones and antibiotics in meat production, genetic engineering of food sources, and health risks associated with fast and processed foods as well as food additives, high-fructose corn syrup, sugar, and sugar substitutes are topics of concern that can arise during an integrative medicine visit. An integrative provider must be aware of the potential benefits as well as the limitations and harms of an elimination diet. An

in-depth discussion of food allergies and food intolerances is provided in [Chapter 31](#).

Despite controversy surrounding food intolerances in the medical community, many Americans believe they are sensitive to particular foods. A subset of the population may indeed be able to alleviate symptoms, slow the progression of their disease, reduce the use of medications, and have a heightened feeling of control and ownership over often frustrating and incurable diseases or symptoms by eliminating certain foods. Almost one-third of adults in the United States have reportedly decreased their intake of gluten.⁷ Most people with irritable bowel syndrome (IBS) believe that certain foods trigger their symptoms,⁸ and 30% of patients with fibromyalgia have attempted to change their diet, trying improve their symptoms.⁹ Twenty percent of parents believe that their child has a food reaction when only about 5% actually do.¹⁰

Current evidence indicates that reportedly 35% of the population in developed countries has food hypersensitivities.¹¹ This does not account for approximately half of U.S. adults who have lactose intolerance.¹² The prevalence of celiac disease is 1 in 160,¹³ and the prevalence of nonceliac gluten sensitivity, which has similar symptoms but without enteropathy, is slightly higher.¹⁴ The prevalence of wine intolerance is 7.2%.¹⁵

Elimination diets may be used for three distinct types of patient encounters: (1) patients who present with multiple symptoms but no clear diagnosis, (2) those who have specific diagnoses for which certain foods have been found to exacerbate symptoms, and (3) for patients who believe they have food intolerances and may have already begun to restrict their diets. This chapter provides an overview of the state of research on elimination diets as a clinical tool, including its potential pitfalls and harms.

A patient handout on elimination diets appears at the end of the chapter.

Pathophysiology of Nonallergic Food Intolerances

A food allergy involves a specific IgE-mediated reaction, usually to a glycoprotein found in a given food. Food intolerance, in contrast, is defined more generally as any adverse physiological response to a food

product. This chapter will focus on food intolerances.

Pathophysiology of Leaky Gut Syndrome: Gut-Immune Barrier

Increased intestinal permeability, or “leaky gut syndrome,” has been proposed as one means by which food or chemical intolerance develops. The epithelial cells of the gastrointestinal tract function as nonprofessional antigen-presenting cells.¹⁶ The gut is constantly sampling various potential antigens, ultimately allowing only 2% of antigens to move into the bloodstream. The epithelial cells, gut dendritic cells, and at least five different T-cell types help regulate intestinal immunity. One of the main T-cell functions is to allow tolerance to develop; that is, the body must be able to minimize allergic reactions to the foreign antigens commonly consumed in foods. In some individuals, this process seems to break down and certain foods begin to elicit symptoms.¹⁷

The breakdown of the intestinal epithelial tight junction barrier allows antigens and bacterial DNA that are typically too large to cross through the intestinal tract to enter into the bloodstream. The introduction of these foreign proteins elicits a number of negative physiological effects, including initiating and perpetuating inflammatory diseases.¹⁸⁻²⁰ Permeability is increased by a number of factors, including inflammation, exposure to medications (e.g., nonsteroidal antiinflammatory drugs), shifts in intestinal microflora, micronutrient deficiencies, and the presence of various disease states such as celiac disease and ulcerative colitis^{18,21} (Table 86.1, list of factors that increase intestinal permeability). There is increasing evidence that the indigenous intestinal microflora, which is influenced by diet, stress, and disease states, plays a role in altering epithelial and mucosal permeability.¹⁸ Tight junction leakage, enhanced by glucose, salt, emulsifiers, organic solvents, gluten, microbial transglutaminase, and nanoparticles used in the food industry, also increases intestinal permeability. Tight junction dysfunction has been shown to be associated with atopic dermatitis and a variety of autoimmune diseases.²²

TABLE 86.1

Differential Diagnosis of Adverse Food Reactions

Intolerance Category	Description	Comments and Clinical Tips
Food allergy ^{11,12}	Immune mediated, usually by IgE, to a food glycoprotein. Symptoms arise in minutes to hours. Manifested the same way with every exposure, usually with rash, angioedema, anaphylaxis. GI symptoms may also arise with histamine release.	Prevalence increasing (4%–8% in children, 1%–4% in adults). One-fourth of the population claims to have a food allergy. One-third of infants with <i>Bifidobacterium</i> spiking up respond to oral challenge testing; 18% who react to cow's milk also react to soy; 41% react to a milk allergy just 1 year after a flare.
Celiac disease ¹³	Gluten, a portion of the grain protein gluten, triggers chronic inflammation through reactive CD4 ⁺ T cells in people with the alleles for HLA DQ2 or DQ8. Affects all ages groups. Two to three times more common in females than in males. May affect multiple organ systems. 30%–20% may develop neurological symptoms, such as idiopathic ataxia and parosmia. Genes that can contribute are wheat, rye, barley, spelt, kamut, emmer, emmer, emmer, and malt. Oats do not have gluten but are often contaminated with it, so many providers encourage avoidance.	Prevalence 1% and increasing as more testing is being done. 50% of adults with disease present with diarrhea. Increased risk with Down syndrome, Turner syndrome, and type 1 diabetes. 75%–55% do not respond to gluten-free diet and are at risk for T-cell lymphoma. Laboratory results may show decreased calcein and proteins as well as increased levels on liver function tests. People with celiac disease have higher risks of iron deficiency and osteoporosis. Best tests are tissue transglutaminase IgA, anti-endomysial antibodies, and tissue transglutaminase (in response that reacts with gluten). There are 90% sensitive, and these indicate degree of damage.
Cross-reactivity ^{14,15}	Arises when foods with similarities to environmental allergens trigger a response. Often characterized by oral itching (oral allergy syndrome).	Examples: Beech, alder, and hazel nut can cross react with apples, pears, cherries, hazelnuts, walnuts, and pistachios. Grass and cereal proteins can be linked to allergy to wheat, rye, and oat flour as well as to nuts, lentils, and celery. In people with latex allergies, pineapple, kiwi, avocado, potato, banana, and nut can cause reactions. Weather allergies can mean allergies to hen's eggs, poultry meat, and gelatin. House-dust mite allergy can be associated with shellfish allergy.
Food intolerance ^{16,17}	Foods trigger most self-degradation without involving IgE antibodies.	Examples: Statins, cholinesterase inhibitors, and nitroglycerin. Sulfinpyrazone (acute cyclo-oxygenase-1 inhibition, leading to abnormal prostaglandin levels) used as food preservative. Histamine (preservative used in fruit drinks, pickled foods, and alcoholic beverages). Tartaric acid (yellow #5).
Eosinophilic esophagitis ^{18,19}	Eosinophils accumulate in any or all layers of the digestive tract wall. One-half to two-thirds will have elevated serum eosinophil counts with no other explanation.	Affects all ages. Diagnosed by endoscopy and colonoscopy; may be related to stress and depression. Responds to elimination diets and medications. Weight loss is in eosinophils and diarrhea, especially if serum eosinophil counts are acceptably high.

Table Continued

Intolerance Category	Description	Comments and Clinical Tips
IgG-related intolerance ^{20,21}	Intolerances slowly develop hours to days after an exposure as IgG is cleared by the immune system. IgG may be the pathogen itself, causing increased small intestinal permeability. IgG half-life is 22–36 days, which makes false-positive results possible on testing.	Delayed IgG testing in patients with irritable bowel syndrome is counter-indicated, and no one test is likely to identify all problem foods. Foods that test positive often do not cause symptoms. Tests are not typically covered by insurance.
Physiological reactions ²²	Foods lead to gas production or cause dyspepsia by slowing the lower esophageal sphincter.	Examples of gas-producing foods include legumes, cabbage, lentils, and other vegetables and grains. Disulfuram and dyspepsia can result from fatty foods, alcohol, meat, chocolate, and citrus.
Pharmacological reactions ^{23,24}	Some foods have drug-like effects. A common example is histaminergic foods, which influence the histamine pathways in the stomach and other GI tract organs. Sulfites, monoamines glutamate (Chinese restaurant syndrome), and biogenic amines may also cause symptoms through drug-like actions.	Histamine intolerance: Is present in 1% of Europeans. Is more common in middle-aged women. Can be associated with other histamine-related symptoms, such as nasal congestion, dyspnea, skin reactions, and headache; dyspareunia may also occur. Leads to opposite effects for histamine-blocking drugs, such as ranitidine.
Toxin-mediated ^{25,26}	A specific toxin is present in a food.	Examples include food poisoning, mycotoxins, perhaps herbicides, and pesticides.
Enzymatic ^{27,28}	Deficiency of an enzyme, such as lactase, leads to poor digestion. GI symptoms result. Lactase intolerance arises as cells lose their ability to make lactase. Symptoms occur 30–120 minutes after lactose is consumed. Other sugar intolerances, such as fructose, sorbitol, xylitol, and erytrose, are less common.	Lactose intolerance: The lowest prevalence is Northern Europeans, highest in Asians, Native Americans, African Americans. Is usually not triggered by less than 12 g of lactose (the amount in a cup of milk). Is usually not affected or masked by yogurt, especially as it ages. Can be triggered by medications; 20% of prescription drugs and 6% of over-the-counter drugs use lactase as a base.
Structural ²⁹	An underlying pathological process leads to intolerance of all flavonoid foods.	Examples include achylia, stenosis, pancreatitis, inflammatory bowel disease, and abdominal angina.
Infectious ³⁰	Chronic infections predispose to adverse food reactions.	Examples include helminths (Giardia), bacteria (overgrowth, especially in immunosuppression, diabetes, or the use of proton pump inhibitors), chronic candidiasis, <i>Clostridium</i> infections, and parasites.
Psychogenic ³¹	Somatoform disorders, eating disorders, or the disengagement from food intolerance itself may lead to food reactions. Note that high eosinophilic levels can trigger histamine release, or stress can cause intolerance through some of the mechanisms previously listed as well.	It is not uncommon in integrative practice to see individuals who become obsessed with their diets. The "orthorexia" can become a pathological process unto itself. Treatment involves working closely with a nutritionist, adding mental health and mind-body approaches to care, and helping these overly rigid regain their ability to enjoy eating.
Other causes ³²	Monoclonal, anticancer and other neuroendocrine tumors, and GI neoplasms may also lead to symptoms.	As always, a careful history and differential diagnosis are necessary.

GI, gastrointestinal; Ig, immunoglobulin.

It has been proposed that many cases of food intolerance may be associated with the overall process of toxicant-induced loss of tolerance, which is thought to be precipitated not only by foods but also by inhalants, chemical exposures, and electrical stimuli.²³ As such, any steps that may reduce overall sensitivity may be helpful in treating food intolerances. Examples include exercise, minimizing body inflammation,

desensitization, and simple, safe detoxification regimens that include evaluation and reduction of chemicals used in daily cleaning and hygiene. It may be helpful to explore whether an individual with food intolerances is also “reactive” in other ways, physically and emotionally, to his or her environment. Reducing intestinal permeability may allow a person to reintroduce substances that were formerly problematic.

Repairing the gut-immune barrier to reduce intestinal permeability requires a multifaceted approach, one that includes addressing sources of inflammation including diet, lack of adequate physical exercise or sleep, high levels of stress, and unaddressed emotional health including unhealthy relationships.²⁴ One common approach for treating intestinal permeability is the 4R method, in which foods or substances that could be causing adverse reactions are *removed*, followed by *replacing* digestive enzymes or hydrochloric acid if needed and *repopulation* of the gut flora with prebiotics and probiotics, and finally, *repairing* the intestines with key nutrients and botanicals. Elimination diets are one part, the *removal* part, of an integrative treatment approach.

Aside from certain tests for IgE-mediated food allergies, most tests for adverse food reactions remain controversial. Such tests are more likely to discover clinically insignificant positive results, leading to unnecessary food restrictions, and to miss clinically important reactions. Remember that an elimination diet can serve, in and of itself, as a useful diagnostic tool.

Prescribing an Elimination Diet

A number of disorders are known to be influenced by food ([Table 86.2](#)). An elimination diet is, put simply, an eating plan that omits a food or group of foods believed to cause an adverse food reaction. Restrictive diets prescribed for long durations without reintroduction of foods may lead to malnutrition and cause fear or anxiety related to food that, in severe cases, may lead to orthorexia or a fear of food. If you have a patient who presents with multiple chronic symptoms but no clear diagnoses, who has a specific diagnosis that has been shown to be affected by certain foods, or who believe they have a food intolerance, a carefully prescribed elimination diet may be a safe and effective treatment and diagnostic, patient-led tool. In general, four principal steps are followed in prescribing any elimination diet.

Step 1: The Planning Phase

Before recommending an elimination diet, the clinician must take a thorough patient history. For patients with a history of eating disorders, children, and pregnant women, an elimination diet must be approached cautiously, if at all. Children and pregnant women are at risk for nutritional deficiencies and inadequate weight gain. Patients with significant food allergies should be followed in conjunction with an allergist. Ideally, patients should provide a recent diet and symptom log that chronicles food and beverage intake for a least 1 week. Patients should note what symptoms they experience and when these symptoms arise relative to mealtimes and time of day, including alcohol use, supplements, medications, exercise, specific stressors, and sleep quality if those are of concern.²⁵ Symptoms may range from gastrointestinal complaints and skin changes to low mood, fatigue, or difficulty with concentration. Free online food tracking apps or websites may be helpful. [Table 86.3](#) lists key issues to address when taking the history of a patient for whom an adverse food reaction is suspected. A sample 1-week dietary log form is included in the Patient Handout. Keep in mind that for patients with an unhealthy diet, simply recommending a healthy diet may be more important than an elimination diet. In a UK study²⁶ of people who believed that they had a food intolerance, 70% were able to improve their symptoms just by following a healthy eating plan for 2 weeks and without any food restrictions. This 2-week healthy eating plan focused on reducing soda, caffeine, and processed foods and eating more whole grains, fruits, and vegetables.

TABLE 86.2

Conditions for Which Elimination Diets Might be Used¹

Cardiovascular	Palpitations Tachycardia
Dermatological	Angioedema ^a Atopic dermatitis ^a Contact dermatitis Dermatitis herpetiformis Pruritus ^a Seborrheic dermatitis Urticaria ^{a,128}
Gastrointestinal	Bloating, belching Celiac disease ^a Cholecystitis, cholelithiasis ^{a,129} Chronic diarrhea ^{a,130} Colic ¹³¹ Constipation, including laxative resistant in children ¹³² Cyclic vomiting syndrome ^{a,133} Encopresis ¹³⁴ Eosinophilic esophagitis ^{a,16} Eosinophilic gastroenteritis ^{a,135} Gastroesophageal reflux ^{a,136} Irritable bowel syndrome ^a Inflammatory bowel disease ^{a,137-139} Nausea, vomiting Pruritus ani ¹⁴⁰ Recurrent abdominal pain in children with confirmed allergy ^{a,141}
Genitourinary	Enuresis ^{a,12,142} Frequency Interstitial cystitis Vulvodynia Chronic pelvic pain
Neurological/psychological	Attention deficit hyperactivity disorder ^a Autistic spectrum disorders ^a Medication-resistant depression Migraine ^a Other types of headache Seizures (by ketogenic diets) ^{a,143}
Respiratory/otolaryngological	Aphthous ulcers (recurrent) ¹⁴⁴ Asthma ^{a,86,145,146} Chronic congestion, rhinitis ^{a,147} Chronic serous otitis ^a Conjunctivitis Laryngeal edema, hoarseness
Rheumatological	Chronic fatigue ^{148,149} Gout ³³ Rheumatoid arthritis ^a Systemic lupus erythematosus ¹⁴⁹ Vasculitis
Miscellaneous	Listlessness, poor concentration Irritability Cold intolerance, low-grade fever Dizziness Excess sweating Pallor

Other foods may also be implicated. It is important to tailor therapy to the individual.

^a Indicates that at least level B evidence (SORT criteria) exists for treatment of this condition with an elimination diet.

TABLE 86.3
Points to Consider Before Prescribing an Elimination Diet

Several key questions may reveal which foods should be removed. ²⁴	<ul style="list-style-type: none"> • What foods do you frequently eat? • What foods do you crave? • What foods make you feel best? • What foods would be difficult to give up or go without?
A history should cover several specific topics: ^{1,13,15}	<ul style="list-style-type: none"> • Timely history of food intolerances, irritability, bowel, headache, and mouth ulcers. • Past medical history of respiratory allergies, chronic upper respiratory congestion, asthma, atopic dermatitis, infant colic, gastrointestinal problems (including lactose intolerance or colic, disease), or unusual reactions to medications or foods. • History of eating disorders (to avoid risk that an elimination diet may exacerbate these conditions). • History of food allergies. • Previous laboratory test findings (e.g., results of skin prick testing). • Evidence of symptoms to exercise (some intolerances are associated with increased activity). • Evidence of symptoms to substance use, including smoking, alcohol,¹⁶ caffeine, and illicit drugs. • Life stresses. • Financial resources. • Social support. • Willingness and ability to make lifestyle changes.²⁵

^a Some clinicians have noted that the development of food intolerance in some patients is preceded by changes in alcohol tolerance. Patients may first note intolerance to red wine and beer and later an inability to drink white wine and spirits.¹⁵³ Ultimately, intolerance to other food items is noted.

Next, it is important to assess the patient’s readiness and motivation to undertake a lifestyle change.²⁵ Do the patients have upcoming stressful life events? Are they on a limited budget? Do they have resources, energy, and willingness to create new grocery lists and menus and to cook new recipes? Are they able to gather support from family and friends and strategize how to eat at work, in restaurants, at events? Are they committed to tracking what they consume and their symptoms? Do they have adequate stress coping skills? Would another time be better to successfully implement an elimination diet?

After a list of potential problem foods is elicited, the next step is to create a list of foods to avoid. The list should be individualized as much as possible for each patient. [Table 86.4](#) lists the foods most likely to cause adverse food reactions. [Table 86.5](#) lists foods linked to symptoms in various disease states.

TABLE 86.4
Common Food Culprits for Food Allergy and Food Intolerance^{1,16}

Food allergy ^a	<ul style="list-style-type: none"> Citrus Dairy products Eggs Fish Peanuts Soy Gluten (barley, oats, rye, and wheat) Shellfish Tree nuts (almonds, pecans, and walnuts)
Food intolerance	<ul style="list-style-type: none"> All of the foods listed for food allergy, plus: Beef products Cum Food additives, including <ul style="list-style-type: none"> Antioxidants (butylated hydroxyanisole, butylated hydroxytoluene) Aspartame (NutraSweet, an artificial sweetener) Flavor enhancers (monosodium glutamate) Food colors (tartrazine and various other Food Dye and Coloring Act [FD&C] dyes, which are derived from coal tar) Nitrates and nitrites (found in preserved meats) Preservatives (sulfites, benzoates, and sorbates) Thickeners/stabilizers (tragacanth, agar-agar) Biogenic amines (histamine, tyramine, octopamine, and phenylethylamine) Disaccharides (lactose) Foods high in nickel and salicylates (see reference 1 for a complete listing) Refined sugars

^a These foods account for roughly 80% of all food hypersensitivity reactions.

Patients often have a sense of which foods are most likely to contribute to their symptoms. The clinician should be sure to explore this issue with them. Trust their “gut feelings.” Remember that comfort foods and foods that are often craved can be important culprits.

Step 2: The Avoidance Phase

Elimination diets vary in terms of intensity.^{1,24} The type of diet chosen varies according to the number of suspected food culprits, patient preference, likelihood of adherence, and the potential effects on the patient’s nutritional status. Patient adherence decreases as diets become more restrictive. The patient handout provides examples of three elimination diets of variable intensity. “Failing” a prescribed elimination diet may cause undue stress or feelings of failure. Begin with the least restrictive diet.

TABLE 86.5

Foods to Eliminate for Specific Disorders and Synopsis of Key Research

Level 1: Food Specific Diet: Elimination of One Food or Food Group

The lowest-intensity elimination diets are referred to as *food-specific diets*. In these, just one food, group of foods, or additive (e.g., aspartame) is eliminated. Which food or foods are to be removed is often determined on the basis of both the patient suspicions and their responses to the questions listed in [Table 86.3](#). For some patients, particularly those for whom maintaining healthy nutrition may be a challenge, it is most appropriate to pursue several low-intensity elimination diets, one after another, rather than to remove multiple foods or food groups simultaneously. However, some individuals display intolerance to combinations of foods or food groups; for them, a low-intensity elimination diet may not prove as useful as one in which multiple food groups are removed simultaneously. Given the high prevalence of lactose intolerance, eliminating dairy may be a good way to start.

Level 2: Elimination of Multiple Food Groups

In a moderate-intensity elimination diet, multiple foods or food groups are eliminated. If successfully done, moderate-intensity diets have the potential to serve as useful diagnostic and therapeutic tools. The list of foods eliminated is tailored to the individual patient; examples include a low-fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMaPS) diet for a patient with IBS (see [Chapter 90](#)); a six-food elimination diet for eosinophilic esophagitis; a gluten-free, casein-free diet for autism; or a gluten and dairy elimination diet for someone with multiple, nonspecific symptoms. A person with seasonal allergies may have crossover allergies. Disease-specific elimination diets, such as those listed in [Table 86.5](#), are available in the reference materials listed at the end of this chapter. Because moderate-intensity elimination diets are more likely to lead to symptom resolution compared with food-specific elimination diets, they are popular with many integrative clinicians.

Level 3: A “Few Foods” Diet

Finally, for a limited number of patients, a high-intensity or “few-foods” diet may be considered. In this diet, only foods on a specific list may be eaten. Higher levels of supervision are necessary with this type of diet to ensure that nutritional needs are met.¹ The patient handout contains an example of this diet as well.

The patient handout also provides a table of common “foods in

disguise.” When a specific group of foods is eliminated, some common ingredients that may cause adverse food reactions must also be eliminated. For example, if a patient is to successfully perform a dairy elimination diet, he or she must also avoid anything containing whey, caramel, casein, or semisweet chocolate.

Duration

Patients should follow an elimination diet for at least 2 weeks; most sources suggest 2–4 weeks.^{1,16} It is hypothesized that symptoms caused by food intolerance may not arise until a few days after the food has been eaten, so it is important to give food-related symptoms time to “wear off” before foods are reintroduced. A longer duration of 6–12 weeks may be beneficial in some patients. In such cases, it may be necessary to add supplements, such as folate, if gluten is being eliminated and be aware of increasing anxiety surrounding the reintroduction of foods.

Patients should be warned that with the elimination diet, it is not uncommon for symptoms to worsen before they begin to improve.

Step 3: The Challenge Phase

If symptoms decrease during the avoidance phase, it is likely that the food or foods that were eliminated were, in fact, contributing to the symptoms. However, symptoms of many chronic conditions relapse and remit spontaneously, so it is important to reintroduce eliminated foods or food groups after symptoms have resolved to determine whether they recur. Because symptoms may take a few days to reappear, foods should be introduced back into the diet only every 3 or 4 days. It is best for a patient to consume a small quantity of the reintroduced food on the first day and then to have a larger serving on subsequent days (assuming no untoward effects are experienced with the first serving). In addition to previously experienced chronic symptoms, food-intolerant patients who reintroduce foods may experience lung congestion, increased mucus production, fatigue, concentration difficulties, digestive problems, constipation and diarrhea, bloating, fluid accumulation, mood swings, and drowsiness.²⁷ The patient handout contains a sample schedule for the elimination and reintroduction of foods in a moderate-intensity elimination diet.

Improvements in symptoms are readily apparent to the patient when

they occur during an elimination diet. In fact, many patients are reluctant to attempt the challenge phase because their symptoms have improved so markedly.

Step 4: Creating a Long-Term Diet Plan

Once the initial three phases of the elimination diet are completed, long-term diet planning is necessary. Additional elimination diets may be needed at some point if symptoms are either unchanged or not fully resolved. Many recommendations exist regarding how long a food causing adverse reactions should be avoided. A reasonable approach is to continue the elimination for at least 3–6 months. After that, another challenge with the eliminated food or foods may be attempted. There is some evidence that when a food is reintroduced after a lengthy period, the intolerance may no longer be found. In a study of 10 patients who had chronic urticaria or perennial rhinitis, 38% found their different food intolerances to be resolved at retesting a year or more after the initial evaluation.²⁸ This finding may be attributable to improvements in the intestinal barrier, including microflora, mucus, and epithelial lining.

Risks of Elimination Diets

Although elimination diets are generally safe, particularly under the supervision of a health care professional, the following potential risks must be acknowledged:

- Elimination diets may activate “latent” eating disorders. The clinician should screen patients for anorexia and bulimia nervosa before initiating an elimination diet. Patients with IBS may be especially vulnerable.²⁹
- A food or food group that has led to an anaphylactic reaction should *never* be reintroduced without appropriate supervision by an allergist. In one small study, seven children with fish allergy eliminated fish from their diets. When fish was reintroduced, their hypersensitivity was more florid.³⁰
- Malnutrition is a risk if a large number of food groups are eliminated. The clinician must ensure that dieters receive adequate fiber, nutrients (including vitamin D and calcium when dairy is restricted), and protein. Patients on gluten-elimination diets often become deficient in zinc, selenium, copper, B₆, and B₁₂ over time; gluten-free grains lack vitamins B₁, B₂, and B₃ as well as folate and iron. Special caution should

be used in the treatment of autistic children, given that they tend to be limited in their diets at baseline.³¹

- The clinician must keep in mind the socioeconomic implications of prescribing an elimination diet because the cost can become prohibitive; for example, various alternatives to gluten-containing grains can be costly or difficult to obtain, and patients following elimination diets have limited ability to eat at restaurants or at other people's homes unless their dietary restrictions are clearly understood by those preparing their meals.³²
- Enjoyment of eating, an important aspect of general health, may be diminished.
- A fear of food may be created. Some patients have significant symptom improvement with removal of a food. This success can lead to inappropriate association of symptoms with other foods that can snowball toward malnutrition. The goal should be temporary removal of a food, repair of the gastrointestinal ecosystem, and slow reintroduction of the food in the future, if possible, for non-IgE food intolerances.
- The likelihood of patient noncompliance with the diet must always be kept in mind; this can often be quite high, especially for diets prescribed for children.

The clinician must be mindful of the potential pitfalls of prescribing elimination diets. Patient compliance, nutritional status, and the psychosocial impacts of such a diet must be given consideration. When judiciously used, elimination diets are associated with minimal risk.

Summary of a Pragmatic Approach for Recommending an Elimination Diet

A number of chronic diseases are associated with inflammation and intestinal permeability, indicating that methods of reducing inflammation and intestinal permeability will be beneficial. A multimodal approach that emphasizes mind-body techniques for stress management, physical activity, emotional health, and adequate sleep and nutrition is necessary to reduce sympathetic overdrive and an associated increased inflammatory state. A focused 4R approach to reduce intestinal

permeability is an example of a multimodal treatment plan. The goal of the nutrition component is to eliminate or reduce potentially inflammatory foods while encouraging antiinflammatory ones. While specific foods may worsen particular diseases, as noted in the following text, a general approach may be used for any disease with an inflammatory component. An ideal elimination diet eliminates as few healthful foods as possible to achieve improvement in symptoms and overall wellbeing. For many people, simply switching to a more healthy diet will provide adequate symptom relief.²⁶

Diseases with an inflammatory component include autoimmune thyroiditis, vitiligo, inflammatory arthritis, lupus, asthma, allergies (food, seasonal, environmental), chronic pain, migraines, diabetes, obesity, coronary artery disease, eczema, fibromyalgia, depression, chronic obstructive pulmonary disease, and cancer.

Step 1

Healthy diet (trial of at least 2 weeks)

Eliminate: high-fructose corn syrup, sugar sweetened beverages, artificial sweeteners (especially aspartame), artificial food dyes, and trans fats

Reduce: alcohol, caffeine, processed foods (with emulsifiers, additives), sugar, saturated fat, and red meat

Encourage: at least five servings of fruits and vegetables daily with a variety of colors, plant-based protein, fatty fish consumption, nuts, legumes, whole grains.

If no improvement, move on to Step 2.

Step 2

A. Diagnosis based elimination (see the following text)

- i. Refer to the following list and eliminate two to three foods eaten most frequently. After 2–4 weeks, reintroduce one food item. On day one, begin with a small amount. On day two, eat a small amount twice during the day. On day three, eat a larger amount. If there is no worsening of symptoms, reintroduce another food item the next day in the same manner and repeat until all eliminated foods have been reintroduced. If symptoms worsen, remove the offending food. Notably, some foods may be tolerated in small amounts but not large amounts, so keeping a close food and symptom diary will be helpful. Repeat until all the listed foods have been eliminated and

- reintroduced
- ii. If a patient prefers to eliminate ALL listed foods, eliminate for 2–4 weeks and reintroduce in stepwise fashion, every 3 days, as previously mentioned.
 - iii. For most patients, begin with the least restrictive diet to maximize adherence.

OR

A. Elimination of gluten and dairy (trial of 2 weeks) followed by stepwise reintroduction

- i. Consider for people without clear diagnoses; vague symptoms; or limited time, ability, or willingness to adhere to a more complicated elimination diet.

Step 3

If there is no improvement with a disease-specific elimination diet, consider either a more restricted elimination diet (if patient willing and able) or focus on other modalities. If there is no improvement with gluten and dairy restriction, consider a disease-specific elimination diet. Only a few people will be able to adhere to and benefit from a few-foods diet, but it is worth considering.

Summary

Step 1: Encourage a healthy diet (2 weeks)

Step 2: Eliminate foods based on evidence by disease OR eliminate gluten and dairy (2–4 weeks)

Step 3: Reintroduce eliminated foods in a stepwise, graduated manner every 3 days.

Encourage patients to keep a food and symptom diary.

Potential Pitfalls

Poor adherence, initial worsening of symptoms, uncovering of underlying eating disorder, enhancing feeling of failure if unable to adhere to diet, and inadequate calcium intake or B-vitamin intake.

Patient Handout: Using an Elimination Diet

An elimination diet can be used to determine whether or not certain foods are contributing to your symptoms. If they are, the diet can also be used as a form of treatment. There are four main steps to an elimination diet:

Step I: Planning

This step involves working with your provider to make a list of foods that might be causing problems. You may be asked to keep a diet journal for a week, listing the foods you eat and when you have symptoms. To decide what foods might be causing problems, ask yourself these questions:

- What foods do I eat most often?
- What foods do I crave?
- What foods do I eat to "feel better" (comfort foods)?
- What foods would be hard for me to stop eating?

The answers are foods you should try to eliminate. Other common problematic foods are listed below.

Step II: Avoiding the Foods on Your List

After you have made a list of foods to avoid, you start the elimination diet. You should stop eating the foods on your list for two weeks. If you make a mistake and eat something on the list, you should start over. The foods on the list should be avoided in their whole form and also when they are ingredients in other foods. For example, if you are avoiding all dairy products, you need to check labels for whey, casein, and lactose so you can avoid them as well. Elimination diets take a lot of willpower. You must pay close attention to food labels, and be careful if you are eating out, since you may not know all the ingredients of the foods you eat.

Many people notice that in the first week, especially in the first few days, their symptoms get worse before they get better. If your symptoms become severe or increase for more than a day or two, consult your healthcare provider.

Step III: Add the Foods Back

If your symptoms have not improved in two weeks, you will need to stop the diet and decide whether or not to try it again with a different list of foods. If you feel better after eliminating the foods, the next step is to see if your symptoms come back when you start eating the foods again. As you do this, keep a written record of your symptoms.

A new food or food group should be added every three days. It takes three days to see if your symptoms come back if they are going to. On the day you introduce an eliminated food back into your diet for the first time, start with just a small amount in the morning. If you don't notice any symptoms, eat a larger portion at lunch and dinner. After a day of eating the new food, wait for two days to see if you notice the symptoms. Then add back another eliminated food or food group. Follow the pattern until all foods are added back. If a food doesn't cause symptoms during a challenge, it is unlikely to be a problem food and can be added back into your diet for good. However, don't add the food back until you have tested ALL the other foods on your list.

Step IV: Create Your New, Long-Term Diet

Based on your results, you can plan how to change what you eat so that you'll be most likely to prevent your symptoms. Remember:

- Some people have problems with more than one food.
- Sometimes symptoms come and go for other reasons besides what foods we eat, so it can be confusing to tell for certain if a specific food is the cause.
- Be sure that you are getting adequate nutrition during the elimination diet and as you change your diet for the long-term. For example, if you give up dairy, you must get calcium from other sources.
- You may need to try several different elimination diets before you identify problematic foods.
- If a food causes you to have an immediate allergic reaction, or causes you to have throat swelling, a severe rash, or other severe allergy symptoms, it is important to seek the care of an allergist before re-introducing foods that cause problems.

The elimination diet is not a perfect test. A lot of other factors could interfere with the results. Try and keep everything else (the other foods you eat, your stress level, etc.) as constant as possible while you are on the diet.

The Three Levels of Elimination Diets

Level 1: The Simple Diet

Eliminates milk, eggs, and wheat.

	FOODS ALLOWED	FOODS ELIMINATED
Animal proteins	Beef, chicken, lamb, pork, turkey	Dairy products Chicken eggs
Grains and starches	Arrowroot, barley, buckwheat, corn, millet, oats, rice, rye, sweet potato, tapioca, white potatoes, yams	Wheat
Oils	Any non-dairy oils	Dairy-based butter and margarine
All fruits, vegetables, salt, spices, sweeteners, and vegetable proteins are allowed		

Level 2: The Stricter Diet

The stricter diet eliminates several foods at once:

	FOODS ALLOWED	FOODS ELIMINATED
Animal proteins	Lamb	All others, including eggs and milk
Vegetable proteins	None	Beans, bean sprouts, lentils, peanuts, peas, soy, all other nuts
Grains and starches	Arrowroot, buckwheat, corn, rice, sweet potato, tapioca, white potato, yams	Barley, millet, oats, rye, wheat
Vegetables	Most allowed	Peas, tomatoes
Fruits	Most allowed	No citrus or strawberries
Sweeteners	Cane or beet sugar, maple syrup, corn syrup	Any others, including aspartame
Oils	Coconut, olive, safflower, sesame	Animal fats (lard), butter, corn, margarine, shortening, soy, peanut, other vegetable oils
Other	Salt, pepper, a minimal number of spices, vanilla, lemon extract	Chocolate, coffee, tea, colas and other soft drinks, alcohol

Level 3: A Few-Foods Diet

Only the foods listed below can be eaten. All others are avoided.

- Apples (juice okay)
- Apricots
- Asparagus
- Beets
- Cane or beet sugar
- Carrots
- Chicken
- Cranberries
- Honey
- Lamb
- Lettuce
- Olive oil
- Peaches
- Pears
- Pineapple
- Rice (including rice cakes and cereal)
- Safflower oil
- Salt
- Sweet potatoes
- White vinegar

Modified from Mahan LK, Escot-Stump S: *Krause's food nutrition and diet therapy*, 11th ed. Philadelphia: Saunders; 2004.

A Sample Elimination Diet Calendar

Day Number	Step
1	Begin Elimination Diet
2-7	You may notice symptoms worsen for a day or two.
8-14	Symptoms should go away if the right foods have been removed
15	Re-introduce food #1 (for example, dairy)
16-17	Stop food #1 and watch for symptoms*
18	Re-introduce food #2 (for example, wheat)
19-20	Stop food #2 again and watch for symptoms
21	Re-introduce food #3
	...And so on, until all eliminated foods have been re-introduced

*You only re-introduce a new food for one day. Until the diet is over, it is not added back into the diet again.

Some Helpful Tips:

A number of foods can be "disguised" when you look at food labels.

If You Are Avoiding	Also Avoid
Dairy	Caramel candy, carob candies, casein and caseinates, custard, curds, lactalbumin, goat's milk, milk chocolate, nougat, protein hydrolysate, semisweet chocolate, yogurt, pudding, whey. Also beware of brown sugar flavoring, butter flavoring, caramel flavoring, coconut cream flavoring, "natural flavoring," and Simplese.
Peanuts	Egg rolls, "high-protein food," hydrolyzed plant protein, hydrolyzed vegetable protein, marzipan, nougat, candy, cheesecake crusts, chili, chocolates, pet feed, sauces.
Egg	Albumin, apovitelin, avidin, béarnaise sauce, eggnog, egg whites, flavoprotein, globulin, hollandaise sauce, imitation egg products, livein, lysozyme, mayonnaise, meringue, ovalbumin, ovoglycoprotein, ovomucin, ovomucoid, ovomucoid, Simplese.
Soy	Chee-fan, ketjap, metauza, miso, natto, soy flour, soy protein concentrates, soy protein shakes, soy sauce, soybean hydrolysates, soy sprouts, sufu, tao-cho, tao-si, tofyo, tempeh, textured soy protein, textured vegetable protein, tofu, whey-soy drink. Also beware of hydrolyzed plant protein, hydrolyzed soy protein, hydrolyzed vegetable protein, natural flavoring, vegetable broth, vegetable gum, vegetable starch.
Wheat	Atta, bal ahar, bread flour, bulgar, cake flour, cereal extract, couscous, cracked wheat, durum flour, farina, gluten, graham flour, high-gluten flour, high-protein flour, kamut flour, laubina, leche alm, malted cereals, minchin, multi-grain products, puffed wheat, red wheat flakes, rolled wheat, semolina, shredded wheat, soft wheat flour, spelt, superamine, tritcale, vital gluten, vitalis macaroni, wheat protein powder, wheat starch, wheat tempoh, white flour, whole-wheat berries. Also beware of gelatinized starch, hydrolyzed vegetable protein, modified food starch, starch, vegetable gum, vegetable starch.

Kidney Stones³⁴

Eliminate: animal protein, sodium, colas, refined grains, white rice, high fructose corn syrup, and beer.

Encourage: dietary approaches to stop hypertension (DASH) diet, fruits, vegetables, coffee, tea, beans, cereals, whole grains, and whole-grain rice.

Chronic Pelvic Pain³⁵

Eliminate: proinflammatory foods (simple carbohydrates, red meat, processed foods, dairy, and sugar and artificial sweeteners).

Encourage: fruits, vegetables, foods rich in omega-3 fatty acids, foods rich in magnesium, and whole grains.

ADHD³⁷⁻⁴³

Eliminate: artificial colors (such as tartrazine yellow dye #5); artificial flavors; artificial sweeteners; sodium benzoate; butylated hydroxyanisole; butylated hydroxytoluene; carrageenan; monosodium glutamate (MSG); any hydrolyzed, textured or modified protein; rapidly absorbed sucrose-containing foods; and high sugar intake.

Benzoates: chewing gum, margarine, pickles, prunes, tea, raspberries, cinnamon, anise, and nutmeg. Nitrates and nitrites: preserved meat like bacon, frankfurters, and pepperoni. Sulfites: dried fruits, mushrooms, potatoes, baked goods, canned fish, pickles, and relishes.

Encourage: healthy breakfast with protein (to prevent hypoglycemia which can exacerbate symptoms), fish, fruits and vegetables, tomatoes, whole grains, and low-fat dairy products.

Note: While up to 50% of patients will improve with dietary intervention and only 8% will respond to elimination of artificial dyes, we are currently unable to predict which subset will respond. Serum IgG

tests are not useful. We recommend beginning with food restriction for people with known food allergies and with elimination of dyes for everyone else. Do not delay conventional treatment if required while undergoing nutritional interventions. Most success occurs when an entire family aims to eat natural foods and follows the same restrictions. During the 2- to 4-week duration, consider repeating a Connors or Vanderbilt form prior to nutritional intervention and every 1–2 weeks during it.

Atopic Dermatitis⁴⁴⁻⁴⁸

Eliminate: Children: cow's milk, eggs, soy, and wheat. Adults: pollen-related foods (carrot, celery, and hazelnut). Artificial colors, benzoates, berries, citrus, currants, fish, legumes, sulfites, tomatoes, beef, chicken, and pork. Food additives (may affect gut and skin microbiome).

Encourage: Diet rich in omega-3 FAs.

Note: One-third of people with moderate to severe atopic dermatitis have verifiable food allergies. Restricting diets of pregnant women has risks of nutritional and growth deficiencies and has no benefit in reducing atopic dermatitis in children. Serum IgE testing has a limited positive predictive value and may lead to unnecessary dietary restrictions and is thus not recommended.

Autism Spectrum Disorder⁴⁹⁻⁵⁶

Eliminate: gluten, casein (gluten free, casein free; GF/CF), soy, food additives, artificial colors, and excess carbohydrates.

Encourage: adequate protein, unrefined and nutrient-rich carbs, and foods rich in omega-3 and antioxidants.

Note: 54% families with children on the autism spectrum disorder have tried dietary modifications. Because up to 43% of children with ASD may have increased intestinal permeability, consider a trial of probiotics 1–2 months before beginning a GF/CF diet. You may also consider testing for celiac disease and/or a trial of dairy elimination to evaluate for lactose intolerance prior to initiating a GF/CF diet. It is clear that a subset of people with ASD may benefit from an elimination diet, but we are unable to predict which subset. People with ASD have a high prevalence of gastrointestinal dysfunction, such as chronic constipation, diarrhea, abdominal pain, chronic duodenitis, and reflux esophagitis. A GF/CF diet has shown reduced aggression, improvement in GI

symptoms, speech, communication, hyperactive behavior, ability to focus, reduction in sleep problems, increased social contact, and reduction in ritualistic behaviors. It has not been shown to cause nutritional deficiencies and works best for motivated families. GFCF diet duration is recommended for at least 8 weeks in length, but positive results have been most noticeable at 18 months.

Rheumatoid Arthritis [18,33,70-74](#)

Eliminate: corn, wheat, bacon, pork, oranges, milk, oats, rye, eggs, beef, coffee, cheese, processed foods, refined carbs, trans FAs, gluten, dairy, corn, legumes, and tobacco use. Night shades: bell peppers, eggplant, potatoes, and tomatoes.

Encourage: Mediterranean diet. Vegetarian diet rich in fruits, vegetables, and low saturated fat decreases total body inflammation; low-fat, high-fiber diet as well as probiotics and prebiotics promote weight loss.

Note: A vegan diet followed by a lactoovo vegetarian diet showed significant improvement in all variables. This could be due to change from an unhealthy diet to a healthier one with more fruits and vegetables and reduced saturated fats. Adherence is particularly difficult for patients with RA who already have an at-risk nutrition status due to difficulty in meal preparation. One proposed method is to begin by eliminating items most consumed first. For example, if a person is vegetarian and consumes lots of wheat, try elimination of grains and legumes. If a person consumes lots of red meat or dairy, consider recommending a plant-based diet. There is limited evidence for elimination of nightshades.

Inflammatory Bowel Disease (IBD) [75-77](#)

Eliminate: high-fructose corn syrup, caloric sweeteners, refined sugar, dairy, wheat, corn, and certain fruits and vegetables with skins or seeds.

Encourage: low-FODMaPS diet and probiotics.

Note: Surprisingly, people with IBS and IBD have a high adherence rate of 70% to a low-FODMAPS diet, and of those who follow the diet, 50% will respond favorably. There is limited evidence that a prolonged diet of small doses of prebiotics induces adaption and may be as beneficial as a low-FODMaPS diet. Recommended duration is 2–4 weeks. Refer to chapter on FODMaPS for further details.

Multiple Sclerosis (MS)^{24,78}

Eliminate: processed foods.

Reduce: High-fat, high-salt diet heavy in animal protein; red meat; sugar-sweetened beverages; and fried food; limit saturated fat up to 15 g per day.

Encourage: low-calorie diet, fruits, vegetables, fish, prebiotics, probiotics, and multivitamins.

Note: Patients with MS have a higher prevalence of celiac disease, so consider a formal evaluation before beginning an elimination diet if symptoms suggest celiac disease. A high intake of salt, animal fat, trans fat, and sugar-sweetened drinks stresses our immune system and should thus be limited or avoided. For motivated patients, consider a low-fat, vegan, or gluten-free diet.

Chronic Fatigue Syndrome^{79,80}

Eliminate: gluten.

Encourage: increase fiber, at least five fruits and vegetables per day, reduce carbs, and increase fish intake.

Note: A low-sugar, low-yeast diet is often recommended in popular press books for chronic fatigue syndrome. In one study, this diet had poor adherence at 24 weeks and no difference in symptoms compared with healthy eating. Any dietary intervention or complex treatment regimen for people with CFS has a high risk of poor adherence because of low physical functioning impeding grocery shopping and food preparation as well as limited social support. People with higher levels of anxiety have even lower rates of adherence.

Migraines^{19,81-92}

Eliminate: cheese, chocolate, citrus fruit, alcohol, coffee, aspartame, beef, corn, and eggs. Histamine-containing foods: fish, cheese, wine, and beer; MSG-containing foods: mushrooms, kelp, scallops, preserved meats, and Chinese food. Nitrates-containing food: preserved meat, oranges, sugar, and tea; and tyramine-containing food: aged cheese, some red wines, and yeast.

Reduce: meat consumption.

Encourage: low-fat, high-fiber vegan or vegetarian plant-based diet.

Note: A low-fat diet has been shown to reduce headache frequency,

intensity, duration, and medication use. A vegan diet is associated with improvements in social and physical functioning. A low-fat, high-fiber vegan diet reduces estrogen activity, which is helpful in relieving migraines exacerbated by menstruation. In one study, patients following a vegan diet had high adherence, and participants refused to return to their baseline diet despite it being a requirement of the study. In another study, 29 out of 55 people had complete symptom resolution with elimination diets and 21 improved. In a blinded study of aspartame compared with placebo, a 100% increase in headache frequency was observed during the aspartame consumption phase. About 90% of children with severe migraine responded to a food elimination diet. Consider beginning with elimination of aspartame.

Not necessarily inflammatory:

IBS [21,29,93-109](#)

Eliminate: Dairy, eggs, wheat, gluten, high FODMAPS, coffee, alcohol, milk, chocolate, beans, onions, cabbage, foods rich in fats and spices, histamine (smooth muscle contraction), salicylates, high-fructose corn syrup, artificial sweeteners, and sorbitol.

Encourage: probiotics (to treat small intestine bacterial overgrowth).

Note: The prevalence of IBS is 10%–20% in the general population. More than 60% of people with IBS believe that specific foods contribute to their symptoms, and half of patients have symptoms that worsen after eating. Up to 81% of patients with IBS have chronic fatigue syndrome and 93% have fibromyalgia. There is an overlap between small intestinal bacterial overgrowth and IBS. Consider evaluating for lactose intolerance and celiac disease. Nonceliac gluten sensitivity has a prevalence of 6%, with symptoms similar to those of celiac disease (abdominal discomfort, bloating, pain, diarrhea, headaches, foggy mind, depression, fatigue, musculoskeletal pain, and skin rash) but with negative testing. If celiac testing is negative, consider gluten elimination. Keep in mind that lactose intolerance occurs in 7%–20% of Europeans, 65%–75% of Africans, and 60%–90% of Asians. People with lactose intolerance can often tolerate dairy in small amounts daily. Hard cheeses, yogurt, and milk up to 8 oz per day are often tolerated. The etiology of IBS is thought to be an increased sensitivity to luminal distention created by intestinal bacteria as a natural byproduct of fermentation of low-digestible carbohydrates. First-line therapy for IBS is now a low-FODMAPS diet for 2–4 weeks, followed by stepwise reintroduction. One study of infantile colic showed

a 100% improvement when mothers switched to a low-FODMaPs diet. Serum IgG tests are often positive in healthy controls and are potentially harmful by leading to unnecessary restrictions. With a low-FODMaPs diet, ensure adequate fiber intake to prevent constipation.

Recurrent Otitis Media (OM)¹¹⁰⁻¹¹³

Eliminate: cow's milk.

Encourage: evaluation for food allergies as well as asthma or reactive airway disease.

Note: 78% of kids with serous OM have food allergies, and children with cow's milk allergy have an elevated risk for recurrent OM. Two-thirds of patients with recurrent OM have respiratory atopy.

Gastroesophageal Reflux Disease (GERD)¹¹⁴⁻¹¹⁷

Eliminate: carbonated beverages, citrus fruits, canned or bottled foods, and cow's milk protein.

Encourage: low-acid diet, low-calorie diet, fruits, vegetables, legumes, fish, prebiotics, probiotics, and exercise.

Note: One possible theory for the increasing incidence of GERD is the acidification of all canned and bottled goods. In 1973, after an outbreak of botulism poisoning, all canned and bottled foods were acidified to a pH < 4 to prevent bacterial growth and prolong shelf life. This includes baby food. Sixty percent of children younger than 2 years with upper GI symptoms had upper airway congestion or dysphagia thought to be due to dairy. Antiulcer, acid-blocking drugs may increase sensitization against oral proteins, induce eosinophilic gastrointestinal inflammation, and lead to development of new food allergies in adults. Twenty percent of adults have GERD weekly, and 50% of patients with GERD are on continuous medical therapy.

CHAPTER 87

Glycemic Index and Glycemic Load

Yue Man Onna Lo, MD, ABIHM

In the past, carbohydrates have been classified as either simple or complex based on the number of simple sugars per molecule. Simple carbohydrates can be categorized as a single sugar (monosaccharides), which include glucose, fructose, and galactose, or double sugars (disaccharides), which include sucrose, lactose, and maltose. Complex carbohydrates, also known as polysaccharides, are starches formed by longer saccharide chains, which means they take longer to break down. It has been assumed that starchy foods cause smaller increases in blood glucose than simple sugars. However, this system is too simplistic and is not predictable because the changes in blood glucose and insulin levels after consuming complex carbohydrates can be very different.¹ For example, complex carbohydrates refer to any starches, including the highly refined starches found in white bread, pastries, and cakes, which induce a very different blood glucose and insulin response than whole grains and starchy vegetables, such as sweet potatoes. As a result, a concept known as the *glycemic index* (GI) was introduced in the early 1980s. It has become a very useful nutritional concept that allows new insight into the relationship between carbohydrate-rich foods and health.

²

Glycemic Index

The GI measures the rises in blood glucose and insulin triggered by a specific food compared with a control food, such as white bread or glucose (Fig. 87.1).

To determine the GI of a specific food, test subjects are given a test

food and a control food (white bread or glucose) on separate dates, each food containing 50 g of available carbohydrates, and changes in blood glucose and insulin are measured every 2 hours. The GI is calculated as the area under the curve of the test food divided by the area under the curve of the control food, then multiplied by 100 to represent a percentage of the control food.³ For example, a baked potato has a GI of 94 relative to glucose, which means that the blood glucose response to the carbohydrate in a baked potato is 94% of the blood glucose response to the same amount of carbohydrate in pure glucose. In contrast, sweet potato, which is also a complex carbohydrate, has a GI of 44 relative to glucose and induces a much lower blood glucose response in comparison with pure glucose.² Therefore, you can say that not all carbohydrates or calories are created equal ([Fig. 87.2](#)).

FIG. 87.1 Mean incremental blood glucose responses to different foods in healthy subjects.

High-GI foods can stimulate the reward and food craving areas of the brain seen with other addictions. The rebound hypoglycemia ([Fig. 87.3](#)) can exacerbate cravings for high-GI foods, which leads to a vicious cycle that can increase insulin, inflammation, and triglyceride levels.⁴

Glycemic Load

The concept of glycemic load (GL) was introduced later as an additional tool to more accurately assess the impact of eating carbohydrates on blood sugar. It gives a more complete picture than GI alone because GI only indicates how rapidly a particular carbohydrate turns into sugar, while GL indicates the amount of carbohydrate in a serving.² Serving sizes can be different based on cultural and dietary practices. GL helps patients to account for both the quantity and the quality of their carbohydrates at the same time. For example, the GI of watermelon is high; however, most of watermelon is water, and the amount of carbohydrates per serving size is low, which results in a low GL. Therefore, consuming one to two servings of watermelon will not raise blood glucose or insulin significantly when compared with other foods that have a high GI and GL. [Table 87.1](#) shows the calculations for GL.⁵

FIG. 87.2 The effect of high glycemic index food versus low glycemic food on glucose and insulin. (From Rakel, D: *Glycemic index and glycemic load* :

<http://www.fammed.wisc.edu/files/webfm->

[uploads/documents/outreach/im/handout_glycemic_index_patient.pdf](http://www.fammed.wisc.edu/files/webfm-uploads/documents/outreach/im/handout_glycemic_index_patient.pdf) . Accessed 12/25/2016.

FIG. 87.3 Blood sugar and insulin levels.

TABLE 87.1

Calculating Glycemic Load

Example: Watermelon

Glycemic index (GI) = 72 (high)

Glycemic load (GL) = 4 (low)

Amount of carbohydrates per serving: 6 g (low)

Calculating Glycemic Load (GL)

$GL = (GI) \times (\text{carbohydrates per serving in grams}) / 100$

GL for watermelon = $72 \times 6 / 100 = 4$

The GL is calculated by using the amount of available carbohydrates in grams per serving size for a certain food multiplied by the GI value of that food, then divided by 100.¹ The higher the GL, the greater the expected elevation in blood glucose and insulin effect of the food.² [Table 87.2](#) shows the interpretation of GI and GL values.

What Can Affect the Glycemic Index in Food?

1. **Ripeness and storage time**—The GI of many fruits such as bananas goes up as they ripen.
2. **Cooking time**—The longer the cooking time for certain grains and starches, like pasta, the higher the GI. Pasta cooked “al dente,” where it is slightly undercooked and is more firm, has a lower GI.
3. **Processing method**—The finer a food is chopped, mashed, or juiced, the higher the GI, e.g., whole potatoes versus chopped potatoes.⁶
4. **Combination with other foods or dressings**—Adding fat, fiber, and acid (such as lemon juice or vinegar) lowers the GI since they help slow down the absorption of sugar into the bloodstream. For example, baked potatoes with butter and sourdough bread have lower GI than just baked potatoes and nonsourdough breads, respectively. Combining high-GI foods with low-GI foods will also decrease blood sugar rise.

TABLE 87.2

How to Interpret Glycemic Index (GI) and Glycemic Load (GL)

Foods that have a low GL almost always have a low GI. Foods with an intermediate or high GL range from a very low to very high GI.⁵

Glycemic Index	Glycemic Load
The smaller the number, the less impact the food has on your blood sugar	The smaller the number, the less impact the food has on your blood sugar per serving size
55 or less = low 56–69 = moderate 70 or higher = high	10 or less = low 11–19 = moderate 20 or more = high

5. **Food variety**—Certain varieties of vegetables, grains, and fruits have different GIs than their counterparts, e.g., short grain rice versus long grain rice and russet potatoes versus red potatoes.⁷
6. **An individual’s metabolism and digestion**—GI is relative to a person’s age, metabolism, and digestive health.⁷

Practical Guidelines

1. Increase consumption of fruits, vegetables, and legumes.
2. Eat multicolored, unprocessed, whole foods.
3. Decrease consumption of “white foods” (e.g., potatoes, fluffy breads, pasta).
4. Consume grain products that are less processed or not overcooked

(e.g., steel-cut oats, al dente pasta, stone-ground breads).

5. Always combine your meal with fiber (vegetables and fruits), fats (oils), and proteins (beans and nuts).
6. Eat low-GI foods regularly and high-GI foods rarely and only in small quantities, preferably with a meal.
7. Eat healthy portions. Excessive consumption of low-GI foods can still trigger a hyperglycemic response.^{8,9}

Disease Prevention and Management

Diabetes and Blood Sugar Control

Medical nutrition therapy is the first line of treatment for the prevention and management of type 2 diabetes and plays an essential part in the management of type 1 diabetes. Although the American Diabetes Association still recommends carbohydrate counting as a main strategy for diabetes management, the Diabetic Associations in Europe, Canada, and Australia have all recommended high-fiber, low-GI foods for individuals with diabetes as a means of improving postprandial glycemia and weight control.^{2,10,11} Many studies have shown that low dietary GI and GL is effective in the prevention¹²⁻¹⁶ and management of diabetes by improving insulin sensitivity and lowering glycated hemoglobin A1c (HbA1c) levels and fructosamine in diabetic patients.^{14,17-19} In a recent cohort study in Hawaii, a high-GL diet showed an increased incidence of diabetes.¹³ In a randomized, open-label, crossover study, a low-GI diet for 3 months produced greater weight loss, body fat reduction, and body mass index (BMI) reduction than a standard diabetes diet.¹⁷ There were also fewer reported episodes of hypoglycemia and hyperglycemia in patients on a low-GI diet compared with those on a carbohydrate exchange diet.¹⁹

Weight Management and Cardiovascular Disease (CVD) Prevention

A low-GL/GI diet has been found to improve weight loss, decrease fat composition, and increase high-density lipoprotein (HDL) cholesterol in obese and overweight subjects.²⁰ It has also been shown to reduce C-reactive protein (CRP), an emerging CVD risk factor.²¹ There are also a

number of cohort studies that show a significant association between the consumption of high-GL/GI diets and increased CVD risk in women, especially in those with higher fat composition, who are overweight or obese, or have diabetes. However, this association has not been established in men. Increases in dietary GL, but not GI, have also been associated with increased risk of stroke and diabetes in both men and women.

Among overweight or obese subjects, dietary GL was associated with increased risk of coronary heart disease (CHD). Among healthy, postmenopausal women, dietary GL has been found to be associated with HDL and triglyceride levels.

Inflammation and Oxidative Stress

Oxidative stress and inflammation have been linked to insulin resistance and cardiometabolic disorders. Postprandial glucose surges correlate directly with an increase in free radicals, resulting in oxidative stress. A blood glucose spike after an excessively high-GL food consumption significantly reduces the mitochondria's capacity for oxidative phosphorylation, driving an increase in free radicals. High-GI foods or meals with a high GL also cause an increase in postprandial inflammatory mediators and markers such as CRP, cytokines, and endothelin-1. On the contrary, minimally processed low-GI foods or meals with a low GL do not result in adverse inflammatory effects. One study showed a strong association between a high dietary GL and elevated CRP levels in 244 middle-aged women where CRP levels almost doubled in the low versus high dietary GL groups. Therefore it is not surprising that most antiinflammatory diets, such as the Mediterranean diet, advocate plant-based, nonprocessed food approaches that are low in GL.

Cancer

A number of prospective cohort studies have shown that diets high in GI and GL are both associated with an increased risk of breast cancer and colorectal cancers. The same association was also demonstrated in a case-control study in Italy for ovarian cancer. A positive association has also been noted in studies with dietary GL, but not GI, on gastric cancers and endometrial cancers. In a large prospective cohort study in Italy

of 47,749 subjects, results showed that a high-GI diet was associated with an increased rate of colorectal cancer, especially in those with a higher waist-to-hip ratio.³¹ However, there are currently no strong associations found for pancreatic cancers.^{37,38}

Other Conditions

High-carbohydrate diets with a high glycemic response may exacerbate the metabolic consequences of an insulin-resistance syndrome. Two studies have found a positive association between high GI and GL values and symptomatic gallstone disease in men and women.^{39,40} This hyperinsulinemia effect also initiates an increase in insulin-like growth factor 1 activity, which is known to stimulate acne pathogenesis,⁴¹ which was confirmed when 43 male acne patients in a randomized controlled trial showed improvement of acne on a 12-week low GI/GL diet when compared to a high GI/GL diet.⁴²

Conclusion

The consumption of low-GI and low-GL foods is positively associated with the prevention of diabetes, CVD, cancer, gallbladder disease, and acne. More information on the GI/GL diet and its effects on hormones, metabolic responses, and cellular changes is emerging. It is certainly a simple, useful tool to offer our patients facing such health issues. [Table 87.3](#) lists GI and GL values for common foods.

TABLE 87.3

Glycemic Index and Glycemic Load Values for Select Foods

Food Item	Glycemic Index (glucose = 100)	Serving Size (g)	Available Carbohydrates (g/serving)	Glycemic Load (per serving)
Bakery Products				
Angel food cake	67	50	29	19
Pound cake	54	53	28	15
Apple muffin (no sugar)	48 ± 10	60	19	9
Bran muffin	60	57	24	15
Oatmeal	69	50	35	24
Pancakes	67 ± 5	80	58	39
Waffles	76	35	12	10
Beverages				
Coca-Cola	63	250 mL	26	16
Smoothie drink, soy, banana	30 ± 3	250 mL	22	7
Apple juice, pure, cloudy, unsweetened	37 ± 3	250 mL	28	10
Cranberry juice cocktail	68 ± 3	250 mL	36	24
Orange juice	50 ± 4	250 mL	26	13
Tomato juice, canned, no sugar	38 ± 4	250 mL	9	4
Granola	78 ± 13	250 mL	15	12
Bread				
Bagel (white)	72	70	35	25
Baguette (white)	95 ± 15	30	15	15
Oat bran bread	44	30	18	8
Rye-kernel bread (whole-grain pumpernickel)	46	30	11	5
Wheat bread (80% intact kernels and 20% white-wheat flour)	52	30	20	10
Wonder enriched white bread	73 ± 2	30	14	10
Healthy Choice Hearty 7-Grain bread	55 ± 6	30	14	8
Breakfast Cereals and Related Products				
All-Bran	38	30	23	9
Cheerios	74	30	20	15
Cornflakes	92	30	26	24
Muesli	66 ± 9	30	24	17
Pop-Tarts, double chocolate	70 ± 2	30	36	25
Raisin Bran	61 ± 5	30	19	12
Special K	69 ± 5	30	21	14
Cereal Grains				
Sweet corn	60	150	33	20
Taco shells, cornmeal	68	20	12	8
White rice, boiled	64 ± 7	150	36	23
Parboiled white rice (high amylose)	35 ± 4	150	39	14
Brown rice, steamed	50	150	33	16
Cracked wheat, bulgur	48 ± 2	150	26	12
Semolina (roasted or steamed)	55 ± 1	150	11	6
Cookies				
Graham wafers	74	25	18	14
Vanilla wafers	77	25	18	14
Crackers				
Bacon crackers (wheat)	67	25	14	10
Corn thins	87 ± 10	25	20	18
Rice cakes (low amylose)	91 ± 7	25	21	19
Rye crispbread	63	25	16	10
Stone wheat thins	67	25	17	12

Table Continued

Food Item	Glycemic Index (glucose = 100)	Serving Size (g)	Available Carbohydrates (g/serving)	Glycemic Load (per serving)
Dairy Products and Alternatives				
Milk	27 ± 4	250	12	3
Milk, condensed, sweetened	61 ± 6	250	136	83
Ice cream	61 ± 7	50	13	8
Yogurt	36 ± 4	200	9	3
Soy milk	44 ± 5	250	17	8
Tofu-based frozen dessert with high-fructose corn syrup	115 ± 14	50	9	10
Fruit and Fruit Products				
Apple (raw)	40	120	13	6
Apple juice (unsweetened)	40	250 mL	29	12
Banana (ripe)	51	120	25	13
Cranberry juice cocktail	68 ± 3	250 mL	35	24
Fruit cocktail (canned)	55	120	16	9
Grapes (raw)	43	120	17	7
Orange (raw)	48	120	11	5
Orange juice (reconstituted from frozen)	57 ± 6	250 mL	26	15
Pineapple (raw)	39 ± 15	120	12	5
Strawberry (raw)	40 ± 7	120	3	1
Strawberry jam	51 ± 10	30	20	10
Watermelon (raw)	72 ± 13	120	6	4
Legumes				
Black-eyed beans	42 ± 9	150	30	13
Chickpeas (garbanzo beans)	28 ± 6	150	30	8
Kidney beans	28 ± 4	150	25	7
Lentils (green)	22	150	18	4
Lentils (red)	26 ± 4	150	18	5
Mung beans	31	150	17	5
Pigeon peas	22	150	20	4
Pinto beans	39	150	26	10
Soya beans	18 ± 3	150	8	1
Pasta and Noodles				
Fettuccine (egg)	40 ± 8	180	46	18
Linguine (thick, durum wheat)	46 ± 3	180	48	22
Mung bean noodles (Lungchow)	26	180	45	12
Macaroni	47 ± 2	180	48	23
Rice noodles (dried)	61 ± 6	180	39	25
Rice noodles (fresh)	40 ± 4	180	39	15
Rice pasta (brown rice)	92 ± 8	180	38	35
Spaghetti (white)	32	180	48	15
Spaghetti (durum wheat)	64 ± 15	180	43	27
Spaghetti (whole meal)	32	180	44	14
Nuts				
Cashew nuts (salted)	22 ± 5	50	13	3
Peanut	14 ± 9	50	6	1
Sport Bars				
PowerBar (chocolate)	56 ± 3	65	42	24
Iceman PR Bar (chocolate)	39	65	26	10
Table Continued				

Food Item	Glycemic Index (glucose = 100)	Serving Size (g)	Available Carbohydrates (g/serving)	Glycemic Load (per serving)
Vegetables				
Beetroot	64 ± 16	80	7	5
Carrots (raw)	16	80	8	1
Corn (sweet, boiled)	60	80	18	11
Green peas	48 ± 5	80	7	3
Parsnips	97 ± 19	80	12	12
Baked potato (in skin)	60	150	30	18
Yam (peeled, boiled)	37 ± 8	150	36	13

CHAPTER 88

Antiinflammatory Diet

Wendy Kohatsu, MD, and Scott Karpowicz, MD

Introduction

The rate of chronic disease related to poor diet has risen to staggering proportions in the United States. A recent large meta-analysis indicates dietary factors are currently the leading risk factor for death and disability in the United States, responsible for more than 700,000 deaths and almost 15% of disability-adjusted life years in 2010.¹ These diseases—including cardiovascular disease, diabetes, asthma, metabolic syndrome, depression, arthritis, and others—are characterized by a state of chronic, low-grade inflammation.² Medications—nonsteroidal antiinflammatory drugs (NSAIDs), statins, and biological agents—certainly can be used to reduce inflammation;³ however, we must also help patients tackle the root causes of chronic inflammation created and perpetuated by a lifetime of unhealthy lifestyle habits.

A large and growing body of evidence indicates that dietary modifications can have a significant impact on this chronic, low-grade inflammatory state.^{4,5} Americans consume 5.5 pounds of food per day.⁶ We can take a more proactive, preventative approach by investing our 5+ pounds of daily food in healthy choices that decrease inflammation and thus chronic disease. To promote health and mitigate inflammation, integrative physicians must promote lifestyle changes and learn to use food as medicine. This chapter provides the most recent data to help integrative physicians tailor an antiinflammatory diet that is effective, acceptable, and delicious to each patient.

Mechanisms and Measurement of Inflammation

Several mechanisms by which food influences inflammation have been

studied:

- Modulation of eicosanoid activity. For example, compounds in culinary spices such as turmeric suppress cyclooxygenase-2 (COX-2) expression and in nutmeg, inhibit tumor necrosis factor (TNF)-alpha release in animal studies.⁷
- Pro- and antioxidant effects. Increased antioxidant food intake is correlated with lower C-reactive protein (CRP) levels⁸ and with a lower incidence of joint inflammation.⁹
- Insulin and glucose levels. A high dietary glycemic load was associated with elevated CRP concentrations,¹⁰ and elevation in inflammatory markers has been shown to precede type 2 diabetes¹¹ (see [Chapter 87](#)).
- Genetic and intracellular expression. A Mediterranean diet¹² and omega-3 fats have been shown to modulate gene expression related to inflammation.¹³
- Modulation of endothelial function. Mediterranean diets powerfully affect endothelial markers.¹⁴
- Gastrointestinal dysbiosis. Numerous recent studies support that disruption to the gut microbiome can trigger a host of diverse inflammatory diseases.¹⁵⁻¹⁷ The gut microbiome may indeed be the frontier on which the battle of dietary inflammation is initially fought.

Measuring Inflammation

Current medical practice is better at diagnosing the multitude of illnesses caused by inflammation than catching it early in the disease process. Having validated ways to measure inflammation can enable us to intervene more proactively. CRP is a commonly used biomarker of inflammation, and CRP levels are elevated with both chronic disease and as an acute-phase reactant. High-sensitivity CRP (hs-CRP) is a more sensitive measure to assess basal levels of CRP at the lower range of 0.20–10.0 mg/L; an hs-CRP > 2.0 may signal higher cardiovascular risk.¹⁸ Other markers, such as TNF-alpha, interleukin-6 (IL-6), IL-1 beta, adhesion molecules, and endothelial function tests are used more widely in research to measure inflammation and are starting to emerge for clinical use. Recent studies have examined our food and its relationship with these inflammatory markers directly. A new dietary inflammatory index (DII)² has been developed to assess the inflammatory potential of various diets, and a Mediterranean diet score is already in use.¹⁹ We anticipate that these tools will be useful for counseling patients on therapeutic diets in the future.

The Mediterranean Diet Is an Archetype of an Antiinflammatory Diet

The antiinflammatory diet is not one specific diet—indeed, there are many different diets that possess antiinflammatory effects. That being said, the Mediterranean diet is perhaps the most well-researched example of an antiinflammatory diet and serves as an archetypal model to further explore features of an antiinflammatory diet. Multiple studies and a recent meta-analysis have demonstrated the antiinflammatory effects of the Mediterranean diet as measured by serum inflammatory markers and measures of endothelial function.²⁰⁻²² The importance of this diet is further underscored by the large and growing body of evidence from both epidemiological studies and randomized controlled trials that demonstrate a significant mortality benefit and reduction in chronic disease with adherence to the Mediterranean diet.^{19,24-26}

The Mediterranean diet is rich in vegetables, fruits, and whole grains; emphasizes nuts and olive oil as sources of fat; and gives preference to legumes, lean poultry, and fish rather than red meat ([Fig. 88.1](#) and [Table 88.1](#)). Sodas, sweets, and refined baked goods; processed meats; and butter or similar spreadable fats are discouraged. Wine in moderation is an important component of the diet for those who choose to drink alcohol. This diet thus stands in stark contrast to the standard American diet, with its heavy intake of refined carbohydrates, red meat, added sugars, and limited portions of green vegetables, fruits, and whole grains.

MEDITERRANEAN DIET PYRAMID

A contemporary approach to delicious, healthy eating

FIG. 88.1 The Mediterranean diet pyramid.

It is important to note that the Mediterranean diet is a pattern of eating, not a collection of specific recipes. Thus, while the traditional Mediterranean diet finds its origin in the Mediterranean region, the dietary pattern itself is broadly applicable across other regions, cultures, and food traditions. Multiple studies have demonstrated significant benefits of the Mediterranean diet when taken out of its traditional cultural context, including studies on Nordic,²⁷ Polish,²⁸ Indian,²⁹ and Okinawan³⁰ diets that follow the overall Mediterranean dietary pattern. Thus, patients whose individual food preferences may not match those of

the Mediterranean region should have little difficulty adapting it successfully to their own taste preferences. It is also cost-effective.^{31,32}

While it is useful to explore in more detail the individual components of the Mediterranean diet, it is also important to note that the overall benefit of the Mediterranean diet is likely a result of the diet as a whole rather than any specific component. For example, in one of the most important epidemiological studies on the Mediterranean diet, the authors demonstrate that while an increase in a single component of the Mediterranean diet did not result in a significant benefit, an increase in any two components resulted in a statistically significant 25% reduction in overall mortality.¹⁹ Furthermore, data indicate that even relatively small changes can have important health impacts. The PREDIMED trial, a recent large randomized controlled trial assessing the impact of the Mediterranean diet on cardiovascular disease, showed that patients who were more adherent to the Mediterranean diet by just two of the component items significantly reduced their rate of cardiovascular disease and its associated mortality.²³

TABLE 88.1
Original Mediterranean Diet Score¹⁹

Give yourself 1 point for each “yes” answer and 0 for each “no”

Dietary Component	YES	NO
Vegetables: 4 or more servings a day		
Legumes: 1 or more servings a week		
Fruit: 3 or more servings a day		
Nuts and seeds: 1 or more servings a week		
Whole grains: 1 or more servings a day		
Fish: 4 or more servings a week		
Fats: More unsaturated fats, such as olive oil, than saturated fats, such as butter		
Alcohol: 1/2 to 1 drink a day for women; 1 to 2 for men		
Red and processed meat: Fewer than 2 servings a day for women, fewer than 3 a day for men		
TOTAL:		

Totals of 6 or higher put you in the range of highest benefit.

Scores less than 4 mean you are getting little or no protection.

Components of an Antiinflammatory Diet

Fats

Famous for their taste and palatability, antiinflammatory diets, especially the traditional Mediterranean diet, are characterized by their typically higher percentage of calories from fat—usually in the 40%–50% range—which adds both high satiety and flavor. Choosing the *right* fats—both the quantity as well as the quality—is important for reaping the key benefits of an antiinflammatory diet ([Table 88.2](#)).

There is a lot of controversy on the amounts of fats in a healthy diet. On one end of the spectrum, the Japanese diet contains only about 7% of its calories from fat, while a Mediterranean diet about 45%. For all types of fats, it is critical to pay attention to the *quality*, not just quantity. Choosing fresh, natural, organic, unrefined oils and fats will ensure protection against rancidity, oxidation, nutrient degradation, and contamination.

The two essential fatty acids—omega-6 and omega-3—need to be obtained from the diet as they cannot be synthesized by the body. In general, omega-6 fats lead to more inflammation, and omega-3 metabolism leads to the formation of less-inflammatory or antiinflammatory prostaglandins and leukotrienes. Thus, it is critical to keep a healthy balance between the two.

TABLE 88.2
The Skinny on Fats

Type	Subtype	Metabolite	Food Sources	Notes
Saturated	Long-chain TG		Animal fat—meat, butter, cheese	Amount in the diet is controversial, 15%–30% of calories.
	MCT SCT		Tropical oils—coconut, palm	Shorter-chain saturated fats may burn in the body more like carbohydrates.
Monounsaturated			Olive oil Nuts Avocado Peanut	Higher EVOO intake associated with a reduction in the CVD mortality by half. ¹⁰ Reduces LDL and increases HDL.
Polyunsaturated	Omega-6 Essential fatty acid	AA GLA	Corn oil Many vegetable oils Soy ^a	Omega-6 fatty acids are essential fatty acids easily obtainable in the diet; however, avoid in gross excess of omega-3s.
	Omega-3 Essential fatty acid	ALA	Flax, hemp, chia, walnuts	ALA conversion to biologically active EPA and DHA is only about 10%–15%.
		EPA DHA	Cold water fish (e.g., salmon), algae	Potential antiinflammatory effects. Eat 2+ fatty fish servings/week. ¹¹

AA, arachidonic acid; ALA, alpha linolenic acid; DHA, docosahexaenoic acid; EPA, eicosapentaenoic acid; GLA, gamma linoleic acid, an antiinflammatory omega-6; MCT, medium-chain TG; SCT, short-chain TG; TG, triglyceride.

^a Soy contains both omega-6 (54%) and omega-3 (7%) fatty acids.

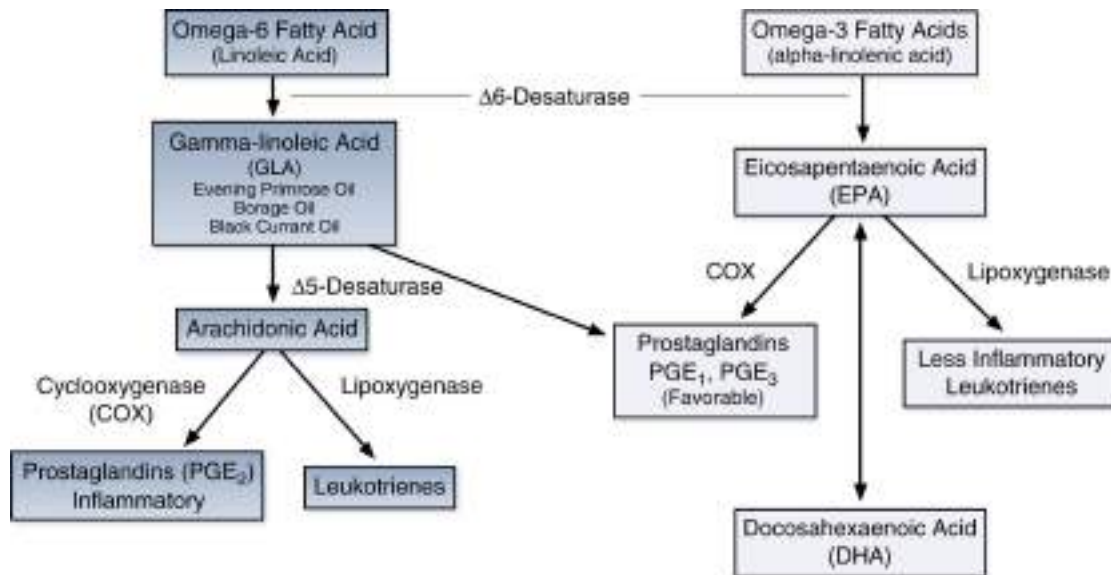

FIG. 88.2 Influence of omega-6 and omega-3 fatty acids on inflammation.

A truly free-range egg has a favorably low omega-6:omega-3 ratio of only 1.3 compared to a conventionally raised egg with a ratio of 19.4.³⁵

A few dietary fat dilemmas are as follows:

1. Omega-6 fats are vastly more abundant in the Western diet (usually 15–20×) compared with omega-3s. A ratio of 1:1–4:1 of omega-6 to omega-3 is recommended.^{36,37} This means that Americans need to cut down on excessive intake of omega-6 fats and ramp up consumption of omega-3s (Fig. 88.2).
2. Omega-3 and -6 fats compete for the same metabolic enzymes, so high levels of omega-6 fats may suppress the already limited metabolism of omega-3 fats. At low levels of omega-3 intake, omega-6 fats are associated with the highest amount of inflammation.³⁸
3. Renewable, plant-based forms of omega-3 fats largely contain alpha-linolenic acid (ALA) rather than eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The body needs to metabolize this ALA into EPA and DHA to exert its antiinflammatory effects, though it is able to do so in only relatively low amounts—only about 10%–15% of ALA is metabolized into EPA and then subsequently into DHA. Cold-water fatty fish, on the other hand, naturally contain higher amounts of preformed EPA and DHA, which exert antiinflammatory effects without the need for further metabolism. However, for environmental, heavy metal

contamination, and cost issues, fish consumption is often limited.

4. Fish oil supplements do not seem to yield the same omega-3 benefits as eating fish itself.^{39,40} Dose, quality, and human genetic variation may explain these differences.⁴¹

FIG. 88.3 Hydrogenation of polyunsaturated fat.

Remember the acronym S.M.A.S.H. for your best sources of omega-3 EPA and DHA in cold-water fish such as Salmon (wild Pacific), Mackerel (Spanish), Anchovies, Sardines, and Herring.

The Evil of Trans-Fatty Acids

When a naturally liquid polyunsaturated fat is chemically converted via hydrogenation to a more solid fat, synthetic trans-fats are formed (Fig. 88.3). While more shelf-stable, these trans-fats (also known as hydrogenated fats, or partially hydrogenated fats) wreak havoc on the body, disrupting the native cis-alignment of membrane fats,⁴² increasing serum levels of lipoprotein(a) and triglycerides,⁴³ as well as inflammatory mediators. In June 2015, the U.S. Food and Drug Administration (FDA)

finally declared that partially hydrogenated oils are not “generally regarded as safe” (GRAS) in human food. Manufacturers have 3 years to remove partially hydrogenated oils from their products.

Olive Oil

Olive oil is a key component of the traditional Mediterranean diet and a growing body of evidence supports its inclusion as an important part of an antiinflammatory diet.¹⁴ Olive oil is rich in oleic acid, a monounsaturated fatty acid. Additionally, virgin and extra virgin olive oils, unrefined versions made by pressing freshly picked olives, have high quantities of polyphenols, which have potent antioxidative properties.^{45,46} The benefits of olive oil likely derive from a synergistic relationship between these key components.⁴⁷

Growing evidence from intervention-based trials indicates that olive oil reduces key cardiovascular risk factors. Olive oil, particularly the high-polyphenol virgin or extra virgin varieties, improves lipid profiles and reduces dyslipidemia through an improvement in the quantity and function of high-density lipoprotein (HDL) cholesterol and reduction in low-density lipoprotein (LDL) cholesterol.^{23,48,49} Additionally, olive oil has been shown to decrease blood pressure in patients with hypertension, improve endothelial function in patients with atherosclerotic disease, and reduce markers of inflammation.^{51,52} Further evidence suggests that regular olive oil consumption, independent of total energy intake, decreases the risk of new-onset diabetes.⁵³

Importantly, evidence from both epidemiological and intervention studies demonstrate a mortality benefit from olive oil consumption. The recent PREDIMED randomized controlled trial demonstrated a significant reduction in cardiovascular events and cardiovascular disease-related mortality in patients consuming a Mediterranean diet supplemented with extra virgin olive oil.²³ Further analysis of these data suggests a 10% reduction in cardiovascular disease for every 10 additional grams of extra virgin olive oil consumed per day.⁵⁵ These data correspond with multiple epidemiological studies that support a significant inverse correlation between olive oil, particularly the extra virgin variety, and coronary heart disease,^{56,57} stroke,⁵⁸ and cardiovascular mortality.⁵⁹

Nuts

Nuts are a rich source of monounsaturated and polyunsaturated fats, in

addition to providing fiber, minerals, and other important nutrients.^{60,61} Increased nut consumption has an important effect on reducing serum inflammatory markers, including CRP and IL-6.⁶² More importantly, multiple recent prospective studies indicate that increased nut consumption decreases metabolic syndrome,⁶³ coronary artery disease,⁶⁴ and total mortality in addition to cancer-specific and cardiovascular disease-specific mortality.^{65,66} These studies support a dose–response relationship, and data from the PREDIMED trial suggest that consuming just three servings of nuts per week can reduce all-cause mortality by 39%.⁶⁶ Despite slightly different fatty acid compositions and nutritional components, similar benefits are observed across a wide range of tree nuts as well as peanuts.⁶⁵

Coconut Oil

Recently, coconut oil has garnered considerable attention in the lay press as a health food with a myriad of purported health benefits.⁶⁹ Saturated fat comprises more than 90% of the fat content of coconut oil, the majority of which is in the form of medium-chain fatty acids.⁷⁰ However, in contrast to the longer-chain saturated fatty acids more typically found in animal fats, medium-chain fatty acids are more easily metabolized.⁷¹ Recent data from a human trial suggest that coconut oil, at least in daily doses of 30 mL, may not have the same dyslipidemic properties and proinflammatory properties as other saturated fats.⁷² In addition, virgin coconut oil contains high concentrations of polyphenols and may therefore have antioxidant as well as antiinflammatory effects, as demonstrated in animal models.^{73,74} Nonetheless, there is a dearth of quality evidence from human trials assessing the antiinflammatory or overall health benefits of coconut oil, and additional data are needed before it can be strongly recommended as a component of an antiinflammatory diet.

Carbohydrates

Whole grains contain naturally occurring fiber, lignans, magnesium, zinc, B vitamins, and vitamin E that may help fight inflammation. Actively replacing refined carbs with whole grains in the diet has been shown to reduce inflammatory markers.⁷⁵ Prospective studies have shown that higher dietary fiber and whole-grain intake is associated with decreased hs-CRP and IL-6.⁷⁶⁻⁷⁸ Whole-grain consumption substantially lowers the risk of inflammation-mediated diseases,⁷⁹ such as cardiovascular disease,

diabetes, cancer, and obesity. One study⁸⁰ of 522 diabetic patients showed that including 15 g of dietary fiber for every 1000 calories consumed daily with lifestyle changes (moderate exercise) significantly reduced CRP by 27%.

Perhaps the most important factor that best represents the inflammatory potential of a carbohydrate-containing food is its glycemic load (GL) (see [Chapter 87](#)). Excessive consumption of highly processed carbohydrates, e.g., white flour and refined sugars, with high GL, cause abnormal surges in blood glucose and insulin levels, which then overloads mitochondrial capacity thus creating free radicals.⁸¹ Immediate increases in CRP and inflammatory cytokines can be seen with a single meal.⁸² One study found a strong link between high dietary GL and elevated CRP concentrations in women; CRP levels were more than doubled (3.7 mg/L) in the group consuming the highest GL compared to the lowest GL (1.6 mg/L).¹⁰ Similarly, higher dietary glycemic index (GI)/GL has been associated with higher levels of TNF-alpha and IL-6.⁸⁴ Even with the same amount of calories, choosing higher-quality carbohydrates with low GLs can lower the inflammatory profile.⁸⁵ Not surprisingly, diets rich in unprocessed, natural plant foods such as the Okinawan or Mediterranean diets have lower GLs, substantially lower postprandial glucose levels, and are associated with improved cardiovascular health and longevity.⁸⁶ Minimally processed low-GL foods—vegetables, fruit, nuts, seeds, and whole grains—do not result in adverse postprandial inflammatory effects, but high-GL foods do.⁸⁷

Other mechanisms besides GL also likely help explain the benefit of whole grains in an antiinflammatory diet. A distinct benefit of whole-grain intake is supporting a more favorable gut microbiome composition that lowers both gut and systemic inflammation.⁸⁸⁻⁹⁰

Furthermore, another reason to consume whole grains is that the active phytochemicals are concentrated in bran (fiber) and the germ (carbohydrate); refining wheat with removal of the fiber causes a 200- to 300-fold loss in phytochemicals and increases the speed of sugar absorption (the GI)⁹¹ ([Fig. 88.4](#))!

Portion control is also important! Overconsumption of even healthy, low-GL foods can trigger a hyperglycemic response and inflammation. Excess calories regardless of source also contribute to obesity, which itself produces inflammation.⁹²

Vegetables and Fruit

Vegetables and fruit—while often classified under the macronutrient “carbohydrate”—deserve their own stand-alone category due to their natural abundance of nutraceutical benefits! Vegetables contain the highest concentrations of vitamins, minerals, and other protective phytochemicals, with a lower caloric density compared with other foods. Rich in biochemical complexity, whole vegetables and fruit are superior to any single isolated nutrient. Citrus fruit, for example, contains not just vitamin C, but some 60 flavonoids, 20 carotenoids, and limonoids. Higher intake of vitamin C from food sources has been associated with lower CRP and tissue plasminogen activator (tPA) levels.⁹³

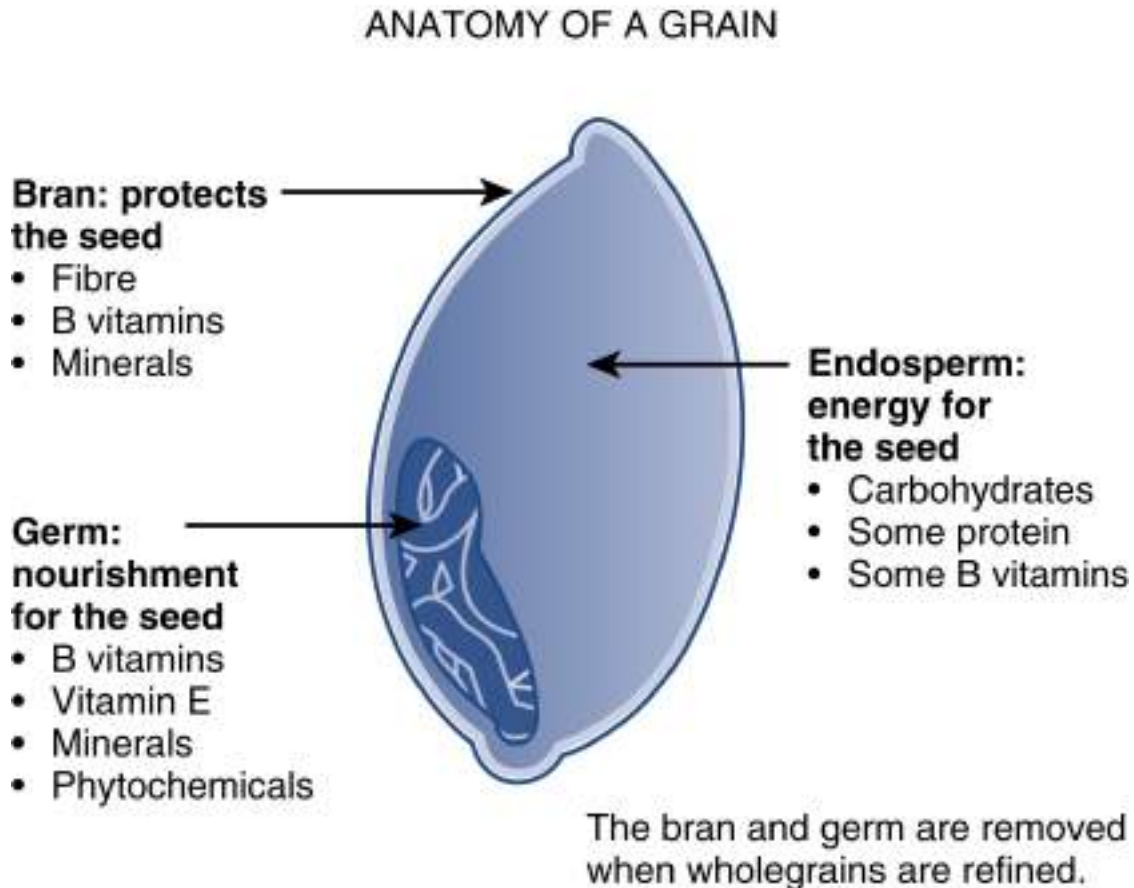

FIG. 88.4 Fiber (bran) helps reduce the speed of sugar (germ) absorption.

The inadequate consumption of vegetables and fruit in the United States is appalling. It is estimated that Americans only consume 1.6 servings of vegetables per day and only one fruit per day.⁹⁴ Fewer than

10% of Americans eat enough fruits and vegetables. Even more concerning is that the largest single contributor to fruit intake was orange juice and that potatoes still dominate vegetable consumption; fried potatoes account for about one-third of the “vegetables” that adolescents consume.⁹⁵

Studies support that people who consume more vegetables and fruit have lower rates of inflammatory disease such as heart disease, insulin resistance, and some cancers.⁹⁶⁻⁹⁹ High intake of vegetables and fruits, greater than five servings per day, has a significant inverse dose–response association with inflammatory markers such as CRP, IL-6, and adhesion factors.^{97,100,101} The more vegetables and fruit one eats, the less inflammation. Estimates from the US Department of Agriculture (USDA) flavonoid databases also show an inverse association between high flavonoid intake (from fruit and vegetables) and lower CRP levels.¹⁰³ Flavonoids are responsible for the deep colors of fruits and vegetables and often are a proxy marker for high nutritional quality. In epidemiological studies, higher fruit and vegetable intake was shown to significantly decrease markers of inflammation in adolescents¹⁰⁴ and in adult women.⁹⁷ Adding fruits and vegetables to the diet, especially those rich in flavonoids, significantly improved microvascular reactivity and lowered CRP values.¹⁰⁶

Watch the sugar! The American Heart Association recommends that women consume no more than 100 calories/day as added sugar. This equals 25 g of sugar or about six teaspoons. For men, the limit is 150 calories, 36 g of sugar, or nine teaspoons per day. Read labels, this adds up quickly! To satisfy your sweet tooth, choose fresh fruit in season.¹⁰⁷

Proteins

A large body of data supports the health benefits of plant-based proteins, and they are a healthy alternative to animal sources of protein.^{108,109} Legumes are high in protein as well as fiber, iron, folic acid, and B vitamins. Most legumes are deficient in the essential amino acids methionine and tryptophan, but these are found in sufficient amounts in most grains. Randomized clinical trials indicate that regular consumption of legumes is associated with a reduction in inflammatory markers and an improvement in both lipid profiles and endothelial function.^{110,111} Legumes make up a substantial part of a healthy antiinflammatory diet,

can be prepared in many tasty ethnic dishes, and provide the majority of protein for a hungry world. Substituting healthy protein sources like legumes for red meat is associated with a lower mortality risk.¹¹²

In contrast, diets high in red and processed meats are correlated with increases in inflammatory markers, markers of glucose dysregulation, and dyslipidemia.¹¹³⁻¹¹⁵ Furthermore, diets higher in red meat, especially in processed forms (e.g., cured meats and sausages, bacon, and processed lunch meats) are associated with higher rates of cardiovascular disease, certain cancers, and all-cause mortality.¹¹⁶⁻¹¹⁸ Although it is not entirely clear what component of red meat contributes to its inflammatory effect, several clinical trials suggest that consuming lean meat may not result in the same proinflammatory effect that is observed with the higher fat, more processed red meats typically found in a modern American diet.¹¹⁹⁻¹²¹ For those who do eat meat, studies support trimming visible fat¹²² and avoiding charring the food to lessen the inflammatory impact.¹²³ In addition to lean meats, animal protein sources from fish¹²⁴ and dairy^{125,126} are suitable components of an antiinflammatory diet.

Fish

While a source of high-quality protein and healthy fat, fish often swim in waters contaminated with heavy metals such as mercury, cadmium, lead, and other pollutants such as polychlorinated biphenyls (PCBs). These are proinflammatory and impair metabolic function. Even taking this into consideration, one review¹²⁷ reports that the health benefits of eating fish exceed the potential risks. Avoid fish highest in methylmercury—shark, swordfish, golden bass (tilefish), and king mackerel. A serving of albacore tuna contains 0.35 ppm methylmercury with 1.0 ppm being the EPA's "allowable" upper limit/day, so limit it to no more than one serving per week.¹²⁸ Some of the safest fish are tilapia, anchovies, and wild salmon.

Other Antiinflammatory Foods, Spices, and Supplements

- **Turmeric:** Turmeric is the queen of antiinflammatory spices! Multiple studies have assessed the potential benefits of curcumin, the main component of turmeric (*Curcuma longa*), on a variety of inflammatory conditions. Several recent randomized controlled trials have shown improvements in inflammatory markers and endothelial function with regular administration of curcumin.¹²⁹⁻¹³¹ Furthermore, trials have found curcumin equivalent in pain relief to ibuprofen and diclofenac

for knee osteoarthritis¹³² and rheumatoid arthritis,¹³³ respectively. Curcumin has shown promise in other inflammatory conditions, including maintenance of remission in ulcerative colitis¹³⁴ and improvement in signs and symptoms of oral lichen planus.¹³⁵ Especially considering its long track record of culinary use and excellent side effect profile in all the trials in which it has been studied, turmeric represents both a safe and effective addition to any antiinflammatory diet.

- **Wine:** While excessive alcohol consumption is clearly linked to excess morbidity and mortality, a large body of epidemiological data suggests that low-to-moderate alcohol consumption is associated with decreased levels of both cardiovascular and all-cause mortality.¹³⁶⁻¹³⁹ Wine is of particular interest in the antiinflammatory diet as it is rich in polyphenols, which likely exert numerous antioxidative and antiinflammatory effects.^{140,141} Randomized trials have demonstrated a reduction in inflammatory markers¹⁴² and improvement in lipid profiles¹⁴³ with regular, moderate consumption of red wine.
- Other spices—ginger, chili pepper, oregano, basil, thyme, and rosemary—also possess antiinflammatory properties^{144,145} and add flavor to a wide variety of cuisines.
- **Cocoa:** Cocoa and cocoa-rich products such as dark chocolate contain high quantities of flavonoids, as well as fiber and other important nutrients.¹⁴⁶ Multiple trials demonstrate a reduction in serum inflammatory markers,¹⁴⁷⁻¹⁴⁹ improvement in lipid profiles,¹⁵⁰⁻¹⁵² and enhanced endothelial function¹⁵³⁻¹⁵⁵ with consumption of flavonoid-rich cocoa. Furthermore, a recent trial demonstrated improvement in both walking distance and time in patients with peripheral artery disease after consumption of 40 g daily of dark chocolate.¹⁵⁶ Evidence from a meta-analysis of randomized controlled trials indicates a reduction in insulin resistance,¹⁵⁷ and epidemiological data suggests a reduction in diabetes incidence with cocoa consumption.¹⁵⁸ Mortality data are limited, though one epidemiological study indicated an inverse correlation between chocolate consumption and cardiovascular and all-cause mortality.¹⁵⁹ Doses used in trials vary widely from less than 10 g daily to 100 g daily—although the lowest effective dose is not known, 1–2 ounces of dark (at least 70%) chocolate as a tasty and healthy treat is a safe suggestion.

Medical Conditions That May Improve With an

Antiinflammatory Diet

[Table 88.3](#) provides a summary of some of the major diseases for which antiinflammatory diet modifications have shown therapeutic promise.

TABLE 88.3

Medical Conditions That May Improve With an Antiinflammatory Diet

Arthritis	Two randomized controlled trials found turmeric extracts to be as good or better than nonsteroidal antiinflammatory drugs (NSAIDs) at controlling symptoms of knee osteoarthritis ¹³² and rheumatoid arthritis. ¹³³ Doses ranged from 500 mg to 1500 mg daily in these trials. Daily administration of a probiotic for 8 weeks was shown in a randomized controlled trial to reduce symptom severity and inflammatory status in patients with rheumatoid arthritis. ¹⁶⁵
Hypertension	Randomized controlled trials found significant reductions in blood pressure in patients who adopted the traditional Mediterranean diet ¹⁶⁶ and the New Nordic Diet, a Mediterranean diet regional variant. ²⁷ Apart from its inclusion in the Mediterranean diet, daily consumption of olive oil results in a clinically significant reduction in blood pressure ¹⁶⁸ —olive oil rich in polyphenols, such as extra virgin olive oil, may be more effective at decreasing blood pressure than regular olive oil. ¹⁶⁹ Olive oil dosing ranged from 30 mL–60 mL (2–4 tablespoons) daily in these trials.
Asthma	A recent small trial found improvement in spirometry and quality of life scores in patients with asthma who adopted a Mediterranean diet. ¹⁷⁰
COPD	In one randomized controlled trial, patients with COPD showed significant improvement in lung function [increased forced expiratory volume in 1 second (FEV ₁)] with greater intake of antioxidant-rich fruits and vegetables. ¹⁷¹
Diabetes	Data from the PREDIMED trial indicate reduced onset of diabetes with increased adherence to an energy-unrestricted Mediterranean diet. ^{53,173} In patients with existing diabetes, adherence to an energy-unrestricted Mediterranean diet resulted in a reduction in hemoglobin A1c equivalent to that from mono-drug therapy. ¹⁷⁴ A low-carbohydrate Mediterranean diet has also been shown to reduce the need for antidiabetic medications in patients with newly diagnosed diabetes. ¹⁷⁵
Cardiovascular Disease	Large randomized controlled trials have demonstrated the Mediterranean diet as an effective means of both primary ²³ and secondary ^{26,177} prevention of cardiovascular events, including myocardial infarction and stroke. Supplementation with olive oil ⁵⁵ and nuts ⁶⁶ likely provides even greater benefit. The effect size of dietary change should not be underestimated—secondary prevention trials indicated risk reductions of nearly two-thirds in those adhering to a Mediterranean-style diet.
Peripheral Artery Disease	The PREDIMED trial suggests that adherence to a Mediterranean diet significantly decreases the rate of new-onset symptomatic peripheral artery disease. ¹⁸¹ In a randomized controlled trial of patients with existing peripheral artery disease, daily administration of 40 g of dark chocolate resulted in a significant improvement in walking autonomy. ¹⁵⁶
Obesity	Adherence to a Mediterranean diet was associated with 51% lower odds of being obese and 59% lower odds of central obesity. ¹⁸³ A high amount of olive oil consumption was not associated with higher weight gain or a significantly higher risk of becoming overweight or obese. ¹⁸⁴ Despite a higher fat content (35% compared to 20%), participants eating a Mediterranean-based diet lost 4.1 kg compared with controls who gained 2.9 kg over 18 months. ¹⁸⁵
Inflammatory Bowel Disease	A randomized controlled trial found that turmeric (<i>Curcumin</i>) at daily doses of 2 g given in conjunction with standard therapy significantly reduced rates of relapse and improved endoscopic and symptom-based disease severity scores. ¹³⁴ A recent case series demonstrated that patients who adhered to a modified antiinflammatory diet showed significant improvement in disease-related symptom scores. ¹⁸⁷
Nonalcoholic Fatty Liver Disease	In adults with nonalcoholic fatty liver disease, data from a randomized controlled trial indicate that patients whose diets are supplemented with olive oil or canola oil at doses up to 20 mg daily showed a reduction in liver span and severity of fatty liver at 6 months. ¹⁸⁸ A recent meta-analysis found that daily supplementation with omega-3 fatty acids reduced hepatic steatosis. ¹⁸⁹ Daily doses above 800 mg are effective, although the ideal dose is not yet known.
Cancer	A recent meta-analysis found that higher adherence to the Mediterranean diet was associated with a 10% reduction in overall cancer incidence and mortality. ¹⁹⁰ This data indicate the effect may be most pronounced in colorectal and prostate cancer, with reductions in incidence of 14% and 4%, respectively, with increased adherence to the Mediterranean diet.
Alzheimer's Disease and	Adherence to a Mediterranean diet supplemented with olive oil or nuts has been shown to improve cognition and slow age-related cognitive decline. ^{191,192} In an observational study, higher adherence to a Mediterranean diet was

Dementia	associated with slower cognitive decline as measured by the Mini Mental State Evaluation. ¹⁹³ A recent small pilot study found that daily supplementation with omega-3 fatty acids and alpha lipoic acid (ALA) reduced the progression of cognitive and functional decline in patients with Alzheimer’s disease. ¹⁹⁴ Doses used in this study were 1.6 g of omega-3 fatty acids and 600 mg of ALA daily.
Depression	A recent meta-analysis of 19 randomized controlled trials found omega-3 fatty acid supplementation effective in treating patients with both major depressive disorder (MDD) and depressive symptoms without a clear MDD diagnosis. ¹⁹⁵ Dosing varied widely across trials but averaged 1.4 g of combined EPA and DHA daily. Additionally, another recent trial found that initiating omega-3 supplementation with a selective serotonin reuptake inhibitor (SSRI) resulted in better reduction in depressive symptoms than the SSRI alone. ¹⁹⁶
Psoriasis	In patients being treated for psoriasis, a randomized controlled trial demonstrated that a hypocaloric, omega-3 rich diet significantly reduced symptom severity at 3 and 6 months. ¹⁹⁷

Conclusion

Inflammation is a common pathophysiological mechanism underlying most chronic disease. The antiinflammatory diet is based on evidence-based principles of sound eating to promote health and prevent and reduce inflammation in the body. It is whole food-based nutrition that emphasizes healthy fats, vegetables and fruit, whole grains, legumes, fish, and limited amounts of meat and dairy. It can be recommended as “food as medicine” for a wide variety of common diseases including heart disease, diabetes, obesity, cancer, Alzheimer’s disease, chronic obstructive pulmonary disease (COPD), depression, and gastrointestinal (GI) disorders.

Patient Handout: The Antiinflammatory Diet

Inflammation in the body is known to contribute to chronic disease such as diabetes, heart disease, asthma, inflammatory gut disorders, arthritis, obesity, cancer, and dementia. Eating an antiinflammatory diet may reduce inflammation and decrease chronic disease. Food as medicine is powerful! Here are some simple guidelines:

Antiinflammatory diet guidelines:

- 1) Choose healthy fats.
 - Substitute extra-virgin olive oil for other vegetable oils, trans-fats, or butter in your cooking for health benefits.
 - Eat two servings (4 ounces each) of fatty fish per week.
 - Reduce use of omega-6 fats (hydrogenated vegetable oils) to keep ratio of omega-6:omega-3 in range of 2:1 – 4:1.
- 2) Increase vegetable and fruit intake (especially vegetables)
 - Eat at least 5 servings of vegetables and fruit per day, with more than half as vegetables.
 - Color your diet – deeply-colored fruits and vegetables contain higher amounts of protective phytochemicals.
 - Use the plate method – the biggest portion (half the plate) is where the vegetables go (excluding potatoes).
- 3) Choose whole grain carbohydrates and limit the portion sizes.
 - Choose carbs that are whole grain (requires chewing!), and aim for at least 25 grams of fiber per day.
 - Rx: double your vegetable intake, and half your intake of refined carbohydrates (anything with flour and/or added sugar!)
- 4) Get your protein from plant sources such as legumes, nuts and seeds, and/or choose lean, natural animal sources of protein in moderate amounts.
- 5) Spice it up! Include antiinflammatory herbs and spices such as garlic, turmeric, rosemary, ginger, oregano, cumin, and cayenne in your diet.
- 6) Eat mindfully
 - Be mindful of your food portions. Quality AND quantity matters. Regardless of how healthy your food choices are, excess calories from any source can increase inflammation and obesity.
 - Chew slowly and savor your food.
- 7) Adopt the Okinawan philosophy of “hara hachi bu” – stopping when nearly 8/10 full and paying attention to your hunger and satiety signals.²³ Remember to focus on the whole diet pattern, not just components. Choose food that is closest to its natural form (i.e., less processed).
- 8) Best dietary advice in 7 words: “Eat food. Not too much. Mostly plants.”¹¹⁶
- 9) Adopt an antiinflammatory LIFESTYLE
 - Incorporate regular exercise that you enjoy into your life.
 - Keep weight under control. It is important to prevent and reduce obesity, especially abdominal obesity, as obesity itself sets up chronic inflammation in the body.¹¹⁷⁻¹¹⁸ Maintain body mass index (BMI) between 18.5 – 24.9.
 - Be aware of, and find healthy ways to reduce stress.
- 10) Enjoy 1–2 ounces of dark chocolate (at least 70%) as an occasional treat!

Eat more:

- Foods high in omega-3 fats
 - Cold water fish (Salmon, Spanish Mackerel, Anchovies, Sardines, Herring)
 - Flax seeds, flax oil, chia, or hemp seeds
 - Walnuts
- Vegetables
 - Yellow, orange, and red veggies (peppers, carrots, beets)
 - Dark leafy greens (spinach, kale, arugula, broccoli)
- Deeply-colored fruit
 - Berries, melons, citrus fruit
- Whole grains
 - Steel-cut or whole rolled oats
 - Sprouted-grain breads
- Antiinflammatory spices
 - Turmeric
 - Ginger
 - Rosemary
 - Oregano
 - Cayenne

Eat less:

- Foods high in trans- and saturated fats
 - Processed and red meats
 - Dairy products
 - Partially hydrogenated oils
- Foods high in omega-6 fats (in order to get a better omega 6:3 ratio)
 - Corn, cottonseed, grapeseed, peanut, soy oils
- Refined carbohydrates (with a high glycemic load)
 - White breads or bagels
 - English muffins
 - Instant or white rice
 - Rice and corn cereals
 - Crackers, cookies, cakes
- Sodas and juices
 - Including “diet” drinks

CHAPTER 89

The DASH Diet

David M. Lessens, MD, MPH, and David Rakel, MD

What is the DASH Diet?

DASH stands for Dietary Approaches to Stop Hypertension. This eating plan was initially developed to lower blood pressure,¹ but it has since been found to modify several disease risk factors and outcomes, including improvements in cholesterol levels and insulin sensitivity. This diet favors meals that are low in animal and dairy fat and rich in fruits, vegetables, and whole grains. It is a well-balanced diet that can be followed by everyone, including those in low socioeconomic strata,² to help lead a healthy lifestyle ([Table 89.1](#)). It is similar to the antiinflammatory diet discussed in [Chapter 88](#).

How Much Can I Expect My Blood Pressure to Come Down?

Two sentinel studies have investigated how adherence to the DASH diet can reduce blood pressure. The original study,¹ which took place among four academic health care centers, divided subjects into three groups: one ate a normal American diet, one ate an American diet but with more fruits and vegetables, and one ate the DASH diet. In those eating the DASH diet and with no high blood pressure, the average systolic value dropped by 5.5 mm Hg and the diastolic value by 3 mm Hg. For those who already had high blood pressure, the systolic value dropped by 11.6 mm Hg and the diastolic value by 5.3. Blood pressure also dropped in the group eating more fruits and vegetables, but not as much. Furthermore, these changes occurred after just 2 weeks on the diet.

The second DASH trial³ examined the effect of a reduced dietary

sodium intake (at three separate levels: 3300, 2300, or 1500 mg daily) as participants consumed a normal American diet or followed the DASH eating plan. Results showed that reducing dietary sodium lowered blood pressure for both eating plans, but at each level, blood pressure was lower for those on the DASH eating plan. These studies emphasize and highlight that nutritional features of the DASH diet may play a role in reducing blood pressure, apart from reducing sodium consumption.

In those with high blood pressure, the DASH diet on an average lowered systolic blood pressure by 11.6 mm Hg and diastolic blood pressure by 5.3 mm Hg.

Besides Lowering Sodium, by What Other Means Might the DASH Diet Benefit Health?

Oxidative stress refers to one's ability to detoxify the products of cellular damage. Much of this damage is caused by inflammation, which plays a foundational role in many chronic diseases, including obesity. In a small study, investigators found that the DASH diet decreased blood pressure and enhanced antioxidant capacity, especially in obese individuals.⁴ In another study, researchers found lower levels of proinflammatory markers, including C-reactive protein and interleukin-6, among those consuming this diet.⁵

Researchers have postulated the importance of potassium, magnesium, and fiber in the DASH diet's role in lowering blood pressure. One crossover study, for example, had obese and lean individuals consume a usual diet, the DASH diet, and a usual diet supplemented with specific amounts of potassium, magnesium, and fiber matching those of the DASH diet. Each eating plan was also matched for calcium and sodium. After 3 weeks, only obese individuals adhering to the DASH diet showed an improvement in blood pressure and endothelial function. The study's investigators concluded that nutritional factors other than these five must be contributing to the observed health benefits, and these remain a topic of further investigation.⁶

The DASH diet also contains nitrate-rich root vegetable like beets,

carrots, and turnips. Consuming nitrates (NO_3^-) from such sources may increase the body's available nitric oxide (NO), which may lead to vasodilation and decreased blood pressure. Ingested nitrates (NO_3^-) are reduced to nitrites (NO_2^-) by enteral bacteria and then are reabsorbed by the intestines and excreted in the stool (the reason manure is such a good fertilizer, which is rich in nitrites). Nitrites are further reduced in the endothelium to NO (Fig. 89.1).

In a study of 72 hypertensive patients, 36 were given 250 mL of beetroot juice once daily (6.4 mmol nitrate) and 36 were given a nitrate-free beetroot juice placebo. The 24-hour blood pressure monitoring showed sustained reductions of 7.7 mm Hg in systolic pressure and 5.2 mm Hg in diastolic pressure in the treatment group. This is just slightly less than the average blood pressure drop with single antihypertensive drug therapy (9.1 mm Hg/5.5 mm Hg). The nitrate-rich beetroot juice also improved endothelial function by ~20%.⁷

TABLE 89.1
The DASH Diet

Food Group	Daily Servings	Serving Sizes	Examples and Notes	Significance of Each Food Group in the DASH Eating Plan
Cereals and grain products	7-8	1 slice bread 1 oz dry cereal † ½ cup cooked rice, pasta, or cereal	Whole wheat bread, English muffin, pita bread, bagel, cornflakes, grits, oatmeal, crackers, unsalted pretzels, and popcorn	Major source of energy and fiber
Vegetables	4-5	1 cup non-starchy vegetables ½ cup cooked vegetables 6 oz vegetable juice	Tomatoes, potatoes, carrots, green peas, squash, broccoli, turnip greens, collards, kale, spinach, artichokes, green beans, lima beans, sweet potatoes	Rich sources of potassium, magnesium, and fiber
Fruit	4-5	8 oz fruit juice 1 medium fruit ½ cup dried fruit ½ cup fresh, frozen, or canned fruit	Apples, bananas, dates, grapes, oranges, orange juice, grapefruit, grapefruit juice, mangoes, melons, peaches, pineapples, pomegranates, strawberries, tangerines	Important sources of potassium, magnesium, and fiber
Low-fat or fat-free dairy foods	3-3	8 oz milk 1 cup yogurt 1.5 oz cheese	Fat-free (skim) or low-fat (1%) milk; fat-free or low-fat buttermilk; fat-free or low-fat regular or flavored yogurt; low-fat and fat-free cheese	Major sources of calcium and protein
Meat, poultry, and fish	2 or less	6 oz cooked meat, poultry, or fish	Select only lean; trim away visible fat; broil, roast, or boil instead of frying; remove skin from poultry	Rich sources of protein and magnesium
Nuts, seeds, and dry beans	4-5 per week	1.5 oz or 1½ cup nuts ½ oz or 2 tbsp seeds ½ cup cooked dry beans and peas	Almonds, filberts, mixed nuts, peanuts, walnuts, sunflower seeds, turkey beans, lentils	Rich sources of energy, magnesium, potassium, protein, and fiber
Fats and oils ‡	3-3	1 tsp soft margarine 1 tsp low-fat mayonnaise 2 tsp light salad dressing 1 tsp vegetable oil	Soft margarine, low-fat mayonnaise, light salad dressing, vegetable oil (pack as olive, canola, or safflower)	DASH has 27% of its calories from fat, including that in or added to foods
Sweets	5 per week	1 tsp sugar 1 tbsp jelly or jam ½ oz jelly beans 8 oz ice cream	Magic syrup, sugar, jelly, jam, fruit-flavored gelatin, jelly beans, hard candy, fruit punch, sorbet, ice	Sweets should be low in fat

† Equals ½–1¼ cup, depending on cereal type. Check the product's nutrition label.

‡ Fat content changes serving counts for fats and oils. For example, 1 tbsp of regular salad dressing equals one serving; 1 tbsp of a low-fat dressing equals ½ serving; 1 tbsp of a fat-free dressing equals zero servings.

From the Dietary Approaches to Stop Hypertension study, as published by the Joint National

Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure and the National High Blood Pressure Education Program Coordination Committee. The sixth report of the Joint National Committee on prevention, detection, evaluation and treatment of high blood pressure. *Arch Intern Med.* 1997;157:2413–2446.

Proton pump inhibitors reduce enzymes (DDAH, ADMA) that are needed to make nitric oxide. Taking this class of medicines may negate the beneficial influence vegetables have on blood pressure and may help explain the increased risk for myocardial infarction seen with long-term use of this class of medicine. H2 blockers do not inhibit these enzymes.

Besides Lowering Blood Pressure, How Else Does this Diet Affect Cardiovascular Health?

A study of 116 men and women with metabolic syndrome showed that consuming a DASH diet versus a control diet can reduce most of the metabolic risks, including total cholesterol, low-density lipoprotein, weight, triglycerides, and fasting blood glucose concentration, while raising high-density lipoprotein. Although the magnitude of the effects varied by sex, they were positive in both groups.⁸ An investigation of 31 type 2 diabetic individuals also found favorable changes in these parameters, including hemoglobin A1c (decrease of 1.7),⁹ and adherence to this diet may actually have the potential to prevent type 2 diabetes.¹⁰ Interestingly, the lipid- and glucose-lowering effects of the DASH diet seem to be independent of sodium intake, which again supports the notion that this eating plan works through several nutritional mechanisms.⁹

In a retrospective analysis using data from the Nurses' Health Study, a DASH score was composed on the basis of foods that individuals had consumed. In comparing the top and bottom 20% on the basis of this score, the investigators found a nearly 50% decrease in kidney stones, even in participants with lower calcium intake.¹¹

Nitric-oxide

- ↓ Blood pressure
- ↓ Arterial stiffness
- ↑ Endothelial function

FIG. 89.1 Nitrites are further reduced in the endothelium to nitric oxide (NO). ADMA, asymmetric dimethylarginine; DDAH, dimethylarginine dimethylaminohydrolase.

Regarding cardiovascular disease-oriented outcomes, the DASH eating plan has been shown to lower the rates of stroke,¹² heart failure events (including mortality),¹³ and coronary artery disease.¹⁴

Does this Diet Reduce the Risk for Cancer?

A prospective study assigning a DASH score to more than 100,000 participants showed an 80% reduction in colorectal cancer between the top and bottom 20% of scores during a 26-year period. Those following a Mediterranean diet had no such decrease in their risk.¹⁵ This study was supported by a Canadian study also showing a reduction in colorectal cancer.¹⁶ A review of the available research suggests an overall reduction in the incidence of cancer among those who eat a DASH diet.¹⁷

How does this Diet Affect Bone Health?

Investigators at Duke University found that those who ate a DASH diet had evidence of less bone turnover that over time resulted in a stronger bone structure. This effect was enhanced when the DASH diet group further reduced their intake of sodium.¹⁸

Can the DASH Diet Slow Cognitive Decline?

In a sample of 826 older adults with an average age of 81 years, participants filled out a food frequency questionnaire related to both the DASH diet and the Mediterranean diet. Those who ate the most foods in both these dietary plans had the slowest rate of cognitive decline. The DASH diet was rated on a scale of 1–10. For a one-unit higher DASH score, rates of cognitive decline were 0.007 standard units slower, which was equivalent to adults aged at least 4.4 years younger.¹⁹

What Foods are Emphasized in this Diet, and How Do they Influence One's Health?

To summarize, the diet is:

- High in fruits and vegetables. These are rich in antioxidants (especially those with vibrant colors), are relatively low in calories, and contain significant fiber.
- Low in dairy, animal meat, and saturated fat. These fats increase the risk for atherosclerosis.
- High in nuts, seeds, and beans. These are high in protein and in monounsaturated and polyunsaturated fats, which can decrease inflammation and cardiovascular disease.
- Low in snacks and sweets. Many of these foods contain partially hydrogenated fats that act to preserve shelf life. These types of fats are sources of trans-fatty acids that play a significant role in increasing the risk for heart disease. Many common snacks are also composed of simple carbohydrates, which cause a rapid rise in insulin after they are consumed. Over time, elevations in insulin result in the body becoming less responsive to its effect. In turn, the body will start to produce excessive amounts of insulin, resulting in more inflammation and elevated risk for cardiovascular disease.
- The diet is based on 2000 calories a day. Large portion sizes are a major contributor to rising obesity rates worldwide. Combining this diet with a regular exercise routine can lead to even more dramatic decreases in blood pressure and other chronic diseases.

CHAPTER 90

The FODMaP Diet

David Rakel, MD

What Does FODMaP Stand For?

Fermentable Oligo-, Di-, and Monosaccharides and Polyol sugars ([Table 90.1](#)). See [Fig. 90.1](#) for a description.

What is the Mechanism of Action?

Having high amounts of fermentable sugars in the diet can result in excess gas production, changes in motility, visceral sensations, immune activation, and bowel permeability. This can result in pain, bloating, and altered bowel movements. The sugars are osmotic, pulling fluid into the intestines, worsening diarrhea. Those fruits that have more fructose than glucose are limited. Many patients who respond to the FODMaP diet may be prone to fructose malabsorption. Fructose-rich fruits include pears, apples, and watermelons. Vegetables that contain fructan, a polymeric chain of fructose, are also avoided. These include onions, leeks, asparagus, and artichokes. In a 2-day study where a high FODMaP diet was consumed, there was an increase in the production of hydrogen gas and irritable bowel syndrome (IBS) symptoms in those with IBS, but it only increased flatus production in healthy volunteers without IBS.¹

TABLE 90.1

The FODMaP Sugars

Sugar	Notes
F = Fermentable Sugars	When these sugars come in contact with the gut microbiome, they ferment gas.

O = Oligosaccharides	These are fructans that include wheat, rye, onion, garlic, beans, and some vegetables. This is unfortunate, as many of these are healthy nutrients. Wheat is omitted for its sugar, not for its protein (gluten). But a crossover benefit may occur in those with gluten intolerance.
D = Disaccharides	Lactose in milk and dairy products
M = Monosaccharides	Fructose in high-fructose corn syrup, honey, and some fruits. Maple syrup is OK to use.
a = and	
P = Polyol sweeteners	Any sugar ending in -ol such as xylitol, sorbitol, etc. Be watchful for sugarless chewing gums and any food with artificial sweeteners.

The FODMaP diet's therapeutic benefit is likely mainly related to reducing sugars that stimulate an osmotic shift of fluid into the lumen of the gut while also reducing fermentation that occurs when the sugars interact with the microbiome causing gas, bloating, and distention.

What Type of Condition is FODMaP Best Used For?

The FODMaP diet has been mainly studied for the treatment of IBS. Since it works in part by reducing the osmotic flow of fluid into the intestinal lumen, it has been shown to have a greater effect on diarrhea-dominant IBS (IBS-D). However, a small (n = 30), well-controlled, crossover study of IBS that compared a FODMaP diet to a typical Australian diet found that there was a 50% improvement in symptoms for both diarrhea- and constipation-dominant IBS (IBS-C).² Thus although it works best for IBS-D, it may also benefit IBS-C.

Which IBS Symptoms are Reduced the Most?

In a prospective study of 90 patients with IBS who were followed for almost 16 months, there was statistically significant improvement in abdominal pain, bloating, flatulence, and diarrhea. Seventy-two percent of the patients enrolled were satisfied with the improvement in their symptoms. All patients received hydrogen/methane breath testing and those found to be fructose intolerant (more than lactose intolerant) were most likely to benefit from the FODMaP diet.³ When the FODMaP diet

was compared to a diet that eliminated food triggers in those with IBS-D, both diets improved symptoms by 40%–50% but the FODMaP diet had greater benefit in reducing pain and bloating.^{3a}

Is it the Elimination of Sugar or Food Proteins that Results in the Greatest Benefit?

Since the FODMaP diet also removes foods that contain common food proteins such as gluten and casein, it is difficult to know if the benefits are from eliminating foods where the patient may have sensitivities to food proteins (e.g., nonceliac gluten sensitivity or celiac disease) or by reducing the sugars that are also included in these food groups (see [Chapter 31](#)). One strategy is similar to what is recommended in the rechallenge phase of an elimination diet (see [Chapter 86](#)); after having the patient on a strict FODMaP diet, reintroduce one food group at a time (e.g., gluten or dairy) and see if there is a significant worsening of symptoms. Generally, if there is a food protein sensitivity, there will be a more dramatic return in symptoms compared with adding more sugar. However, this is a subjective assessment.

FIG. 90.1 How a bean becomes fuel and gas as it passes through the gastrointestinal tract.

Polyol sugars are added to foods as sweeteners. They are often found in chewing gum since they are not broken down by bacteria in the mouth and metabolized to acids that can cause tooth decay. Encourage patients to read labels and watch for sugars that end in “-ol.” These include maltitol, sorbitol, xylitol, and erythritol. One that does not end in “-ol” is isomalt, which is used to make sugar-free candy.

What to Tell Your Patients When Placing them on the FODMaP Diet

The diet is dose-dependent. The fewer fermentable sugars they eat, the more benefit they will achieve. Most will see a benefit in 1 week. Since this is a difficult diet to sustain, it is important to educate patients that most of them do not require long-term strict adherence. Encourage patients to begin with a strict adherence, but then over time, slowly reintroduce foods based on personal tolerability.⁴ Many benefit by simply reducing the total sugar load, which alone can improve quality of life while also reducing enteric inflammatory triggers (Fig. 90.2). [Table 90.2](#) summarizes the foods to avoid (high FODMaP diet) and suitable substitutes (Low FODMaP diet).

TABLE 90.2
Examples of a High (Top) and Low (Bottom) FODMaP Diet⁸

FODMaP	Excess Fructose	Lactose	Oligosaccharides (Fructose and/or galactose)	Polyols
Prohibit high-FODMaP food source	Fruct: apple, pear, bush pear, clementine, peach, nectarine, sugar snap pea, watermelon, mixed fruit in natural juice Maltol: Maltol Sorbitol: fruitose, high-fructose corn syrup Large siall (fructose) also concentrated fruit sources, large servings of fruit, dried fruit, fruit juice	Milk: cow, goat, and sheep (regular & low-fat), ice cream Yogurt: regular & low-fat Cheese: soft & fresh (e.g., ricotta, cottage)	Fragaria: strawberries, raspberries, blackberries, blueberries, kiwifruit, cabbage, fennel, garlic, leeks, shallots, onions, peas, chickpeas Cereals: wheat & rye wheat eaten in large amounts (e.g., bread, pasta, cereals, crackers, biscuits) Legumes: chickpeas, lentils, red kidney beans, black beans Fruit: watermelon, cantaloupe, apple, white peaches, nectarine, persimmon	Fruct: apple, apricot, cherry, lingon, lychee, nashi pear, nectarine, pear, peach, plum, grape, watermelon Fragaria: strawberry, red flared, watermelon, rose pear Sorbitol: maltitol (E951), isomalt (E952), xylitol (E967), maltol (E955), isomalt (E951), & others ending in “-ol”
Permit alternative low-FODMaP food source	Fruct: banana, blueberry, cantaloupe, date, grapefruit, grape, honeydew melon, kiwifruit, lemon, lime, mandarin, orange, guava, kiwifruit, paw paw, raspberry, rockmelon, strawberry, mango Maltol substitute: maple syrup, golden syrup Sorbitol: any except polyols	Milk: lactose-free, rice milk Cheese: “hard” cheeses including cheddar, parmesan Yogurt: lactose-free Ice cream: soft-serve Gelatin: gelatin, agar	Fragaria: banana, kiwifruit, black cherry, carrot, celery, capsicum, chik, choy, corn, cucumber, green beans, lettuce, olive, parsnip, pumpkin, silverbeet, spring onion (green only), tomato Onion/garlic substitute: garlic-infused oil Cereals: gluten-free & egg-free cereal products	Fruct: banana, blueberry, cantaloupe, date, grapefruit, grape, honeydew melon, kiwifruit, lemon, lime, mandarin, orange, paw paw, raspberry, rockmelon Sorbitol: sugar (sucrose), glucose, other artificial sweeteners not ending in “-ol”

From Gibson PR, Shepherd SJ. Evidence-based dietary management of functional gastrointestinal symptoms: the FODMAP approach. *J Gastroenterol Hepatol*. 2010;25:252-258.

What are the Limitations of the FODMaP Diet?

The FODMaP diet runs the risk of significantly reducing the intake of fruits and vegetables, which could have negative long-term health consequences. A deficiency in dietary calcium due to the restriction of lactose and dairy has been reported.⁵ The diet may also alter the microbiome by restricting prebiotic (food for bacteria to grow) sources.^{5,6} There is also a concern for creating a fear of food, which can result in significant malnutrition. Many studies investigating particular diets for gastrointestinal symptoms demonstrated a significant nocebo effect.⁷ The goal should be towards improving overall nutrition while reducing the fear of particular food groups.

The majority of the positive research for the FODMaP diet comes from one center: Monash University in Australia. A lack of diversity of research sources should always elicit caution because of the risk of institutional research bias.

The long-term goal is not to create a fear of food, but an improvement in food choices that results in nourishment and an improved quality of life.

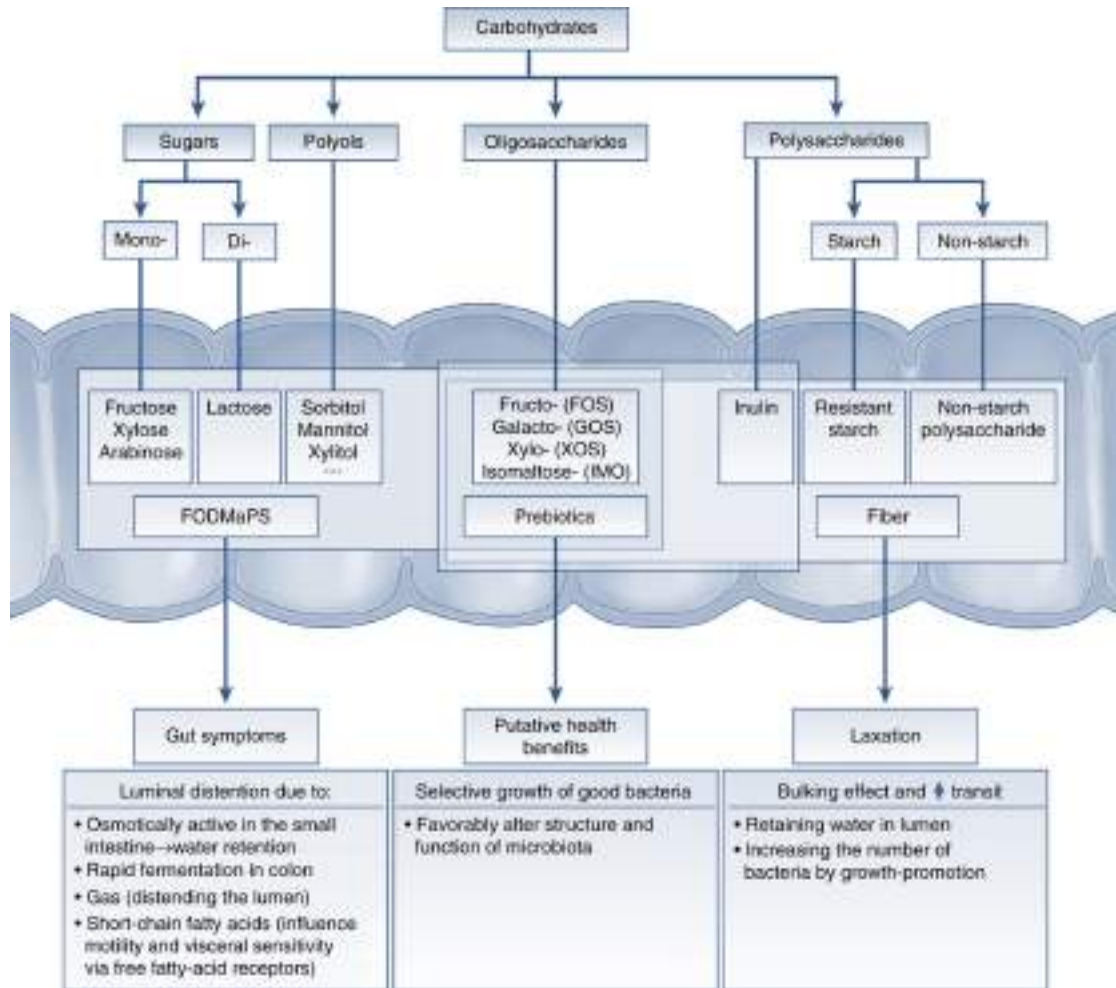

FIG. 90.2 Classification of carbohydrates based on their functional influence on gastrointestinal mechanisms. The FODMaP diet mainly avoids those sugars on the left side of the graphic. SECTION IB

Lifestyle: Exercise

OUTLINE

[Chapter 91. Writing an Exercise Prescription](#)

[Chapter 92. Therapeutic Breathing](#)

[Chapter 93. Low Back Pain Exercises](#)

CHAPTER 91

Writing an Exercise Prescription

Michael J. Hewitt, PhD

With the exception of a small number of sessile species, movement is one of the defining characteristics of animals. In humans, regular physical activity, whether it is accomplished through recreation, sport, labor, or participation in a structured exercise program, has been demonstrated to enhance function; to reduce, reverse, and prevent age-related physiological decline; and to lower the risks of a sedentary lifestyle.¹ Most physicians recognize the benefit of exercise, and most medical groups recommend regular physical activity.² However, because few medical training programs include even an overview of exercise physiology and few clinical rotations address exercise prescription, it is the rare physician who has experience in the decision-making process associated with recommending physical activity. Prescribing exercise is no different from prescribing medication, surgery, or therapy; it is a thoughtful compromise between the potential benefits of the treatment and its potential adverse effects.³

Basic Principles

Two principles form the framework for making exercise recommendations: the overload principle and the concept of specificity of exercise. The overload principle, based on Hans Selye's general adaptation syndrome model, suggests that a body or a physiological system repeatedly exposed to a stressor of appropriate intensity ultimately adapts to that stressor. To scientists who specialize in exercise, this principle underlies the adaptations that occur after cardiorespiratory conditioning or strength training. In general, there is an inverted J-curve relationship between the volume or intensity of the stimulus and the physiological adaptation. Infrequent strength training or work with light

resistance brings about only modest increases in muscle strength, but consistent work with heavier loads results in greater strength gains. Too much load and consecutive lifting days, however, are often associated with injury. Cardiorespiratory and flexibility adaptations to exercise training follow similar patterns; some is good, more is usually better, but too much can cause injury.

The challenge for physicians and their patients is to determine the appropriate exercise frequency and intensity to safely achieve an optimal functional enhancement.

Specificity of exercise refers to the relationship between the type of physiological adaptation and the type of activity performed. It is widely accepted that strength training is beneficial, many believe essential, for enhanced performance in sports. It is an unusual collegiate athletic team that does not have a strength coach. However, if one wishes to become a competitive swimmer or an Alpine skier, strength training alone is woefully inadequate. One must spend time in the pool or on the mountain. For similar reasons, sprinters train differently than middle- or long-distance runners. The implication for physicians is that cardiorespiratory health concerns, weight loss, and osteoporosis prevention all require different modes of exercise therapy.

The Five Components of Fitness

A useful model for exercise programming is one that addresses five components of fitness: cardiorespiratory or aerobic fitness, muscle strength and endurance, flexibility, body composition, and balance/agility. One could make an argument to include muscle power (i.e., the explosive application of strength), but lack of power is rarely a health limitation. In addition to percentage of body fat and fat-free body mass (FFB), measurement of bone mineral content (BMC) is another important component of body composition assessment. Balance and agility are the most commonly overlooked aspects of physical function, but they have significant implications for fall prevention and mobility and therefore are important for aging patients.⁴

There is typically an age-related decline in each of these components (with the exception of percentage of body fat, which usually increases) that can be attenuated or reversed by appropriate physical activity. In

fact, much of the functional decline associated with aging can be more accurately called disuse atrophy.

The five components of fitness are as follows:

- Cardiorespiratory fitness (the ability of the heart, lungs, and vascular network to deliver oxygen to the working muscles)
- Muscle strength (the ability of the musculoskeletal system to move a heavy load) and muscle endurance (the ability to move a moderate load repeatedly)
- Flexibility (an index of joint range of motion)
- Body composition (typically, the level of body fat, but a measure of fat-free body mass [FFB] is of equal clinical significance)
- Balance and agility

Body Composition

Body composition is the one component of fitness that does not require a specific exercise recommendation. Body composition changes as a consequence of cardiorespiratory exercise, strength training, and nutrient intake.⁵ However, an initial measure and repeated assessments of body composition are highly useful tools to determine how patients should use their limited exercise time. For instance, a man with more than 25% body fat and a woman with more than 38% body fat are in a group with a statistically greater risk of heart disease, type 2 diabetes mellitus, hyperlipidemia, and hypertension.⁶ Exercise programming should attempt to specifically address those risks as well as help reduce the level of body fat.

Quantification of FFB further refines the exercise prescription and can be used to accurately predict resting metabolic rate (RMR).⁷ Many adults are at an appropriate weight on the weight-to-height scales or body mass index (BMI; weight in kg/height in m²) value, but are underlean as indicated by a lower than optimal FFB. In general, cardiorespiratory exercise results in a reduction of percentage body fat but has a limited effect on FFB. In contrast, strength training increases FFB (as well as muscle strength), which will modestly raise RMR, ultimately resulting in a reduction in the percentage body fat. Many obese patients develop adequate FFB simply by transporting themselves and gain only limited benefit from strength training, but their percentage of body fat responds

favorably to cardiorespiratory activity. Smaller individuals who have acceptable weight-to-height values despite excess body fat have low FFB and benefit most from combined cardiorespiratory and strength programs.

In addition to the measures of body fat, the determination of BMC (in grams) or bone mineral density (BMD, g/cm²) further enhances exercise programming. Dual-energy x-ray absorptiometry (DEXA) is considered the new “gold standard” for simultaneous determination of percentage body fat, FFB, and BMC.⁶ Its drawbacks are that the technique requires expensive equipment and patients experience a very small x-ray exposure. However, DEXA is fast, accurate, and reliable, and it does not depend on patient skills (as does underwater weighing) or measurer’s technique (as does anthropometry). If DEXA is not readily available or is cost-prohibitive and BMD data are not essential, bioelectric impedance analysis (BIA) is a practical alternative. As long as hydration status is controlled, BIA can rapidly and inexpensively provide accurate and repeatable measures of percentage fat and FFB. It eliminates measurement technique and patient cooperation errors and provides significantly more data, as well as a more meaningful assessment of health status, compared with that provided by the ubiquitous determination of BMI. Several other field techniques can be effectively administered in a physician’s office; these provide useful body composition data, but each method has limitations. A discussion of body composition assessment methodology is beyond the scope of this text, but interested readers are referred to three excellent summaries.⁸⁻⁹

DEXA can determine percentage of body fat, FFB, and BMC.

The FITT Principle for Exercise Programming

For cardiorespiratory conditioning, strength training, flexibility, and balance-agility training, a simple exercise prescription tool is the FITT principle. FITT is an acronym for the following:

- Frequency
- Intensity
- Type
- Time (duration)

These are the four variables that must be considered in exercise programming, and physicians should write a prescription specifically addressing each ([Fig. 91.1](#)). For example, individuals with elevated risk for heart disease should be encouraged to improve their cardiorespiratory condition. The type of exercise can be walking, jogging, or running, either outdoors or on a treadmill; bicycling, swimming, or hiking; aerobics and use of any of a variety of aerobic machines (stair climbers, rowing machines, cycle ergometers); or dancing, tennis, and many other possibilities. The choice is affected by geographic concerns (cycling in northern climates during January is difficult) and economic limitations (some patients cannot afford a treadmill or the cost of membership at a fitness center), but the most important factor is usually patient preference. Exercise equipment manufacturers often promote their devices on the basis of efficiency and the effectiveness of the workout they provide. Practically, much of the advantage of one type of exercise device over another is irrelevant when patients miss exercise sessions because they simply do not like the activity. The very best cardiorespiratory exercise is one that the patient will perform. Of course, a patient with knee limitations may not tolerate distance running, and a patient with severe osteoporosis should not be advised to take up ice skating.

In 2011, the American College of Sports Medicine (ACSM) published a position stand on the recommended quantity and quality of exercise that is an excellent reference and should be in the library of any health professional who recommends physical activity.¹⁰ In this position stand, quantity refers to the frequency and duration and quality refer to the intensity of physical activity.

Cardiorespiratory Training

The frequency of cardiorespiratory training is limited more often by patient compliance than by physiology. It is not inappropriate for one to exercise daily, but few people do. The ACSM recommends a duration of 20–60 minutes of continuous or intermittent exercise and a frequency of 3–5 days per week for cardiorespiratory fitness and body composition enhancement. Intermittent exercise is described as a minimum of 10-minute bouts accumulated throughout the day. The recommended intensity is 65%–90% of maximum heart rate (HR_{max}) in healthy adults and 55%–65% in very unfit individuals. The challenge, of course, is to know one's maximal heart rate. Graded exercise tests rarely continue to

exhaustion; therefore, they do not provide a true HR_{max} , and prediction equations for HR_{max} (e.g., $220 - \text{age in years}$) lack sufficient precision to be clinically useful. A maximal or submaximal exercise tolerance test performed by an exercise physiologist, especially if it includes measures of oxygen consumption, can provide a useful estimate of HR_{max} and a target heart range.

EXERCISE PRESCRIPTION

Name: _____ Date: _____

COMPONENT OF FITNESS	EXERCISE	FREQUENCY	DURATION	INTENSITY
Cardiorespiratory Fitness	_____ _____ _____	_____ days/week	_____ minutes	_____ beats/minute _____ beats/10 seconds
Strength	Free Weights Machines Elastic bands Floorwork	_____ days/week	_____ minutes _____ sets	_____ repetitions
Flexibility	Static	_____ days/week _____ repetitions	_____ seconds	Hold below pain threshold

 Exercise Physiologist

FIG. 91.1 Sample of an exercise prescription showing the first three components of fitness, with areas for the prescription to be individualized for the patient.

Graded exercise stress tests can identify hypertensive responses to activity and clinically significant electrocardiographic abnormalities during exercise and are thereby highly useful for providing a safe and effective cardiorespiratory exercise intensity range for at-risk patients. In healthy adults, heart rate is useful but not essential for monitoring of exercise intensity. The Borg scale has been demonstrated to be an effective tool to assess cardiorespiratory exercise intensity ([Table 91.1](#)).¹¹ Healthy adults should maintain a subjective rating of perceived exertion (RPE) of “moderate” to “heavy” or about 13–15 on the scale. Beginners can improve compliance by limiting intensity to “light” to “moderate”

(RPE 11–13). It is not uncommon for athletes to reach “very, very heavy” (RPE 19–20) for short bursts, particularly during interval training such as wind sprints, but there is little reason to recommend these levels for patients. The OMNI RPE scale, which provides illustrations representing exercise intensity as well as a 0–10 numerical rating scale, may be more appropriate for children or anyone for whom English is not the primary language.¹²

Another approach to recommending appropriate cardiorespiratory exercise intensity is based on the measured energy cost of the activity, reported in metabolic equivalents (METs). One MET, defined as the energy expenditure of sitting quietly,¹³ about 1 kcal/kg body weight/hour, requires about 3.5 mL of oxygen/kg body weight/minute. Level walking on a firm surface at 3.5 mph is rated at 3.7 METs, and running at 7 mph (8.6 min per mile) is 11.8 METs. A listing of the MET level of more than 400 recreational and occupational activities has been compiled.¹³ This compendium provides a simple comparison of the energy costs of the activities, allowing physicians to suggest several equivalent options. Its utility is further enhanced if a graded exercise test has been performed to quantify the patient’s sustainable and maximal MET capacities.

Because cardiorespiratory exercise is a foundation for disease prevention and longevity, any program that increases participation should be welcomed. A 10,000-step program, *Walk to a Healthy Future*, has been endorsed by health providers and is promoted by the International Longevity Center.¹⁴ Requiring only good walking shoes and an inexpensive digital pedometer, this program encourages participants to accumulate 10,000 steps daily, the equivalent of about 5–6 miles. The recommendations are based on research by a Japanese physician, Yoshiro Hatano, who reported that the typical (Japanese) adult takes between 3000 and 5000 steps per day.¹⁵ In contrast, a 7-day study on the walking behavior of an Old Order Amish community in Ontario, Canada, whose members do not use electricity or motorized vehicles, found average daily step totals of $18,425 \pm 4685$ for adult men and $14,196 \pm 4078$ steps for adult women.¹⁶ The highest recorded single-day total was 51,514 steps! It is not surprising that rates of obesity (BMI ≥ 30) and overweight (BMI ≥ 25) among Amish adults average only 4% and 26%, respectively; in contrast, these rates are 34.9% and 68.5%, respectively, for the adult U.S. population.¹⁷

Electronic Activity Monitors

Pedometers continue to be useful tools to monitor physical activity, but are dinosaurs compared to the wearable electronic activity monitoring devices that have been developed in recent years. These sophisticated fitness trackers can be worn on the wrist, clipped to clothing, or incorporated into smartphones. Most utilize an accelerometer to monitor movement, even during sleep, and some versions add GPS technology. Optical sensors for heart rate are common and provide useful data to optimize exercise intensity. Virtually all monitors sync with smartphones or personal computers for tracking and graphic display of physical activity, calorie expenditure, and more. A list of recommended fitness trackers here would be useful to physicians, but development of new devices proceeds much faster than revisions of printed books. However, publications like *PC Magazine* publish online annual reviews of these tools and can provide comparative data for the latest models. It is worth noting that not all activity monitors are water resistant. Like most consumer electronics, function increases and cost decreases almost exponentially each year, so physicians can recommend these devices for patients in all economic groups.

Resistance Training

A nearly universal physiological change associated with aging is sarcopenia, the age- or disuse-related loss of muscle and FFB.^{4,18-20} A reduction in FFB typically brings about a proportional drop in metabolic rate. In addition, the decline in FFB negatively influences strength, mobility, and balance, ultimately jeopardizing a person's independence.²⁰ Clinical rates for sarcopenia are 8%–13% in persons younger than 70 years, about 17.5% in those aged 75 years, and more than 50% in the oldest old.^{16,20} Subclinical levels of muscle loss are even more common. As prevalent and as significant as sarcopenia is, few physicians address it, and very few patients have heard the term. Fortunately, sarcopenia is highly preventable, and much of its effects can be reversed with resistance (strength) training. Although cardiorespiratory disease influences morbidity and mortality more than any other factor in our culture and appropriate preventive exercises should be prescribed for it, the prevention of sarcopenia and its long-term effects warrant nearly equivalent attention.

Sarcopenia, the age- or disuse-related loss of muscle and fat-free body mass, reduces strength, mobility, metabolism, balance, and independence in older adults. Its effects can be attenuated or reversed by resistance training.

Resistance training has also been shown to be effective in combating osteoporosis, the bone loss analogue to sarcopenic loss of muscle. The Bone, Estrogen, Strength Training (BEST) study demonstrated that postmenopausal women, when exposed to a sufficient strength challenge with or without estrogen replacement therapy, could achieve small but significant increases in bone mineral density at the trochanter and lumbar spine (L2–4) sites.²¹ Although the increases recorded during the 1-year study were modest (+ 0.77% to + 2.00% for resistance training with estrogen; + 0.02% to + 1.13% for resistance training alone), they were in sharp contrast to the –0.13% and –0.57% losses recorded at the trochanter and L2–4 areas for women in the nonexercise, no-estrogen control group during the same period. The positive outcome in the BEST study can be attributed primarily to the significant and increasing weight challenge (intensity) that participants faced during the study as well as to the frequency, time, and types of strength intervention imposed.

Thus, the FITT principle as suggested for cardiorespiratory programming can also be applied to resistance training. The ACSM suggests that one set of 8–10 weight exercises that work all major muscle groups be performed 2 or 3 days per week. A weight load that causes muscle fatigue in 8–12 repetitions is recommended. Older or frail individuals may find lighter weights that allow 10–15 repetitions before fatigue to be more appropriate.^{10,20,22} A second or third set may be advantageous if time and patient interest permit, but the majority of the benefit is derived in the first set.²² Although many physicians refer patients for an initial session with an exercise physiologist, physical therapist, or personal fitness trainer to learn the specifics of a strength training program, a program can be designed on the basis of general advice.²³ Flexibility and balance-agility recommendations should also follow the FITT principle.

TABLE 91.2
Basics of Exercise Prescription

Exercise/Fitness Component	For Disease Prevention	For Basic Health	For Enhanced Fitness	For Performance-Level Fitness
Cardiorespiratory exercise	Accumulate 20–60 min of physical activity most days	Play or large muscle repetitive activity 20 + min ^a 3 + times/week	Play or aerobic exercise 40–60 + min ^a 4–6 times/week	All interval training or competition
Strength training	Include weight-bearing activity most days	Key Three ^b or equivalent program 1–2 sets two times/week Lift to a “challenging” level to 8–12 or 12–15 repetitions	Balanced whole-body machine or free-weight program 2–3 sets three times/week. Resist “functional failure” to 8–12 repetitions	All muscle endurance or power training All 30-min work All ascending or descending pyramids
Flexibility	Maintain range of motion by teaching and stretching to daily activities	Perform 2–4 limitation-specific stretches after activity, 1 repetition Hold about 10–30 s	Perform 6–10 whole-body stretches after activity and before competition, 1–2 repetitions	All yoga, Pilates work, or facilitated stretches with a partner
Body composition	Men	25%–29% fat	12%–20% fat	8%–15% fat
		Maintain fat-free (lean) body mass at 125–150 lb, or more		
	Women	21–41% (20% fat)	20%–26% fat	17%–25% fat
		Maintain fat-free (lean) body mass at 80 to 110 lb, or more		
Balanced and agility	—	Act “like a child” Walk a balance line “Don’t step on a crack...” Brush teeth while standing on one foot	Recreational sports: tennis, pickleball, etc. Social dancing Stability ball training	High-level sports: skiing, skating, surfing Yoga Martial arts Performance dancing Agility drills

^a At a challenging intensity.

^b Key Three consists of a double-leg press or squat, chest press, and lat pulldown or single-arm row.

Levels of Exercise Prescription

When prescribing exercise, the health care provider should determine the patient’s desired outcome. Strategies exist to help patients overcome

their physical and psychological barriers to exercise compliance.²⁴ Individuals whose primary goal is simply to reduce disease risk may have a level of commitment lower than that of others who seek true physical fitness or athletic performance. [Table 91.2](#) summarizes exercise recommendations for four levels in the cardiorespiratory, strength, flexibility, body composition, and balance-agility areas. General recommendations for body fat and FFB at each level are also reported; however, body composition standards are subject to significant individual variation. A useful approach is to encourage patients to perform at least the recommended activity for the prevention of disease but to strive to consistently exercise at the “basic health” level. When these patterns become habitual, the health care provider can encourage physical activity at the level to achieve “enhanced fitness” (see [Table 91.2](#)).³

The most effective exercise prescriptions provide guidelines for variety and allow a progression of activity. The programs of long-term participants bear little resemblance to those of new exercisers. Compliance is enhanced if the initial program is broad enough and sufficiently challenging to effect measurable improvement, but compact enough to fit into a patient’s busy schedule. An experienced physician or exercise physiologist will develop a small starting program and suggest a progression during a specific time frame. One may start with a 10-minute walking or bicycle ergometer program three times weekly and progress to 20 minutes four times weekly within 2 or 3 months, ultimately striving for 40 minutes or longer on most days.

The Key Three Strength Program

In strength work, a simple starting program such as the Key Three^{20,25} allows a basic whole-body strength workout to be completed in less than 10 minutes ([Fig. 91.2](#)). Few patients have an effective argument for why they cannot find 10 minutes for strength work twice a week. The Key Three can be performed using weight machines, inexpensive hand-held dumbbells, or even elastic resistance bands, making equipment and space limitations moot. The three exercises (and the primary muscle groups targeted) are the double-leg press machine or dumbbell squat, which can be performed against the wall for additional support (quadriceps, hamstrings, gluteals); the chest press machine or supine dumbbell bench press (pectoralis major and minor, anterior deltoid, triceps brachii); and either the lat pulldown or seated row machine or the

single-arm dumbbell row (trapezius, latissimus dorsi, and biceps brachii). These three exercises challenge approximately 85% of the muscle system. Although bodybuilders might scoff at a basic program such as the Key Three, even smaller series of lifts have been demonstrated to rapidly improve strength, muscle mass, and mobility in older adults,²⁶⁻²⁸ and these three core exercises can form the framework for more sophisticated lifting regimens.

FIG. 91.2 Key Three exercises: A, Dumbbell squat (quadriceps, hamstrings, and gluteals). B, Supine bench press (pectoralis major and minor, anterior deltoid, and triceps). C, Single-arm dumbbell row (trapezius, latissimus dorsi, and biceps). (From Hewitt MJ. *The Key Three strength program* .

Flexibility Versus Stability

Traditional thinking among exercise professionals and fitness enthusiasts is that more flexibility is preferable to less. Certainly this is true for dancers, gymnasts, and figure skaters, but it is not always the case for healthy adults. More modern thinking recognizes that optimal control of range of motion (ROM) requires an appropriate balance between limb flexibility and joint stability. Stretching programs have been demonstrated to effectively increase ROM, but physicians should use caution in recommending flexibility training regimens to patients exhibiting hypermobility tendencies (e.g., they can extend the thumb to touch the forearm or can extend the elbows or knees beyond 180 degrees). Hypermobility patients should be encouraged to preferentially participate in strength training to stabilize their joints. Most adults, however, will respond favorably to a modest flexibility program.

Static stretching, in which a joint is moved to a position eliciting mild tension and is held stationary, is the most commonly practiced method to improve joint ROM. There are places where ballistic stretching (incorporating bouncing movements), proprioceptive neuromuscular facilitation (PNF), hold-relax cycles (with a partner or against an immobile object), and dynamic stretching (exaggerated movement mimicking sports-related activity) are indicated, but most patients will see effective adaptations using a compact static stretching program.²⁹ The scientific evidence is equivocal in support for the common belief that improved flexibility reduces the risk of injury, but enhanced and stable ROM is always desirable. Similarly, recommendations for the optimal time for holding a static stretch vary from as little as 2 or 3 seconds to well above 60 seconds, but most fitness professionals find that patients respond favorably to a hold period of 20–30 seconds.²⁹ Activities like yoga and pilates also improve joint ROM, although a compact program of two or three static stretches performed daily is often preferable to a larger and more complex program that might be performed only intermittently.

Balance and Agility

Balance and agility are the most commonly overlooked components of fitness, yet poor balance and its associated risk of falling are potentially the greatest health concerns for many older adults. Balance and agility require a rapid central nervous system (CNS) response to signals from the inner ears (vestibular signals), eyes (visual signals), postural muscles in the legs and back (proprioceptive signals), and touch (tactile signals). Although some deterioration in the quality of these signals occurs with age, it is primarily a slower rate of integration and response by the CNS that appears to cause the loss of function (disuse atrophy). Function loss is cyclical; low function results in reduced confidence, which leads to avoidance of balance challenges, and further reduction in function follows in a destructive cycle. Even highly skilled athletes lose function rapidly if they become injured or fail to practice.

Balance and agility can be restored by safe challenges to the system with appropriate exercises. Tai chi, dance, and simple balance exercises such as standing on one foot while brushing the teeth or hair provide effective signals to stimulate CNS adaptation.³⁰ In severe cases, ai chi, a form of tai chi performed in a swimming pool, provides a no-falling-risk stimulus to the balance control system. Sports such as tennis and bicycling are greater challenges and are associated with both higher risk and greater potential to achieve improvement. High-level activities, including skiing, skating, and martial arts, are appropriate for a select group of patients.

Therapeutic Review

The ACSM^{4,5,26} provides guidelines that illustrate the standard of care and prove invaluable for clinicians and physiologists who make exercise recommendations. This organization also offers a resource manual to support these guidelines, which includes background summaries in applied anatomy, exercise physiology, exercise testing and programming, emergency procedures, terminology, and more.³¹⁻³²

A comprehensive exercise program has a synergistic effect. Improved strength in the postural muscles is reflected in better balance because those muscles can more effectively respond to signals from the balance centers. Better cardiorespiratory conditioning allows a more challenging strength training program, and improved body

composition allows greater range of motion for more effective stretching. Equally important, enhanced function allows greater participation, usually resulting in better compliance. Exercise prescription need not be complicated; virtually any activity has positive effects. The key is to gently challenge each of the physiological systems in such a way to allow patients to experience enhanced function and then encourage them to modestly increase the stimulus.

Key Web Resources

ACSM Position Stand: The American College of Sports Medicine (ACSM) is an international resource for information and certification for exercise physiologists, sports medicine physicians, physical therapists, and other allied health professionals. The ACSM has published position stands on multiple topics of interest to physicians wanting to optimize exercise prescription for various situations. The list can be viewed at no cost at ACSM.org .	http://www.acsm.org/across-publication/information/position-stands
The website for the American Council on Exercise, a not-for-profit organization that trains and certifies health and fitness professionals.	http://www.aacefitness.org
An issue brief written by this author and published by the International Longevity Center on the topic of a small strength training program for the promotion of sarcopenia. All ILCAUSA issue briefs can be reprinted for patients.	http://www.internationalcenterforlongevity.org/51021/51021.pdf
Another International Longevity Center issue brief, this one written by Robert N. Butler, MD, Founding Director of the National Institutes on Aging and late CEO and Founder of the I.L.C. Walk to a Healthy Future, introduces the 30,000-step program and can be reprinted for patients.	http://www.internationalcenterforlongevity.org/51021/51021.pdf
Members of the National Strength and Conditioning Association earn certification preparing them to be personal trainers and team strength coaches. The NSCA website's publications and education sections provide additional information for readers interested in a deeper understanding of this important component of physical activity.	http://www.nsca-ll.org

Chapter 92

Therapeutic Breathing

Vincent J. Minichiello, MD

And the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul.

GENESIS 2:7, KING JAMES VERSION BIBLE¹

As long as there is breath in the body, there is life. When breath departs, so too does life. Therefore, regulate the breath.

Hatha Yoga Pradipika, [CH. 2](#)²

What is Therapeutic Breathing?

The importance of breath in the context of health has been understood for millennia. Frequently, the terms used for breath in ancient cultures also carried a broader connotation, implying breath to be a “vital energy”: pneuma in ancient Greek, prana in Sanskrit, qi in Chinese, and ruach in Hebrew. The tradition of using breath for health and healing has

been transmitted from generation to generation through a variety of practices, including religion/prayer, meditation, martial arts, yoga, and qigong, amongst others. These techniques have now become the focus of medical research, with a dramatic rise in the number of publications related to the therapeutic use of breath for multiple disease states over the past 20 years.³ The purpose of this chapter is to focus on how the physiology of breathing affects the mind-body unit, to provide a framework for broadly classifying specific techniques, and to highlight the strongest evidence for practices that could be utilized in a clinical setting.

As both voluntary and involuntary processes, breathing is one form of nonpharmacological medicine that can be practiced easily in any setting, at any time of the day.

The Mechanism of Breathing

While there is perhaps no single “correct” way of breathing, evidence from millennia of practitioners of the healing arts as well as evidence from modern research has shown that there are ways to

voluntarily modulate natural breathing to attain better mental and physical health. Typically, respiration involves a continuous cycle of inhalation and exhalation either through the nose or the mouth. On inhalation, the diaphragm contracts and moves downward, creating an increase in negative pressure in the lungs and chest cavity, thus allowing air from the atmosphere to travel down a pressure gradient to fill the lungs. With the help of intercostal and abdominal muscles, the chest wall and/or abdomen will expand outwards with inhalation. The shoulders may rise. Upon exhalation, the reverse happens—relaxation of the diaphragm decreases the volume of the intrapleural space, air leaves the lungs, chest/abdominal walls contract inwards, and the shoulders fall. At multiple phases of this respiratory mechanism, changes can be made to affect cellular oxygenation, stimulation of the autonomic nervous system, lymphatic flow, and thus total body health and healing ([Fig. 92.1](#)).

Many of the techniques used in therapeutic breathing modify this typical breathing cycle.

Variations can occur in the following ways and in combinations of the following ([Table 92.1](#)):

1. Changing the pace and pattern of breathing
2. Emphasizing different muscles during a breathing cycle

3. Increasing / decreasing airway resistance during therapeutic breathing
4. Linking guided / mental imagery to the breathing process
5. Coordinating breath with movement

Of note, while several studies suggest that breathing modifications will have an immediate effect on the autonomic nervous system, as with other forms of mind-body medicine, the longer the practice period, the more prevalent the positive physiological changes and the more accessible these tools are in settings such as an acute episode of anxiety.

Paced and Patterned Breathing

First of all, the timing of the respiratory cycle can vary in many ways, and counting can be used to help keep track of this timing. One basic principle for promoting a relaxed state involves simply increasing the length of time spent inhaling and exhaling. This principle comes from the idea that there is a mutual connection between the nervous system and the breath. Shorter breaths or an increased respiratory rate can be the product of an activated nervous system via anxiety, anger, stress, etc. By voluntarily slowing the breathing rate, emotions and stress levels can be more easily

stabilized.

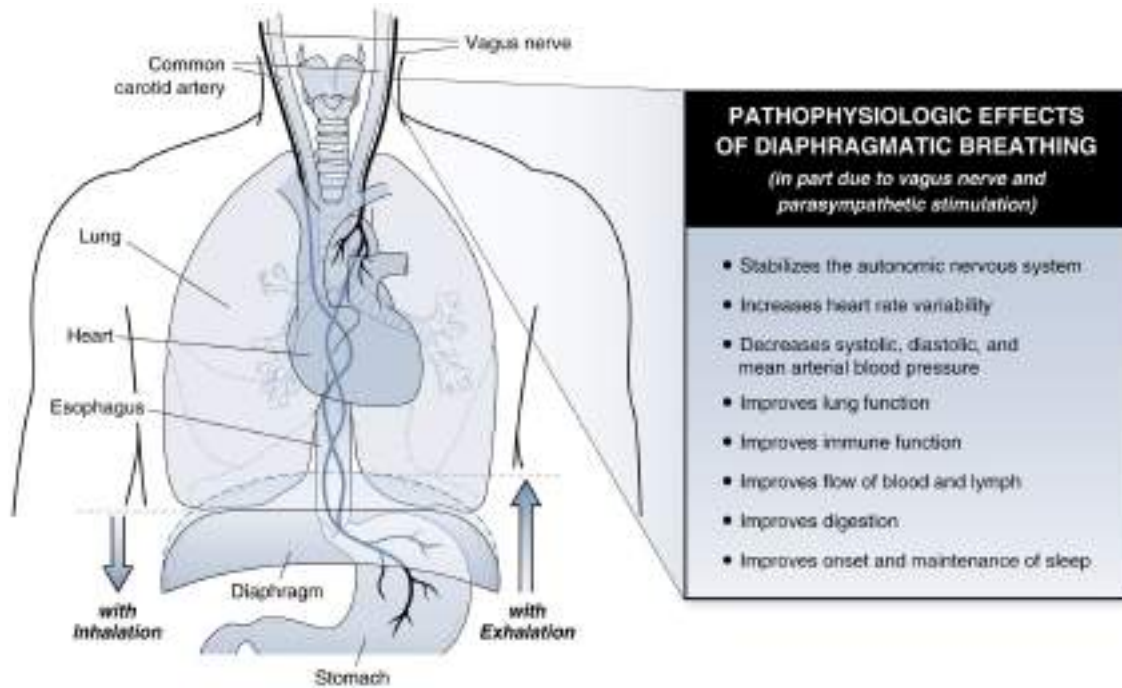

FIG. 92.1 Pathophysiological effects of diaphragmatic breathing.

TABLE 92.1

Techniques Used in Therapeutic Breathing

Categories of Therapeutic Breathing	Examples
Paced or Patterned Breathing	6 breaths / minute, Buteyko method, 1:2 inhalation / exhalation ratio, Kapalabhati breathing, Bellows breathing, "Relaxing Breath"

Body Area / Muscle-Focused Breathing	Thoracic, abdominal / diaphragmatic
Breathing With Increased Airway Resistance	Pursed-lip breathing, alternate-nostril breathing, singing, chanting, vocal prayer, tip of the tongue to roof of the mouth
Imagery Combined With Breathing	Tonglen meditation, 3-Minute Breathing Space, Dan Tian breathing
Movement With Breath Work	Running, yoga, martial arts

It has been suggested that the optimal respiratory rate to enter a state of relaxation is approximately 6 breaths / minute.

Studies have shown that breathing at 6 cycles / minute improves heart rate variability, helps with insomnia,⁴ treats hypertension (by increasing baroreflex sensitivity), decreases muscle sympathetic nerve activity,⁵ and may help decrease hot flashes in menopausal women⁶ (see [Chapter 96](#)).

The RESPeRATE biofeedback device, which is the only FDA-approved nonpharmacological treatment for hypertension, enhances the benefits of this so-called “paced breathing,” or intentionally slowed breathing. RESPeRATE consists of a control box, a respiration sensor, and headphones. The device senses a person’s respiratory rate and then produces tones to indicate when to inhale and when to exhale. Over time, the tones sound at longer intervals, ultimately slowing a person’s breathing pace to an ideal respiratory rate. The Buteyko method was developed in the 1950s under the principle that biochemical disturbances lead to dysfunctional breathing. This method teaches breath-holding techniques to “normalize” carbon dioxide levels, and research has shown moderate benefit in children with hyperventilation syndrome and in asthmatics.⁷

Another variation on this practice is that by intentionally increasing the respiratory rate; an overall increase in the body’s parasympathetic tone can also be achieved. Kapalabhati breathing as well as Bellows (Bhastrika) breathing from the yogic tradition function in this manner. Both forms of isolated abdominal breathing work on bringing the respiratory rate to about 1–4 breaths/second. While both practices increase respiratory rate, Kapalabhati

breathing emphasizes sharp exhalations and passive inhalations. These stimulating practices can be used in the short term to help with fatigue, depression, and feeling cold.⁸ In the long term, it has been shown that it is possible to decrease baseline heart rate and blood pressure as well as improve heart rate variability,⁹ pulmonary function tests,¹⁰ and cognitive function.¹¹

An inhalation-to-exhalation ratio of 1:2 has been shown to promote relaxation.

Some evidence suggests that in addition to modifying respiratory rates, practicing prolonged exhalations activates the parasympathetic nervous system and thus slows the heart rate and produces a relaxation response from the body. Multiple variations on this theme exist based on the particular teacher or tradition that is being practiced. The “Relaxing Breath” or “4-7-8” breathing exercise espoused by Dr. Andrew Weil suggests inhaling for a count of four, holding the breath for a count of seven, and then exhaling for a count of eight. What is most important is not the duration of each inhalation and exhalation, but simply the ratio between the two.¹² Some evidence supports a lower inhalation/exhalation ratio in

promoting increased self-reported relaxation and energy as well as improved heart rate variability,¹³ although other studies suggest that the breathing rate is more important than the pattern.^{14,15}

Muscle/Body Emphasis in Breath Work

Most simply, breathing can be categorized as thoracic, abdominal, or diaphragmatic. Although the thorax, abdomen, and diaphragm have a continual interplay in nearly all types of breathing, certain breathing practices emphasize one over the others.

Thoracic breathing typically involves an expansion of the chest wall with inhalation and a contraction of the chest wall with exhalation. In settings of highly emotional states, such as sadness, anxiety, or anger, thoracic breathing often becomes the principal pattern of breathing. Shallow thoracic breathing then perpetuates the stress response by increasing respiratory rate, heart rate, and the overall sympathetic tone of the body. While these are critical functions of the body for survival, to be in a chronic state of activation can have negative health effects on nearly every organ system. It is

important to note, however, that sometimes thoracic breathing can be used therapeutically. With complete, deep breathing, the rib cage and chest are intentionally expanded to create increased vital capacity. This may be beneficial for asthmatics.¹⁶ Abdominal breathing—often used synonymously with the term “diaphragmatic breathing” in published research—allows for a relaxed abdominal wall to expand and contract with every inhalation and exhalation, with minimal movement of the chest wall. This practice is commonly used in relaxation techniques and is often the breathing method used in research protocols. Some studies that have shown benefit from abdominal breathing including using this type of breathing alone or in conjunction with other therapies for the treatment of gastroesophageal reflux disease,¹⁷ anxiety in patients receiving chemotherapy,¹⁸ motion sickness,¹⁹ chronic obstructive pulmonary disease (COPD),^{20,21} pediatric functional constipation,²² quality of life in patients with asthma,²³ and total body oxidative stress.²⁴

Abdominal breathing in most studies is practiced by having the patient either sit or lie supine with one hand on the abdomen and one hand on the chest. Slow, deep breathing is then initiated with careful attention to move the hand resting on the

abdomen with each breath while maintaining a stillness in the hand that is on the chest.

Airway Resistance in Breath Work

Intentional modifications to increase the resistance to the normal flow of air in and out of the lungs can be another therapeutic variance in some breathing exercises. These modifications can be either from changes in posturing while breathing or from external sources.

One common practice that has been well studied is that of pursed-lip breathing. Used effectively in people with chronic obstructive pulmonary disease, pursed-lip breathing helps to prop open bronchioles and alveoli by creating an increased pressure behind the lips (and subsequently, down to the lower airways) as air is forced through the smaller opening created by pursed lips. By keeping these lower airways open, more oxygen is able to diffuse through the alveoli to the general circulation and less carbon dioxide accumulates in the body.

Hyperventilation and exhaustion from increased respiratory effort are thus diminished. A typical breathing exercise would involve inhaling through the nose with the mouth closed for a count of two,

then exhaling through pursed lips for a count of four.²⁵ Increasing airflow resistance in this manner has been effective in improving exercise tolerance in patients with COPD²⁶ and treating dyspnea in the setting of COPD²⁷ as well as treating dyspnea secondary to lung cancer.²⁸

Some forms of yogic breathing also incorporate therapeutic resistance; for example, Nadi Shodhana is translated from Sanskrit as “clearing the channels.” Specifically, this term is used in reference to alternate-nostril breathing techniques.

One variation of Nadi Shodhana: Using the right thumb to block the right nostril, inhale through the left nostril. At the end of the inhalation, block the left nostril with the right ring and small fingers and exhale through the right nostril. At the end of the exhalation, inhale again through the right nostril. Once again, use the right thumb to block the right nostril and exhale through the left nostril. Inhale through the left nostril and continue this cycle (<http://www.chopra.com/nadi-shodhana-channel-clearing-breath>).

A fairly strong evidence base suggests that alternate-nostril breathing has therapeutic effects including decreased systolic blood pressure,^{29,30}

increased heart rate variability,^{29,31} improved metabolic resilience to stress,³² improved mental attentiveness,³⁰ and improved coordination.³⁰ While pursed-lip breathing and alternate-nostril breathing are two well-researched forms of therapeutic breathing that involve increasing airflow resistance, it is important to note that there are many other disciplines that involve modulating resistance. Singing, chanting, and praying are forms of therapeutic breathing that alter resistance by changing the shape of the vocal cords through which air passes. Some other breathing practices such as those of traditional Chinese medicine will suggest that the tip of the tongue be placed against the inside of the upper teeth. There is limited, if any, literature to explain how this would improve clinical outcomes; however, on a physical level, it does increase the resistance of the outflow of air from the mouth. From a Chinese medicine standpoint, the belief is that by touching the tip of the tongue to the back of the upper teeth, qi, or the body's "vital energy," may circulate more smoothly from the anterior Ren Mai meridian channel to the posterior Du Mai meridian channel, as these two energy channels meet at this location in the mouth.

Internal Imagery Linked to the Breathing Process

In addition to a focus on the timing and mechanics of breath work, imagery used in conjunction with breathing can have an added therapeutic benefit. The following are just a few examples in which breath work and imagery are used together. Qigong and Zen meditation practices will use Dan Tian-focused (in Chinese) or Tanden-focused (in Japanese) breathing techniques. The Dan Tian (specifically the “lower” Dan Tian) refers to an internal area of the body located between the level of the umbilicus and the pubic symphysis. From a traditional Chinese medicine standpoint, this area is critical to maintaining the body’s overall sense of balance and grounding. While there are many variations and traditions, Dan Tian breathing often involves the abdominal or diaphragmatic breathing, previously described, used in conjunction with a visualization of a ball of light located at the Dan Tian. With each inhalation, this focus of light may expand, while the exhalation either stabilizes the light or releases “smoke” or “darkness” from the body. While there is little, if any, research to support the therapeutic benefits of Dan Tian breathing, it is relevant to this discussion in that this practice overlaps to some extent with the realms of both guided imagery (see [Chapter 97](#)) and energy / biofield therapies (see [Chapter 116](#)), both of

which have their own health benefits in the literature.

One of the more researched areas of medicine that incorporates breathing techniques with imagery is the Mindfulness-Based Stress Reduction program (MBSR) as well as the Mindfulness-Based Cognitive Therapy program (MBCT), the latter of which combines the principles of MBSR with cognitive behavioral therapy. These programs have been shown to be effective in treating depression, anxiety, posttraumatic stress disorder (PTSD), pain, and stress.³³ “Mindful Breathing” is a part of the training program that allows for a present moment awareness of the breath and its physical effects on the body, thoughts, and emotions. One technique taught in MBSR is Tonglen meditation, which comes from Tibetan Buddhist practices and utilizes a combination of breathing exercises and guided imagery. Both techniques are also used in the 3-Minute Breathing Space practiced in MBCT.

Tonglen Meditation:

With inhalation through the nose, visualize breathing in one’s own anxiety, stress, and worries or those of the world. Then imagine these feelings/emotions being transformed within the body. With exhalation, visualize compassion and

serenity leaving the mouth.

3-Minute Breathing Space:

The first minute of this breathing practice involves bringing the attention to the present moment—body sensations, thoughts, and emotions. The second minute involves abdominal breathing and becoming aware of the sensations in the body that arise with this focus. The final minute of this practice involves envisioning / feeling not just the abdominal wall moving with each respiratory cycle but also the rest of the body—all the way to the fingers and toes.

Coordination of Breathing With Movement

One final classification of therapeutic breath work is intentional breathing coordinated with movement. While there are no particular studies showing the direct clinical benefits of well-coordinated breath with physical activity, these two practices need to be synchronized to elicit the most effective level of physical movement. Many examples of this coordination exist. When jogging or running, finding a breathing pattern timed to the footfall is important. Variations based on different coaching styles include inhaling for two to four steps and exhaling for the same number of steps or inhaling

for two to four steps and then exhaling for a different number of steps to ensure the start of exhalation on a different foot with each respiratory cycle.^{34,35} Either way, the breath is synchronized with the steps. Walking meditation also brings an intention to coordinating footsteps with the respiratory cycle.

As previously described, therapeutic breathing through pranayama is essential to the practice of yoga. The word pranayama is explained by B.K.S. Iyengar, who was known for founding the Iyengar style of yoga as well helping to bring the practice of yoga to the Western world: “Prana” means breath, respiration, life, vitality, energy, or strength. When used in the plural, it denotes certain vital breaths or currents of energy. “Ayama” means stretch, extension, expansion, length, breadth, regulation, prolongation, restraint, or control. “Pranayama” thus means the prolongation of breath and its restraint.² When combined with the movement practice of yoga, pranayama allows for smooth physical flow and mindful presence between and during the postures.

One last example is the kiai, or forceful expulsion of air in conjunction with a loud vocalization, used in martial arts. The term for this yell comes from Japanese traditions; however, it permeates other

styles as well. The kiai is often used in synchrony with offensive movements as a way of accentuating the groundedness and power of a particular technique.

Resources for Practicing Therapeutic Breathing

A variety of mobile device applications have been developed to assist with the practice of the principles of the previously described therapeutic breathing. One of the original applications developed by a division of the U.S. Department of Defense is called “Breathe2Relax.” Adjustments can be made to increase and decrease the pacing of the respiratory cycle. There are also instructional videos that explain how to perform abdominal breathing (although it is referred to as “diaphragmatic breathing” in the application). This particular application does not allow for changing the pattern of the respiratory cycle. Applications such as “Pranayama” and “Breath Pacer” have functionality in adapting pace as well as the pattern of breathing.

Patient Handout

A stepwise approach to decreasing sympathetic tone through therapeutic breathing

1) Posture

Correct posture is a critical component to effective therapeutic breathing. Typically, these techniques are practice in one of three positions – lying supine, sitting, or standing. Below are descriptions of proper posture in these positions.

Lying supine: lie flat on the back, arms by the side with palms facing upwards. The feet may be separated from each other by several inches. To add comfort and support, a pillow or bolster may be placed under the head and/or under both knees

Sitting: sit upright in a chair or on a cushion with the sitting bones resting closer to the edge of the chair or cushion. Both feet are flat on the ground, separated by a few inches, if seated in a chair. If sitting on a cushion the legs may be folded and resting on the ground or mat beneath the cushion. The back is straight – without slouching and also without over extending the back. Hands may rest palm down on the top of the knees. Shoulders may relax down and back – paying attention that the shoulders neither slouch forward nor strain backwards too much. Sometimes it is helpful to imagine a string connected to the top of the head gently pulling upwards, allowing the spine's natural curvature to be maintained.

Standing: similar to sitting, maintaining the integrity of a natural upright posture without straining is important to allowing for effective therapeutic breathing. Feet may be hip-width apart with a very slight bend to the knees. Similar positioning of the back, shoulders and head may be used as with sitting. Arms may rest lightly by the side of the body.

2) Breath awareness

Once the body has been positioned in a restfully alert way, the attention may shift to the breath. Place the left hand on the lower abdomen and the right hand on the chest. Begin by noticing how the hands move with a normal, unmodified breath. Particularly pay attention to which hand moves and how much that hand moves during each breath.

3) Abdominal breathing

After taking 5–10 "aware" breaths, shift the focus of the breath to the abdomen. With each inhale, allow the abdomen to expand outwards and with each exhale allow the abdomen to naturally contract inwards. The hand that is resting on the abdomen should be moving almost exclusively, while the hand on the chest has minimal movements. This attention to only moving the abdominal wall allows for cultivation of "abdominal breathing" and ultimately increased relaxation response during this breathing exercise. Of note, placing a book or a sandbag on the lower abdomen during reclining therapeutic breathing may help to provide some direction with regard to how to focus the movement of the breath on the abdomen versus the thoracic cavity.

4) Paced breathing

The next step is to incorporate a pace or tempo to the breath. The ideal respiratory rate to promote a relaxation response in the body is 6 breaths per minute or one respiratory cycle every ten seconds. Begin with inhalation for a count of two and exhalation for a count of two. Gradually increase to inhaling for a count of five and exhaling for a count of five, as this would result in one breathing cycle in 10 seconds, or 6 breaths per minute.

5) Patterned breathing

Lastly, to add some variation or pattern to the breath work, the lengths of inhalation and exhalation may be varied. One way to promote a relaxed state is to exhale twice as long as inhale. If breathing at 6 breaths per minute has become comfortable with practice, then inhaling for 3 seconds and exhaling for 7 seconds is an option and a good place to start practicing. Some practices involve varying the length of time that the breath is held between inhalation and exhalation as well as between exhalation and inhalation; however, research does not clearly state how variations in these pauses change the relaxation response.

CHAPTER 93

Low Back Pain Exercises

Brian Degenhardt, DO, and Coleen Smith, DO

The management of patients who seek treatment for low back pain can be difficult for any practitioner. The cause of low back pain can be the skin, soft tissue, or skeletal components. Low back pain can be referred from other sources, even visceral structures, or it can be secondary to postural decompensation.

History and physical findings should guide the practitioner to further evaluation and a treatment plan. Multidisciplinary treatment approaches are often necessary to facilitate healing for the patient with low back pain. Understanding of the patient's belief system about his or her low back pain may be an important component of recovery.¹ A treatment plan may include an exercise prescription. Movement, strengthening, and flexibility in patients with chronic lumbar back pain has demonstrated benefit.²

The traditional exercise prescription is a written description of the exercise, including the number of repetitions per set, number of sets per session, and frequency of sessions. This format is specific for strength exercises and has been applied to flexibility exercises. Many traditional exercise routines are assigned and performed too literally, without recognition of the subtle changes the patient experiences day to day in a healing exercise program. The goal of any complementary exercise recommendation is to encourage a dynamic interchange between the patient's awareness and the body. With appropriate education, the patient can become more sensitive to information being generated from the body and perform the exercise program in a much more precise, safe, and effective manner. Attention to the body's feedback mechanisms should be encouraged to allow the patient to modify any portion of the exercise prescription. This enables the patient to achieve optimal outcomes from the rehabilitation program. The outcomes of an exercise plan are to enhance flexibility, to minimize or to eliminate pain by

reducing muscle tension, and to improve strength, thereby encouraging joint stability. A complementary exercise plan for a person with lumbar back pain should include the following approaches:

- Breathing and relaxation training
- Flexibility training
- Strength training
- Coordination training

The National Institute of Health and Clinical Excellence (NICE) has reviewed the evidence of therapies that have been found to be most useful for low back pain. Of all therapies used for low back pain, the evidence for benefit with least harm supported an exercise program, manual therapy, and acupuncture.³

The Patient Handout at the end of this chapter contains examples of the exercises and approaches discussed here.

Breathing and Relaxation Training

Flexibility and relaxation techniques are often great starting points in a patient's exercise prescription. They calm the patient and foster awareness of information from the body that helps guide and individualize the exercise prescription. These exercises enhance diaphragmatic function and improve oxygenation, lymphatic flow, and autonomic nervous system regulation. To begin this component of the exercise prescription, the patient should choose a comfortable position and minimize distraction, perhaps by listening to soothing background music. The patient must use the abdominal diaphragm while taking a slow, deep breath and both the diaphragm and the rib cage as inspiration continues (see [Chapter 92](#), Breathing Exercises). The number of repetitions is likely to vary from day to day because stress and tightness also change daily. The patient needs to learn to recognize when the body is relaxed and ready to move on to other components of the exercise prescription. Once relaxation and focus have been obtained, participants should use deep breathing throughout all cycles of the exercise plan.

Flexibility Training

The flexibility portion of an exercise plan uses stretching to promote greater range of motion in all planes. Properly performed, stretching allows better neuromusculoskeletal function, promoting less pain and

more motion. To stretch properly, the patient must move to the point of tension and then perform deep breaths to gently stretch the tight tissue. It is important to move slowly and gently in and out of stretches. Other models describe how to stretch, but this approach minimizes the chance of exacerbating a patient's back pain by overstretching. Although an outline of a stretch gives the patient a guide to promote flexibility of specific areas of the body, the patient listens each day to the information the body is generating to determine where the tightness is. This approach allows the patient to modify a stretch and to maximize its effectiveness each day. The stretch is considered complete only after the patient appreciates a change in the tension while holding the stretch. This change can occur after only one or two repetitions, or it may need more repetitions, as determined by the patient through attention to the body's feedback system. Patients must stay within their pain limitations to prevent reflex muscle tightening and injury.

In most patients with chronic low back pain, specific instruction is necessary for hip flexors and extensors. For recovery from muscle tightness and to decrease pain, it is also important to achieve greater flexibility as well as a balance of flexibility between the same muscles on the two sides of the body and between reciprocal muscles, particularly with the hamstring, iliopsoas, and piriformis muscles.

Strength Training

Strengthening exercises encourage active use of muscle groups, leading to better muscle tone and greater strength. It is important not to sacrifice flexibility for strength; the two are equally important for proper lumbar mechanics in patients with low back pain. The clinician can evaluate the patient's strength clinically by having the patient perform isometric contractions against the physician's resistance to determine whether there is gross asymmetry of strength. Asymmetry of strength may lead to or be secondary to hypertonicity in one muscle group and weakness in the opposing muscle groups. Once strength asymmetry or weakness has been diagnosed, specific instructions must be given first to stretch the hypertonic muscles and then to motivate the patient to exercise the weakened muscles. Patients are often unaware of this local muscle weakness. In many exercise programs, patients focus on rote repetition of exercises, strengthening hypertonic muscles rather than conditioning weakened muscle groups. It can be beneficial for the patient with hypertonic lumbar extensors to perform abdominal curl-ups to

strengthen weakened antagonistic abdominal muscles after stretching the lumbar erector spinae muscles. Both exercises decrease hypertonicity in the lumbar extensor muscle group.

In many cases of lumbar back pain, strengthening activities must start out as isometric exercises instead of the typical isotonic exercises because isometric exercises are safer. Isometric exercises allow the origin and insertion of the involved muscle to remain in constant position while the patient presses against a resisting force that is equal to the patient's force.

An example of an isometric exercise is pushing against a solid wall without moving. Isometric exercises are often useful for patients who have arthritis, in which joint movement causes pain and limitation.

Coordination Training

Differences in proprioception exist in individuals with and without back pain. Coordination training in patients with low back pain is based on the observation that the response of a patient's spine to stress causes the postural muscles to tighten and the antagonist muscles to react with inhibition, weakness, and atrophy.⁴ Coordination training is imperative for improvement of overall postural balance in the patient with lumbar back pain. Proprioceptive education in patients with low back pain begins with improving ankle, knee, and pelvis coordination, perhaps through the use of a wobble board or fitness ball. The physician must remind the patient of safety precautions at the start of coordination training. Basic coordination exercises can usually be taught in the office and then performed by the patient independently. Advanced proprioceptive training usually requires supervision to ensure correct technique and safety.

Key Web Resources

The Egoscue technique addresses strengthening and balancing of the whole body unit to reduce back pain. A book that includes back stretching exercises from this method is Escogue P, Gitnes R: <i>Pain Free: A Revolutionary Method for Stopping Chronic Pain</i> . New York: Bantam Books; 2000.	http://www.egoscue.com/
Video on how Feldenkrais therapy can be used for low back pain from the University of Wisconsin Integrative Medicine Program.	http://www.fammed.wisc.edu/feldenkrais/low-back-pain/

Patient Handout: Exercise Program for Low Back Pain

1. Listen to your body signals; the amount of exercise may vary from day to day. Always stay within pain limitations when performing any exercises.
2. It is important to breathe properly. While performing all aspects of your stretching program, breathe into your abdomen and feel the sides of your rib cage expand.
3. Move slowly and gently during stretching exercises. Do not bounce!
4. If you experience pain during or after a specific exercise, decrease the duration and intensity of the exercise. If the pain reoccurs, eliminate that exercise from your routine and consult with an exercise professional.

Breathing and Relaxation Exercises

Breathing and Body Stretch

1. Lie on your back. Place your hands on your abdomen. Relax. This is your time to focus on yourself.
2. Breathe deeply into your abdomen so that your hands rise and fall with each breath. Feel the sides of your rib cage expand.
3. Hold your breath in for 3 to 5 seconds, and then exhale slowly.
4. Repeat steps 2 and 3 slowly and gently for 2 minutes.
5. Place your arms above your head and reach upward as you point your toes downward.
6. Hold the stretch for 5 slow, deep breaths.
7. Slowly return to the starting position, and repeat the stretch until the tissue tension experienced during the first stretch has resolved (often 2 times).

Stretching Exercises

Pelvic Tilt Exercise

1. Lie on your back. Bend your knees, placing your feet flat on the floor and allowing your knees to touch.
2. Roll your pelvis backward by pushing your belly button toward your spine.
3. Hold this position for 20 to 40 seconds or until fatigued, while breathing slowly and deeply.
4. Release slowly. Repeat.

Low Back Flexion Exercise

1. Sit. Curl your spine forward one vertebra at a time, from the head, to the neck, chest, and low back. Stop at and hold at any area of muscle tightness.
2. Hold position for 3 deep breaths or until the tissue relaxes.
3. Gently return to a sitting position.
4. Repeat at least 2 times, likely curling farther than the time before, until the tissue tension experienced along the spine has resolved, or if soreness has developed. Be patient with this stretch. It may take weeks before you can easily stretch all the way down the back.

Low Back Extension Exercise

1. Lie on your stomach with your feet shoulder-width apart and your toes pointing downward.
2. Bring your elbows under your shoulders to support your weight.
3. Gently raise your head and slowly arch your back, letting your belly relax forward toward the floor. Go only as far as is painless until your muscles are more flexible.
4. Hold position and breathe into your abdomen for at least 3 deep breaths or until the tightness in your back releases.
5. Repeat until the tissue tension experienced during first stretch has resolved (often 2 times).

Cat/Dog Stretch Exercise

1. Kneel on the floor with your knees hip-width apart. Place your hands on the floor shoulder-width apart and palms down.
2. Slowly arch your back from your tailbone to your upper back like a cat stretches. Allow your head to lower comfortably. Hold position for 3 slow breaths.
3. Slowly release the stretch in the reverse order.
4. Once in the starting position, lift your buttocks upward, let your belly relax forward toward the floor, and slowly look toward the ceiling.
5. Hold this position for 3 breaths and gradually return to the starting position.
6. Repeat until the tissue tension experienced during the first stretch has resolved (often 2 times).

Hip Flexor Stretch Exercise

1. Kneel on one knee. Bend your other knee to 90 degrees and place your hands on it for balance.
2. Lean your trunk forward while keeping your low back straight.
3. Hold this position for 3 slow breaths, and then slowly return to the starting position.
4. Repeat until the tissue tension experienced during the first stretch has resolved (often 2 times).

Piriformis Exercise

1. Lie on your back with your legs straight. To stretch the left side, bend your left knee and place your left ankle over your right knee with the left foot on floor.
2. Place your left hand on the left side of the pelvis and your right hand on your left knee.
3. Slowly pull your left knee across the right leg, feeling the stretch in your left buttock. Keep your pelvis from rotating off the floor with your left hand.
4. Hold this position for at least 3 slow deep breaths.
5. Slowly and gently return to the resting position.
6. Repeat steps 1 thru 6 until the tissue tension experienced during the first stretch has resolved (often 2 times).
7. Repeat with the right leg.

Hamstring Exercise

1. Lie on your back with your legs straight.
2. Gently bend one knee and grasp behind the thigh. Do not lift your pelvis or other knee off the floor during this exercise.
3. Straighten your knee. Go only as far as your flexibility will comfortably allow, and hold for 3 slow breaths.
4. Slowly lower your leg to the floor, and repeat for the other leg.
5. Repeat each side until the tissue tension experienced during the first stretch has resolved (often 2 times).

Strength Exercises

Abdominal Curl-Up Exercise

1. Lie on your back with your knees comfortably bent and your arms placed across your chest.
2. Keeping your neck and shoulders relaxed, lift your rib cage from the floor. Move only as far as your body will allow without pain. Hold position for 1 or 2 deep breaths.
3. Slowly and gently return to resting position.
4. Repeat until your abdominal muscles weaken or you notice that you are using your neck and shoulder muscles to perform the exercise.

Gluteus Maximus Exercise

1. Lie on your stomach with your toes pointing downward and your legs straight.
2. Slowly raise one leg as far as is comfortable. Keep your pelvis flat on the floor and the buttock on that side tight.
3. Hold position for 3 deep breaths, or until muscles feel fatigued.
4. Gently return to the resting position. Repeat with the other leg.
5. Repeat with both legs until your muscles feel fatigued.

Gluteus Medius Exercise

1. Lie on one side, keeping the leg that is on the floor straight or bent at the hip and knee and your top hand on the floor in front of you to maintain stability.
2. Raise your upper leg as far as is comfortable and painless, using your hip muscles only.
3. Hold this position for 3 slow breaths, and slowly return the leg to the resting position.
4. Repeat until fatigued or until you are using other than your hip muscles, and increase repetitions as tolerated.
5. Turn to your other side and repeat steps 1 through 4.

Coordination Exercises

Standing on-One-Leg Exercise

1. Stand on one leg and maintain your balance. Keep your back straight and your arms across your upper chest.
2. Hold this position for 1 minute while continuing slow, deep breaths.
3. Gently return to resting position and repeat 2 times on each leg.
4. After mastering this exercise, perform step 2 with your eyes closed.

Relaxation Techniques

Vincent J. Minichiello, MD

“... stress, in addition to being itself and the result of itself, is also the cause of itself”

F. ROBERTS, “STRESS AND THE GENERAL ADAPTATION SYNDROME,” BRITISH MEDICAL JOURNAL, JULY 8, 1950, PAGES 104-105, IN AN ATTEMPT TO UNDERSTAND THE NEW TERM “STRESS” AS USED BY DR. HANS SELYE¹

“... it is not the potential stressor itself but how you perceive it and then how you handle it that will determine whether or not it will lead to stress.”

JON KABAT-ZINN, PHD, FULL CATASTROPHE LIVING, REVISED EDITION, PAGE 290²

“... mind body science has now reached a stage where it should be accepted as the third major treatment and prevention option, standing as an equal alongside drugs and surgery in the clinical medical pantheon.”

Herbert Benson, MD, Relaxation Revolution, Preface.³

Introduction

As suggested by Dr. Benson in the above excerpt, mind-body medicine—within which relaxation techniques play a central role—currently has an adequate foundation in evidence-based medical practices to be an important consideration in the treatment of a vast number of disease

states as well as in the maintenance of overall wellbeing. This chapter will briefly review the history and science of stress and its opposite—relaxation. A small sampling of the research in these fields over the past half century will be introduced followed by a discussion of a variety of relaxation techniques, advice about how to prescribe them, and some resources for practice. Using these techniques on a regular basis allows for relaxation to become a habituated response to the stressors of both daily life and chronic disease, ultimately promoting systemic health and healing.

A Brief History of Stress and Relaxation

The concept of stress in relation to the health of human beings spans back to ancient civilizations. Hippocrates is attributed with the statement that disease not only involved *pathos* (suffering) but also *ponos* (toil), suggesting that illness is not purely an organic process.⁴ While this understanding may have been inherent in ancient Greece, as Western medicine evolved, a schism developed in the scientific community when René Descartes, the 17th century mathematician, proposed that the mind and body are two distinct “substances” in *The Principles of Philosophy* written in 1644. Not until the early 20th century did this theory come into question. In 1926, Dr. William Cannon wrote an article entitled, “Physiological Regulation of Normal States: Some Tentative Postulates Concerning Biological Homeostatics,” in which he discussed what is known today as the fight-or-flight response. He proposed that mammals have the ability to react to outside stimuli that disturb the body’s “homeostasis” by increasing levels of hormones such as norepinephrine, which in turn create life-saving physiological changes including increased heart rate, respiratory rate, blood pressure, etc.⁵ In 1936, Dr. Hans Selye, a Hungarian endocrinologist, built on Cannon’s work, publishing an article in the journal *Nature* that described his research on rats showing that when these animals were exposed to different “stressors,” such as cold, surgical injury, or toxic drugs, their bodies all yielded the same pathological changes on both macroscopic and microscopic scales.⁶ In his 1956 book *The Stress of Life*, Dr. Selye defined stress as “the nonspecific response of the body to any demand made upon it.”⁷ Henceforth, “stress” became a part of the international vernacular. As the damaging effects of stress on the body were more and more understood, Dr. Herbert Benson, a cardiologist at Harvard Medical School, discovered the antidote to stress, which he termed the *relaxation*

response. In the 1975 book with that title, he described the relaxation response simply as the opposite of the fight-or-flight response. This landmark book discussed research proving that elicitation of a state of relaxation will help decrease blood pressure, heart rate, respiratory rate, and metabolic rate.⁸ Since its publication, many other studies have shown the benefits of relaxation in treating various disease states (see the section [The Science of Stress and Relaxation](#)). Most recently, relaxation research has moved in the direction of epigenetics as studies have begun to show that relaxation training can modify gene expression.

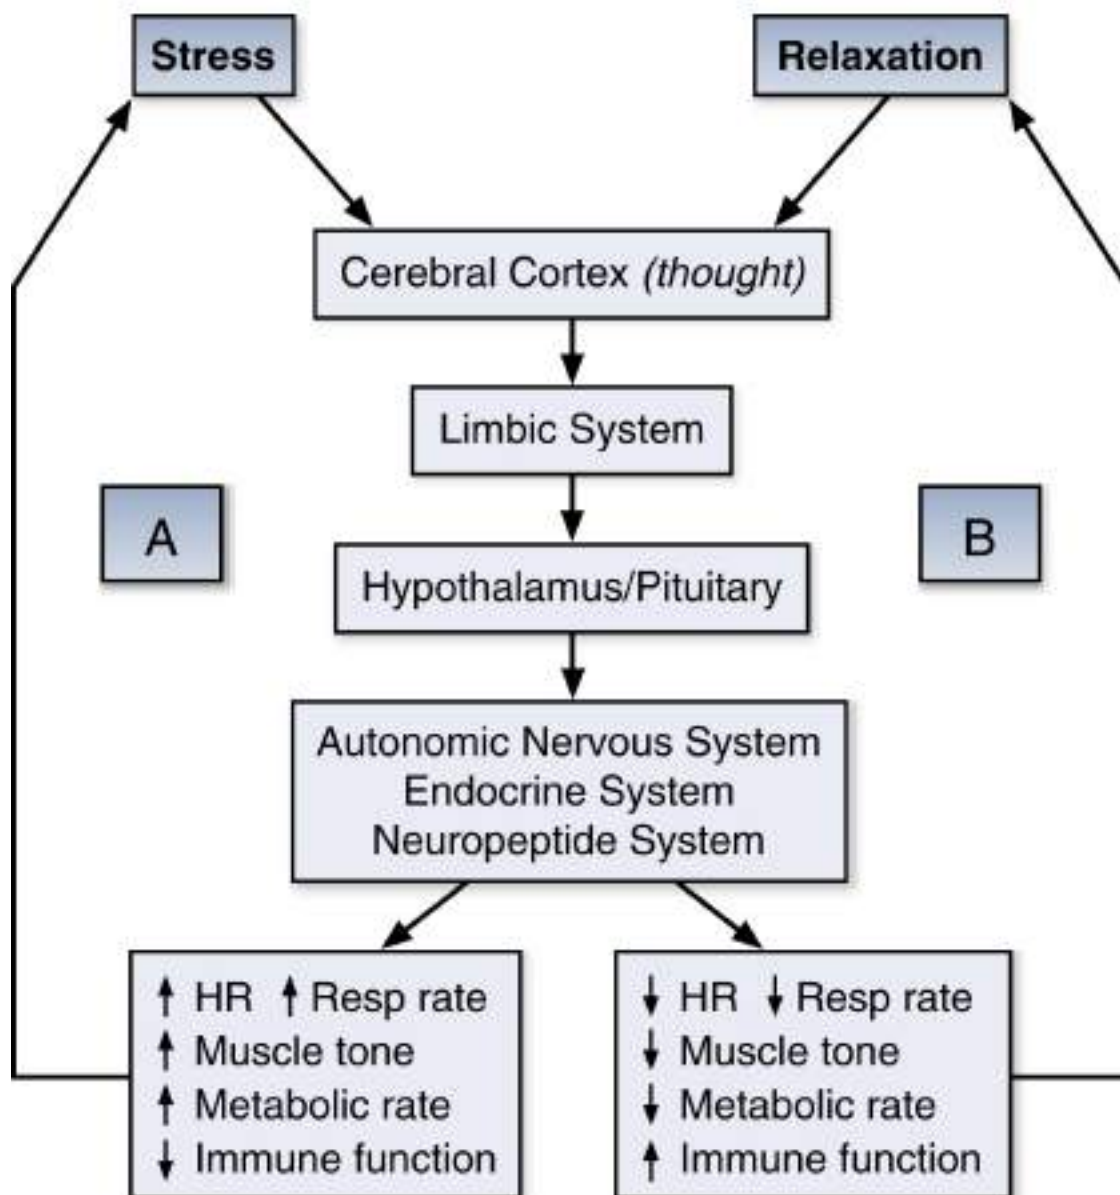

FIG. 94.1 A simplified chart showing the cyclic mind-body and body-mind influences of stress (A) and relaxation (B) on health. As our body experiences the physical responses to stress and relaxation, our central nervous system remembers them, thus causing a continuation of the cycle with long-term positive or negative physical consequences. *HR*, heart rate; *Resp*, respiratory.

The Science of Stress and Relaxation

Both the flight-or-fight and relaxation responses involve a complex interplay of endocrine, immune, neurological, and psychological systems ([Fig. 94.1](#)). From a neurological standpoint, when a stress response is elicited, the sympathetic nervous system is activated—norepinephrine is released from the locus coeruleus in the brainstem, triggering systemic changes including increased blood pressure, increased heart rate, increased respiratory rate, increased glucose production, and decreased stimulation of the gastrointestinal tract. The hypothalamus in the brain is also triggered as a result of the stress response, allowing for downstream endocrine-related hormonal changes as a part of the hypothalamus-pituitary-adrenal axis. The hypothalamus releases corticotropin-releasing hormone (CRH), which triggers the anterior pituitary gland to release adrenocorticotrophic hormone (ACTH), which acts on the adrenal glands and ultimately leads to an increase in systemic cortisol. Cortisol then helps with the redistribution of glucose to vital organs, which is needed to cope with the stress response. The immune system is intricately connected as well because elevated levels of cortisol have an immunosuppressive effect, primarily on T cells, thus leading to an increased potential for infection. Increased cortisol levels inhibit interleukin (IL)-2 (a T-cell growth factor), induce T-cell apoptosis, and impair release of these immune cells from lymphoid tissue.⁹ In a healthy system, after the acute stress response is elicited, cortisol will become part of a negative feedback loop, suppressing further release of CRH and ACTH.

While all of these physiological changes are beneficial in the case of acute, short-term stressors, with continually elevated stress levels, a chronic stress syndrome will evolve. Dr. Hans Selye described this progression in what he termed the *general adaptation syndrome* ([Fig. 94.2](#)).

FIG. 94.2 General adaptation syndrome.

General Adaptation Syndrome: The first phase of this syndrome is the “alarm” response, in which the body is shocked and then attempts to adapt to the stressor. The second “resistance” phase involves further adaptation to the stressful stimulus. As long as the stressor is temporary, this resistance phase will result in a return to the body’s homeostasis; however, if the stress continues, the body’s resistance will decrease, ultimately resulting in the third phase, which Dr. Selye described as the “exhaustion” phase.

Chronic stress will thus result in more permanent physiological changes, including hypertension, insulin resistance, and chronic immunosuppression, among many other conditions.

So how does relaxation fit in? From a physiological standpoint, the relaxation response—as it is elicited by any of the techniques outlined in [Table 94.1](#)—will produce the opposite biochemical and hormonal changes that result from the fight-or-flight response. From the standpoint

of the general adaptation syndrome, regular practice of relaxation techniques improves a person's overall resistance to stressors and promotes homeostasis. While the exact mechanism of action is still unclear, over the past 40 years since the realization of the relaxation response, numerous high-quality studies have shown the benefit of relaxation techniques in treating the following conditions: headaches,^{10,11} hypertension,¹²⁻¹⁴ premature ventricular contractions,¹⁵ anxiety,¹⁶⁻¹⁹ depression,¹⁷⁻²¹ premenstrual syndrome,²² female infertility,^{23,24} insomnia,²⁵ diminished cognition,²⁶ irritable bowel syndrome (IBS),^{27,28} and chronic pain.²⁹ Two seminal papers in the field of mind-body medicine suggest possible mechanisms by which relaxation produces the previously described effects. One article, published in 2006, suggests that the relaxation response increases fractional exhalation of nitric oxide, an outcome that has been associated with antibacterial, antiviral, and cardioprotective effects on the body.^{3,30} Another article published in 2008 showed that the relaxation response can modify gene expression by counteracting the cellular changes that occur as a result of chronic stress.³¹ Other studies continue to build on this research with some data to suggest that meditation techniques may suppress stress-induced inflammatory responses as well as upregulate mitochondrial function, insulin secretion, and telomerase maintenance.^{32,33} More research is necessary to determine these as well as other possible mechanisms by which relaxation techniques have a salutogenic effect on the mind-body unit.

TABLE 94.1**Relaxation Techniques**

Relaxation Technique	Brief Description	Resources
Autogenic Training	Developed by German psychiatrist Johannes Schultz, this technique promotes relaxation by training the body to decrease sympathetic tone via self-suggestions such as “my arms and legs are heavy.” Similar to guided imagery and hypnosis, this technique involves visualization, and while it is often self-guided, it may also be facilitated by a trained practitioner.	Script to use for self-guided autogenic training: http://www.stressreliefworks.com/autogenic-relaxation.html The British Autogenic Society: http://www.autogenic-therapy.org.uk/
Covering Prayer	A contemplative form of prayer originating from Christianity that involves focusing on a “sacred word,” acknowledging other thoughts and then letting them go, and, in general, being more receptive in communication with God. Though its origins come from as early as the 1st century AD, this practice has been brought to modern religious practice by Father William M. Barr, Basil Pennington, and Albert Thomas Keating.	A resource for learning about covering prayer and a listing of workshops: http://www.contemplativemethod.org/ Covering Prayer: Promoting an Ancient Christian Prayer Form, by M. Basil Pennington Open Mind, Open Heart, by Thomas Keating
Clitoral Hypnosis	Similar to the practice of guided imagery is that this technique may be self-guided or guided by an outside source. Typically, hypnosis is individualized and involves an induction phase, the visualization/relaxation itself, and then guidance over a five-minute state-of-mind.	See Chapter 97 http://www.healingwithhypnosis.com American Society of Clinical Hypnosis Practitioner Search Engine: http://www.asch.net/Pdf/MemberSearch.aspx
Exercise	Just as tai chi and yoga are able to elicit a relaxation response, aerobic exercise that involves a focused mind and coordination of physical activity with breathing can also help with stress management.	See Chapter 91 Beyond the Alexander Technique, by Herbert Benson
Guided Imagery	A variety of techniques involving visualizations—either self-guided or from an outside source—that can enhance relaxing thoughts and emotions.	See Chapter 97 http://www.healingwithhypnosis.com http://www.healthymedia.com/keyword/relaxation , http://www.healthymedia.com/keyword/relaxation Academy for Guided Imagery Practitioner Search Engine: http://www.healthymedia.com/keyword/relaxation
Meditation	This is a general term that encompasses a great variety of techniques originating from multiple cultures and belief systems, each with their own body of research proving improved health outcomes related to their ability to help manage stress. In general, these techniques promote relaxation by utilizing principles discussed in this chapter, including an active participation in the meditation, a “letting go” of all stress, and consistent practice. Some of the commonly practiced forms of meditation include mindfulness meditation, transcendental meditation, and Zen meditation.	See Chapter 100 Phil Callahan’s Living: Using the Wisdom of Your Body and Mind to Live Stress, Pain and Illness, by Jon Kabat-Zinn (introduction to Mindfulness Meditation) http://www.tm.org (introduction to transcendental meditation [TM] and source for finding local TM practitioners) Zen meditation centers may be searched by city: http://www.buddhism.com/meditation-for-beginners (a free website designed to introduce the basic concepts of meditation in general)
Music Therapy	This practice uses music to induce relaxation. Depending on the individual, this type of therapy may be receptive or active and may be practiced alone or with the assistance of a trained music therapist.	American Music Therapy Association Practitioner Search Engine: http://www.musictherapy.org/about.html
Progressive Muscle Relaxation (PMR)	This technique involves bringing one’s attention to various parts of the body followed by a glowing then relaxing each part of the body in a progressive fashion. The relaxation portion of this practice is typically coordinated with European breathing.	Audio files for PMR practice: http://www.bbc.com/1/health/2014/04/140416_fmri_relaxation http://www.healthymedia.com/keyword/relaxation http://www.healthymedia.com/keyword/relaxation
Tai Chi (Tai Ji) Qigong	Tai Chi is a Chinese martial art practiced typically with slower, intentional movements coordinated with breathing. There are traditionally five “Taijilian” or styles of tai chi. Qigong, translated as “cultivation of qi,” usually involves stationary breathing movement techniques with a goal to reach promoting healthy flow and development of qi, or “vital energy.” Tai chi, when practiced well, may be considered a form of qigong.	The Way of Qigong, by Kenneth Cohen—an introduction to the history, philosophy, and practice of Qigong The Harvard Medical School Guide to Tai Chi, by Peter Wayan Tai Chi and Qigong Teacher Search Engine (an exhaustive, but easy-to-use, starting place): http://www.mindandbody.com/TaiChiQigongClass.asp

Relaxation Technique	Brief Description	Resources
Therapeutic Breathing	As the basis for many of the relaxation techniques described, therapeutic breathing begins by simply bringing an awareness to one’s natural respiratory mechanism. A relaxation response may be further elicited by practicing abdominal breathing, changing the respiratory rate to 6 breaths/minute, as well as by breathing with an inhalation/exhalation ratio of 1:2.	See Chapter 92 http://health.usci.edu/~wainfield/scarl/awariness-of-breathing/ http://www.dnews.com/news/ART00521/ther-breathing-exercises.html
Yoga	A collection of practices originating from beliefs that involve not only physical postures (asana) but also focuses on breathing, relaxation, diet, and meditation. There are many styles with variations in the way that the asanas are practiced. Yoga therapy is a newer modality that often involves one-on-one instruction to individualize the yoga practice for a particular condition or medical problem. Relaxation Technique Essentials

As outlined in [Table 94.1](#), variety of relaxation techniques have been utilized for millennia with the purpose of promoting overall wellbeing, preventing illness, and treating disease. What are some of the common components of these techniques?

Active Participation

While the word “relaxation” may sound like a person need not do anything and could simply become “flaccid” or “passive” in mind and body, the opposite is in fact true for these relaxation techniques to have a positive health effect. Whether the technique involves movement or not, both the mind and the body are engaged. In practicing tai chi, for

example, when there are pauses in the movements, the arms and hands do not become relaxed in the sense that they are flaccid. Instead, there is an intention, awareness, and mindful presence within the still and “relaxed” limbs and entire body. Likewise, when sitting to meditate, the mind remains active even in stillness. Though meditation may sometimes lead to falling asleep, the state of mind during sleep will not elicit the physiological changes produced by practicing with an alert and relaxed mind.

“Let-It-Be” Mindset

This aspect of relaxation techniques is explicitly mentioned in practicing mindfulness meditation as well as in eliciting the relaxation response; however, it is central to other practices as well. As human beings, the mind will naturally wander—for some people more than others. Jon Kabat-Zinn, founder of the Mindfulness-Based Stress Reduction program, describes mindfulness meditation as “paying attention on purpose, in the present moment, and nonjudgmentally, to the unfolding experience moment to moment.”³⁴ A common image used in this particular style of meditation is that of the person meditating being a large mountain—steady and unchanging—as clouds (thoughts) float by, everpresent but not affecting the mountain. Another way to describe this “let-it-be” mindset is “passive concentration,”⁸ which, according to Herbert Benson, is one of the most important steps in the practice of the relaxation response.

Duration and Frequency of Practice

One final commonality to the majority of relaxation techniques is the requirement of regular (ideally daily) practice over an extended period of time (months to years). In the short term, practices such as autogenic training or yoga may help decrease stress and overall sympathetic tone; however, with consistent practice, there is a greater possibility of developing increased baseline resistance to stressors as well as increased ability to call upon a relaxed response when faced with an acute stressor. Also, as with any skill, once a person stops practicing a particular relaxation technique, the physiological benefits will also diminish. The importance of this “dose response” of relaxation techniques is described in multiple studies.³⁵⁻³⁷

Prescribing Relaxation Techniques

When recommending relaxation techniques to patients as part of their care plan, it is important to select practices in the context of not only the patients’ personal health, but also in relation to their daily lives, families, communities, and belief systems. Following are some questions to raise when discussing relaxation techniques with patients based on these various contexts and recommendations based on the answers.

Context	Questions to Ask	Recommendations
Personal	What is your medical history? Do you prefer being a part of a group or alone? What, if any, relaxation techniques have you tried in the past?	Consider matching a relaxation technique that has evidence for a particular medical condition. Consider tai chi, yoga, qigong, and meditation classes if a group environment is preferred—many of these can also be practiced in private once introductory knowledge is obtained. Be mindful of the patient’s positive or negative experiences with certain techniques in the past.
Daily Life	What type of work do you do? Do you prefer waking up early or staying up late?	To help make specific and attainable goals regarding their regular practice of relaxation techniques, consider the structures of patients’ day-to-day lives.
Family	How is your relationship with your partner, children, and/or extended family? What are their levels of interest/previous experience with relaxation techniques?	Consider the level of activity or stress in the home environment in determining when to practice relaxation. Involving the family in a regular practice may also be of benefit in maintaining a new relaxation routine.
Community	What schools, studios, and community centers are available where you live? How safe do you feel in your environment?	As a clinician, maintain awareness of the local community and the reputable resources for learning relaxation techniques in the area. In areas that are less safe or where it is harder to find these resources, consider teaching these techniques in the clinic setting and encourage regular home practice.
Belief Systems	What, if any, religious or spiritual beliefs do you have?	Working with a patient’s belief system may enhance the relaxation experience, e.g., centering prayer for those with a Christian faith.

Key Web Resources

A nonprofit online resource that includes definitions/descriptions of a variety of relaxation techniques, scripts for practicing these techniques, as well as links to free audio files for meditation, guided imagery, and others. Developed by James Segal, PhD.	http://www.balypacific.org/center/centerforrelaxation-techniques-for-stress-reduction.html
A website developed by the University of Texas, Austin, to promote student wellness. Includes free access to and a file of relaxation techniques including deep breathing, progressive muscle relaxation, guided imagery, and other meditations.	http://cshc.utexas.edu/health/bodylib.html
A collection of free audio files and video lectures discussing the keys of mindfulness practice. Includes guided meditations of varying lengths developed by the University of Wisconsin-Madison Integrative Medicine and Mindfulness Center faculty.	http://www.fammed.wisc.edu/mindfulness/
“Mindquest” Mobile Application A mobile application that introduces the listener to mindfulness meditation in a step-by-step fashion. A good resource for people with no previous background in contemplative practices. The first 10 recordings are free.	http://www.hondapass.com
“ThinkBility 2” Mobile Application Designed for the busy mind and commuter on-the-go person, this application has a large selection of guided meditations that help to promote mindfulness in a variety of communitarily activities. Costs \$3.99.	http://thinkbility.com/

CHAPTER 95

Self-Hypnosis Techniques

Steven Gurgevich, PhD

Reviewing the many conceptual and theoretical perspectives that would provide a concise definition of hypnosis is beyond the scope of this chapter. The reader is directed to a special issue of the *American Journal of Clinical Hypnosis*¹ that is devoted entirely to the competing and integration of ideas for a definition of hypnosis. This chapter will simply describe hypnosis as a system or collection of methods that allows us to enhance the communication and sharing of information between and within the mind-body. Because the body “hears” everything that enters the subconscious mind, these methods are a way of accessing and influencing subconscious effects on the body. We can do this entirely by ourselves, with the help of others, or through the use of learning materials such as books, videos, and audio programs. Whether someone helps us (such as a trained therapist) or we do it by ourselves, all hypnosis is self-hypnosis.

One of these methods is trance. A hypnotic trance is a state of consciousness in which our focus of awareness allows us to become greatly absorbed in the experience and sensations of our ideas. A daydream is a good example of trance. In a daydream, we are aware of where we are and what we are doing, but at the same time, we are absorbed in the experience and sensations of the daydream—our thoughts, ideas, and images. As a state of absorption, a hypnotic trance and a daydream are very similar; or at least it feels that way to the patient. Although most daydreams might occur spontaneously when we are bored or have too little to actively think about, a hypnotic trance is a state of consciousness we create deliberately. One user-friendly description might be “daydreaming with a purpose” or “an intentional daydream.” Learning to use this exquisite tool to enhance mind-body communication for healing, greater performance, comfort, and relaxation is easy and beneficial.

Hypnosis includes many different ways of creating that daydream-like state of mind or focused concentration. Among them are induction techniques; imagery methods; focusing concentration; and forms of passive concentration, relaxation, and meditation. Once we learn them and discover how to achieve the desired results, we own those abilities for as long as we practice them.

What kinds of abilities might we learn this way? A very short list includes overcoming anxiety on an airplane, relaxing the smooth muscle of the intestines for more comfortable digestion, relieving pain, healing skin conditions, improving sleep patterns, changing habits, improving concentration skills, alleviating nausea associated with chemotherapy, improving surgical outcomes, and unlearning physiological stress response patterns. The list of applications where hypnosis can be beneficial is almost endless. Andrew Weil, MD, says, "In general, I believe that no condition is out of bounds for trying hypnotherapy on."

Although there are many different techniques to access subconscious influence on the body, for practicality, this chapter focuses on one process of steps that primary care providers can easily use and teach their patients. This process requires the following six main steps:

- **Educate** to remove preconceived fears and prevailing misconceptions
- **Tailor** to match images, ideas, and hypnotic suggestions to the individual
- **Induce trance:** e.g., eye-fixation, breath technique, thumb-and-finger release technique to trigger trance and staircase technique to help with progressive muscle relaxation and deepening of trance
- **Utilization:** Use trance for a specific purpose (headache, surgery, gastrointestinal disorders, etc.)
- **Re-alert** to guide the patient out of trance
- **Debriefing** to develop insight into what worked and how to implement future techniques

The Six Main Steps

Educate

To remove any fear and misunderstanding and to achieve a better clinical response, you must take time to educate your patient about hypnosis. Your first task is to dispel the myths and misconceptions. The most predominant misconceptions and their corrections are as follows.

- That hypnosis is "done to someone." Hypnosis is not done to anyone; it

may be guided and taught, as all hypnosis is self-hypnosis.

- The subject loses consciousness and conscious control: At all times, the subject is consciously aware of where he is and what he is doing.
- The subject can be made to do things or to reveal things that she ordinarily would not do in a waking state: The subject is very much aware and is always in control of what she is choosing to experience.
- The subject must be gullible or weak minded to be hypnotized: Again, this concept is false. Research has shown that some of the best subjects are those with greater intellectual capacity, open-mindedness, and creativity.

The next task is to define trance as a heightened state of conscious awareness in which an individual is more prone to suggestion.

Emphasize that everyone has experienced trance many times. One example is daydreaming. Another is being absorbed in a good movie, when we are less aware of activities around us and more responsive to suggestions emanating from the screen. We might jump at the sudden appearance of the hideous alien monster or we might cry at the plight of a character. At the same time, we are always in control and can go get popcorn if we want.

Like being absorbed in a good movie, hypnosis involves three factors: absorption, dissociation, and suggestibility. Through an induction technique, the subject becomes fully absorbed in the matter at hand, resulting in dissociation from various distractions. This creates a heightened state of awareness that allows the subject to be more receptive to suggestions that can influence physical and behavioral changes. In addition to these factors, the vital ingredients² that enhance therapeutic effectiveness are the patient's motivation, belief, and expectations for success.

Hypnosis requires three key factors: absorption, dissociation, and suggestibility and requires three vital ingredients: motivation, belief, and expectation.

Tailor

The talented therapist tailors the hypnotic technique to the subject's unique needs and beliefs. The more the technique relates to the subject, the more that person will accept hypnosis and find it useful. In contrast, if you use a technique that encourages an image associated with anger or

fear or that is simply foreign to the patient, the process is counterproductive. Think of tailoring as your effort to make the hypnotic experience personally familiar to the subject.

Although there are more complex ways of performing this tailoring, here are a few easily remembered questions or suggestions you can use to help personalize the hypnosis to a patient's beliefs and interests:

- Imagine a favorite place, one that brings comfort and a sense of peace.
- What is your favorite color?
- What are some of your favorite activities and pastimes?
- What kinds of events and activities give you the greatest pleasure?
- What are the times and places where you feel safe and peacefully at ease?

Testing Hypnotic Talent

In familiarizing yourself and your patients with their current level of hypnotic talent, inform them that you would like to explore their present ability for "mind-body communication" with one or both of these simple procedures.

The Hand Clasp

- Clasp your hands together and interlace your fingers. Imagine that your hands are glued together. Feel how tight the glue holds them.
- Now imagine that the glue between your hands has grown even stronger, or you can imagine that your hands are in a vise that keeps them together.
- Continue to concentrate on how firmly your hands are stuck together. Perhaps you have felt how strong superglue is. Keeping the "stuckness" firmly in mind, try to pull your hands apart while focusing on the image or idea of your hands being stuck together.
- If your hands remain stuck to one another, let yourself play with the idea and how well your body responded to your thoughts.
- Then, imagine your hands free of each other and gently pull them apart.
- If your hands did not remain stuck together, even a little, play some more and see what happens. Sooner or later, your subconscious will accept the idea and image in your mind. The key is to make the image in your mind the dominant idea as you do this.

Ask your patient, were you able to feel as if your hands were stuck together, even momentarily? The greater the ability, the more the

hypnotic talent.

Ideosensory Experience

The ideosensory experience refers to the ability or capacity of the mind-body to respond to the idea or imagination of sensory stimuli (idea + sensory = ideosensory), that is, an idea in the mind that produces a sensory response. Proceed by speaking through each step as you help your patient develop the image as fully as possible in the imagination.

- Imagine that you have a freshly picked lemon in your hand. Imagine holding the lemon, feeling its weight, examining the texture of the skin and the color.
- Imagine scraping the skin enough to release some of the oil from the skin. If you are demonstrating this to your patient, squint or act as if lemon oil is squirting from the rind as you scrape it.
- Imagine the smell of the freshly released lemon scent.
- Now imagine that you are placing the lemon on a cutting board and slicing it slowly into two parts.
- See, in your imagination, the lemon juice released as the knife cuts through the lemon.
- Picture the lemon juice on the cutting board as you pick up one half of the freshly cut lemon.
- Imagine bringing the lemon half to your mouth and licking the juicy surface with your tongue.
- If needed or desired, have the patient close the eyes and repeat the instructions.

Ask the patient, could you feel the weight of the lemon? Were you able to smell the lemon? Could you see the oil released when the rind was scraped or the juice released when you cut or squeezed it? Could you taste it? The stronger the sensation, the more the hypnotic talent.

If the patient is not able to experience either of these sensations, that person may not be an ideal candidate for hypnotherapy or will require more time and training with the practitioner.

Induce Trance

The practitioner performs trance induction for the first hypnosis session so that the patient can become familiar with it. It will be helpful if you can walk the patient through this so he or she feels comfortable doing it himself or herself. Children can do this easily, but adults often need a little practice.

In trance induction, it is helpful to use a trigger (i.e., a conditioned response) to tell the body it is time to relax and focus. Each time the individual uses or rehearses hypnosis with that particular method of induction, the procedure signals the associated responses, and the body “learns” and becomes conditioned. This creates a more automatic response to the trigger, and the more it is used, the easier it becomes to induce a trance. It is important to use your voice to convey the message you intend. That is, use inflections, pauses, tone and volume, and accent to emphasize your message. It is also important to embed statements of positive reinforcement during the trance work so patients can develop the ability to do this on their own.

There are many different techniques for trance induction. Four examples are described here.

Thumb-and-Finger Technique

Instruct the patient to gently press the tips of the thumb and index finger together in the OK sign. Then tell him/her that when ready, he/she may close the eyes, take a deep breath, and hold that breath while you count to five. With each increasing number, tell the patient that he/she is deliberately increasing some acceptable anxiety and to make it a physical experience by pressing his thumb and finger more tightly together. Let the patient know that he/she is in control of this form of tension and anxiety, and when you reach five, he/she is to exhale the breath and release and relax the thumb and finger. Tell the patient to continue with the eyes closed and to permit the hand to relax and to allow breathing to become calm and regular. You may say that this acts as a cue or signal for him/her to relax and go into a trance. This technique can be used at any time by the patient for self-hypnosis. Again, with repetition, it creates a conditioned response that facilitates a faster and easier induction.

Imagining a Relaxation Staircase

By imagining a beautiful staircase with 10 steps, the patient can use each step to focus on relaxing a different part of the body as he/she descends to her favorite place. In the brackets in the following passage, insert the patient’s preferences that you learned during tailoring, such as a favorite place or color. The relaxation staircase technique, which is also a technique for deepening of the trance, may go something like this:

Imagine a beautiful [favorite color] staircase that has 10 steps. These 10 steps lead to a peaceful and relaxing [favorite place]. In a moment, I am going to start

counting backward from 10 to 1. With each step, you can notice your body relaxing more comfortably, allowing you to gently relax deeper and deeper with each step. It will be so very nice to discover which parts of your body relax more quickly and easily, as tension is automatically released.

As you start at the top of the staircase, allow each exhalation to release any tension or strain in your body. Let each breath now be a "relaxing breath."

10...Relax your face and jaw, letting your tongue gently rest on the floor of your mouth.

9...Relax your temples, eyes, and eyelids as we step down to...

8...Relax the back of your neck and shoulders, simply letting go.

7...Relax your arms, knowing that there is nothing for them to do.

And sometimes, you will notice that your body is already getting ahead of my voice and the numbers, and sometimes it feels so comfortable when your body catches up to your relaxation.

6...Relax your chest, with each rise and fall of the breath.

5...Relax your abdomen, setting the muscles free.

4...Relax your pelvis, allowing it to sink into the chair.

Sometimes your body may feel so "heavy" that it feels like you are sinking, and other times you feel so "light" that it may seem that you are floating.

Whatever you experience, it is correct for you...let it happen.

3...Relax your legs, giving them the day off with nothing to support.

2...Relax your toes as we arrive at...

1...And continue past zero as you feel comfortable and at ease with this very relaxed form of concentration.

Eye Fixation and Closure

This technique is helpful for a more reluctant or nervous patient as it begins with their eyes open and involves the common everyday experience of "staring." The instructions may go like this:

While you are sitting upright with your eyes open, select a place or a spot out in front of you above the horizon or midline to let your eyes rest upon. The spot you are seeing is not changing, and it is normal that your eyes would want to wander away. But continue to bring your gaze back to that spot and direct your attention to create "staring." That is, your eyes remain open and you are seeing...but sooner or later...you are not looking at what your eyes are seeing in the same way...you are staring. When you observe that you are staring (seeing but not looking), begin to imagine that your eyelids are becoming comfortably tired and becoming heavier and heavier. You may notice that it is becoming more difficult for your eyes to remain open. Let your eyelids become increasingly and pleasantly heavy and allow them to begin to close by themselves as they become

heavier and heavier. If your eyes do not begin closing in 5 minutes, I will count from five down to zero to deepen your experience and close your eyes at zero.

5...sometimes your eyes may flutter as they become comfortably tired.

4...your eyes may even produce some gentle tears to keep them moist.

3...perhaps you can remember how it feels when you want to stay up late to watch a movie, but by the time the movie begins, it would feel so good to let your eyes rest closed.

2...heavier and heavier...allowing them to close.

1...and now as I say "zero," close your eyes and take my voice with you as you begin a very gentle journey to that place or feeling of a place within you where all is well and where you feel safe and peacefully at ease.

Let yourself rest into this place or feeling of comfort for as long as you like, letting go of any "trying."

Tell yourself relaxing suggestions, or picture them as if they are already achieved, and tell yourself that you can return to this level of comfort and relaxation at future sessions.

Now, shift over to bringing yourself to a fully alert, waking state, feeling refreshed and calm as I count from one up to five.

1...you begin orienting yourself to this chair, this room

2...arms and legs begin to feel refreshing energy flowing

3...preparing arms, legs, and hands to move and do activities

4...you bring this refreshment to the front of your mind and at

5...you open your eyes feeling refreshed, alert, and comfortable.

Breathing and Breath Technique

Suggest that your patients adjust their position to be as comfortable as they like, and when ready, to begin to let their eyes close. When they close their eyes you may say:

While sitting, reclining, or lying down with your eyes closed, take three deep breaths, paying attention to any tightness and tension with each inhalation and focusing on comfort and peace with each exhalation. With each of these three deep-breath exhalations, notice the feeling of "letting go."

With each exhaled breath, notice the "letting go" of the breath from your body as a means of releasing tension.

Scan your body from the head to toes or the toes to head and find any places of stored tension or tightness.

Associate each inhaled breath with gathering up some of the tension or tightness and associate each exhaled breath with releasing the tension or tightness. Your breath enters your body to gather up tension, and your breath goes out releasing the tension with it.

Imagine a seashore or something that contains the idea of gathering and releasing.
Each breath is like a wave onto the shore that returns to the sea...each breath rinsing away any tension from your body.
Each breath is now a relaxation breath.
Associate each breath with a deepening of your trance. With each breath, go deeper and deeper into a comfortable relaxation.
Let yourself ease into and rest in this comfort for as long as you like, letting go of any "trying."
Tell yourself relaxing suggestions or picture what you desire as if it has already been achieved. You can return to this level of relaxation whenever you repeat this experience.
When you desire, return to a fully alert, waking state feeling refreshed, alert, calm, and comfortable.

Hypnotic Strategies

We distinguish two hypnotic strategies or approaches in using clinical hypnosis in practice. One strategy is symptomatic, in which the emphasis of the hypnotic work is exclusively directed toward altering or removing symptoms. In most cases, the symptomatic approach is simple and effective. However, when symptoms do not respond to the symptomatic approach, or when "symptom substitution" follows the removal of the original condition (when one symptom resolves but is replaced by another), then we look for a possible underlying or subconscious origin. That is, we look for underlying emotional conflicts that are being expressed by the body. This other strategy is called psychodynamic, and it more specifically addresses the origins or causes of the symptoms. The metaphor for exploring symptoms psychodynamically might best be thought of as the symptoms being "out of mind, but not out of body."

An example to illustrate the two strategies might involve a headache, for which the symptomatic approach relies on relaxation and imagery of comfort to relieve tension. The psychodynamic approach for a headache resilient to the symptomatic approach would address metaphorical questions, such as who is the pain in the neck? or what is the pain in the neck for you? In later examples, we are exploring the possibility of an underlying psychodynamic process in which emotional stresses are being expressed as physical symptoms. For our purposes in this chapter on self-hypnosis techniques, we will limit our examples and exercises to the symptomatic strategy or symptomatic approach. Psychodynamic and interactive approaches are best done with a qualified practitioner.

Utilization

Utilization is the process of focused attention (trance) for a therapeutic purpose, such as symptom relief. This phase is what distinguishes hypnosis from meditation and relaxation exercises. This section describes scenarios that may be used for some common problems seen in the primary care setting.

Gastrointestinal Disorders: Gentle Movement or Healing Color

Hypnosis is an excellent tool for unlearning and relieving gastrointestinal conditions such as irritable bowel syndrome, although the imagery you use can be modified to describe healing comfort from upper gastric distress, constipation, or other gastrointestinal symptoms.

One easy method to use with patients is to have them visualize a soothing color as it travels the entire alimentary canal from the mouth to rectum, calming and healing as it goes. For example, you might speak as follows to your patient:

Recognize that your digestive system and your alimentary canal, from the mouth to rectum, are lined with smooth muscle that functions automatically. Furthermore, throughout the alimentary canal, the smooth muscle produces a gentle, wavelike motion called peristalsis, which moves food through you in the proper direction from swallowing to elimination. Your thoughts and mental images are messages that slow or speed up this gentle wavelike motion so that you are comfortable and can enjoy natural, healthy, and comfortable digestion.

Now imagine that you are swallowing [patient's favorite color] in the form of a gentle light or a soothing liquid that will travel all the way through your digestive system in a comfortable, peaceful, healthy way. Follow that soothing [color] from your mouth and down your esophagus. As the [color] flows downward, let yourself feel a calm inner peace as your digestive tract begins to relax and restore itself so that you can easily digest a wide variety of foods comfortably and easily and with peace of mind. As the soothing [color] gently moves down your esophagus, it comes to your stomach. Visualize the lining of your stomach as healthy and producing exactly the right amount of digestive juices to easily and comfortably digest your food. And as the soothing [color] begins to move into your intestine, you can know that it helps your food move through at the proper rate so your body absorbs all the nutrients from your food to provide you with vitality, energy, and resources for healing.

The beautiful [color] continues to move through your intestines, easily guided by the gentle wavelike motion of peristalsis, as your body remains calm and

relaxed and unaware of this motion. Your body is learning from this experience, and now you have the ability to choose a great comfort, a wonderful soothing comfort throughout your stomach, intestines, and colon. Even when your body lets you know there are stresses around you, you can quickly override the bodily stress response by making a conscious decision to give your body the message for comfort as you are doing right now. You can now “let go” of stress, and “let go” is a phrase that will now provide a powerful and soothing message whenever you want to detach from stress around or within you. Let yourself “feel” the calm inner peace and comfort within your digestive tract, the healthy, gentle, calm process by which you easily digest and eliminate your food. Your body has just memorized this experience with you.

Headache: The Cool Breeze Technique

The imagery of cooling the head helps facilitate vasoconstriction. Add the imagery of warming the hands to direct greater circulation to the extremities and to help reduce pressure and pain in the head, particularly for migraines.

This induction technique often also reduces pain by facilitating relaxation. Further time spent on relaxation of the head muscles is warranted because tension is often involved in the pathogenesis of headaches. You might say the following or something similar to your patient:

Feel the muscles in your temples relax, focus your attention on your eyes and forehead, and let them relax with each breath out. With each breath, let the muscles relax more and more. Now follow the muscles through the scalp to the base of the skull and relax this area, exhale, and feel the whole head relax. Imagine walking along a snowy path in the mountains with a cool breeze blowing across your face, cooling your head, your face, and your eyes. Imagine a cool and soothing sensation across your forehead and above each eye. Your hands are tucked in your pockets, so they are warming, and they are warm. Your hands are warm and comfortable, while a cool breeze and cold air make your head feel cooler, soothing and relaxing every muscle, releasing any tightness, any stress. Just feel a calm sensation flow through your eyes and forehead. You are calm and comfortable and relaxed. Just notice the cool breeze of each breath coming in your nose and softly blowing up and into your forehead, and the air warmed by your hands and body now being exhaled. Cool air in, soothing your head...warm air out, relaxing your body.

Repeat if needed.

Hot Flashes

Just as the imagery and suggestion of coolness can be used to relieve headache, it can also be applied to lessen the discomfort of postmenopausal hot flashes. Dr. Gary Elkins³ has published much research with colleagues on the effectiveness of using hypnosis to relieve hot flashes after menopause and after breast cancer. Begin by asking your patient about the types of cooling ideas and images that they find most pleasant. This may include ideas of a cool mountain stream, a cooling breeze, or even just noticing the cool air that is felt when opening the freezer or refrigerator. Once you know what types of “coolness” are pleasing to your patient, begin a relaxing experience with something like:

With your eyes closed, you can turn on your imagination; in your imagination, you can travel to any place you would enjoy feeling a very pleasant coolness. I might be describing a cool breeze on a mountain trail or putting your hands in a cool mountain stream. But you may be imagining what it feels like as your body begins releasing any excess heat, like opening a faucet that lets heat flow out of your arms, hands, feet, and toes. You can picture yourself walking barefoot in a cool stream or sitting at the shore or edge of a mountain lake and letting your feet rest in the cool water. Sooner or later, the coolness flows from your feet up your legs into your hips, and as the coolness continues you may even imagine that you are even swimming in a cool lake...allowing your body to absorb the coolness. As you imagine the coolness, you can feel the coolness spreading deeply within to quench and quiet your body. Your mind-body is memorizing this experience of coolness right now, so that whenever you need to feel cool you can close your eyes and imagine the scene, the feelings, and all the comforting cooling sensations that can now flow through every part of your body. Each time you practice or mentally rehearse coolness with your self-hypnosis your body is responding with a cooling comfort. You are training your brain, body, and entire endocrine system of hormones to now memorize this experience, and you are able to feel the coolness flow freely throughout your body. When you are ready to bring a comfortable coolness with you to a full alert waking state, allow your eyes to open and enjoy feeling alert and refreshed as the coolness you created remains within you now.

Localized Pain From Injury or Preparation for a Painful Procedure: Glove Anesthesia Technique

The glove anesthesia technique involves creating numbness in one of the patient's hands that then can be transferred from the hand to any part of the body for pain relief. Tailor the technique by asking the patient's favorite color and say something like the following:

Focus your attention on one of your hands. Direct all of your attention on that

hand and begin to imagine that hand becoming numb. Recall a time your hand fell asleep and how wooden your hand felt. As you numb your hand, imagine it gradually turning [insert favorite color]. Your hand is turning [favorite color], and as it does, there is a tingling in your fingertips, and warmth flows through your hand. Soon, all the feeling will drain out of your hand as it turns a deeper [favorite color]. Let it go, let the feeling drain from your hand. That hand is feeling so numb, so very numb. That hand feels heavy, and it feels as if it were made of wood. Let all the feeling drain from your hand, so it now begins to glow a beautiful [favorite color]. Let your hand feel numb; let it feel numb as it glows brighter, glows like a beautiful [favorite color] light bulb. Your hand is now completely numb and filled with [favorite color] light.

Now place your numb [favorite color] hand on your [insert part of body... knee, jaw], place your hand on your [body part], and now let the numbness and the [favorite color] light drain into your [body part]. Feel your [body part] become numb, and watch as the numbing [favorite color] light slowly leaves your hand and covers your [body part], making it numb, wooden-like, heavy, numb, numb, thick, as if it were made of wood. When all the [favorite color] light has left your hand numbing your [body part], place your hand back down into a comfortable position [pause]. You can keep your [body part] numb for as long as you need to, as long as you need to. When you have completed this process, just let go and feel the numbness and the [favorite color] light drain away, drain away, and your [body part] returns to normal. When you no longer need it to be numb, it returns to normal.

FIG. 95.1 Patient's location of warts on a tracing of the hands.

Warts: The Hand Tracing Technique

This technique is best used for children with warts. Proceed as follows:

1. Have the patient trace both hands (or draw other parts of the body that may contain warts) on a piece of paper.
2. Have the patient draw where the warts are located on the tracing ([Fig. 95.1](#)).
3. Tailor the technique by asking about his or her favorite place and color.
4. Have the patient go to this favorite place (children are able to do this quickly and easily, but adults may have to use the induction technique discussed previously).

Then say something like the following to the patient:

Imagine that you are miniaturized. Small enough to get in a beautiful [favorite color] spaceship and travel through your body to where your warts are.

Look at the roots of the wart and see what they are like. What would you like to do to prevent the roots from getting any nourishment from your body? Would

you like to spray them or paint them with a powerful chemical that only warts can feel? Or would you like to cap them off with a plastic bubble, or cut them off and take them out of your body?

As the patient invents a method to “treat” the roots of the warts, you might give some brief suggestions that reinforce the patient’s power to do this from within himself or herself.

Go ahead and do that now and make sure that you treat all your warts.

Do you need more time to work on the warts?

When the patient says that he or she has finished, ask him or her to do “one more thing” to ensure that these warts do not stand a chance.

Your body will continue to work on these warts, even while you are sleeping.

How long do you think it will take your body to remove these warts? I wonder how quickly your body will get the job done for you?

1. Then, have the patient return to normal size and come out of the body. Offer encouragement on how well he or she did, how powerful his or her images seem, and how well his or her body heard everything it needed to do its part of the job.

2. After the patient comes out of the trance, have him or her erase the warts on the tracing created previously.

3. Have the patient perform this technique one more time at home.

Success with wart resolution has been found with two or three imagery sessions.

Improving Surgical Outcomes

Much evidence shows that patients can use hypnosis to make surgery a more comfortable experience by lessening pain, blood loss, nausea and vomiting due to anesthesia, and also by speeding up wound healing and overall recovery. Furthermore, studies have shown that hypnotic suggestions to these ends are equally effective if they are delivered by a person or by an audio program.

If at all possible, patients should practice this technique on their own for at least 3 days before surgery. It is not necessary to use or listen to audio devices during surgery. Be sure to emphasize that they are preparing themselves very well for their healing experience by doing so. Postoperatively, they should begin the technique as soon as possible and continue for as long as needed. Overall, the suggestions should indicate that the surgical experience is comfortable and that recovery is rapid, effective, and easy for them.

Before surgery, the following suggestions will be effective:

You are preparing for a wonderful healing experience. Your body and mind

are using only your positive words, images, and expectations for a comfortable and effective healing experience. Each time you practice or rehearse with your self-hypnosis, your body and mind are memorizing the positive messages as special instructions for comfortable healing. Any anxiety is easily replaced now by relaxing thoughts and feelings of comfort. You are in control of your inner comfort and can use any sounds or sensations from the environment around you to deepen your comfort.

Whenever you are distracted, you can quickly and easily return to your special place within you, your place of inner peace and confidence that reminds you that you are doing well, all is going well, and that you are preparing for a wonderfully comfortable and effective healing experience. Your body has begun performing its natural function of protecting you from any infection, managing a healthy blood flow, and using the procedure to enhance its inner-healing work. During and after the procedure, you will have all the “comfort control” [spoken with emphasis] that you need to awaken feeling peacefully at ease and comfortable.

The following postoperative suggestions will assist in rapid recovery:

You have done very well, and now your body is concentrating its powerful healing energy to mend the cells and tissues as your immune system maintains a peaceful balance of protection. Your body is releasing an abundance of the natural chemicals of comfort called endorphins, which circulate everywhere within you and concentrate themselves where you need the greatest comfort now. Immediately after the procedure, your body awakens each system and function to continue the healing process. Your intestines and bowels awaken comfortably and gently begin their natural action. Sensations of hunger and thirst awaken gently, and you welcome the nourishment. Your body is healing rapidly and effectively, and you are feeling confidently in control through this rapid recovery time. You recognize how well you have done, and you deserve to take credit for how well you have done.

Re-Alert

Re-alerting the patient out of trance is simply the reversal of the induction technique, such as climbing the staircase with energy coming back into the relaxed muscles, with a suggestion to return to a fully alert, waking state feeling refreshed and at ease. The process of re-alerting involves not only speech but also tone of voice. As you come closer to having the patient open the eyes, the tone of your voice should reflect “refreshment” accordingly. You should reinforce the idea that the patient has done well and can comfortably use this technique as needed in the

future.

For re-alerting, say the following or something like it to the patient:

It is now time to shift over and bring yourself to a fully alert, waking state. As we climb the staircase, counting each step, afterward you will be happy that you have done well with this method and proud because you realize that you can revisit this place whenever you need or desire.

As you proceed up the first step, feel the energy awakening your body, starting at your toes...

2...and now allow it to flow up your legs...

3...into your pelvis and lower back...

4...traveling to your abdomen, as you feel your body refreshing itself.

5...Take in this energy with each rise of your chest.

Your voice can become stronger as you return to a more normal pattern of speech.

6...as you feel it travel into your arms...

7...going up to your shoulders and neck....

8...into your temples, eyes, and eyelids.

Your voice should now be normal for the waking state.

9...Feel your tongue, jaw, and the muscles of your face energize and allow your eyes to open when you are ready to feel wonderfully refreshed and energized.

You want to make sure that your patients are out of trance, and that can be done by taking time to engage in conversation, asking them how they are feeling, and ensuring that they are fully reoriented to time, place, and person. The debriefing conversation that follows the trance work is also a good time to make sure that they are fully alert and oriented.

Debrief

After the procedure, when the patients are alert, engage them in a conversation that allows you to assess their experience during the self-hypnosis. You might ask about physical sensations, nature of any resistance, what they liked, what they did not like, and so on. The time to debrief after the hypnotic trance work lets you gain insight not only into what they experienced but also into what you want to remember to use with them in future sessions. The debriefing is an excellent opportunity to provide patients with encouragement about what they achieved and how they will continue to improve these mind-body skills with practice.

Homework for the Patient

Your patients should first undergo induction, use, and re-alerting from a trance with you as a learning experience in a clinical setting so they can see how to do it on their own. Think of it as a rehearsal for what you want your patients to practice by themselves. With the exception of removing warts (which requires only one or two sessions because further sessions may actually hinder the process), it is important to encourage your patients to practice or rehearse their self-hypnosis method to become more proficient with it. For conditions such as pain, there is no limit on the frequency of use.

Educate your patients to use this tool on their own by practicing at home what they experienced with you in the office. Review from the beginning to the end the steps the patients took with you; remind them that the body reacts to everything the patient may say, hear, think, and imagine and that it uses the patient's thoughts and ideas as instructions for the inner work to be achieved. Ask your patients to tell you where they plan to practice at home and what they are going to say or think to themselves to make it happen. Provide instructions as necessary to set them in motion for a positive experience at home. You might even give them a handout containing the words you spoke, along with instructions, or recommend an audio CD or audio program specific to them.

Patient Encouragement and Neuroplasticity

It is very important that your patient practices their self-hypnosis. It is believed that it takes about 21–30 days to create a habit. I like to encourage my patients by helping them see their practice of self-hypnosis as neuroplasticity. That is, I want them to understand that by mentally rehearsing their hypnosis they are exercising neurons such that they create new patterns of learning in the brain, much like creating new circuits. I remind them:

- There are approximately 500 billion neurons in the brain, and each one makes about 5000 connections or synapses to other neurons. This means trillions of connections are created.
- Repetitive stimulation such as their mental rehearsal of self-hypnosis causes neurons to make specific connections consistent with what they are mentally rehearsing. That is, “patterns of learning” or “learned patterns” or new circuits are being created that replace past and undesired patterns.

- Neurons that fire together, wire together⁴
- Think of your self-hypnosis as your self-neuroplasticity

Hypnotic induction and suggestion is an art that takes time and practice, yet simple techniques such as those discussed should be used to enhance care in the primary care setting. For more complicated cases, referral should be made to a licensed practitioner.

What to Look for in a Consultant

When referring your patient for hypnosis, be sure to review the therapist's qualifications to treat the underlying condition. A good rule of thumb: never refer a patient to a practitioner who does not have the qualifications to treat the specific condition without hypnosis.

There are many so-called certified hypnotherapists advertising their services. Frequently, their certification comes from a lay school of hypnosis that teaches them only the techniques of hypnosis, and they do not possess any education in medicine, psychology, social work, or dentistry. Choose a practitioner licensed in a clinical specialty that is certified by the American Society of Clinical Hypnosis (ASCH). This professional organization provides extensive, comprehensive training and requires supervised practice before granting certification. The American Society of Clinical Hypnosis website (www.asch.net) provides referrals to qualified practitioners.

CHAPTER 96

Enhancing Heart Rate Variability

Malynn L. Utzinger, MD, MA

The healthy human heart does not beat at a steady rate, but rather fluctuates from beat to beat, creating patterns that demonstrate complexity (including a fractal-like variability) and stability over time.¹⁻⁴ In medicine, such patterns can be described as regular, as in respiratory sinus arrhythmia, or irregular, as in atrial fibrillation. Collectively, these beat-to-beat changes and larger patterns are called heart rate variability (HRV), which reflects and predicts an organism's degree of healthy functioning in terms of physiological and emotional self-regulatory capacity, adaptability, and resilience.^{1,5-10} While in general, high HRV is an indicator of health, there is an optimal range; too much variability is related to instability in a system (e.g., arrhythmias) and inefficient use of energy, whereas too little variability is a predictor of disease.^{11,12} This is exemplified by research showing that low baseline measures of HRV are predictive of all-cause mortality¹³ and *independently* predict cardiovascular death.^{14,15}

HRV reflects sympathovagal balance, which in turn affects inflammatory pathways now understood to be critical and common to many illnesses.¹⁶⁻²⁴ In fact, research reveals links between HRV and diseases in almost every system of the body, including cardiovascular and metabolic,^{11,15,25-40} neurological,⁴¹⁻⁵² psychological,⁵³⁻⁶⁸ immune,¹⁷ endocrine,⁶⁹⁻⁷⁵ rheumatological and autoimmune,^{4,23,24,76-88} pulmonary,⁸⁹⁻⁹² gastroenterological,^{23,93-96} and dermatological^{97,98} systems. Even cognitive capacities⁹⁹⁻¹⁰³ and levels of stress¹⁰⁴⁻¹⁰⁶ are associated with HRV. As health care moves toward better systems for disease prediction and early detection, it is important to note that some studies demonstrate significant alterations in the cardiac autonomic modulation capacities of even children of parents with diseases such as hypertension¹⁰⁷ and in first-degree (otherwise healthy) relatives of people with schizophrenia.⁶⁵

Despite our growing understanding that healthy HRV appears to be inversely correlated with multiple disease states, not all studies corroborate these associations^{108,109} and some show mixed results;⁸⁸ thus, greater refinement of our early findings will improve our capacity to establish clinical and lifestyle guidelines.

The ultimate aim of this chapter is to provide clinicians and patients with practical, meaningful, and effective tools to monitor and improve HRV. Preceding this is a review of basic physiology, followed by a discussion of the associations between HRV and health.

Background

HRV is driven by a highly dynamic, bidirectional interplay between the heart and the respiratory system, mediated by two branches of the autonomic nervous system (ANS): the sympathetic and parasympathetic nervous systems,¹¹⁰ the latter of which is under vagal control. A standard explanation for the association between disease states and lowered HRV is that neural damage from disease impairs vagus nerve functioning and thereby lowers parasympathetic tone. One of the most fascinating alternative considerations to emerge from research on inflammatory reflexes is that loss of normal vagal tone may lead to diminished functioning of the cholinergic antiinflammatory pathway that may result in downstream immune dysfunction and exaggerated cytokine release triggered by otherwise harmless stimuli.^{18,111} In simple terms, loss of vagal function may *allow* inflammation and disease in the first place.¹⁸ This means that clinicians have a potential opportunity to prevent or slow many conditions by helping people maintain sympathovagal balance.¹¹¹

Downregulation of vagal function can worsen chronic inflammation by reducing parasympathetic tone and the cholinergic antiinflammatory pathway.

Before exploring HRV physiology, we shall look at the heart itself, which plays a more complex role in health compared with that previously appreciated.^{6,99,112-114} The heart not only has novel endocrine roles, such as those of the cardiac receptors for oxytocin (the bonding hormone normally associated with reproduction),¹¹⁵ but also it has an

extensive, intrinsic nervous system that allows it to process and respond to certain emotional and physiological cues even before the brain does.^{112,116,117} Moreover, the heart is the body's strongest generator of electrical and magnetic signals, which are 60 times and 5000 times stronger, respectively, than those coming from the brain. These signals can be detected throughout the body by electrocardiography (ECG) or even several feet away by magnetocardiography.^{118,119} A theory reviewed and developed by McCraty et al. at the Institute of HeartMath is that the heart is not merely a pump. Rather, it provides an organizing force throughout the body, especially in the brain where synchronization has been observed between R waves on the ECG and alpha waves on the electroencephalogram (EEG).^{112,120} Pulsatile signals from the heart travel afferent vagal pathways and arrive in the brainstem and thalamus, where pacemaker cells appear to mediate synchronization of millions of incoming signals from the sensory cortex.¹²¹ In other words, the heart itself may participate in interpreting our experience of the world by synchronizing cortical signals. The positive emotional states and biofeedback tools discussed later appear to increase this synchronization and improve cognitive performance.^{53,58,99-101,112,122} In summary, the heart is a pump, a rhythm generator, a sensory organ, and a key node in body-wide communication.

The heart itself may participate in interpreting our experience of the world by synchronizing cortical signals.

Polyvagal Theory

A brief overview of an elegant theory, developed by Porges,¹²³⁻¹²⁹ deepens our understanding of the mechanisms and pathways through which the heart and vagus nerve serve to shape our physiological and emotional responses to the world. Polyvagal theory holds that there are two vagal circuits: ancient, responsible for defense, and modern, responsible for growth, spontaneous behavior, and social engagement. When a person feels safe, there is an increase in the activity of myelinated (fast) efferent vagal fibers that run to the heart and immediately slow the cardiac pacemaker, inhibit the sympathetic branch responsible for the fight or flight response, lower inflammation through the mediation of cytokines, and dampen the entire stress response of the hypothalamic-pituitary-adrenal axis (e.g., cortisol). All of this allows the body to grow, repair, and restore itself properly. This biological pathway activates a strong social engagement system, seen in the relationship between mothers who sing to and smile at their babies lovingly, thus promoting a physiological and emotional thriving.

On the other hand, when a threat is perceived, in early stages the system gets ready to mobilize in the classical flight or fight response, driven by sympathetic activation and parasympathetic withdrawal to mobilize for high-energy consuming processes. If the level of threat escalates, an even more primitive neural response may kick in, mediated by unmyelinated fibers, which slow the heart, inhibit digestion, and take the organism into a state of complete collapse, a “freeze” response akin to playing dead, meant to protect the organism from harm. For some people, in response to severe trauma, such a response is initiated, causing the person to become all but paralyzed in an extreme attempt to cope.¹²⁸ People who suffer from posttraumatic stress may experience this paralysis all too frequently.

A key to treatment in restoring health comes through research and data that suggest that the newer system (the fast, myelinated vagal fibers seen only in mammals) has the power to repress the older, “primitive” vagal defense circuit. In other words, it is impossible to feel afraid when you are feeling appreciation or love. This idea was first scientifically published by John Hughlings Jackson,¹³⁰ who held that the more modern neural circuit could override the earlier pathway, and in fact, it appears to be true. When slow, deep breathing is initiated, for example, or when feelings of appreciation are cultivated, as seen in later sections, the body

immediately moves into the “safety, growth, and repair” mode.^{[6,100,112,117,119,131](#)} Indeed, reviewed in the following text are also studies of the effects of singing a hymn or chanting a mantra,^{[132,133](#)} all of which might be have some correlation to hearing the voice of one’s mother, which instantly triggers the infant that it is okay to relax.

Physiology and Measurement of Heart Rate Variability

In healthy people, sympathetic tone and parasympathetic tone are finely tuned, each rising and falling as demand changes. Unfortunately, daily stress, which can be felt as threatening, often erroneously triggers increased catecholamines. When this happens on a long-term basis, the body pumps out stress hormones more often than what is healthy or necessary. The ANS may try to compensate by turning up parasympathetic control. Ultimately, sympathetic drive that simmers continuously can deplete the reserve needed to meet true challenges. This depletion usually translates into a feeling of being constantly “on edge,” yet sluggish, and lacking vitality.¹¹²

When the two systems compete inappropriately, the heart’s electrical system can become unstable, causing arrhythmias, platelet aggregation, coronary artery constriction, increased stress on the left ventricular wall, and unhealthy remodeling. Reestablishing proper vagal input antagonizes these sympathetic overcompensations and rebalances the system. This happens in part through cardiac baroreceptors or mechanosensory receptors, which are sensitive to stretch and pressure changes and act centrally to restore proper vagal tone and blood pressure.

Baroreceptor sensitivity is a marker of the body’s capacity to augment vagal tone reflexively and has a direct link to HRV, observed in respiratory sinus arrhythmia. During inspiration, intrathoracic pressure decreases and the heart rate increases to compensate. During expiration, intrathoracic pressure rises and the heart rate drops. In general, with faster breathing, sympathetic tone increases and the heart rate climbs. With slower breathing, between six and four breaths/minute,^{131,132} the balance shifts toward the parasympathetic system and the heart rate slows.

Therefore, the healthy heart does not beat at a steady rate, but rather varies in coordination with the breath and environmental cues. A well-known example of this phenomenon is in obstetrics, in which the fetus is assessed for adequate heart rate accelerations higher than the baseline to ensure a favorable response to the challenges of labor ([Fig. 96.1](#)).

A flexible, well-coordinated ANS helps us respond appropriately to stress, and positive emotions seem to cultivate this dynamic synergy. In

the state of appreciation, for example, parasympathetic and sympathetic systems both show moderate output, and they oscillate in relative regularity to produce what is known as a coherent HRV pattern, which is a smooth, sine wave-like curve and shows an overall shift toward parasympathetic dominance.¹¹² In contrast, during stress, anger, or chronic illness, the HRV curve becomes more erratic and shallow thus reflecting the less-coordinated functioning between the two branches of ANS and a shift toward sympathetic drive, as in congestive heart failure, depicted in [Fig. 96.2](#).¹¹⁷

FIG. 96.1 Fetal heart tones. This fetal heart tone strip shows that the baby's heart rate regularly rises higher than the baseline of 130 beats/minute.

FIG. 96.2 Cheyne-Stokes breathing in congestive heart failure (CHF). Here, the heart rate is regular, but dangerously so. Apparently, some ability to oscillate and respond to bodily cues has been lost in this end stage of CHF.

Figs. [96.3](#) and [96.4](#) are examples of graphed HRV plots. The tachogram

in [Fig. 96.3](#), from the HeartMath Institute, demonstrates the use of a biofeedback technique to shift from frustration, shown with the erratic HRV curve, to appreciation, with a smooth curve. Although both graphs demonstrate similar peak-to-nadir differences in heart rate in beats per minute (bpm) (reflecting the same absolute amount of variability), the patterns of the curves are quite different. Each segment of the frustration tachogram is erratic and shallow, reflecting low coherence. In contrast, the appreciation curve is higher in amplitude, more regularly oscillating, and smoother. This *pattern* of variability, and not absolute amount of variability, determines coherence and optimal ANS output.^{[61,117](#)}

In [Fig. 96.4](#), three emotional states are compared: anger, relaxation, and appreciation. Tachograms are displayed along with power spectra density (psd) analyses, which plot power (variability) distributed as a function of frequency. Short-term power spectra analyses produce peaks or clusters of data points mostly within three main regions^{[12](#)}:

1. High frequency (HF), from 0.15 to 0.40 Hz, reflects the activity of the parasympathetic system and efferent vagal flow.
2. Low frequency (LF), from 0.04 to 0.15 Hz, most likely reflects both parasympathetic and sympathetic activity.

Changing Heart Rhythms

FIG. 96.3 Frustration to appreciation. Here a person's heart rate variability (HRV) goes from erratic and shallow during frustration to smooth, with a more regularly oscillating HRV curve, during appreciation. (From McCraty R, Childre D. *The appreciative heart: the psychophysiology of positive emotions and optimal functioning*. Boulder Creek, CA; Institute of HeartMath; 2000.)

3. Very low frequency (VLF), from 0.003 to 0.04 Hz, reflects the sympathetic nervous system and factors possibly including input from chemoreceptors, thermoreceptors, and the renin-angiotensin system.

The Ultralow-frequency region (ULF) is relevant for long-term measurements, such as 24-hour Holter monitor readings.

The *anger* curve demonstrates a disordered pattern with increasing heart rate. The spike in the VLF range demonstrates sympathetic dominance.

In *relaxation*, the tachogram shows an HF, low-amplitude pattern, reflecting an overall *decrease* in ANS outflow. The spike in the HF range correlates with parasympathetic dominance.

In *appreciation*, a smooth, highly ordered (or coherent) sine wave is seen. The large, narrow spike in the LF band at 0.1 Hz is indicative of optimization between the sympathetic and parasympathetic branches of the ANS as well as an entrainment among heart rate, respiration, and

blood pressure.^{112,134}

Although appreciation and relaxation share a shift toward parasympathetic dominance, appreciation has higher outflow of both parasympathetic and sympathetic drives (higher amplitude), and the two branches are more highly synchronized, shown by the smoothness of the curve and the spike seen at 0.1 Hz in the LF zone of the power spectrum. These qualities define coherence or resonance in HRV.^{112,134} Several studies indicated that coherence leads to even greater improvements in health than does relaxation alone.^{99,100,112,113,135,136}

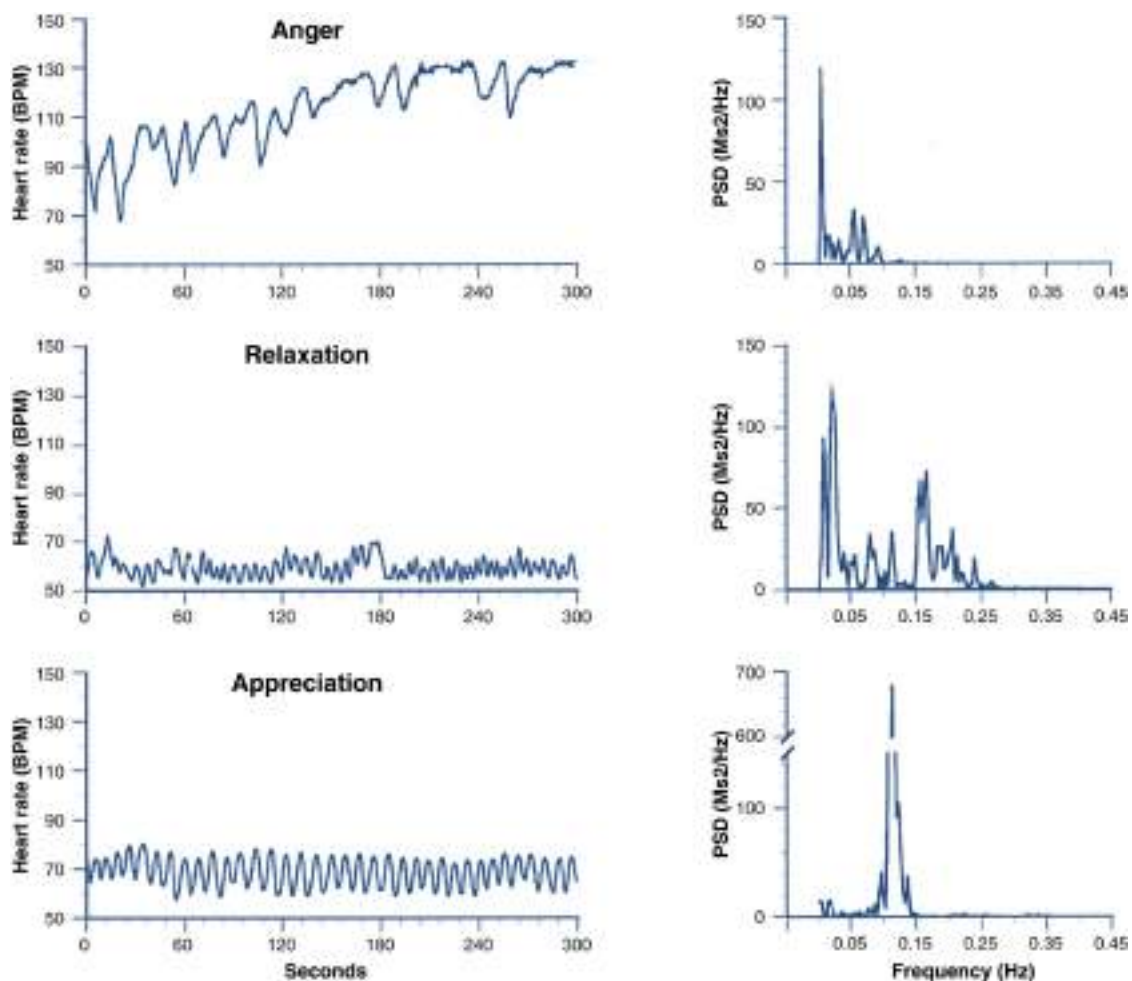

FIG. 96.4 Anger, relaxation, and appreciation. In these three conditions, note the shift from the erratic heart rate variability curve of anger to the somewhat more regular, but low-amplitude, curve of relaxation and finally, into the smooth, sine wave–like curve of appreciation, consistent with “coherence” or good synchronization between sympathetic and parasympathetic systems and the rest of the body-wide network of inputs.

BPM, beats per minute; PSD, power spectral density, a form of HRV analysis based on power distribution across given frequencies. (From McCraty R, Childre D. *The appreciative heart: the psychophysiology of positive emotions and optimal functioning* . Boulder Creek, CA; Institute of HeartMath; 2000.)

In theory, coherence may be achieved at a higher average heart rate (e.g., during light exercise), but obtaining accurate readings is difficult when a subject is moving. Novel technologies including sensors embedded in a T-shirt, a mattress or pillow, using wireless ECG, in a Web cam, or using microwave technology soon will make it possible to track HRV coherence under dynamic conditions.

Some researchers have gathered data to suggest that it is not the mere balance between sympathetic and parasympathetic systems that is important for health, but rather a measure called cardiac autonomic regulation (CAR), reflecting total autonomic control over both branches, which is most predictive of health. [137-139](#)

Heart Rate Variability and Health

Although HRV is linked to system-wide health, an important caveat to the following section is that normative data are still limited, and existing reviews show up to 260,000% individual variation, especially in spectral measures.¹⁴⁰ More research and experience are needed to contextualize test results for individual patients.

Many studies have found that HRV declines with age, potentially as one loses time in deep sleep.^{141,142} However, the decline slows after the fifth decade. Parasympathetic function reaches its nadir in the eighth decade and increases in extreme old age, possibly aiding longevity.¹⁴³ HRV tends to be lower in postmenopausal women than in girls and younger women,¹⁴⁴ and it has not been shown to improve with hormone replacement therapy.¹⁴⁵ Men have higher sympathetic tone and lower parasympathetic tone than women in general; as women age, however, they appear to lose their parasympathetic dominance more markedly than men do.¹⁴¹

In cardiovascular health, low HRV is an independent predictor of future events and mortality, including cardiac-related sudden death from myocardial infarction, fatal arrhythmias, and all-cause mortality in certain populations.^{15,17,19,25,29,31} HRV profile stratifies risk for worsening congestive heart failure,¹⁴⁶⁻¹⁴⁸ coronary heart disease,²⁸ and atherosclerotic plaques, even in young, asymptomatic adults¹⁴⁹⁻¹⁵¹; it also stratifies risk for elevated triglycerides.¹⁵² Similarly, HRV correlates with early insulin resistance,^{15,39,153} obesity in children and adults,^{40,70,152,154-157} multiple metabolic syndrome,^{38,158} and hypertension.^{156,159-163} Hot flashes are associated with a significant decrease in vagal tone⁷³ and hence may be a cardiac risk.

Research has verified significant links between HRV and the following conditions: neurological disorders, such as epilepsy, Parkinson disease, restless leg syndrome, migraine, and insomnia;^{41-47,49,51,52,164} rheumatological disorders, including fibromyalgia, rheumatoid arthritis, and lupus;^{4,76-78,81-88} gastroenterological dysfunctions, including functional dyspepsia and irritable bowel syndrome (IBS);^{23,95,96,165,166} and other inflammatory diseases, such as asthma^{89,90} and atopic dermatitis.^{97,98} In addition, many studies have tracked the effects of HRV on markers of inflammation and immunity.^{16-22,111} Innovative researchers are now using HRV to *predict* the onset of infection several days before appearance of

symptoms and track its severity.¹⁶⁷⁻¹⁶⁹ Similarly, low HRV can independently predict complicated recovery after abdominal surgery.¹⁷⁰ Conversely, using techniques designed to improve HRV appears to reduce perception of pain.¹⁷¹

In mental health, low HRV is linked with depression, anxiety, social isolation, bereavement, posttraumatic stress disorder, and suppressed anger,^{37,53-68,172-174} and it may partially mediate the significantly increased risk of cardiac mortality in depressed individuals after myocardial infarction, although even when antidepressants are used to improve symptoms, they do not always improve HRV.⁵⁵ Even in otherwise healthy individuals, stress has been demonstrated to change short-term HRV profiles, for example, in teenagers in socially disengaging situations,^{105,106} in surgeons performing high-stress operations,^{104,170,127} and in physicians during and after a call,¹⁷⁵ to take on too much at a time. Small steps with repeated, intermittent practice may be best.

Environmental and work-related factors also affect HRV. Although results of studies are mixed, most suggest that pollution and tobacco smoke worsen HRV.¹⁷⁶⁻¹⁸² Exposure to factory toxicants, job stress, and shift work diminished HRV,¹⁸³ whereas improving workspace and ambient light improved HRV and cortisol rhythms.¹⁸⁴ Disturbingly, a Japanese study showed that people with the provisional tolerable weekly intake (PTWI) of methylmercury (3.4 mcg/kg per week) from bigeye tuna and swordfish for 14 weeks had significant increases in sympathovagal imbalance, which returned to normal 15 weeks later.¹⁸⁵ However, another study on mercury suggests that early-life exposure may cause long-lasting damage to the parasympathetic nervous system, negatively affecting its protective capacities years down the road.¹⁸⁶

Factors That Improve Heart Rate Variability

Pharmaceuticals

Fortunately, many interventions improve HRV. In the case of lethal arrhythmias, cardiac resynchronization therapy (pacing) is sometimes necessary.^{142,187} Other medical procedures, including spinal stimulation,^{143,188} vagal nerve stimulation,^{66,122,144,145,189,190} and acupuncture (especially points ST36 and PC6),^{191,192,146} show positive effects. Among pharmaceuticals and supplements for people with cardiovascular disease (CVD), beta-blockers and some calcium channel blockers appear to be useful,^{54,147-150,193-196} and their effect is larger than that of exercise and

biopsychological interventions, although both of these nonpharmacologic interventions are useful, showing effect-sizes in the moderate range.^{54,196a} Angiotensin-converting enzyme (ACE) inhibitors appear to be less useful than other antihypertensives.¹⁹⁷ In depressed individuals, selective serotonin receptor inhibitors (SSRIs) and cognitive-behavioral therapy improve HRV,^{151,152,198-200} whereas tricyclic antidepressants and caffeine lower it.^{153,154,201,202} Of note, in the previously mentioned 2012 Blumenthal study on depression in people with CVD, both exercise and sertraline improved depressive symptoms and HRV, but exercise tended to have a larger effect on HRV than did the SSRI. St. John's wort was associated both with improvements and no change in two separate studies,^{155,156,203,204} and gamma-aminobutyric acid (GABA)-covered chocolate boosted HRV recovery after stress.^{157,205}

Nutrition

Certain foods, including green, leafy vegetables,^{158,206} omega-3 polyunsaturated fatty acids in fish and fish oil,^{159,160,207-209} and a Mediterranean diet,^{161,210} improve HRV. Wine paired with omega-3 fatty acid intake shows some benefit, but whether this benefit exists independently is unclear.^{162,211} In fact, separate studies found that both long-term moderate alcohol consumption and alcohol mixed with energy drinks had deleterious effects on HRV.^{163,212}

Lifestyle links with clear benefit include smoking cessation, which results in immediate improvements in HRV.^{164,165,213}

Exercise

Exercise showed no HRV benefit or mixed results in a minority of studies^{83,106,166,214-216} and in two meta-analyses,^{217,218} each of which, due to methodological inconsistencies, were able to analyze only two studies. However, the majority of research demonstrates significant exercise-related improvements in HRV parameters in healthy adults;^{219,220} the elderly;^{156,221,222} fetuses of exercising mothers;²²³ and in people with a range of diseases, including cancer,²²⁴ cardiovascular disease,^{162,200} obesity, pain and autoimmune disorders, recent surgical procedures, and even congenital disorders.* Research on exercise has even shown improvements in HRV to correlate with physiological regeneration, such as reversal of cardiac neural remodeling after myocardial infarction^{232,171} and crucial clinical outcomes such as improved quality of life.⁸⁵ However, it should be noted that some studies of maximal and

supramaximal exercise exertion show a prolonged parasympathetic suppression through the recovery phase up to an hour or longer,^{233,234} which may represent a period of higher risk for some participants.

Temperature Changes

Entering a hotter or colder ambient temperature also shifts HRV; cold environments acutely (such as a cold lake plunge after a sauna) decrease heart rate and raise HRV temporarily. Whether these conditions result in lasting benefit is unclear.^{172,235}

Demonstrating Willpower

Fascinatingly, if people fail to exercise self-control or willpower when faced with a challenge or goal, their HRV goes down, but a host of simple practices discussed in the following text seem to help raise HRV and improve people's ability to exert willpower.

For all people invested in shaping human health behaviors, a most striking finding is that HRV is the strongest known predictor of a person's willpower or reserve of self-control for consciously modifying behavior and achieving goals.^{10,101,236,237} For example, hungry research subjects asked to resist eating freshly baked cookies demonstrated a climbing HRV when they successfully held off, but when the next group of research subjects were told that they could go ahead and eat unlimited chocolate chip cookies, their HRV showed no change.¹⁰ Likewise, alcoholics whose HRV goes up when they are tempted with a drink are better able to resist than those whose HRV remain low.²³⁸ Segerstrom et al. have dubbed this successful activation of willpower as the "Pause and Plan Response," a first response of pausing, breathing, and thereby activating the prefrontal cortex (PFC) to help make good executive decisions that override impulses, which can be destructive or self-defeating. Although most people do not equate clear-minded planning with *relaxing*, it turns out that the two have a strong connection. In a relaxed, focused state of mind, there is a lucidity that emerges. The PFC can be trained to respond positively when interfering signals (fear, shame, or panic) from the amygdala arise, which do in everyone, even in expert meditators. Simply by taking a deep breath, or consciously slowing the breath, we increase HRV and activate the PFC, which can return us to a state of greater peace and clarity for healthy planning in our lives.¹⁰

HRV increases during time of heightened willpower where the PFC is activated to make decisions that override primitive urges.

In fact, HRV seems to be related to a whole host of behaviors that serve positively in helping people reach their goals. People who can successfully increase their HRV are able to ignore distractions, delay gratification, manage stressful situations (see the examples in this chapter from HRV training among students, cops and correctional officers, and surgeons),^{99,100,135} and return to difficult tasks even after they fail.¹⁰ As we have seen, several factors may control HRV, but people who are able to increase their HRV through simple procedures such as lowering their breath rate to four to six breaths/minute for just 1–2 minutes or exercising modestly are better able to increase their self-control or willpower to accomplish goals. However, in an important corollary to this finding, it has also been shown that self-control can be depleted by certain kinds of draining mental or physical tasks, even including practicing unfamiliar relaxation techniques, especially in the context of a draining illness such as chronic pain.²³⁹ Thus for people with pain conditions, learning new techniques to control HRV, it may be important to begin with relaxation-based strategies so as not to drain total mental resources during early learning stages.

Meditation and Prayer

Zen meditators show progressive changes in HRV in advancing stages of practice, likely mediated by change in breath rate.^{240,241} Encouragingly, people who have just been introduced to a simple mind-body training technique over 5 days show increased HRV in the short term.²⁴² Furthermore, the Fiorentini study suggested that 5-year practitioners appeared to maintain increased HRV even during normal daytime periods when they were not practicing special breathing techniques, suggesting that over time, the HRV changes during meditation may become permanent.²⁴¹ Practicing conscious slowing of breath even outside of yoga or meditation¹³⁹ or chanting a prayer or a mantra strongly affects HRV and baroreceptor sensitivity even in people with advanced congestive heart failure.^{68,132,133,173} Prayer in itself, especially centering prayer and prayers of gratitude, can produce high measures of HRV coherence^{57,113} as does expressive writing.^{174,243} Listening to classical music or meditation music also significantly improves HRV.^{175,244}

Biofeedback With Paced Slow Breathing

Biofeedback based on control of breath rate or focus on positive emotion is one of the most highly researched therapies to improve HRV.^{176,245} Studies have shown improvements in the following: cortisol and dehydroepiandrosterone levels; symptoms of depression, posttraumatic stress disorder, and mood regulation;^{35,57,59,113,177,246} blood pressure;^{71,72,135,136} cholesterol levels; aggression levels; and job satisfaction among correctional officers.^{84,135} This same technique allowed high school students to perform better in standardized tests and function at a new, higher baseline of HRV coherence after training in biofeedback.^{50,99,100} Most of the research has been done on techniques that target four to six breaths/minute, but for practical purposes, any decrease in respiratory rate to slower than 12 breaths/minute is helpful.^{131,246} In summary, much evidence indicates that mind-body techniques have a positive effect not only on HRV itself but also on health, emotions, and cognitive performance.

The Basics Matter

In keeping the HRV profile healthy, the most powerful, safe, and reliable measures are the simple ones, namely, learning to develop a positive or appreciative view on life. Acting out these feelings daily in a healthy dose of fun or compassion makes a difference. So be sure to tell your patient that he or she will be practicing good medicine by evaluating life and priorities and by maintaining gratitude and social connectedness.

Making Recommendations to the Patient

Given the foregoing data, you can develop an integrative plan to help patients maintain or enhance their HRV. In making an integrative treatment plan, you should ask the following questions: What are the known effects? What are the risks? What is the evidence? What is the cost or the availability? And, importantly, what does the patient believe or value? As a practitioner, your relationship with the patient and your own experience with a particular approach to healing strongly affect this last point. For this reason, you may want to experiment with several of these approaches yourself before talking to patients about them. Not only will you have the chance to improve your own health and well-being but also you will have a personal experience that allows you to step on a common path with the patient. This kind of mutual and personal teaching honors the spirit of integrative medicine, in which the health and wisdom of both patient and health care practitioners are important, indeed critical, to healing! Luckily, many of the approaches listed here are fun. You may even want to try them with your office staff or at home for your own learning. The Institute of HeartMath offers just such office-based trainings (see [Key Web Resources](#)).

Steps to Enhance Heart Rate Variability

Remember that patients do not need to attempt all or even most of these therapies immediately. A wise approach is to suggest that patients pick a few therapies that appeal to them first and then modify them as they come to know their own needs.

Step 1: Follow Good Preventive Measures

- Quit smoking.
- Maintain a healthy weight.
- Keep cholesterol levels in check.
- Eat a diet rich in omega-3 fatty acids, either from fish or from fish oils (see [Chapter 88](#)).
- Keep alcohol consumption low to moderate.
- Exercise regularly but moderately, with guidance from a physician if heart disease or other significant illness is present.

Step 2: Maintain a Healthy State of Mind

- Keep up social connections or make new ones. Healthy relationships are powerful determinants of heart health.
- Obtain professional help for serious symptoms of depression or anxiety.
- Develop practices that help you feel calm, centered, present, and appreciative (see [Chapter 94](#)). Music often makes this easier.

Deep, Slow Breathing

This breathing exercise is cheap, safe, and easy to perform in just a few minutes. The best results are achieved when people maintain six breaths/minute or simply focus on an appreciative or caring emotion that slows the breath and creates coherence automatically.

Meditation

Choose walking meditation, mindfulness meditation, chanting, or any other form that is appealing (see [Chapter 100](#)).

Prayer

Pray either on your own or in a group for the social connection.

Journaling

Even writing down a few words and phrases per day can be healing (see [Chapter 98](#)).

A Simple Beginning

In the office, a simple way to help patients begin enhancing HRV is to teach them a deep-breathing technique.

1. Have the patient place a hand on his or her belly—while you demonstrate!
2. Make sure to have him or her “deep belly breathe” so that the stomach rises on inhalation; on exhalation, the belly falls.
3. In general, have the patient aim to breathe out for twice as long, or whatever he or she can sustain, as compared with the in-breath. A 4–8 count, for example, works well. Imagining exhaling through a straw helps some people to slow down their out-breath.
4. Have the patient repeat this twice a day, morning and night, or whenever stress arises for 3–5 minutes to train the body-mind. If focusing on the breath per se is difficult, focusing on a positive feeling can work just as well.

Biofeedback

Several good computerized tools are on the market to help you learn to use biofeedback.

- www.wilddivine.com. This visually intriguing computerized adventure is driven as you learn skills to control your bodily rhythms through biofeedback.
- www.heartmath.com. This organization provides literature, handheld devices, and desktop biofeedback software, as well as thorough training for health care professionals and lay people. One limitation is that a person must be still to use these devices, but seeing live feedback is tremendously engaging to many who try it. Music can also be included in the program to assist you. Ultimately, the tools train you to function well without them.

Guided Imagery

Excellent resources for tapes or CDs are as follows:

- www.healthjourneys.com
- www.soundstrue.com

Step 3: Consider Medical Therapies and Supplements

- Beta-blockers, verapamil (and possibly other calcium channel blockers), and antiarrhythmics may improve HRV, but their use must be guided by a physician.
- Regarding depression, tricyclic antidepressants appear to worsen HRV, whereas SSRIs appear to improve it. St. John's wort may be beneficial. GABA appears to help with HRV recovery from stress.

Key Web Resources

HeartMath: This organization provides live events, biofield devices, and desktop biofeedback software, as well as thorough training for health care professionals and lay people. They offer the software computer biofeedback system, which runs approximately \$200.	http://www.heartmath.com/
Willi Davis: This visually engaging, computerized adventure teaches skills to control your body's response through biofeedback. The program costs approximately \$200.	http://www.willidavis.com/
Fidelis Charge 2: This new product has integrated HRV analysis into its tracking and has included sleep breathing statistics designed to improve HRV. A basic unit costs \$150. Many other similar products are still in development.	http://www.fidelis.com/charge2 http://www.oxyfitdata.com/ http://www.biofeedback.com/ http://www.polar.com/en-us/support/Heart_Rate_Variability_HRV

CHAPTER 97

Guided Imagery and Interactive Guided Imagery*

Martin L. Rossman, MD

Imagination is more important than knowledge.

Albert Einstein

As a physician treating primarily people with chronic and life-threatening illnesses for over 40 years, I have found working with mental imagery, especially in an interactive manner, one of the most useful approaches I have ever encountered.

As doctors, we are trained to diagnose and treat physically observable manifestations of disease and illness. In some instances, we can provide definitive, even lifesaving interventions, and both we and our patients are pleased and grateful. In many circumstances, however, our attempts to help do not result in a neat and acceptable result. We may not be able to diagnose the source of our patient's condition (84% of the 15 most common symptoms presented to a primary care doctor never come to be diagnosed as a disease state), or alternatively, we can give the condition a name and perhaps provide some relief but can do little or nothing about much of the suffering that accompanies it. This is especially true for our patients with chronic illness, who often represent the most challenging and time-consuming aspects of our practices.

People with chronic illness need not only excellent medical care but also attention to what we may call the invisible yet important aspects of health care that are accessible only through their own awareness. A skilled clinician with sophisticated imagery skills can help such patients work effectively with their own strengths to help them fare better, whatever their medical condition may be.

What is Guided Imagery?

Guided imagery is a term variously used to describe a range of techniques from simple visualization and direct imagery-based suggestion through metaphor and storytelling. Guided imagery is used to help teach psycho-physiological relaxation, to relieve pain and other symptoms, to stimulate healing responses in the body, and to help people tolerate procedures and treatments more easily.

Interactive Guided Imagery (IGI) is a service-marked term coined by the Academy for Guided Imagery for a process in which imagery is used in a highly interactive format to evoke a patient's autonomy. This technique gives patients ways to draw on their own inner resources to support healing, make appropriate adaptations to changes in health, and understand more clearly what their symptoms may be signaling.

Imagery is a natural way that the human nervous system stores, accesses, and processes information. It is the coding system in which memories, fantasies, dreams, daydreams, and expectations are stored. It is a way of thinking with sensory attributes, and in the absence of competing sensory cues, the body tends to respond to imagery as it would to a genuine external experience. The most common and familiar example of this phenomenon is sexual fantasy with its attendant physiological responses.

Imagery has been shown in dozens of research studies to be able to affect almost all major physiological control systems of the body—respiration, heart rate, blood pressure, metabolic rates in cells, gastrointestinal mobility and secretion, sexual function, and even immune responsiveness. Imagery is also a rapid way to access emotional and symbolic information that may affect both physiology and the way that patients care for themselves. For instance, a patient may talk at length about the nature of his or her back pain, yet the clinician may not appreciate it as much as when the patient uses imagery-laden language and says, "It feels like a knife twisting in my back." Not only does this give a graphic, sensory description of the symptom but also it may lead to important psychosocial information involved in the perception of the pain. In this case, respectful questioning about betrayals or related feelings would be appropriate ([Box 97.1](#)).

The following personal case history shows how imagery can help us become more aware of the interplay of feelings, physiology, and symptoms.

Case History (Headaches)

A 28-year-old woman with chronic mixed headaches came to my office with a severe migraine. We had worked together before, so I guided her through a simple progressive relaxation technique and asked her to focus directly on her pain and invite an image to come to mind that could tell her something useful about the pain. An image came of a large mynah bird sitting on her head and pecking away in the area of her pain.

BOX 97.1 Indications for Guided Imagery

- To help reduce acute or chronic stress and anxiety
- To reduce or relieve symptoms once they are diagnosed
- To prepare for a surgical operation or other procedure
- To help reduce or manage side effects of medications or procedures
- To help patients and practitioners better understand symptoms
- To increase coping abilities with chronic illness
- To help fight illness through working with the body's own healing processes
- To help manage anxiety, fear, and pain
- To help people prepare for changes including lifestyle, habits, adaptation to illness, and even death

"Why's he doing that?" she asked, and I suggested that she ask him and imagine that he could answer in a way she could understand.

To her surprise, the bird answered, "Why not? You let everyone else pick on you!" She started crying and told me that the day before she had accidentally overheard a fellow employee making fun of her in the coffee room. She started to get angry, but then became nauseated and started to feel a migraine aura. She went home for the day, and the migraine developed into the headache that brought her in to see me. In her imagery dialogue, the bird agreed to work with her to understand and prevent her headaches more effectively. She left feeling 90% relieved without any other intervention.

The patient's continuing dialogues with the mynah revealed a long-standing pattern of low self-esteem and lack of assertiveness. The bird told her that the result was holding anger and directing it toward herself, a process that ultimately led to her headaches. I referred her to a good therapist; after 18 months, she was not only relieved of headaches but also much happier and heading in a more successful direction in her life.

Applications in Medicine

Because imagery is a natural language of the unconscious and the human nervous system, its potential uses in the healing professions are protean. Guided imagery is essentially a way of working with the patient, rather than of treating particular disease entities, but it is especially effective in the following areas:

- Relaxation training and stress reduction
- Pain relief
- Management of chronic illness and prevention of acute exacerbations
- Preparation for surgery and medical procedures
- Medication compliance and adherence issues
- Cancer treatment and life-threatening illnesses
- Terminal illnesses and end-of-life care
- Fertility, birthing, and delivery
- Grief therapy
- Posttraumatic stress disorder
- Anxiety disorders
- Depression

Guided imagery is a broad term comprising techniques that are applicable in the course of brief medical office visits or in longer counseling or psychotherapy formats. Physicians may practice it themselves or may employ ancillary health professionals to offer longer sessions. Physicians may also teach their patients guided imagery skills for self-care by educating them about it and recommending or prescribing appropriate guided imagery books, compact discs (CDs), and audio downloads (see the later section on resources and the [Key Web Resources](#) box).

Is Research Literature Available on Guided Imagery?

A large body of clinical research supports the everyday use of imagery in medicine, and research in this area has significantly increased in the past few years. Of more than 1200 PubMed articles on guided imagery research since 1969, nearly 500 have appeared since 2005, and half of them have been published since 2009. More than 90% of the studies show positive benefits in clinical situations that include stroke rehabilitation, preparing for childbirth, treating anxiety disorders and posttraumatic stress disorder, relieving pain in both children and adults, preparing for

surgery and medical procedures, changing eating habits, smoking and drug cessation, and supporting patients during cancer treatment. A summary of the evidence on guided imagery and visualization on immune function is summarized in [Box 97.2](#).

How does Imagery Work?

Research with functional magnetic resonance imaging indicates that when people visualize things or events, they activate the occipital cortex in the same way they do when they actually see the same things or events. Similarly, the temporal cortex is activated when music or speech is imagined, and the motor or premotor areas of the cortex are activated when a person imagines movement. We believe that this cortical activation sends neural and neurochemical messages to lower centers of the brain that can activate or deactivate stress responses. Neuropeptides can also affect physiology at a distance and can modify physiological states, including blood pressure, clotting mechanisms, and immunity.

Clinically, we have known for many years that when people worry, which is an imaginative function, they can activate stress physiology, which over time can lead to physiological exhaustion, maladaptive behavior, and vulnerability to illness. In the same way, when a patient imagines himself or herself in a beautiful, peaceful, safe place and concentrates on what he or she imagines seeing, hearing, and feeling there, the patient tends to induce a state of relaxation similar to what he or she would feel if actually in that place. The physiology of the “relaxation response,” as described by Benson, takes over, thus allowing a break in the chronic stress state and facilitating certain reparative and restorative processes the body uses for healing. With regular practice, the creation of this state can help reverse some of the effects of chronic stress.

BOX 97.2 Guided Imagery Effects on Immune Function as Summarized by Trakhtenberg

- A relationship exists between immune system functioning and guided imagery and stress/relaxation.
- Guided imagery and relaxation interventions can reduce distress and allow the immune system to function more effectively.
- Changes in immune system functioning are correlated with either an increase or a decrease in white blood cell (WBC) count or with

changes in neutrophil adherence.

- Stress/relaxation may account for qualitative (the nature of neutrophil adherence) or quantitative (WBC count) changes in immune system functioning.
- Cell-specific imagery may predict in which WBC category (i.e., type of WBC—neutrophils or lymphocytes) changes in WBC count will occur.
- An active cognitive exercise or process involved in the initial stages of guided imagery is associated with decreases in neutrophil adherence. In contrast, relaxation without an active imagery exercise is associated with increases in neutrophil adherence.
- Decreases in WBC count occur only in the initial stages of exposure to guided imagery or relaxation interventions. After 4–5 weeks of training, however, WBC count increases.
- Increases in WBC count may be caused by an increase in WBC production as a result of enhanced relaxation ensuing from extensive visualization practice, and decreases in WBC count in the initial stage of visualization training are secondary to a decrease in WBC production as a result of possible pressure ensuing from an attempt to learn new training techniques.
- Decreases and increases in WBC count may be caused by the effect of margination. This means that imagery training may change the movement of WBCs and their location within the body, rather than decreasing or increasing production of WBCs.
- The change in WBC count may occur earlier in medical patients with a depressed WBC count and later in physiologically normal, healthy individuals.

Adapted from Trakhtenberg EC. The effects of guided imagery on the immune system: a critical review. *Int J Neurosci.* 2008;118:839-855.

The creation of a relaxed state also allows the patient to experience that he or she has some choice in feelings about and response to stressors, which can lead to greater self-efficacy and changes in lifestyle patterns that affect health. Finally, in a relaxed yet aware state, the body is more responsive to images and suggestions of pain relief, comfort, enhanced or reduced blood flow, and even upregulation of immunity.

Worry is an example of how negative images can trigger stress physiology. Imagery can also be directed toward positive physiological responses.

Imagery is sometimes referred to as a “right brain” type of thinking because it tends to be synthetic, creative, and emotional. This type of thinking contrasts with the “left brain” form of linear, logical thinking with which we are all highly familiar.

These attributions are best considered a shorthand way of referring to modes of thinking that are associated with, but not restricted to, the respective hemispheres of the brain. They may be more accurately termed simultaneous versus sequential information processing. To illustrate the difference between these two types of thinking, let us imagine watching a train go by from two different perspectives. From the left brain or sequential processing perspective, one would observe the train from the level of the track. One would see the engine go by, then the first car, then the next, and the next, and so on—one car at a time, each following the one before. The right brain or simultaneous perspective would place one high above the train, where one could see not only the whole train, but also the tracks for miles ahead and behind, the countryside through which it travels, the place it started, and its next destination. Similarly, the holistic perspective of imagery shows one the forest, whereas the analytic perspective of linear thinking lets one more closely examine the trees; both are useful.

Perhaps the reason that imagery seems so mysteriously powerful is that we have almost systematically ignored it in scientific culture and, as it is rediscovered, its many advantages in mind-body healing make us marvel at its utility. Imagery provides many advantages over analytical thinking when it is applied to personal healing. One is the big-picture perspective that it offers. As the previous case history and the following example illustrate, imagery can often show how life events, emotions, and physical symptoms are connected.

Case History (Lumpy Breasts)

A patient with lumpy breasts was invited to allow an image to come that represented the lumps. She was surprised that she imagined them as pearls. On exploring the pearl image, she realized that pearls are formed in response to something irritating that could eventually turn harmful. Her orientation changed as she considered this idea. “Maybe the lumps

are trying to protect me,” she said. “They want me to reduce the stress I’ve been living with and the caffeine I’ve been using to try to keep up.” This understanding led her to stop drinking coffee and change the way she was living to reduce her stress; her fibrocystic lumps soon disappeared.

Another advantage of imagery in mind-body healing is that it is closely related to emotion. Imagery is the basis of the arts and the essence of painting and sculpture as well as of poetry, storytelling, dance, drama, and even music. Imagery moves us and can represent what affects us emotionally. Because unexpressed emotions are often expressed in the body, many common and unexplainable symptoms that doctors see represent patients’ feelings that are unrecognized and unattended. Imagery can bring these connections to light and make them available for expression and potential resolution (see [Chapter 102](#)).

Imagery is also closely related to physiology. Imagining sucking on a lemon stimulates salivation in most people, whereas imagining frightening events elevates the heart rate and blood pressure. Imagining muscle relaxation produces muscle relaxation, and regular imagining of an activated immune system increases both the number and aggressiveness of natural killer cells. This psychophysiological connection may account for the wide range of syndromes in which imagery has proved useful. These diagnoses include, but are not limited to, asthma, allergic rhinitis, tension and migraine headaches, neck and back pain, irritable bowel syndrome, premenstrual dysphoria, dysmenorrhea, Raynaud syndrome, anxiety, depression, hypertension, angina, and even diabetes. Imagery has also been shown to relieve anxiety and complications of invasive medical and surgical procedures, including endoscopy, colonoscopy, biopsy, and angiography, as well as childbirth.

Guided imagery acts as a bridge of communication of information between the subconscious and conscious mind that the patient can use to find health.

Commonly Used Treatment Techniques

The list of techniques used in guided imagery is quite extensive because this approach has been applied to problems ranging from chronic pain to

posttraumatic stress, to stimulating healing responses in the body, to enhancing mind-body awareness, and more. However, some of the more basic techniques are described here.

Mental and Physical Relaxation

Imagery is often the easiest way for many Western patients to learn to relax. Typically, patients are instructed in abdominal breathing and sequential or progressive relaxation suggestions and are then invited simply to daydream themselves to a place of great beauty, safety, or peacefulness or a place that they experience as healing. Patients are guided to notice what they see, hear, feel, and even smell as they imagine themselves in a relaxing place. As they immerse themselves in the imagery in this way, they tend to relax easily and deeply.

Symptom Relief Through Healing Imagery

Symptomatic imagery techniques reduce physical symptoms such as pain, anxiety, and insomnia without concern for the causes. Such techniques are useful alternatives or complements to medications and are particularly helpful when discomfort has a stress-related or functional basis. Many different situations and techniques are used, such as relaxation and then imagining how healing could happen in an area that is symptomatic. When patients are successful in relieving pain or other symptoms with imagery, they find the experience profoundly therapeutic and empowering.

Interactive Imagery Dialogue

Interactive imagery dialogue can be used with an image that represents anything the client or therapist wants to know more about; in many ways, it is the quintessential insight technique. This method is used to explore an image of a symptom (whether physical, emotional, or behavioral), an image that represents resistance arising anywhere in the process, an image of an inner resource that can help the client deal with the current problem, or an image of the solution.

With interactive imagery, the point is not to analyze the images but to communicate with them as if they are alive (which, of course, they are). This is not to say that the images have an existence apart from the client, but rather that they represent complexes of thoughts, beliefs, attitudes,

feelings, body sensations, expectations, and values that at times can function as relatively autonomous aspects of the personality. These constellations were referred to as “subpersonalities” by Roberto Assagioli,¹ the originator of psychosynthesis, and as “ego states” by Watkins and Watkins.²

The Inner Advisor

The inner advisor is a specific type of IGI dialogue whereby clients are invited to converse with an imaginary figure that is specified to be both wise and loving or, as characterized in analytic terms, an “ego ideal.” This figure can be referred to as the “inner guide,” “inner healer,” “inner wisdom,” “inner helper,” “inner physician,” “higher self,” or any other term that is meaningful to and comfortable for the client. Because the client is invited to imagine a figure that has these qualities, a dialogue with whatever figure arises is usually meaningful and helpful. Specifying the positive qualities offers some safety to clients if they find themselves exploring issues that may be emotionally difficult. When used properly, this is one of the most useful imagery dialogue techniques.

Evocative Imagery

The state-dependent technique called evocative imagery helps clients to shift moods and affective states at will, thus making new behaviors and insights more accessible to consciousness. Through the structured use of memory, fantasy, and sensory recruitment, the client is encouraged to identify a personal quality or qualities that would serve especially well in his or her current situation. For instance, a client may feel the need for more “calmness” or “peace of mind” to deal more effectively with a life issue or a medical illness. The guide then invites the client to relax and recall a time when peace of mind was actually experienced. Through the use of sensory recruitment and present-tense recall, the client is encouraged to imagine that he or she is in that time again now, feeling that peace of mind. Once this peaceful feeling state has been well established and amplified, the patient is invited to let the past images go, but to come back to the present, bringing along the feelings of peace of mind. As the client now becomes aware of the situation while strongly in touch with this feeling, he or she is usually able to tolerate it far more effectively.

Dr. Sheldon Cohen³ at Carnegie-Mellon University in Pittsburgh

researched evocative imagery and found it to be highly effective in shifting affective states. Research aimed at assessing the effects of those altered affective states on subsequent behavior, problem solving, and self-efficacy remains to be done and offers a fertile field for future psychological and behavioral study.

Grounding: Moving From Insight to Action

Grounding is the process by which the insights evoked by imagery are turned into actions and greater awareness and motivations are focused into a specific plan for attitudinal, emotional, or behavioral change. This process of adding the will to the imagination involves clarification of insights, brainstorming, choosing the best option, affirmations, action planning, imagery rehearsal, and constant reformulation of the plan until it actually succeeds. It is often the missing link in insight-oriented therapies because it connects the new awareness to a specific action plan. Grounding is “where the rubber meets the road,” and imagery can be used to enhance the process by providing creative options for action; the guide and client can use imagery rehearsal to troubleshoot and anticipate obstacles to success.

How to Get Started with Guided Imagery

The first thing the practitioner should do is notice how much imagery-laden language and suggestion are used in daily interactions with patients. Notice the terms patients use when they describe “knife-like” pains or the feeling of a “hot poker in my stomach.” The practitioner should notice his or her own uses of imagery, too, such as in describing the mechanisms of a medication or intervention. Simple word pictures are commonly used when we prescribe and try to motivate patients to follow the regimen. Simple descriptions such as “This will relax the little muscles in your blood vessels and that will lower your blood pressure” and “Acupuncture releases brain chemicals that relax your muscles and relieve pain” are very brief forms of what can be called guided imagery. Physicians can sometimes forget this effect when they become caught up in the necessities of informed consent, which tends to focus too much on the negative potential of treatments. Without “overpromising,” physicians should accompany any prescription or recommendation with an expectation that it will be of help, and a brief word picture of how that can happen conveys a large amount of information in a concise way.

The practitioner should read books on guided imagery and experiment personally with guided imagery CDs or audios available through mp3 downloads (see [Key Web Resources](#), later). The more personal experience a practitioner has with guided imagery, the easier it will be to teach these skills to patients or simply to recommend or prescribe particular guided imagery exercises, lessons, or techniques. Some physicians recommend that patients listen to guided imagery audios and write about their experiences. The physician then debriefs the experience with the patient at a later time, answers questions, and offers guidance on how to use the technique on a continuing basis.

The physician who wishes to guide patients through imagery experiences but has no experience or training in any form of relaxation, hypnosis, or meditation should pursue such training. Continuing medical education courses or local classes at community colleges or through other local sources are means of becoming familiar with mind-body approaches. Training that is specifically created for physicians or health professionals is more likely to be quickly usable with patients. For example, the Academy for Guided Imagery offers an excellent introductory course in a home study format, “The Fundamentals of Interactive Guided Imagery.” This course provides rationale, references, and an introduction to clinical skills that can allow the physician to explore guided imagery safely in practice. I consider such a course the minimum a professional should study before using guided imagery in practice.

The Structure of a Typical Interactive Guided Imagery Session

At the Academy for Guided Imagery, we refer to the time spent before entering into a formal guided imagery exploration as the “foresight” part of the process. Along with evaluating the appropriateness of using imagery with the client or patient, the guide works with the client to establish the desired goals and objectives for their work together.

As with any medical or psychological situation, goals can be defined in physical, emotional, or behavioral terms, and a reasonable trial period of exploration is agreed on by the client and guide. We often ask patients to have three exploratory sessions and then decide whether this approach seems useful to them, whether they can best use guided imagery as self-care, in a brief, time-limited period of work (10–15 sessions), or whether

longer-term work seems to be needed.

The typical processes involved are described here. Not every session uses the same approach; all sessions may use any of a wide variety of processes and methods of exploration drawn from the guide's training and experience (Boxes [97.3](#) and [97.4](#)).

Precautions and Contraindications

Although directive guided imagery sessions are generally quite safe, receptive imagery, as used in IGI, can be a powerful tool that can connect people with emotional material very quickly. If patients are emotionally fragile, have a history of psychosis, or have repressed traumatic material, receptive imagery can reveal affective content that can be overwhelming. The practitioner should be sufficiently trained in guided imagery skills to be able to recognize potentially problematic situations and to prevent or remedy them when encountered unexpectedly.

BOX 97.3 A Typical Interactive Guided Imagery Session (see also [Box 97.4](#))

1. Assessment (foresight):

- a. Ask what symptom, illness, or thoughts the patient would like to explore.
- b. Ask what the patient wants to get out of the session.
- c. Ask the patient to narrow the problem to a short phrase or question.
- d. Formulate a one-sentence summary of goals.
- e. Obtain the patient's consent.

2. Imagery process (insight):

- a. Relaxation:
 - (1) Ask how the patient best relaxes.
 - (2) Use the patient's best method or teach him or her a method.
- b. Imagine a beautiful, safe place:
 - (1) "Allow yourself to imagine a comfortable and peaceful place. It may be a place that you have been before or something that's just coming into your imagination now. If you imagine several places coming to mind, allow yourself to pick just one to explore now."

- (2) Ask the patient to describe the place in regard to sensations (“What do you see, hear, smell, feel, and taste? What makes you feel comfortable there?”)
 - (3) Invite the patient to find a comfortable place to settle down.
- c. Imagery dialogue:
- (1) Invite the patient to form an image that represents the illness, symptom, or issue.
 - (2) Ask the patient to describe the image in detail. (Have him or her describe at least three things, such as the appearance, character, and emotions of the image.)
 - (3) Ask the patient to describe the qualities that the image portrays.
 - (4) What feelings does the patient have about the image?
 - (5) Invite the patient to express these feelings to the image, and allow the image to respond.
 - (6) “Imagine that it can communicate with you in a way you can easily understand.”
 - (7) Facilitate the imaginary conversation as needed, using “content-free” questions and suggestions such as the following:
 - (a) “Do you have any questions you would like to ask the image?”
 - (b) “How does it respond?”
 - (c) “Ask the image what it wants from you, and let it respond.”
 - (d) “What does it want you to know?”
 - (e) “What does it need from you?”
 - (f) “What does it have in common with you?”
 - (g) “What does it have to offer you?”
 - (h) “Ask the image what it can tell you about the problem so you can better understand.”
 - (i) “Ask the image what it can tell you about the solution so you can better understand.”
 - (j) “Go back to the safe place, and return from the inner place.”
- d. When the image communicates, you may ask the patient how he or she feels about that or wants to respond, then encourage the patient to respond, and let the image respond to that. Your role is to facilitate the dialogue, not provide the answers.
- e. If the patient appears frightened, ask whether he or she feels safe; if not, have the patient go back to the safe place or ask what he or she

needs to feel safe.

3. Evaluation (hindsight):

- a. Ask the patient what he or she felt was interesting or significant about the dialogue.
- b. Ask the patient whether he or she learned anything from or about the image or the symptom.
- c. Ask the patient whether the information changes his or her perspective or how he or she wants to respond.
- d. Ask the patient what he or she would do next with what was learned.

Many physicians, nurses, and therapists work for a defined period of time (6–20 sessions) with patients in a psychoeducational or counseling model, with well-defined symptomatic or behavioral goals, and they refer patients to mental health practitioners if their work becomes psychologically complex. At the same time, we urge mental health practitioners to take precautions to ascertain the medical status of any patient and to ensure that the patient is also aware of the medical options.

At the end of each session, and at the end of the agreed-on period, the goals of the work are reviewed and progress is assessed. After this evaluation, an agreement is made to terminate treatment, to continue for another period, to refer the patient to another practitioner, or to define a period in which the patient will do “ownwork” and then return to report his or her progress.

BOX 97.4 Common Interactive Guided Imagery Suggestions and Questions

- Allow an image to form.
- What do you notice about it?
- What are you aware of?
- What are you experiencing?
- What would you like to notice yourself having?
- What would you like to say to it?
- What sensations are you aware of?
- Let me know when you are ready to move on.

Although guided imagery can sometimes help shed light on a puzzling diagnostic situation, it should not be used in lieu of a proper medical diagnosis to avoid overlooking necessary medical treatment. With due attention to this issue and the precautions and contraindications listed in Boxes [97.5](#) and [97.6](#), the practitioner can practice guided imagery safely and help patients become more active participants in their own health.

Resources

Training

Simple guided imagery for relaxation and healing is generally safe if the guidelines provided are followed. IGI is a powerful proprietary method of personal and psychological inquiry that can rapidly expose high levels of affect that can be overwhelming to certain patients. Practitioners desiring to use IGI should have an appropriate level of training for the applications they choose. The “Fundamentals of Interactive Guided Imagery” is a 13-hour home study course that will give you a thorough and meaningful introduction to this form of treatment and its roles in medicine, along with several essential skills you can begin to use in your practice. The Academy for Guided Imagery (800-726-2070; see also the [Key Web Resources](#) box) also offers in-depth training that leads to certification in IGI.

BOX 97.5 Contraindications to Guided Imagery

- Strong religious beliefs proscribing the use of imagery
- Disorientation, dementia, or impaired cognition in response to pharmacological or other agents
- Inability to hold a train of thought for at least 5–10 minutes
- Potential litigation (guided imagery may be considered a form of hypnosis, which affects the legal status of information obtained with its use)

BOX 97.6 Conditions in Which Guided Imagery Should Be Used With Caution*

- History of physical or sexual abuse

- Active psychosis or a prepsychotic state
- Diffused dissociative disorders
- Posttraumatic stress disorder or anxiety disorders
- Personal history of a suicide attempt or family history of suicide or a suicide attempt
- Unstable medical problems, such as severe asthma, heart disease, and pain

* Practitioners treating people with these conditions/situations should be very well versed in both the treatment of the underlying disorder and the use of guided imagery.

Guided Imagery Recordings and Self-Study Programs

Audio recordings and self-study programs can be helpful tools to facilitate healing. Some respected resources for imagery tapes and CDs are listed in the [Key Web Resources](#) box. These website listings offer disease-specific recordings as well as recordings addressing general topics such as surgical preparation and recovery, immune support, and cancer therapy.

Key Web Resources

The Healing Mind: This website offers many guided imagery CDs and self-study programs by Dr. Martin Rossman and others, based on interactive imagery principles, as well as research, health tracker, interactive opportunities, and other material useful to patients and professionals.	http://www.thehealingmind.org
The Science: Dr. Barbara Miller has spent many years studying and practicing psychophysiological medicine and offers a wide variety of excellent health-oriented guided imagery and hypnosis recordings.	http://www.drbarbaramiller.com
Health Journey: This large selection of excellent guided imagery CDs on many health topics is created by Deborah Nigamsky, LISW.	http://www.healthjourney.com
Academy for Guided Imagery (AGI): This website provides information, research, resources, and certification in guided imagery.	http://www.agi.org/links
Kaiser Permanente audio library: This audio library contains free downloadable guided visualizations for various health conditions including preparing for surgery.	http://www.kaiserpermanente.org/healthcare/learn?hp_startsite_referrer=hp.org/links
Mind Body Solutions: This website app offers over 500 stimulating audio experiences including guided imagery, self-hypnosis, transcendental meditation, and more.	http://www.mindbodysolutions.com

CHAPTER 98

Journaling for Health

Adrienne Hampton, MD, and David Rakel, MD

I find, by experience, that the mind and the body are more than married, for they are most intimately united; and when one suffers, the other sympathizes.

LORD CHESTERFIELD

The sorrow that hath no vent in tears may make other organs weep.

Henry Maudsley

Pathophysiology of Disclosure

The expression of emotionally upsetting experiences by writing or talking has been found to improve physical health, enhance immune function, and result in fewer visits to medical practitioners.¹

In attempting to understand the pathophysiology behind the positive clinical effects of disclosure, we can review a study by James Pennebaker,² a pioneer in the field. He interviewed polygraphers (operators of lie detectors) who worked for the Federal Bureau of Investigation and Central Intelligence Agency. In performing these tests, the polygraphers would look for changes in parameters of the autonomic nervous system, such as heart rate, blood pressure, respiratory rate, and skin conductance, for clues of validity. Pennebaker described what was called the polygraph confession effect, in which readings in these areas significantly dropped after a person confessed. These changes were consistent with those seen with relaxation. Investigators believe that to inhibit actively one's thoughts, feelings, and behaviors requires physical work that can result in chronic low-grade stress to the autonomic

nervous system, which may, in turn, lead to disease. This inhibition can also lead to dysregulation of the hypothalamic-pituitary-adrenal axis and cause hypercortisolemia and immune suppression.³

Disclosing stressful events transfers repressed thoughts from the unconscious to the conscious level, at which they can be organized and controlled. This transfer removes the need for chronic low-grade stress to stimulate the autonomic nervous system and the hypothalamic-pituitary-adrenal axis that can lead to disease and somatic symptoms. Disclosing allows the mind to interpret this new information from the subconscious and unlocks emotions that can stimulate positive physical results.

To illustrate how a stressor is stored in the mind, let us consider the money machine that is often an attraction at a county or state fair. The machine consists of an enclosed booth, a pile of paper money, and a fan. A lucky person wins the chance to enter the booth and grab as much money as possible while the fan blows it all around. When the human mind stores a stressful event, the event is not organized and stored as a concrete thought, but rather exists as a chaotic accumulation of a multitude of images, sensations, and emotions, like the money in the booth. Not until we grab the money, hold it in our hand, and count it are we aware of what we have. Disclosing is the process of organizing chaotic thoughts, thus allowing a person to interpret and evaluate the stressor. When this is done, the chronic somatic stress improves because the body no longer needs to sympathize.

When people put their emotional upheavals into words, either through expressive writing or talking, their physical and mental health improves.

Journaling After a Stressful Event

A review of online journal entries before and after the World Trade Center destruction in New York City on September 11, 2001 (9/11) offers insight into how a community discloses and communicates after a tragic event. If a community opens up and talks about the event, the health of the community improves. After 9/11, the city of New York had fewer visits to health care providers. It appears that this tragic event opened people up and stimulated communication that fostered relationships and a sense of community. The words they used in their writing switched to include less use of the ego-centered “I” to a more communal use of “we.” This event brought the community together and reduced social isolation, in part by allowing its members to express their emotions ([Box 98.1](#)).⁴

This process happens naturally in the first 2–3 weeks after a tragic

event. This period is called the emergency phase, during which people and the media open up and discuss the event openly. Approximately 3 weeks after the event, the amount of discussion significantly declines, even though emotions and thoughts about it remain (Fig. 98.1). At this time, called the inhibition phase, when thoughts of the event remain but no one is talking about it, one may wish to encourage continued emotional expression.

Although seeing how this process unfolds in communities is interesting, how may this process of disclosure help us facilitate better health for individual patients? Let us first explore some key studies that show benefit.

BOX 98.1 How to Journal

1. Find a quiet place where you will not be disturbed.
2. Using pen, pencil, or computer, write about an upsetting or troubling experience in your life, something that has affected you deeply and that you have not discussed at length with others.
3. First, describe the event in detail. Write about the situation, surroundings, and sensations that you remember.
4. Then, describe your deepest feelings about the event. Let go and allow your emotions to run freely in your writing. Describe how you felt about the event then and how you feel now.
5. Write continuously. Do not worry about grammar, spelling, or sentence structure. If you come to a “block,” simply repeat what you have already written.
6. Before finishing, write about what you may have learned or how you may have grown from the event.
7. Write for 20 minutes for at least 4 days. You can write about different events or reflect on the same one each day.
8. If the process proves helpful, consider keeping a journal regularly.

Adapted from Rakel DP, Shapiro D. Mind-body medicine. In: Rakel RE, ed. *Textbook of family practice*. 6th ed. Philadelphia: Saunders; 2001.

Key Areas of Research

Asthma and Rheumatoid Arthritis

Smyth et al.⁵ asked 107 patients with asthma or rheumatoid arthritis to write either about the most stressful event of their lives (study group) or about daily events (control group) for just 20 minutes over 3 consecutive days. Four months after journaling, the asthmatic patients in the treatment group showed a 20% improvement in lung function compared with no improvement in the control group. The patients with rheumatoid arthritis who wrote about stressful events showed a 28% reduction in disease severity, whereas the control group showed no change. These are excellent results requiring only paper, pencil, and 60 minutes of a patient's time.

Memory Function

Writing about emotional events may enhance cognitive function and memory. In one study, college freshmen at North Carolina State University who were assigned to write about their thoughts and feelings about coming to school showed better working memory after 7 weeks compared with students who wrote about trivial topics.⁶ Another group in the same study who wrote about their negative emotions had not only better memory but also less intrusive thinking; they were better able to focus on their studies. When students wrote about the stress of an upcoming test, they performed better on the examination.⁷ Other research has linked such writing to higher grades among college students.^{8,9}

Wound Healing

A study of similar design showed that writing about emotional events resulted in quicker wound healing than writing about trivial topics such as time management.¹⁰ (No noticeable health benefit has been found in control groups who write about managing time in their lives.) In the second week, after writing for 20 minutes a day for 3 days, the subjects underwent a punch biopsy in the upper arm. Those who wrote about traumatic events had significantly smaller wounds 14 days after the puncture than did those who wrote about trivial topics.¹⁰

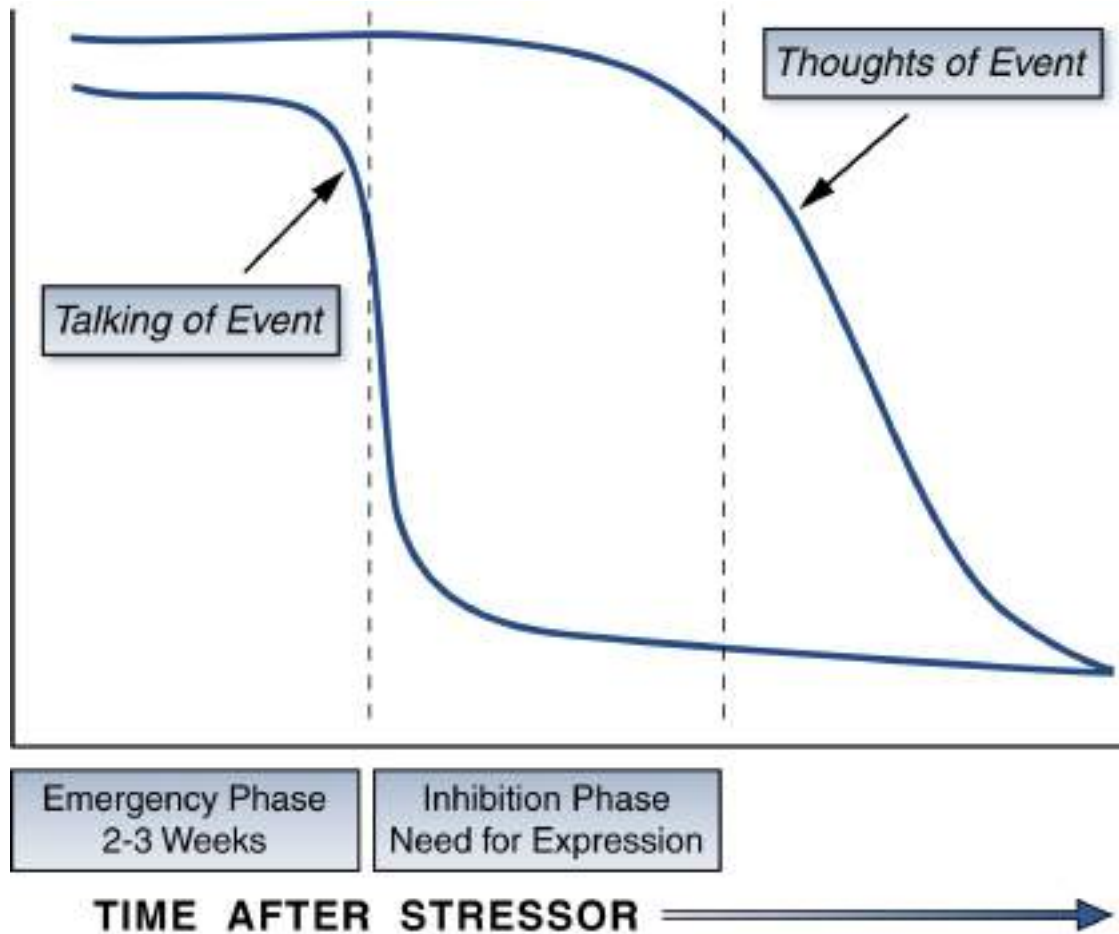

FIG. 98.1 The pattern of talking compared with thinking about a traumatic event. Journaling is most beneficial during the inhibition phase when talking decreases but thoughts remain. (Adapted from Rakel DP. Journaling: the effects of disclosure on health. *Altern Med Alert.* 2004;7:8-11.)

Irritable Bowel Syndrome

Of 103 study subjects with irritable bowel syndrome, 82 in the writing group were asked to write for 30 minutes at an online portal for 4 consecutive days about their deepest thoughts, emotions, and beliefs regarding the disease and their perception of its effects. Compared with the nonwriting control group, the expressive writing resulted in improved disease severity and fewer negative thoughts about their irritable bowel syndrome.¹¹

Blood Pressure and Infectious Disease

Steffen et al.¹² reported that African-American subjects who had a higher level of perceived racism with the suppression of anger were also found to have higher blood pressure than subjects with lower levels of perceived racism. The first group also had higher blood pressure during sleep, a finding suggesting a baseline elevation in sympathetic tone.

Another study showed a higher incidence of infectious diseases and cancer in homosexual men who concealed their homosexual identity than in those who were open about their sexuality.¹³

Employment

In times of challenging economies and job layoffs, learning how the expression of emotions through writing can enhance the ability to obtain a job can be helpful. A group of senior level engineers who wrote about the emotions of being laid off found new jobs more quickly than did those who did not write. The writing allowed the former group to address the anger, deal with it, and move on. The researchers of the study concluded that this work allowed the first group to have a more positive interview presence when they were looking for a job.¹⁴

Writing Characteristics Associated with Health

For therapeutic benefit, the health care practitioner does not need to read what is written. In fact, more harm can come from having patients read their writing to others. The therapeutic benefit comes from the expression of the emotions themselves. In evaluations of such writing, however, the following key characteristics have been most commonly associated with a shift toward improved health:^{15,16}

- The writer constructed an evolving story. People who created a story with a beginning, middle, and end did better than those who wrote the same story day after day. Creating a story transforms the event into one that is easier to understand and learn from.
- The writer developed insight and used more causal words (realize, understand).
- The writer developed more optimism, with greater use of positive words and a moderate number of negative words.
- As the story evolved, pronouns changed from the first person singular (I, me, my) to the second person plural (we, us), suggesting that with

writing, the person became less isolated and more connected to his or her community.

The writing topic is less important than the exploration of emotions and thoughts related to a topic.

Precautions

The process of disclosure may improve physical but not always mental health.¹⁷ Our minds suppress traumatic events for a reason, and uncovering these events can be difficult for the conscious mind to handle, especially in children. In many cases, patients should work closely with a licensed therapist so they can continue to heal from this expression.

The timing of disclosure is also important. When the mind-body is ready to deal with repressed emotions, it generally has a way of letting us know. The danger comes in encouraging someone to write or express emotions when he or she is not ready to do so. This gives meaning to the old Zen saying, “Don’t push the river.” Do not encourage writing immediately after a stressful emotional event. Research suggests that this is not helpful and may be harmful.¹⁸ A general recommendation on when to write is to consider expressive writing when the individual finds his or her mind focusing on an event repetitively or ruminating over something.

In helping others explore emotions of past events, one must avoid creating guilt. Little evidence shows that traumatic events in our lives can increase the risk of a disease such as cancer. We must not create this association but simply learn how these events can help us improve our current and future health.

Relationship-Centered Care

The primary care practitioner is in an ideal position to help patients heal through disclosure because people are more likely to discuss stressful events with someone who is accepting and whom they trust.¹⁵ This relationship takes time to develop to a point at which a patient feels comfortable with disclosure. It takes an average of 1 month for children to discuss an abusive event with a psychotherapist.¹⁹ The most important aspect of relationship-centered care is that we provide an environment in

which the patient feels comfortable exploring issues that allow us to discover the root of what can influence long-term health. In doing this, whatever tool we use, be it journaling or counseling, will work better because our patients have a connection with someone with whom they feel comfortable sharing their deepest and most meaningful stories. Listening with intention and compassion may be our most valuable therapeutic tool.

The Patient Handout at the end of this chapter offers directions for patients on how to journal to improve health.

Chapter 99

Forgiveness

J. Adam Rindfleisch, MPhil, MD

I forgive you. You took something very precious from me. I will never talk to her again. I will never, ever hold her again. But I forgive you. And have mercy on your soul.

Nadine Collier, daughter of Ethel Lance, who was killed in the 2015 Charleston church shootings, speaking in court to the man who killed her mother¹

It is estimated that more than 90% of people experience severe trauma at least once in their lives, and recent research confirms what clinicians instinctively know: Traumatic experiences can lead to lasting health effects.² A 2010 review found that childhood traumatic events greatly increase the likelihood of several negative outcomes, including tobacco dependence, injection drug use, alcoholism, posttraumatic stress disorder, and other psychiatric issues.³ Childhood traumatic events are also linked to a decrease in overall quality of life,⁴ increased incidence of chronic pain,^{5,6} shorter lifespan,⁷ and a

multitude of other chronic physical problems. Unfortunately, the effects of trauma can even have negative consequences for a traumatized person's descendants as a result of epigenetic and other influences.⁸

Many traumas—violent crime, domestic violence, rape, child abuse, automobile accidents, or the effects of war—are the result of the actions one person or group of people perpetrates on others. Pain inflicted by others, from minor slights and insults to the most horrifying experiences of brutality or betrayal, can have lasting health effects. How can healing occur? For many people, being able to forgive is vital to reclaiming wholeness after traumatic events.

Integrative medicine is built upon empathic, trusting relationships between caregivers and patients. If patients have the time, opportunity, and safety to do so, they may disclose traumatic experiences that they may not have ever shared before. Some people recognize the role of forgiveness in healing the damage caused by traumatic experiences, whereas many others do not. How and when to address issues of forgiveness can be one of the most challenging aspects of caring for those who have been traumatized; however, the potential benefits make it well worth the effort.

Indeed, a 2014 study of 148 young adults indicated what was described as a “Stress x Forgiveness Interaction Effect.” For people who were more predisposed to forgive, stress had a relatively lower negative impact on their health.⁹

This chapter describes how forgiveness can influence health. It provides an overview of many of the key elements that are part of the forgiveness process and describes ways clinicians can make use of the power forgiveness in their practices.

Resources for further learning are provided at the end of the chapter.

The Health Effects of Forgiveness

In the past several years, increasing numbers of studies have demonstrated that forgiveness favorably influences physiology and a number of physical and mental health outcomes. These effects are described in the following text; however, it should be noted that, as is the case for many therapeutic approaches, one need not have a specific health problem to make good use of forgiveness for supporting overall well-being.

- Longevity. A 2012 review of data from a nationally representative sample of 1232 US adults concluded that “conditional forgiveness of others is

associated with [reduced] risk for all-cause mortality, and that the mortality risk of conditional forgiveness may be conferred by its influences on physical health.”¹⁰

- Vital signs. Simply imagining oneself granting forgiveness alters physiology. Blood pressure is lowered, heart rate decreases, and skin conductance changes.¹¹

- Immune function. Forgiveness of self is associated with decreased blood viscosity and improved ratios of helper T to cytotoxic T white blood cells.¹²

- Mental and emotional health.¹³ People who are more inclined to forgive are less likely to experience symptoms of depression,¹⁴ anxiety,^{15,16} and posttraumatic stress.¹⁷ In women suffering from spousal emotional abuse, forgiveness therapy was found to lower depression, anxiety, and posttraumatic stress and to improve self-esteem, emotional mastery, and the ability to find meaning in suffering.¹⁸ Forgiveness improves mental health by decreasing the tendency to ruminate, and probably improves social relationships as well.¹²

College students who were able to forgive others had less suicidal ideation than their peers, and those who were more capable of self-forgiveness had lower levels of depression.¹⁹ People with borderline personality²⁰ and eating disorders²¹ are less

predisposed to forgive and may benefit from forgiveness training.

A strong relationship exists between traumatic experiences and the emergence of physical and mental health problems. Strong evidence also indicates that forgiveness negates the harmful effects of trauma.

- Chronic pain. A 2005 study of 61 people with chronic low back pain found a direct relationship between an inability to forgive and pain intensity; the more a person could forgive, the less psychological distress and pain he or she experienced.²²
- Cardiovascular effects. Forgiveness is associated with lower cardiovascular risk, possibly due to decreased anger and hostility.²³ It has even been linked to improvements in lipid measures and has been found to have the opposite effects to anger when it comes to cardiac function measures,²⁴ with a recent study reporting decreased anger-induced myocardial ischemic events.²⁵ In a 2015 study, forgiveness was found to provide cardioprotection, at least in part because it decreases aortic blood pressure.²⁶
- Substance use disorder. Forgiveness has been

shown to decrease anger, depression, anxiety, and vulnerability to drug use in former substance abusers.²⁷ Forgiveness of self, but not forgiveness of others, has also been found to be linked to lower levels of high-risk alcohol use in college students.²⁸

- Oncology and palliative care. A 4-week intervention helped terminally ill older patients with cancer to enhance levels of hope and quality of life.²⁹ Use of a course entitled “Restore: The Journey Toward Self-Forgiveness” led to significant changes not only in self-forgiveness but in acceptance, self-improvement, and pessimism.³⁰
- Other chronic health disorders. Investigators have suggested that forgiveness therapy may hold great potential in the treatment of fibromyalgia and chronic fatigue.³¹ A small 2014 pilot study found that a forgiveness intervention decreased fibromyalgia symptoms.³²
- Miscellaneous benefits. Meta-analyses have also pointed out the benefits of forgiveness for healing intergenerational pain, recovery from sexual abuse and incest, and abortion-related guilt.^{33,34}

The Nature of Forgiveness

Several different measurement instruments are used to conduct research studies, and many have proven

quite useful. Ultimately, however, each person must discern his or her own way of defining forgiveness and knowing when and how it has occurred. Even when people do not actually feel equipped to forgive, they are often able to recognize that forgiving is important. When patients are ready, integrative providers can guide them through the process. As Jack Kornfield, a well-known writer and teacher of Buddhist meditation, noted, “We have all heard stories about the mysterious power of compassion and forgiveness in the lives of others. Each time we are inspired by these accounts, we remember that we, too, can forgive.”³⁵ As is so often the case in integrative practice, trying these approaches ourselves as clinicians before suggesting them for others is likely to be beneficial.

The Nature of Forgiveness

The following perspectives are based in part on the work of Enright and Luskin, as provided in the reference list.

- Forgiveness is a transformation. The key is to release suffering and thereby increase inner peace and understanding.
- Forgiveness is not forgetting. In fact, you have to remember and acknowledge negative emotions and events before forgiveness can occur.

- Forgiveness is not pardoning, excusing, or saying that something will be treated as acceptable behavior in the future.
- Forgiveness is, first and foremost, done for the person doing the forgiving. It is paradoxical in that when you forgive others, you heal yourself.
- Forgiveness is a path to freedom. It frees you from the control of the person who caused the harm. That person loses his or her power to cause you to feel negative emotions.
- Forgiveness can break old patterns that may otherwise interfere when you try to create new relationships.
- Forgiveness can take a long time and much hard work.
- Forgiveness need not require “making up” with the person who caused the harm. It is an internal process. It is primarily for you. The goal is to help you heal, to help you grow.
- Thinking about forgiveness may not be enough. For many, tapping into principles described in various spiritual traditions from around the world is necessary. Meditation, interpersonal dialogues, and intense emotional work may be essential parts of the forgiveness process for many people (see the reference list and [Key Web Resources](#)).

Guidelines for Helping People to Forgive

William Meninger defines the process of forgiveness as follows:

We begin to deal with our wounds by denying or minimizing them. When we finally do face them squarely and recognize the ones who inflicted them, we move on to the next step. This usually involves trying to excuse the perpetrator and blaming ourselves for causing or, at least, not stopping, the original wounds. When we are able to cease the self-blame, we begin to feel sorry for ourselves and to wallow in a mud hole of self-pity, bitterness, and recrimination. The next step is anger. We determine that we will do something about what happened to us and move forward with our lives. We stop rubbing salt in our wounds, and we actively seek healing. This leads us to the final stage, wholeness.³⁶

[Fig. 99.1](#) illustrates some of the key steps that occur as a person goes through the forgiveness process. These steps need not always occur in a particular order, and not every person experiences every step before forgiveness occurs.

Stepwise approaches guiding forgiveness have been developed by several authorities, and suggestions derived from several of these are summarized in the patient handout at the end of this chapter. For further information, clinicians are referred to the work of Robert Enright^{37,38} at the University of Wisconsin, Madison, and Frederic Luskin,^{39,40} coordinator of the Stanford Forgiveness Project in Palo Alto, California. Additional recommended books and websites for both patients and providers are listed in the previously mentioned patient handout.⁴¹⁻⁴⁸

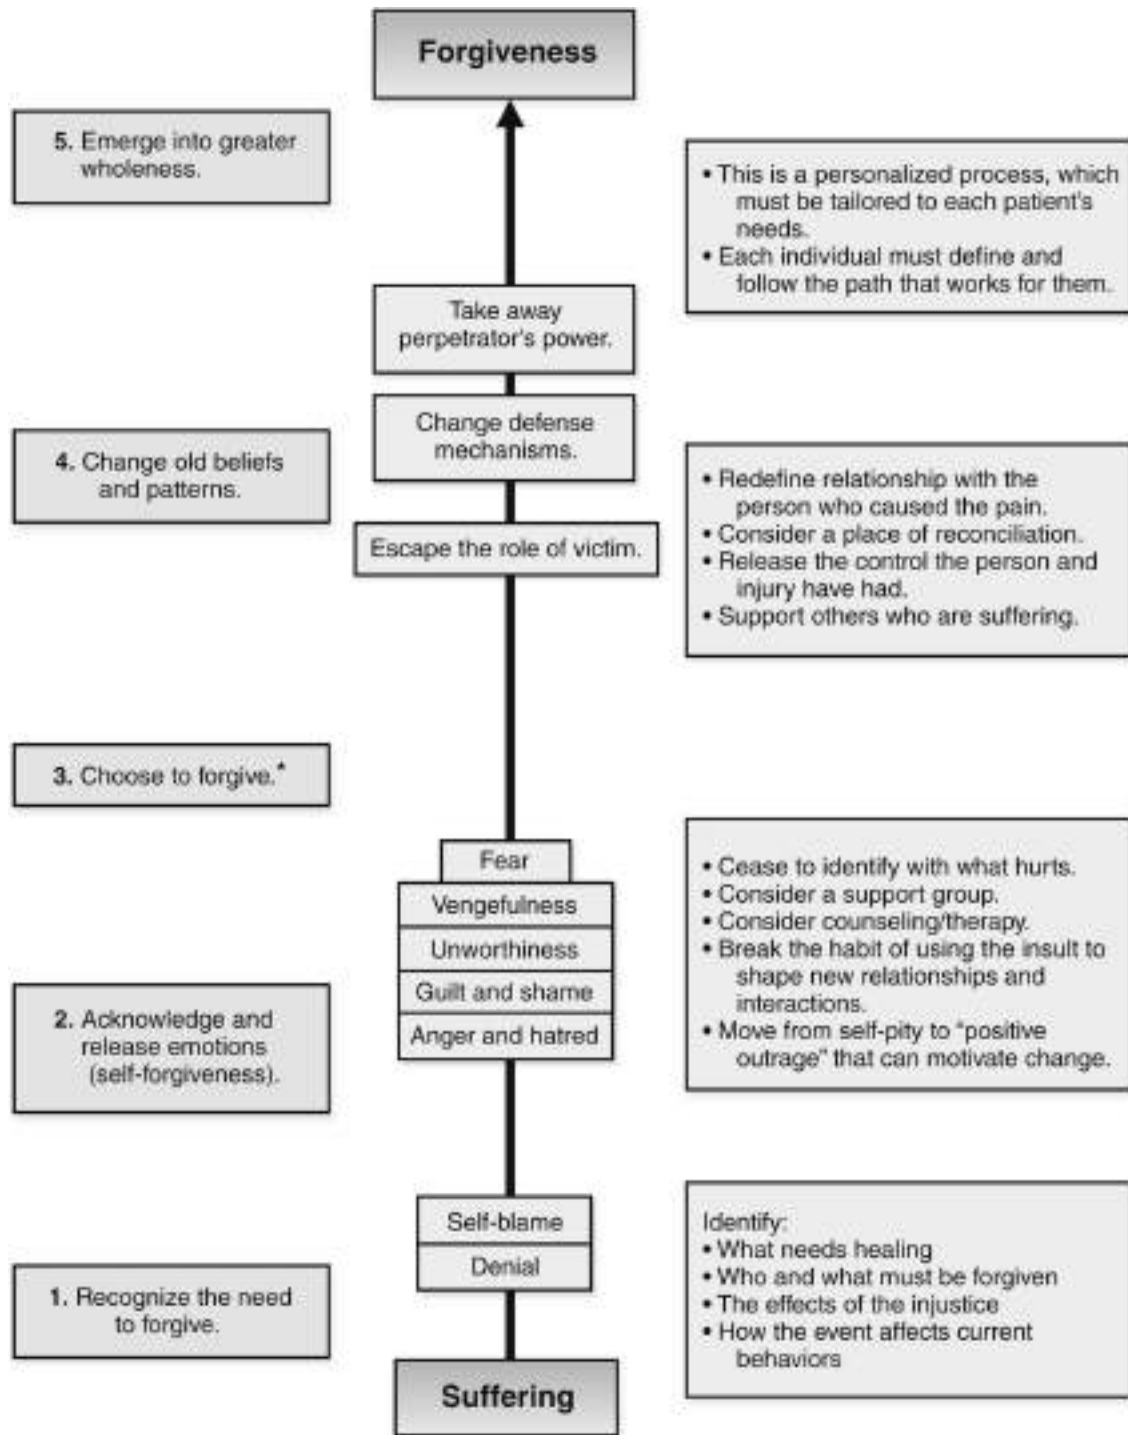

FIG. 99.1 The forgiveness process. General stages in the process are listed in the column on the left. Boxes overlying the arrow list major

obstacles to forgiving. Specific actions are listed on the right. More detailed steps are outlined in the resource list in the patient handout at the end of this chapter. *Often the most difficult step.

In discussing forgiveness with patients and using the patient handout, keep the following in mind:

- As with counseling for weight loss, substance abuse, or other types of behavioral change, suggesting that people cultivate forgiveness is only likely to be useful if people are “in a place” where they are willing and able to consider doing so. Some people may be offended if they are encouraged to forgive when they are not yet prepared to begin the process. As in motivational interviewing for substance use, the provider must assess readiness for change. Is the patient precontemplative, contemplative, or already taking steps toward forgiveness?
- The provider should emphasize, as noted in the patient handout, that forgiveness is not the same as tolerance, passivity, or forgetting what happened. No expectation exists that the patient must accept the perpetrator’s behavior as acceptable or allowable. Forgiveness is done for the person doing the forgiving; the goal is to free him or her as much

as possible from the negative consequences of a traumatic experience.

- Moving through the steps described in this chapter may be associated with an intense release of emotions. The provider must carefully assess whether mental health professionals are needed to assist a patient with the forgiveness process.
- Asking a person to forgive may be asking him or her to move away from a pattern of thoughts and feelings that has been present for many years. It is not a simple process for many people. Follow-up is important. The process takes time.
- A person's concept of forgiveness is based on his or her cultural and religious background. The provider should take a spiritual history and be aware of cultural beliefs, to suggest forgiveness as part of an individualized treatment plan that respects these beliefs and encourages appropriate social support.
- Meditation has shown promise in bringing about forgiveness and should be considered.⁴⁹
- Forgiveness is not just a therapeutic intervention, it is an end point—a healthier state of being—unto itself.⁵⁰

An integrative provider must carefully gauge whether a person is prepared to do forgiveness

work. Readiness to change must be carefully assessed.

A spiritual history can be useful in guiding a discussion of forgiveness as a tool for improving health.

Forgiving can be a difficult, emotion-laden, and time-consuming process. Be certain someone has the support he or she needs before beginning the process. Strongly consider requesting assistance from mental health professionals.

Unconditional forgiveness is a different model of forgiveness than the gift with strings. This is forgiveness as a grace, a free gift freely given. In this model, forgiveness frees the person who inflicted the harm from the weight of the victim's whim—what the victim may demand in order to grant forgiveness—and the victim's threat of vengeance. But it also frees the one who forgives. The one who offers forgiveness as a grace is immediately untethered from the yoke that bound him or her to the person who caused the harm. When you forgive, you are free to move on in life, to grow, to no longer be a victim. When you forgive, you slip the yoke, and your future is unshackled from your past.

Desmond and Mpho Tutu*

Father William Meninger describes the tale of Sister Catherine, a 55-year-old nun who was informed that a physician had mistakenly injected a lethal medication into her during the brain operation she had just undergone. Her response was to call in her fellow church officials and declare, “There will be no repercussions. No one is to be held at fault...I forgive without reservation anyone who may have been in any way responsible for what has happened.” She died 2 hours later.³⁶

Conclusion

Viktor E. Frankl, a psychiatrist and Holocaust survivor, summarizes the importance of how we deal with traumatic experiences in his work, *Man’s Search for Meaning*:

We must never forget that we may also find meaning in life even when confronted with a hopeless situation, when facing a fate that cannot be changed. For what then matters is to bear witness to the uniquely human potential at its best, which is to transform a personal tragedy into a triumph, to turn one’s predicament into a human achievement.⁵²

Patients continually seek the meaning underlying

their illnesses, their suffering, and their terrible losses. As healers, we can help to guide this search. Forgiveness is one tool that may help us all move through tragedy and pain toward greater wholeness.

If you want to see the heroic, look at those who can love in return for hatred. If you want to see the brave, look for those who can forgive.

Patient Handout: Healing Through Forgiveness

To err is human; to forgive, divine.
—Alexander Pope

Scientific research has indicated that forgiving past wrongs can be helpful for a variety of health problems, including anxiety, depression, substance abuse, and chronic pain. When we focus on forgiving, our blood pressure drops and our heart rate slows down. Our mood improves. Forgiveness can alter the state of our health.

What follows is a series of steps designed to help you forgive a past wrong. Follow each step, one at a time, and take a moment to write down your answers to each question. You need not share your answers with others. This process should be based on what feels best for you.

1. Think of a person who has wronged you, someone who you have not been able or willing to forgive thus far.
2. Describe the experience or experiences in which this "offender" harmed you or treated you unjustly. Does it help to have the pain and unfairness validated by a trusted person?
3. Describe the emotions you feel as you consider these events. Do you feel anger? Shame? Guilt? How much time do you spend thinking about or reliving what happened? Take as much time as you need to acknowledge your feelings and experiences and put them into words.
4. How has being unable to forgive affected your health? Has it affected your ability to relate to others? Did it change your view of the world? How has being hurt in the past caused you to protect yourself? Does how you defend yourself limit you in any way?
5. Consider what it means to forgive as well as the potential benefits of forgiving.
6. Are you ready and willing to forgive? When you feel that the answer is "yes," continue with the steps described below. Sometimes just deciding to forgive is the most difficult step of all! (Note: The following guidelines/suggestions are inspired by the works listed in the Further Reading section at the end of this chapter. Follow the steps in whatever order works best for you.)
7. Consider a situation in which another person had to forgive you for something. How did you feel? Recognize that everyone is involved in both forgiving and being forgiven. If you put yourself in the position of the person who hurt you, considering his or her life history and current circumstances, can you understand why he or she did this? (Again, understanding helps you to develop empathy for the person; it does not mean you are minimizing, condoning, or excusing what he or she did.)
8. Practice withholding resentment and developing goodwill toward the one who hurt you. You could consider performing an act of kindness toward the person who hurt you, if it is safe and possible to do so, but any attitude of goodwill that honors your decision to forgive is important. Do what respects your inherent worth as a human being as well as the inherent worth of the one who hurt you.
9. Consider that being realistic about the relationship with the person who hurt you can also be an aspect of goodwill. It can be helpful for both you and the person who hurt you to break any harmful patterns or connections.
10. Mourn and release the pain and emotions that the unjust event(s) caused you. Ask for support from friends or family members as you do this. In this way, you will no longer waste energy on this past injury, and you will be able to avoid passing the pain from the injury back to the person who hurt you and to other people around you.
11. Now that you are facing the pain in order to move through it, what virtues will you choose to follow to turn your suffering into triumph? Will you choose courage, compassion, kindness, love... forgiveness itself? What meaning will you discover? What kind of person are you becoming?
12. As you experience meaning and release, offer support to others who are experiencing similar difficulties. Helping others who have been suffering can help you find renewed purpose as a result of your own painful experiences.
13. For additional insight and assistance, consider discussing these issues with a health professional (counselor, psychologist, physician) or referring to the books mentioned in the Further Reading section of this chapter.

CHAPTER 100

Recommending Meditation

Luke Fortney, MD, FAAFP

What is Meditation?

Found in cultures, spiritual traditions, and healing systems throughout the world, meditation is a mind-body practice with many methods and variations. Most are grounded in the silence and stillness of compassionate, present-moment awareness. Although contemplative meditation practices are rooted largely in the world's spiritual traditions, the practice of meditation does not require belief in any particular religious system. In fact, secular familiarization with meditation and increased research within the fields of neuroscience, psychology, and medicine have led to an increased understanding of consciousness and improved treatment for many health conditions.

Mindfulness is one aspect of the meditation experience that reflects a fundamental human capacity to attend to relevant aspects of experience in a nonjudgmental and nonreactive way, which in turn cultivates clear thinking, equanimity, compassion, and open-heartedness. According to University of Massachusetts Center for Mindfulness founder Jon Kabat-Zinn, "Meditation is simplicity itself. It's about stopping and being present. That is all." Stated as simply as possible, *meditation means being present with what is*.

The goal of mindfulness is to maintain fluid awareness in a moment-by-moment experiential process that helps one disengage from strong attachment to beliefs, thoughts, or emotions in a way that generates a greater sense of emotional balance and well-being.¹ This simple yet radical assertion holds the potential for wide-reaching therapeutic benefit for many current health care challenges such as rising costs,² chronic diseases of lifestyle,³ clinician burnout,^{4,5,7} patient dissatisfaction,⁶ and generalized stress.⁸

Mindfulness is one aspect of the meditation experience that reflects a fundamental human capacity to attend to relevant aspects of experience in a nonjudgmental and nonreactive way, which in turn cultivates clear thinking, equanimity, compassion, and open-heartedness.

Why Meditate?
